About the Conference

IEMTRONICS 2021

Continuing with the outstanding success of IEEE IEMCON, IEEE CCWC, IEEE UEMCON, IEMANTENNA we are proud to present IEMTRONICS 2021 (International IOT, Electronics and Mechatronics Conference) which will be held during **21st- 24th April, 2021 at Toronto, Canada, in online mode**. Keeping in mind the pandemic situation prevalent globally due to Covid 19 and following the legacy of organizing highly successful conferences, we have planned for the online conference. The conference aims to bring together scholars from different backgrounds to emphasize dissemination of ongoing research broadly in the fields of IOT, Electronics and Mechatronics. Research papers are invited describing original works in above mentioned fields and related technologies. The conference will include a peer-reviewed program of technical sessions, special sessions, tutorials and demonstration sessions.

All accepted papers which will be presented during the parallel sessions of the Conference will be submitted for publication in IEEE Xplore Digital Library (Scopus, DBLP, Ei Compendex, Web of Science and Google Scholar).

This conference will also promote an intense dialogue between academia and industry to bridge the gap between academic research, industry initiatives, and governmental policies. This is fostered through panel discussions, keynotes, invited talks and industry exhibits where academia is exposed to state-of-practice and results from trials and interoperability experiments. The industry in turn benefits by exposure to leading-edge research in networking as well as the opportunity to communicate with academic researchers regarding practical problems that require further research.

Our Reviewers

IEMTRONICS 2021 followed a rigorous triple-blind review process in order to identify suitable papers for both presentation and publication. This process helped the organizers to shortlist good quality papers from diverse regional areas and across various domains. A detailed review process was possible due to the excellent and enthusiastic support extended by the strong technical review team of IEMTRONICS 2021. For every stage of submission, IEMTRONICS had a specific template review procedure to analyze the submissions and provide suitable comments for the authors to incorporate. The review team which formed the technical backbone for the selection of submissions for the edited book and the conference presentation was supervised by:

NAME	AFFILIATION
Ranjay Hazra	NIT, Silchar
Arighna Deb	KIIT University
Sukomal Dey	Indian Istitute of Technology, Delhi
Rohit Singh	University of Colorado Denver
Mainak Adak	WBUT
Riya Agarwal	Manipal Institute of Technology
Navid Bin Ahmed	Independent University Bangladesh (IUB)
Ritesh Ajoodha	The University of the Witwatersrand, Johannesburg
Md L Ali	Rider University
Mohammad Anees	Xilinx
Mohamed Imran Mohamed Ariff	Universiti Teknologi MARA Perak Branch
Haissam Badih	Oakland University
Anindya Bal	BRAC University
Ke-Lin Du	Concordia University
Patricia Enrique	University of Waterloo
Vilas H Gaidhane	Birla Institute of Technology and Science Pilani, Dubai Campus
Sasirekha Gvk	Electronics City
William P. Haggerty	Georgia Southern University
Qaiser Ijaz	University of Burgundy
Gustavo Jamanca-Lino	Colorado School of Mines
Haruo Kobayashi	Gunma University
Anna Kuwana	Gunma University
Moises Levy	West Texas A&M University
Regina Lionnie	Universitas Indonesia

Soliman Mahmoud	University of Sharjah
John Joshua F. Montañez	Bicol State College of Applied Sciences and Technology
Kumar Rahul	XILINX
Sowmya Sanagavarapu	Anna University
Jiacheng Shang	Montclair State University
Mario E. B. G. N. Silva	University of Campinas
Shahab Tayeb	California State University, Fresno
Ashleigh Townsend	North-West University, Potchefstroom
Tri Minh Tran	Gunma University
Doina Bein	California State University, Fullerton
Aleksandr V. Belov	National Research University Higher School of Economics
Jason Brown	University of Southern Queensland
Bhabendu Kumar Mohanta	International Institute of Information Technology, Bhubaneswar
Gopal Venkata Tadepalli	College of Engineering, Guindy Campus
Soham Ghosh	University of Kansas
Kamran Hameed	Imam AbdulRahman Bin Faisal UNiversity
Maryam Heidari	George Mason University
Banage Kumara	Sabaragamuwa University of Sri Lanka
Sashank Sridhar	Anna University
Olusiji O Medaiyese	University of Louisville
Kanika Sood	California State University, Fullerton
Md Imtiaz Ahmed	Daffodil Institute of IT
Ahmed Ammari	INSAT - Carthage University Tunisia
Pratik Chattopadhyay	Indian Institute of Technology (BHU), Varanasi
Sangay Chedup	Jigme Namgyel Engineering College
Monica Isabel Costa	Polytechnic Institute of Castelo Branco
Ashiq Sakib	Florida Polytechnic University
Gameel Saleh	Imam Abdulrahman Bin Faisal University
Nikhilkumar Shardoor	MIT School of Engineering, MIT-ADT University
José Cornejo	Bioastronautics and Space Mechatronics Research Group
S Dhivya	VIT University
Rajib Kumar Halder	Jagannath Universuty
Rasha Kashef	Ryerson University
Banujan Kuhaneswaran	Sabaragamuwa University of Sri Lanka
Pravir Malik	Deep Order Technologies
Moses O. Onibonoje	Afe Babalola University, Ado Ekiti
Deep Roy	WBUT
Mrinal Sen	Indian Institute of Technology(ISM), Dhanbad
Qasem Abu Al-Haija	University of Petra (UoP)

Kehinde Adeniji	Afe Babalola University, Ado Ekiti
Vaibhav Anu	Montclair State University
Mouna Gassara	Sfax University
Dawei Li	Montclair State University
Nasar Aldian Shashoa	The Libyan Academy
Fadi Abusafat	University of Minho
Naheem Adesina	Louisiana State University
Sushree Bibhuprada B. Priyadarshini	SOA University Bhubaneswar
Harikrishna Bommala	KG Reddy College of Engineering and Technology Moinabad Hyderabad
Kevin Matthe Caramancion	University at Albany
John Hurley	Defense Intelligence Agency
Rania Majdoubi	Mohammed V University in Rabat
Arup Mohanty	SOA University Bhubaneswar
Asterios Mpatziakas	Centre for Research and Technology Hellas
Gedalia Nabe Razafindrobelina	ITS
Debabrata Singh	ITER, SOA University, Bhubaneswar
Mudrik Alaydrus	Universitas Mercu Buana
Enrico Angeles	Abu Dhabi Polytechnic
Narayana Darapaneni	Great Learning
Debashreet Das	GIET University Gunupur
Amin A. M. Fadlalla	King Fahd University of Petroleum & Minerals
Joaquin Gonzalez	Pontificia Universidad Catolica del Peru
Binayak Kar	National Taiwan University of Science and Technology
Asif Uddin Khan	Sillicon Institute of Technology, Bhubaneswar
Shahriar Khan	Independent University
Mohan K N	KLEF Deemed to be University
Sivaselvan N	Manipal Institute of Technology
Vikul Pawar	Government Engineering College Aurangabad (An Autonomous) M. S. INDIA
Mohammed Rajhi	University of California Santa Cruz
Santosh Kumar Sahoo	Trident Academy of Technology Bhubaneswar
Ahmed Shafkat	Fareast International University
Charles Shibu	Abu Dhabi Polytechnic
Sodessa Soma Shonkora	Arba Minch University
Bevek Subba	Jigme Namgyel Engineering College
Mohammad Nayeem Teli	University of Maryland
Sudarshan Kumar Babu Valluru	Delhi Technological University
Marvin S Verdadero	Bicol State College of Applied Sciences and Technology
Wael M.S Yafooz	Taibah University

Dr. Tarek El Salti	Sheridan College, Canada
Dr. Sukomal Dey	Indian Institute of Technology, Palakkad
Dr. Maysam Chamanzar	Carnegie Mellon University, USA
Dr. Kean Boon Lee	Sheffield University, UK

Track Topics:

IoT & Data Science:

- IoT and blockchain
- IoT and big data
- Next-generation infrastructure for IoT
- Cloud computing and IoT
- Edge computing and IoT
- IoT platforms, tools, and applications
- IoT systems development methodologies
- IoT applications

Electronics:

- Antenna and wireless communication
- Microwave Engineering
- Photonics
- Nano science & Quantum Technology
- VLSI and Microelectronic Circuit Embedded Systems
- System on Chip (SoC) Design
- FPGA (Field Programmable Gate Array) Design and Applications
- Electronic Instrumentations
- Sensors & Systems
- NEMS & MEMS
- Integrated circuits & power electronics
- Electronic Power Converters and Inverters
- Electric Vehicle Technologies
- Control Theory, Optimization and Applications
- Robotics and Autonomous Systems
- Intelligent,Optimal,Robust,Adaptive Control
- Linear and Nonlinear Control Systems
- Complex Adaptive Systems
- Industrial Automation and Control Systems Technology
- Modern Electronic Devices
- Biomedical devices & Imaging
- Energy Harvesting & Conversions
- Energy Efficient Hardware systems

Mechatronics:

- Sensing and Control Systems
- Mechatronics Systems
- Mechanical Systems
- Artificial Intelligence
- Applications of Robotics

Information Technology:

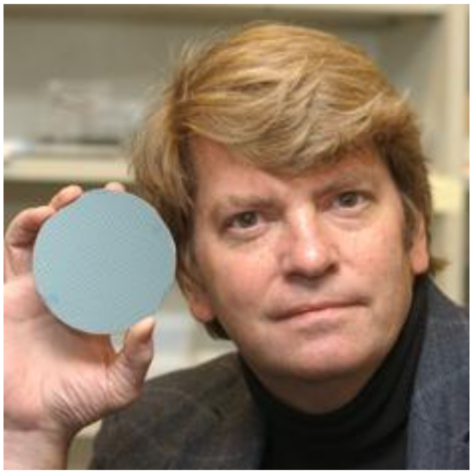
- Business Intelligence and Applications
- Computer Network
- Evolutionary Computation and Algorithms
- Intelligent Information Processing
- Information System Integration and Decision Support

- Image Processing and Multimedia Technology
- Signal Detection and Processing
- Technique and Application of Database
- Software Engineering
- Mobile Computing
- Distributed Systems
- Artificial Intelligence
- Visualization and Computer Graphic
- Natural Language Processing
- Deep Learning
- Machine Learning
- Internet of Things, Data Mining
- Data Science
- Cloud Computing in E-Commerce Scenarios
- E-Business Systems Integration and Standardization, E-government
- Electronic Business Model and Method
- E-Commerce Risk Management
- Recommender system
- Semantic Web Service Architecture for E-Commerce
- Service Oriented E-Commerce and Business Processes
- Data Analytics and Big Data
- Software defined networking
- Secured distributed systems

Mobile Communication:

- Ad hoc networks
- Body and personal area networks
- Cloud and virtual networks
- Cognitive radio networks
- Cyber security
- Cooperative communications
- Delay tolerant networks
- Future wireless Internet
- Local dependent networks
- Location management
- Mobile and wireless IP, Mobile computing
- Multi-hop networks
- Network architectures
- Network Security, Information Security, Encoding Technology
- Routing, QoS and scheduling
- Satellite communications
- Self-organising networks
- Telecommunication Systems
- Vehicular networks
- Wireless multicasting, Wireless sensor networks

Keynote speakers



Prof. Mark Arthur Reed

Professor, Department of Electrical Engineering, Yale University, USA

Bio: Mark Arthur Reed is an American physicist and professor at Yale University. He coined the term quantum dots, for demonstrating the first zero-dimensional electronic device that had fully quantized energy states. Reed does research in electronic transport in nanoscale and mesoscopic systems, artificially structured materials and devices, molecular electronics, biosensors and bioelectronic systems, and nanofluidics. He is the author of more than 200 publications, has given over 75 plenary and over 400 invited talks, and holds 33 U.S. and foreign patents on quantum effect, heterojunction, and molecular devices. He was the Editor in Chief of the journal Nanotechnology (2009-2019), is the present Editor in Chief of the journal Nano Futures, and holds numerous other editorial and advisory board positions.

Reed received his Ph.D. from Syracuse University in 1983. He worked at Texas Instruments from 1983 to 1990, where he demonstrated the first quantum dot device. He has been at Yale School of Engineering and Applied Science since 1990, where he holds the Harold Hodgkinson Chair of Engineering and Applied Science. Notable work there includes the first conductance measurement of a single molecule, the first single molecule transistor and the development of CMOS nanowire biosensors.

Reed has been elected to the Connecticut Academy of Science and Engineering and Who's Who in the World. His awards include; Fortune Magazine "Most Promising Young Scientist" (1990), the Kilby Young Innovator Award (1994), the Fujitsu ISCS Quantum Device Award (2001), the Yale Science and Engineering Association Award for Advancement of Basic and Applied Science (2002), Fellow of the American Physical Society (2003), the IEEE Pioneer Award in Nanotechnology (2007), Fellow of the Institute of Electrical and Electronics Engineers (2009), and a Finalist for the World Technology Award (2010).

Prof. Nicholas Bambos

Professor, Department of Electrical Engineering and Management Science, Stanford University, USA

Bio : Nick Bambos is a Professor at Stanford University, having a joint appointment in the Department of Electrical Engineering and the Department of Management Science & Engineering. He heads the Network Architecture and Performance Engineering research group at Stanford, conducting research in wireless network architectures, the Internet infrastructure, packet switching, network management and information service engineering, engaged in various projects of his Network Architecture Laboratory (NetLab). His current technology research interests include high-performance networking, autonomic computing, and service engineering. His methodological interests are in network control, online task scheduling, queueing systems and stochastic processing networks.

He has graduated over 20 Ph.D. students, who are now at leadership positions in academia (Stanford, CalTech, Michigan, GaTech, NYU, UBC, etc.) and the information technology industry (Cisco, Broadcom, IBM Labs, Qualcomm, Nokia, MITRE, Sun Labs, ST Micro, Intel, Samsung, TI, etc.) or have become successful entrepreneurs. From 1999 to 2005 he served as the director of the Stanford Networking Research Center, a major partnership/consortium between Stanford and information technology industries, involving tens of corporate members, faculty and doctoral students. He is now heading a new research initiative at Stanford on Networked Information Service Engineering.

He is on the Editorial Boards of several research journals and serves on various international technical committees and review panels for networking research and information technologies. He has been serving on the boards of various start-up companies in the Silicon Valley, consults on high technology development and management matters, and has served as lead expert witness in high-profile patent litigation cases in networking and computing.

Prof. Sanjay Lall

Professor, Department of Electrical Engineering, Stanford University, USA

Bio: Sanjay Lall is Professor of Electrical Engineering in the Information Systems Laboratory and Professor of Aeronautics and Astronautics at Stanford University. He received a B.A. degree in Mathematics with first-class honors in 1990 and a Ph.D. degree in Engineering in 1995, both from the University of Cambridge, England. His research group focuses on algorithms for control, optimization, and machine learning. From 2018 to 2019 he was Director in the Autonomous Systems Group at Apple. Before joining Stanford he was a Research Fellow at the California Institute of Technology in the Department of Control and Dynamical Systems, and prior to that he was a NATO Research Fellow at Massachusetts Institute of Technology, in the Laboratory for Information and Decision Systems. He was also a visiting scholar at Lund Institute of Technology in the Department of Automatic Control. He has significant industrial experience applying advanced algorithms to problems including satellite systems, advanced audio systems, Formula 1 racing, the America’s cup, cloud services monitoring, and integrated circuit diagnostic systems, in addition to several startup companies. Professor Lall has served as Associate Editor for the journal Automatica, on the steering and program committees of several international conferences, and as a reviewer for the National Science Foundation, DARPA, and the Air Force Office of Scientific Research. He is the author of over 130 peer-refereed publications.

Prof. Krishna Saraswat

Rickey/Nielsen Chair Professor, Stanford University, USA

Bio : Saraswat is working on a variety of problems related to new and innovative materials, structures, and process technology of silicon, germanium and III-V devices and interconnects for VLSI and nanoelectronics. Areas of his current interest are: new device structures to continue scaling MOS transistors, DRAMs and flash memories to nanometer regime, 3-dimentional ICs with multiple layers of heterogeneous devices, metal and optical interconnections and high efficiency and low cost solar cells.

Prof. Fakhri Karray

Professor, Department of Electrical and Computer Engineering, University of Waterloo, Canada

Bio: Prof. Fakhri Karray is the Loblaws Research Chair Professor in Artificial Intelligence in the department of electrical and computer engineering and is the founding co-director of the Waterloo AI Institute. He is the co-author of a textbook on applied artificial intelligence: Soft Computing and Intelligent Systems Design, Addison Wesley Publishing, 2004. He has authored extensively in his field of research (whether applied or theoretical), and has been issued 20 patents (US registered). He is the Associate Editor (AE) of the IEEE Transactions on Cybernetics, the IEEE Transactions on Neural Networks and Learning, and served as AE for the IEEE Transactions on Mechatronics, the IEEE Computational Intelligence Magazine. He also serves on the editorial board of the Elsevier Journal of Information Fusion, International Journal of Robotics and Automation, the Journal of Control and Intelligent Systems, and the Journal of Advances in Artificial Intelligence. Recent work of Fakhri and his research team's work on deep learning-based driver behaviour recognition and prediction has been featured on The Washington Post, Wired Magazine, Globe and Mail, CBC radio and Canada's Discovery Channel. He is a Fellow of the IEEE, a Fellow of the Canadian Academy of Engineering, a Fellow of the Engineering Institute of Canada and the President of the Association for Image and Machine Intelligence. He served as a Distinguished Lecturer for the IEEE and is a Fellow of the Kavli Frontiers of Science (a major research and symposium program of the US National Academy of Sciences)
Recent areas of research include:

Operational artificial intelligence and machine learning
Predictive analytics with application to virtual care
Multi-sensor data fusion
Cognitive robotics and autonomous machines
Smart mobility and big data analytics
Concept extraction and natural speech understanding

Prof. Raafat R. Mansour

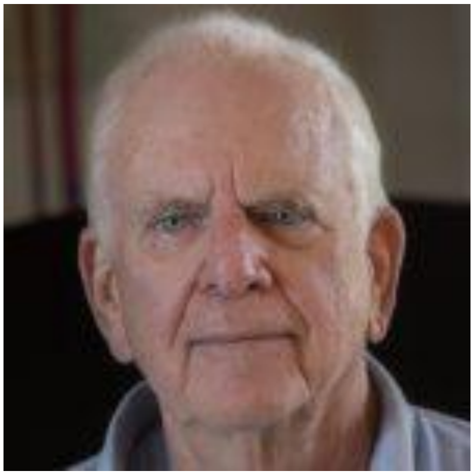
Professor, Canada Research Chair, Electrical and Computer Engineering Department, University of Waterloo, Canada

Bio: Dr. Mansour is a Professor of Electrical and Computer Engineering at the University of Waterloo and holds Tier 1 – Canada Research Chair (CRC) in Micro-Nano Integrated RF Systems. He held an NSERC Industrial Research Chair (IRC) for two terms (2001-2005) and (2006-2010). Prior to joining the University of Waterloo in January 2000, Dr. Mansour was with COM DEV Cambridge, Ontario, over the period 1986-1999, where he held various technical and management positions in COM DEV's Corporate R&D Department. Professor Mansour holds 37 US and Canadian patents and more than 380 refereed publications to his credit. He is a co-author of a 23-chapter Book published by Wiley and has contributed 6 chapters to four other books. Since joining the University of Waterloo in 2000, Professor Mansour has graduated 37 Ph.D, 32 M.Sc students and trained 14 Postdoctoral Fellows. His students hold key positions in academia and industry, including 5 holding faculty positions. Professor Mansour founded the Centre for Integrated RF Engineering (CIRFE) at the University of Waterloo https://uwaterloo.ca/centre-integrated-rf-engineering/. It houses a clean room and a state-of-the-art RF test and characterization laboratory. Professor Mansour has acted as a catalyst for ideas inspiring the next generation of Waterloo entrepreneurs to bring their work to market. Out of research carried out in his research Lab at the University of Waterloo, Professor Mansour and his graduate students co-founded two companies: AdHawk Microsystem http://www.adhawkmicrosystems.com/ and Integrated Circuit Scanning Probe Instruments (ICSPI-Corp) https://www.icspicorp.com/. Professor Mansour is a Fellow of IEEE, a Fellow of the Canadian Academy of Engineering (CAE), a Fellow of the Engineering Institute of Canada (EIC). He was the recipient of the 2014 Professional Engineers Ontario (PEO) Engineering Medal for Research and Development and the 2019 IEEE Canada A.G.L. McNaughton Gold Medal Award.

Prof. David Campbell

Professor, Department of Electrical and Computer Engineering, Boston University, USA

Bio: Professor David K. Campbell received his bachelor's degree in physics and chemistry from Harvard College in 1966, Part III Mathematics Tripos, with distinction, from Cambridge University in 1967, and his Ph.D. in theoretical physics and applied mathematics from Cambridge in 1970. He has pioneered the systematic study of inherently nonlinear phenomena throughout physics. The central theme of his work is the role of nonlinear excitations—solitons—in novel states of matter. His contributions span many distinct subfields of physics from high-energy field theory to condensed matter. Professor Campbell is a leader in the emerging field of nonlinear science. His influential overview articles and his direction of the flagship journal Chaos, of which he was the founding editor, have established key interdisciplinary organizing principles—the paradigms of solitons, chaos, and patterns—and have played a seminal role in defining the research agenda in nonlinear science.



Steven J. Davis

Founder, Golem Labs, USA

Bio : Steve Davis received his Bachelor of Electrical Engineering at the City College of New York, and a master's degree of Electrical Engineering from Drexel University in 1968, specializing in information theory and signal processing. His started his career doing research and development of highly compressed speech communication systems used in aircraft and later in deep space voice communications. He then was recruited by General DataComm Industries in 1978 to convert the original Bell modems and line interface devices, from mechanical logic devices to miniaturized solid state modems. This was achieved using custom integrated circuits with analog and digital elements on the same substrate.

Steve then in 1983, moved on to Warner Communications to be the chief technologist in implementing the first two-way interactive cable network for Warner Cable. After the completion of the system, Steve headed west to be director of the Atari Advanced Research Lab , located on the Burbank Studio lot. Here the first LAN network was developed for home computers using the Atari 800 device. An interactive video disk system was presented in Paris showing how the combination of video and a consumer computer could be used to create unique experiences. This work was part of the many projects Mr. Alan Kay directed.
Steven then started his own venture, Golem Labs . At Golem Labs a wireless games and data systems were developed using FM Sub Carrier technology. Steve has since moved on to bring several conceptual systems to reality. Navigation devices used in tunnels, hand held IED jamming, focused energy beams , wireless watering controllers, miniature ferrite antenna systems, planar antennas, and stealth communication under a DARPA contract. Presently Steve is consulting on secure cloud computing systems, and on secure handheld financial devices that are Quantum proof. He holds 14 patents.

Dr. Bonita Bhaskaran

Principal Engineer, NVIDIA, USA

Bio : With 13+ years of VLSI Design industry experience, **Dr. Bonita Bhaskaran** have worked cross-functionally on a few high-visibility projects @NVIDIA. A strong believer of "Where there is a will, there is way", she has not let impediments stop her in solving tough engineering problems. During her career span, a diverse background in Asynchronous Design, Design for Test, Signal Integrity, Power Integrity and Low Power VLSI has honed her skills as a Domain Expert in Low Power DFT.

Specialties – DFT, ATPG Tools, Verification, Silicon Power Measurements, Die-Pkg Co-Simulation, On-Chip Power Integrity

Prof. Sean Follmer

Department of Mechanical Engineering and Computer Science, Stanford University, USA

Bio : Sean Follmer is an Assistant Professor of Mechanical Engineering and Computer Science (by courtesy) at Stanford University. His Research in Human Computer Interaction, Haptics, and Human Robot Interaction explores the design of novel tactile physical interfaces and novel robotic devices. Dr. Follmer directs the Stanford Shape Lab and is a faculty member of the Stanford HCI Group. He is a core faculty member of the Design Impact masters program focusing on innovation and human centered design at Stanford.

Dr. Follmer received a PhD and a Masters from the MIT Media Lab in 2015 and 2011 (respectively) for his work in human-computer interaction, and a BS in Engineering with a focus on Product Design from Stanford University. His talk featured on TED.com was named one of the best science and tech TED talks of 2015 and has been viewed more than 1.4 million times. He has received numerous awards for his research and design work such as Best Paper Awards and nominations from premier conferences in human-computer interaction (ACM UIST and CHI conferences), Fast Company Innovation By Design Award, Red Dot Design Award, and a Laval Virtual Award. His work has been shown at the Smithsonian Cooper Hewitt Design Museum, Ars Electronica Center, and the Milan Design Week. Dr. Follmer also leads workshops and executive education around design thinking and innovation.

***Abstract*—In the Internet of Things, it is more important than ever to effectively address the problem of secure transmission based on steganographic substitution by synthesizing digital sensor data. In this case, the degree to which the grayscale message is obscured is a necessary issue. To ensure information security in IoT systems, various methods are used and information security problems are solved to one degree or another. The article proposes a method and algorithm for a computer image in grayscale, in which the value of each pixel is one sample, representing the amount of light, carrying only information about the intensity. The proposed method in grayscale using steganographic coding provides a secure implementation of data transmission in the IoT system. Study results were analyzed using PSNR (Peak Signal to Noise Ratio).**

***Index Terms*—IoT, steganography, LSB, information security, grayscale metod, PSNR, stego image, histogram, RGB.**

I. Introduction

Internet of Things (IoT) incorporate Smart devices, sensor networks and wearable devices with the reason of trading data and administrations while sensor networks are the key for making smart environments. IoT systems are developing quickly due to the quick increase of remote networks and improved range of sensing devices. IoT technology deals with millions and billions of sensing objects, machines and virtual entities that interact with each other [1]. A new forecast from International Data Corporation (IDC) estimates that there will be 41.6 billion connected IoT devices, or ”things”, generating 79.4 zettabytes (ZB) of data in 2025 [2]. The Internet has become the most convenient and effective means of communication. Over the Internet, messages can be transmitted quickly and cheaply in various areas, such as government agencies, the private sector, the military, and medical fields. In many cases, the confidentiality of the transmitted message must be preserved [3]. To guarantee that the message is exchanged safely and securely over the network, an appropriate method is required. Steganography demonstrates as a trust able method for accomplishing this aim. In steganography, the information are covered up within the cover media. The cover medium can be within the form of image file, text record, video record, or sound file. Steganography is characterized as a science or craftsmanship of covering up the message interior a few covers medium (Figure 1). The word stenography is built up of two words of ancient Greek origin steganos meaning covered, concealed, or protected and ”graphie” meaning ”writing” [4]. The concept of steganography isn’t unused; its utilization can be seen within the past moreover. Chronicled records delineate that around 440 BC, Herodotus sent secret messages utilizing the concept of steganography.

IoT is the technology of the decade which moreover in turn has parts of potential focuses for a breach of data. This article explores the security issue and proposes an improved steganography scheme for IoT devices. The advancement of the IoT and inescapable computing makes a significant affect within the data and communication. The development rate of the gadgets appeared to be climbed in exponential way. In the general objective appears to be giving superior administrations for the conclusion client with the development of the new age gadgets. Steganography exists the total of conceal a file, message, image, or video interior another file. The benefit of steganography in overload of cryptography alone be to the planned secret communication doing not attract attention to itself as an object of security [5]. Doubtlessly able to be lively see encrypted messages, no matter how unbreakable they are, stimulate intrigued and may in themselves be there implicating in countries in which encryption is illicit. This investigates proposes a method, which can cover up the secret information in image layers, and steganography for IoT. The proposed technique is LSB substitution ciphers for the IoT. Experiments are conducted with different aspect ratio images, which show that proposed algorithms seem to work better. The proposed method performs well in specifically in RGB color model. The simple LSB method seems to have a lack which is rectified with the proposed method Vacillating LSB in terms of the

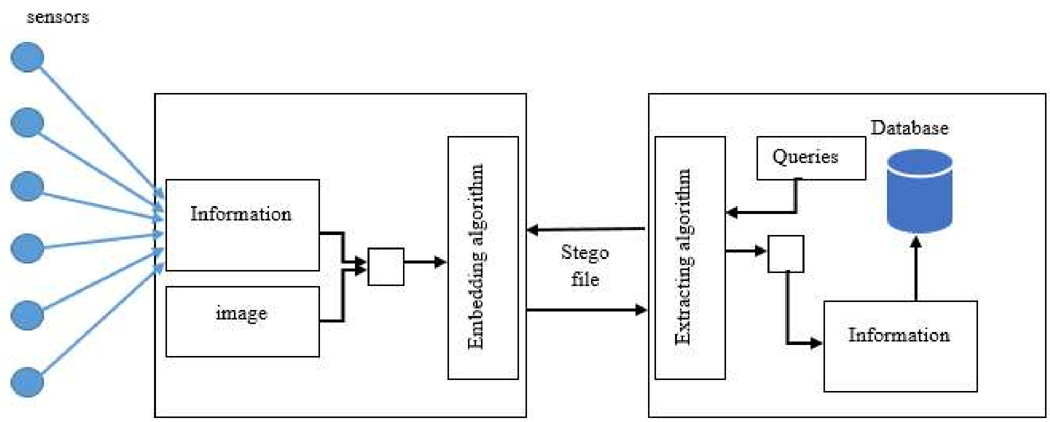

Fig. 1. Original pictures in BMP and JPEG format

MSE and PSNR. 3-3-2 LSB image steganography is analyzed using Grayscale methods.

II. Schematic of the RGB color model

Typically, a graphics palette consists of three color components such as red, green and blue. Each of the components has 256 shades. In total, all three components form a palette of 16,777,216 colors, which is a 24-bit color. Let's consider one of the color components. The shades of the color change linearly in accordance with the growth of the value itself, hence the close colors differ in the values of the least significant bits. The human eye as a whole does not distinguish between minimal differences in color shades. Based on these facts, if, to manipulate the values of the least significant bits of the three color palettes, then the whole picture will not change. It is suggested to use the three low-order bits of the red and green component and the two low-order bits of the blue component to write one message byte.

TABLE I
8 bits representing color

Bit	7	6	5	4	3	2	1	0
Data	R	R	R	G	G	G	B	B

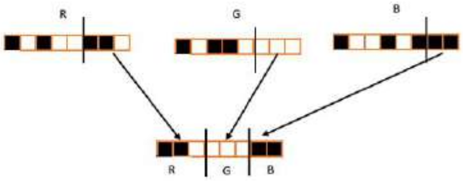

Fig. 2. 8-bit color, with 3 bits of red, 3 bits of green, and 2 bits of blue

A 24-bit color image is taken into account the most effective in accordance with the definition of RGB color model during which every color shows as in its primary spectral component of red, green and blue. This model is based on Cartesian coordinate system as shown in Figure 3. In this way, the RGB essential values are laid in three corners. The secondary colors acknowledge as cyan, magenta, and yellow, they're targeted at 3 alternative corners. Black color is at the origin and white is at the farthest corner from the origin. Equal values embrace red, green, blue are consisted the line that links 2 corners. Therefore, this produces various shades of grey.

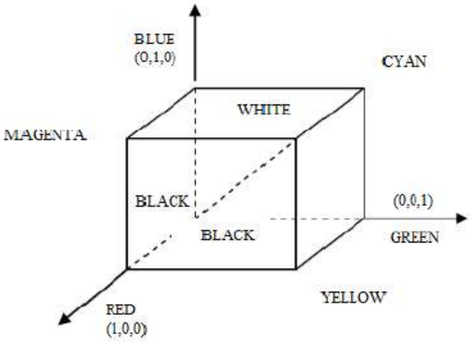

Fig. 3. Schematic of the RGB color model

The locus of these points is called the gray line. In fact, every pixel within the RGB model composes of RGB values. So, every of those colors needs 8-bit for its illustration. Consequently, every pixel signifies by twenty four bits in total. So the sum of possible colors with 24-bit RGB image reaches $(2^8)^3 = 16,777,216$ [6].

III. Gray scale Methods

The use of three-component RGB colors in BMP image format for graphics is not rational. More preferable to use JPEG format. The JPEG format has two key features. The first is the use of color subsampling, the second is the discrete cosine transform. At the same time, if we go to a single-component color, for example, a shade of gray, then in the background of the peculiarities of the JPEG format, further operations with the picture take place at the brightness level as shown in Figure 2 [7]. For example, the picture below with dimensions of 256x256 pixels in BMP format has a volume of 192 kB, and the same picture in grayscale JPEG format has a volume of 16.2 KB.

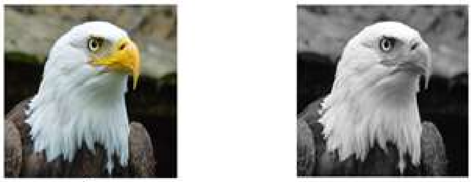

Fig. 4. Original pictures in BMP and JPEG format

To write a message to a grayscale picture, a similar method is used as for color. Three image pixels are used to write one byte of the message, in the ratio of 3 least significant bits + 3 least significant bits + 2 least significant bits. With this approach, a 10 kB message of English text can be placed in the specified picture.

IV. Proposed Algorithm

Let N be the image consist of $H * W$ elements, C be the M-bite safes note, y be the elements value of N and C be the bite of safes note, then the picture set of values can be show on (1) and C can be show on (2) [8]

$$N = \{y_{ij} | 1 \leq i \leq H, 1 \leq j \leq W, y_{ij} \in \{0, 1, ..., 255\}\} \quad (1)$$

$$C = \{C_M | 1 \leq M \leq m, C_M \in \{0, 1, ..., 255\}\} \quad (2)$$

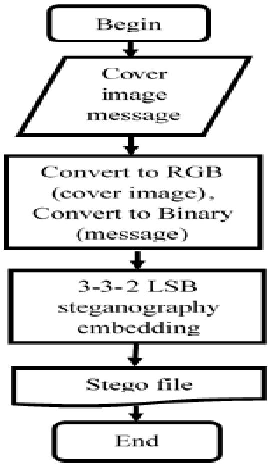
$$L = \{255 * l_w + l_r | 0 \leq l_w \leq 255, 0 \leq l_r \leq 255\} \quad (3)$$

Let C is the note to be covert, Y is the picture, L is the length of notes (3), E and O are the encoding and decoding algorithms, accordingly and Y' is the steganographic document (4). Perhaps the encoding event is given by the resulting equation:

$$Y' = E(C, Y, L) \quad (4)$$

The encoding algorithm is show in Block scheme 1. At the other end, the inverse event is executed and the note is extracted applying the algorithm in Block scheme 2. The note is extract from the picture by (5). Perhaps the decoding event is given by the resulting equation:

$$X = O(Y', L) \quad (5)$$



Begin
Cover image message
Convert to RGB (cover image), Convert to Binary (message)
3-3-2 LSB steganography embedding
Stego file
End

Fig. 6. Extracting algorithm

V. Experimental Results

The performance is tested on the base of two parameters, that is, PSNR and MSE [8]. The most effective grayscale method should be identified:

$$MSE = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} (y_{ij} - {y'}_{ij})^2 \quad (6)$$

Where H and W show the measurements of the picture set of values y_{ij}, shows the original picture and ${y'}_{ij}$ shows the steganographic picture.

$$PSNR = 10 \log[\frac{255^2}{MSE}] \quad (7)$$

VII. Conclusion

This article explores the security issue and proposes an improved steganography scheme for IoT devices. The paper proposes a steganography method using an improved LSB (least significant bit) replacement algorithm for a 24-bit color image capable of creating a hidden embedded image that is completely indistinguishable from the original image by the human eye. The steganographic grayscale technique allows data to be hidden within the grayscale medium. Moreover, each pixel stores eight message bits inside a pixel, while other methods, such as LSB, allow only two message bits inside a pixel. A fairly simple mathematical bit comparison function is used, which meets the basic requirement of steganography, which consists in sending a secret message inside the carrier of the image without creating much difference from the original image. Finally, the proposed steganography method provides a good PSNR.

***Abstract*—Blockchain technology has recently witnessed a rapid proliferation across multiple industries and has the potential to evolve as a popular energy transaction platform for grid operators and general users. The current proof-of-work consensus algorithm used by many blockchain protocols suffer from vulnerabilities such as the majority attacks problem and strip mining. The algorithm often requires specialized application-specific hardware and involves energy-intensive computation, making it an unlikely candidate for power grid applications. On the other hand, the proof-of-stake consensus algorithm is susceptible to the well-known nothing-at-stake vulnerability issue, making it equally unlikely to be used in large-scale secured energy transactions. An energy-efficient locational marginal pricing-based hybrid proof-of-work, proof-of-stake consensus algorithm is proposed to mitigate such risks. The hybrid consensus algorithm uses an optimized market-based energy pricing model to select the mining and forging nodes. A detailed framework of the hybrid consensus algorithm is provided, along with an overview of its potential application to record large volumes of energy transactions and execute obligatory smart-contract agreements.**

Keywords—Energy blockchains, proof of work, proof of stake, hybrid consensus, locational marginal price, smart-contract, initial coin offering.

I. Nomenclature

Sets, indices, and parameters:

g	set of generators
n, m	set of nodes
k	set of branches (lines and/or transformers)
$k_{(\leftarrow n)}$	set of branches with n as the incoming node
$k_{(n\rightarrow)}$	set of branches with n as the outgoing node
P_k^{max}	maximum thermal rating of the branch k
P_g^{max}	maximum thermal rating of the generator g
C_g	the variable production cost of generator g
P_n	real power load at node n
Im(Y)	the imaginary part of admittance

Variables:

P_g	real power supply ∀ g
P_k	real power-flow through branch ∀ k
θ_m, θ_n	the voltage at node m, n
$\tau, \tilde{\alpha}, \overline{\alpha}, \overline{\overline{\beta}}, \overset{\frown}{\tilde{\beta}}$	dual variables corresponding to the primal constraints

II. Introduction

Blockchain technology has rapidly evolved ever since it was first introduced in 2008, with protocols as Bitcoin and Ethereum gaining significant popularity. In the original whitepaper [1], the author/working group demonstrated the concept of an immutable blockchain ledger that can be used to record timestamped network transactions using the hash-based proof-of-work (PoW) algorithm. The PoW algorithm searches for a unique nonce value in a block that will produce a definite number of leading zeros as defined by the protocol's difficulty level when hashed. The difficulty level of the cryptographic problem is periodically increased to compensate for the effects of new hardware being introduced with increasing hashing power. Increasing the level of difficulty over the years has caused the establishment of colossal blockchain mining pools, consuming enormous energy, significant enough to congest electrical flow-gates and affect energy prices at specific electrical nodes. As reported in [2], Bitcoin's energy consumption's upper bounds are estimated to be 125 TWh. Current 2020 projections indicate the Bitcoin network operating on the PoW algorithm at its core consumes energy at an amount comparable to the yearly consumption of the Netherlands [3]. In addition to the outrageous energy consumption issue, the PoW algorithm suffers from well-known vulnerabilities such as the 51% attack and strip mining [4, 5].

The proof-of-stake (PoS) consensus algorithm relies on validators staking their cryptocurrency token or voting tickets to improve their chances of being selected as the forger of the next block using a pseudo-random process. Chances of selection as the next forger in the pseudo-random selection process is linearly proportional to the amount each validator puts up as a stake. This linear relationship prevents large stakeholders from gaining competitive advantage through economies of scale, as often witnessed in the PoW consensus algorithm [6].

Though the PoS consensus algorithm has its merit, it still suffers from the nothing-at-stake problem, which exists whenever there is an accidental or malicious fork in the blockchain. Given that forging a block doesn't incur any significant cost, and a fork creates an equivalent amount of stake on the new blockchain, the block creators often have the incentive to create blocks on both the forks. The nothing-at-stake vulnerability could potentially result in a double-spend attack. The solution offered in most cases for the nothing-at-stake problem centers around an identity-based [7] or a slashing-based [8] staking mechanism.

There is a clear gap in the availability of a blockchain consensus algorithm for energy application that is efficient, relatively secured, and optimized based on the electric grid's

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

topology. In response to the limitations of both the PoW and PoS consensus algorithms and accounting for the network topology in terms of the generation, load, and the thermal limits of the transmission grid, a hybrid PoW-PoS consensus algorithm framework is proposed. This hybrid consensus algorithm selects mining and forging nodes based on the locational marginal pricing (LMP) of electricity and overcomes individual consensus algorithms' limitations. The proposed hybrid framework's energy efficiency and security features can be implemented for wide-scale energy applications, including mandatory smart-contract agreements.

The remainder of the paper is organized as follows: Section III provides a comprehensive discussion of the two most popular consensus mechanisms and their relative merits; section IV highlights the hybrid PoW-PoS consensus algorithm in conjunction with the LMP based nodes selection. This section also highlights necessary design considerations to be made in the blockchain protocol layer in terms of reward and difficulty adjustments, application-specific integrated circuit (ASIC) resistance, and selection of hashing algorithm, among other issues. The application of the proposed hybrid consensus in energy blockchain transactions and smart contract applications are discussed in section V. Finally, concluding remarks are provided in section VI.

III. Popular Consensus Algorithms in Use

There are several consensus algorithms documented in the blockchain technology literature [9, 10, 11], mostly serving two primary functions: guaranteeing that the proposed new block is the only valid version of the chain and preventing users with malicious intent from manipulating the records in the blockchain or introducing an unintentional chain fork.

Besides PoW and PoS, the two most popular consensus algorithm, some of the other less known algorithms include proof-of-burn (PoB), proof-of-capacity (PoC), delegated proof-of-stake (dPoS), and Cardano Ouroboros. Given the current trends and the relative merits, future consensus algorithms would likely be a hybrid or standalone derivative of either the PoW or PoS algorithm, and hence they require further discussion.

A. Proof-of-Work Algorithm

The PoW algorithm relies on proof that an adequate amount of resources in terms of computing power and energy has been spent to propose a value acceptable by the distributed network. This algorithm is popular with blockchain protocols as Bitcoin, Bitcoin Cash, Litecoin, and Monero. Most of these blockchain protocols implement a periodic difficulty adjustment algorithm (DAA) of the hashing target (h_{max}), effectively readjusting the feasible solution-space proportional to the total hashing power across the network. For a message (m) to be incorporated in a block, a nonce (n) is computed such that the hashed output (h_{output}) is below the target difficulty and (1) holds. Most of the cryptographically secured hashing functions commonly used are variants of the secured hash algorithm (SHA) [12]. The popular SHA-256 hashing algorithm yields a 64 character hexadecimal output, and the addition of every single leading zero as a target constraint effectively reduces the feasible solution space by sixteen times.

$$hash(m,n) = h_{output}\,; h_{output} < h_{max} \tag{1}$$

1) Advantages of the Proof-of-Work Algorithm

One of the great strengths of the PoW consensus algorithm is that the smallest change in the input results in a massive uncorrelated change in the hash output, giving all attempts equal probability. Also, the PoW consensus algorithm is a Poisson process [13], given the probability of the next block generated within a specific timeframe can be statistically predicted using the Poisson distribution function. A nonnegative random integer value (X), with an intensity parameter (λ), is said to follow a Poisson distribution if (2) holds.

$$P(X = x|\lambda) = \frac{e^{-\lambda}\lambda^{x}}{x!};\ x = 0,1,\ldots \tag{2}$$

To demonstrate the nature of the discrete-event distribution, consider, on average, a single Bitcoin block is mined every ten minutes (λ = 0.1). Under a Poisson process, one can estimate using the generalization from (2) other outcomes, such as the probability of at least two blocks being mined in the next minute. As shown in (3), the event has a probability of 0.00468.

$$\begin{aligned} P(\text{at least two blocks in the next minute}) &= P(X \geq 2) \\ &= 1 - P(X < 2) \\ &= 1 - \frac{e^{-\frac{1}{10}}\left(\frac{1}{10}\right)^{0}}{0!} - \frac{e^{-\frac{1}{10}}\left(\frac{1}{10}\right)^{1}}{1!} \\ &= 0.00468 \end{aligned} \tag{3}$$

Another strength of the PoW consensus algorithm is its resistance to Sybil attacks [14], a type of attack where a single malicious user creates several fake identities on the system to gain influence. As long as the malicious user is not in control of more than 50% of the network's hashing power, any attempts to add a fake block will be rejected due to an insufficient amount of work.

2) Vulnerabilities of the Proof-of-Work Algorithm

The most well-documented vulnerability of the PoW consensus algorithm is the 51% attack, where a single malicious miner or mining group controls more than 50% of the network's hashing power. Having this dominant hashing power will allow the malicious party to mine and verify fraudulent transaction blocks at a rate faster than the regular miner, potentially leading to a gamed double-spend transaction scenario. This issue can be further aggravated, given that most mining pools for popular blockchain protocols are centralized in regions where there is access to cheap electric power. At present, no regulations prevent the biggest mining pools from merging to trigger a 51% attack.

As documented in [4, 15], another vulnerability of the PoW consensus algorithm is the issue of strip mining. Big mining pools can effectively game the blockchain protocol's current difficulty level to their advantage by timing their network participation close to the difficulty adjustment timeframe. For instance, a mining pool with significant hash power may quit from the network soon after a difficulty target readjustment, resulting in a significant increase in the mining time for the next blocks, and leading to a backlog of unconfirmed transactions, effectively chocking out the system.

B. Proof-of-Stake Algorithm

First introduced by Peercoin, the proof-of-stake consensus algorithm relies on the fact that well-invested users have a sufficient degree of vested interest in the network to prevent them from any malicious attempt. Under a PoS consensus, the probability of selecting a node as the next forger is linearly proportional to its staked cryptocurrency tokens (as in NXT) or voting tickets (as in Decred).

1) Advantages of the Proof-of-Stake Algorithm

The PoS algorithm is not computationally intensive and is thus resistant to centralization in regions where electric and hardware resources are cheaply available. Further, as block verification under a PoS algorithm doesn't follow a Poisson process, the algorithm can be scaled up to support much larger transaction volumes. Ethereum, which currently uses the PoW consensus algorithm, has proposed an iterative upgrade to Serenity by 2022. Serenity is a modified version of PoS [16] to support the platform's scalability.

2) Vulnerabilities of the Proof-of-Stake Algorithm

In PoW, the miners have an incentive to mine on the longest chain because of the higher likelihood of adding the next block to the longest chain. However, in the PoS consensus algorithm, under a theoretical gaming scenario, forgers will have the incentive to vote on all forks, to maximize their chances of receiving the transaction fee. This issue is referred to as nothing-at-stake vulnerability. Two of the well-known mitigation strategies implemented are:

- Peercoin [17]: Introduced the concept of coinage, which is consumed upon minting a block. Successful block validators need to wait for thirty days before their coins in the wallet requalify.
- Ethereum Slasher 2.0 [18]: Introduced a voter penalty concept for voting on the wrong fork.

IV. Hybrid Consensus Algorithm

The drawbacks of both the popular PoW and PoS consensus algorithm for energy application demands the development of an alternative consensus mechanism that is more energy-efficient and provides better security against majority attacks and systematic gaming. The PoW and PoS consensus algorithm's strengths can be combined to create a hybrid model where the PoW mining nodes are responsible for mining a new block for validation, and the PoS validators vote on each candidate block to be incorporated into the chain.

A crucial consideration in selecting the mining and validating nodes is the locational marginal price (LMP) of electricity at the grid's major electrical nodes. In a deregulated energy market, electric prices at different nodes often experience a price separation due to congestion in the grid. Economic benefits can be realized if nodes with lower real-time LMP are selected for mining the blocks using PoW consensus, while the high the higher-priced nodes may act as PoS validators. The following section presents a mathematical derivation of LMP from an optimal power-flow (OPF) formulation.

A. Locational Marginal Price Based Nodes Selection

The concept of LMP (also referred to as spot pricing) was originally introduced in [19], and is usually derived from either the AC or DC model of the OPF formulation. However, the existence of strong NP-hardness of the AC-OPF problem [20] and its divergence propensity [21] makes the DC-OPF model a better choice and is widely used in commercial power market software. Many variations of the DC-OPF are available in the literature [21, 22, 23, 24, 25], and the dual interpretation changes are subjected to the primal problem formulation. The below DC-OPF formulation draws its inspiration from [21, 22, 26], intending to develop the various components of LMP.

1) Locational Marginal Price Computation

A DC approximation of the AC-OPF problem typically involves removing the reactive power-flow component from problem formulation and assuming a small voltage angle difference sufficient for linear approximation [21]. These approximations yield the following DC-OPF formulation (4)-(9).

Objective function: $$min \sum_{\forall g}(C_g P_g) \qquad (4)$$

Subject to the following constraints:

$$\sum_{\forall k_{(\leftarrow n)}} P_k - \sum_{\forall k_{(n\rightarrow)}} P_k + \sum_{\forall g} P_g = P_n \,\forall n \qquad (\tau) \qquad (5)$$

$$-P_k \geq -P_k^{max} \,\forall k \qquad (\tilde{\alpha}) \qquad (6)$$

$$-P_k \geq P_k^{max} \,\forall k \qquad (\bar{\alpha}) \qquad (7)$$

$$Im(Y)\,(\theta_n - \theta_m) - P_k = 0 \qquad (\bar{\bar{\beta}}) \qquad (8)$$

$$-P_g \geq -P_g^{max} \qquad (\overbrace{\beta}) \qquad (9)$$

The objective function and optimization constraints of the DC-OPF formulation are explained as below:

Equation 4: *Objective function*: The objective function is to minimize generation cost while being subjected to the constraints (5) – (9).

Equation 5: *Node's real power balance constraint*: The constraint balances the real power consumption of node *n* with the incoming and outgoing real power-flow through the node's associated branches and the generation associated with the node. The dual variable for this constraint is τ.

Equations 6 and 7: *Branch power-flow constraint*: The power-flow through a branch is constrained to its maximum thermal limit. Given that power-flow is a direction vector, two sets of equations are derived. The dual variables for these two constraints are $\tilde{\alpha}$ *and* $\bar{\alpha}$.

Equation 8: *Power-flow constraint*: With sufficient small voltage angles between two nodes, real power-flow can be approximated, as shown in (8). The dual variable for this constraint is $\bar{\bar{\beta}}$.

Equation 9: *Generator constraint*: This equation denotes the generator's upper power limit, assuming that the generator can be ramped down to a minimum power level of zero. The dual variable associated with this constraint is $\overset{\sim}{\overset{\frown}{\beta}}$.

The objective function of the dual formulation based on the primal problem formulation (4)-(9) can be expressed as (10).

$$max\ (\textstyle\sum_n \tau\, P_n\ -\ \sum_k P_k^{max}\tilde{\alpha}\ +\ \sum_k P_k^{max}\bar{\alpha}\ - \sum_g P_g^{max}\overset{\sim}{\overset{\frown}{\beta}})\ (10)$$

Assuming no duality gap exists, optimality (11) will hold. As can be seen, the cumulative load payment of the system ($\sum_n \tau\, P_n$) is the cumulative sum of all the generation cost ($\sum_{\forall\, \mathrm{g}}(C_g P_g)$), congestion rent ($\sum_{\mathrm{k}} P_k^{max}\tilde{\alpha}\ -\ \sum_k P_k^{max}\bar{\alpha}$) and generation rent ($\sum_g P_g^{max}\overset{\sim}{\overset{\frown}{\beta}}$).

$$\textstyle\sum_n \tau\, P_n = \sum_{\forall\, g}(C_g P_g) + \sum_k P_k^{max}(\tilde{\alpha}\ -\ \bar{\alpha})\ + \sum_g P_g^{max}\overset{\sim}{\overset{\frown}{\beta}}\ (11)$$

The cumulative load payment of the system ($\sum_n \tau\, P_n$) is of particular interest, given this term is composed of the real power load at node (n), and the LMP (τ) at the node. As such, assuming strong duality holds, the LMP of each node accounts for generation cost, congestion cost, and generation rent and can be used as a suitable representation of the grid to select the mining and forging nodes.

2) *Characteristics of Locational Marginal Price*

LMP is the incremental cost to withdraw 1 MW of energy from an electrical node and reflects a price proportional to the power system's constraints [21]. An interesting property of LMP is its dynamic nature, in the sense that real-time LMP of electrical nodes varies over time based on the generation and load levels at individual nodes and ongoing outages of electrical flow gates. The dynamic nature of LMP proves to be valuable in preventing systematic gaming of the electric grid, as there are no probabilistic methods to predict node prices without solving the DC-OPF problem in real-time. The dynamic nature of LMP is demonstrated through an example case study.

Example Case: Using a three-node example, as shown in Fig. 1, while simulating a DC-OPF using AMPL, results in an LMP$_{(a)}$ at \$80/MWh, LMP$_{(b)}$ at \$45/MWh, and LMP$_{(c)}$ at \$115/MWh. Under the present network scenario, node B is ideal to be selected as a mining node, given the low nodal energy price, while node C may serve as a validator node.

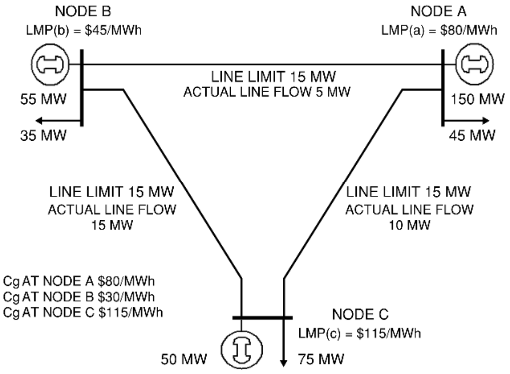

Fig. 1. LMP calculation through simulation for a three-node network

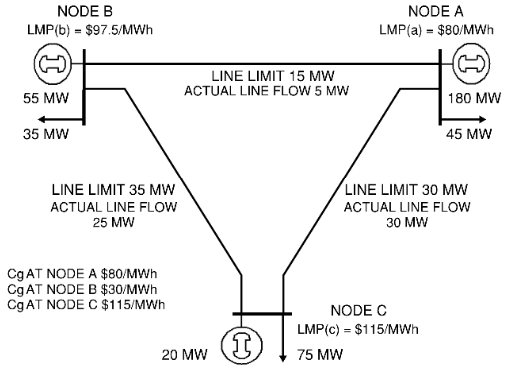

Fig. 2. LMP redistribution following a system transmission capacity increase

A mere transmission capacity upgrades on this three-node network for branch A-C and B-C will drastically change the nodal pricing, as shown in Fig. 2. With new thermal ratings of 30 MW for branch A-C and 35 MW for branch B-C, the LMP$_{(b)}$ changes to \$97.5/MWh. Under the modified network topography, node A turns out to be the cheapest node and best suited to serve as a mining node, with node C still qualifying as a validator node. For simulation purposes in both cases, the maximum generator real power output was constrained at 250 MW for nodes A and C, and 55 MW for node B.

3) *Selection of Miner and Validator Nodes from Locational Marginal Price*

A pricing distribution can be derived based on the LMPs of all the system nodes. Extreme value nodes beyond certain thresholds (both higher and lower values) may then be selected as forging and mining nodes, respectively. Fig. 3 shows the hourly day-ahead LMP distribution plot of all the system nodes of the US energy region ISO New England (ISO-NE) [27] for August 1st, 2020. The right-skewed frequency distribution represents a higher number of mining nodes than forging nodes, thus favorably providing sufficient hashing power. Distribution density plot analysis for all remaining months of the year reveals sufficient separation between the extreme values for distinct node segregation.

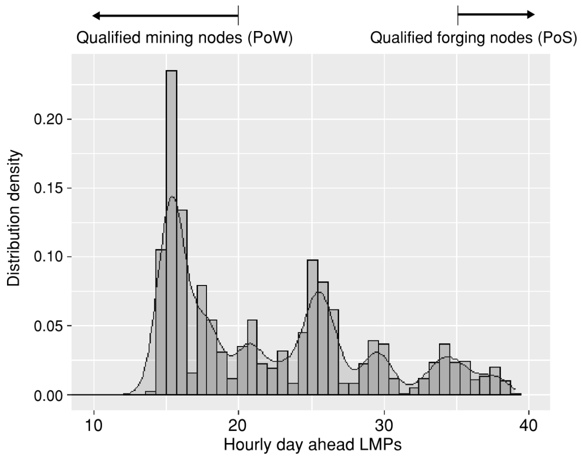

Fig. 3. Distribution density plot of the hourly day-ahead LMP for node segregation

4) Validity Assessment of Miners by Proof-of-Stake Voters

The nature of the LMP distribution plot will inherently enforce node segregation between miners and forgers, effectively preventing collusion. On the other hand, the forger (validator) needs to perform several checks on the newly minted block, such as validation of the last block hash, validation of the signature of the transactions, validation of the block count, and validation of the transactions against the publicly broadcasted set of transactions.

A potential form of network attack vector exists and has been reported in [28] where a malicious network node using the same public key and the broadcasting node may broadcast similar set transactions and the issue requires further discussion.

Given PoW mining follows a Poisson process, the fraudulent node may be successful in guessing the next mined block's timing and can time the broadcast of these fraudulent transactions. The PoS validators validating the PoW block transaction might notice these transactions as contradicting entries resulting in a majority vote to reject the mined block. A sustained network attack of this form could essentially create a backlog of transactions and freeze the network. To prevent this attack vector from gaining an advantage, the validators node needs a timing function. A timing function of this nature essentially segregates real transactions arriving from a node address (while some transactions from this node address are already present in the PoW block) versus fake transactions originating from this node aimed to prevent a block validation. The timing function essentially takes advantage of the fact that even with the network's broadcasting latency, real transactions from a node address are likely to be broadcasted with a smaller time difference than a set of malicious attack transactions, where the attack node guesses the time of the next mined block. A Gudermannian function (12) is thus proposed to act as a timing filter, with ΔT as the time difference between the present time and the discovery time of the transaction. If the timing filter's output score is more than a certain threshold, the validator blocks are made aware of an attack attempt and may choose to scrutinize the transactions' validation against the publicly broadcasted set of transactions before validation.

$$gd(\Delta T) = 2tan^{-1}\left[tanh\left(\frac{a}{2}\Delta T\right)\right] \quad where\ \Delta T \geq 0 \qquad (12)$$

Table I shows two scenarios and the Gudermannian output score being used to distinguish potential transactions from fraudulent ones originating from the same node under the scenario described above. Scenario 1 involves several transactions with the minimal time difference between the present network time and the transaction's discovery time and possibly indicates network latency. These transactions are most likely valid and should be added to the memory-pool to be picked up for mining by the next block. Gudermannian output score from scenario 2 involves a much larger time difference beyond possible network lags and is beyond the cumulative cutoff threshold. The transactions in this scenario indicate a possible network attack attempt. The blockchain validators much ignore these transactions, given these require further scrutiny. Network addresses with fraudulent, duplicate transactions detected by the Gudermannian function's output score may be blocked and flagged for further investigation.

TABLE I. GUDERMANNIAN OUTPUT SCORE FOR TRANSACTION CLASSIFICATION

Scenario 1[a]		*Scenario 2*[a]	
Time difference (ΔT)	***Gudermannian output score***	***Time difference (ΔT)***	***Gudermannian output score***
0.001	0.00399	0.039	0.11673
0.014	0.04198	0.055	0.16425
0.0162	0.04858	0.162	0.46792
0.052	0.15537	1.320	1.53267
$\sum \Delta T$	0.24893	$\sum \Delta T$	2.28159

[a] Assuming an 'a' value of 3 and an output cutoff score as 0.3

B. Design Considerations in the Blockchain Protocol Layer

A blockchain protocol layer running a hybrid consensus algorithm and aimed to serve energy applications need to account for a few design considerations, as discussed in this section.

1) Difficulty and Reward Adjustments

The proposed hybrid consensus is expected to serve as a transaction and smart-contract platform in major energy regions with commercial and private energy users participating in the network. Further, given the dynamic nature of the LMP spread, appropriate cutoff values can always be selected to only include a certain number of nodes as qualified mining nodes. Under these conditions, the blockchain's initial difficulty may be set such the average time for mining a block, under a Poisson process, is an integral multiple of the LMP refresh rate (δ). As such, most independent system operators (ISOs) in the US updates their LMP every five minutes [29].

If large electrical areas are integrated into the current operating region's electrical footprint, a difficulty adjustment might be necessary and can be accomplished using a process similar to (13a,b).

$$Difficulty = \frac{HEX(Max-target)}{HEX(Current-target)} \qquad (13a)$$

$$s.t.\ Pois(\lambda) = n\delta, \forall\, n \in I\ or\ \frac{1}{I} \qquad (13b)$$

Reward adjustment, on the other hand, should reflect a factor to include an average time required to set up new greenfield electrical transmission and distribution nodes (X). Assuming a new block under a hybrid consensus is mined every five minutes on average, two hundred and eighty-eight blocks are expected per calendar day. The current block reward (ω_n) can then be computed using the initial block reward at genesis (ω_i) and a decrement factor (ε), as shown in (14).

$$\omega_n = \omega_i(1-\varepsilon)^{\left(\frac{Block\ height}{288X}\right)}, \forall\, \varepsilon << 1 \qquad (14)$$

2) ASIC Resistance and Hashing Algorithm

Though it is implausible for any hashing algorithm to be utterly resistant against an ASIC implementation, a large memory utilization requirement capable of preventing parallelization or pipeline [30] is usually a strong deterrent. Two other approaches [31] in the construction of the ASIC-resistant

PoW algorithm consist of either using several hash functions to calculate the valid state of the block (multi-hash PoW) or selection of mathematic functions from a large pool for hashing, thereby rending specialized hardware useless (programmatic PoW).

A hashing algorithm for the given hybrid consensus needs to demonstrate some form of ASIC resistance to ensure no mining node enjoys an unfair advantage compared to CPU/GPU users. At present, Equihash, Ethash, SHA3, and its variants SHAKE 128 and SHAKE256 are among the popular algorithms that are reported to be reasonably ASIC-resistant [4, 32].

3) *Transaction Block Weight*

To prevent a denial-of-service attack (DoS attack), the legacy Bitcoin nodes required a block size to be less than 1 Mb. However, the block size specification severely restricted transaction volumes going into a single block. To accommodate larger transaction volumes and mitigate transaction malleability issues, Bitcoin introduces a soft fork in its transaction format, named Segregated Witness. A similar block architecture may be implemented for the hybrid consensus, where the block size is limited to 4 Mb, with 1 Mb of space given to store transactions and 3 Mb to hold the witness data. However, two separate size limitations would make the miner's transaction fee estimation extremely difficult. To solve this problem, block weight [33], as in (15), may be used as a selection factor.

$$Block\ weight\ =\ 3 \times \text{(Base TX size)} + \text{full TX size} \quad (15)$$

4) *Turing Completeness and Gas*

To implement a blockchain transaction environment, as shown in Fig. 4, with the capability of executing obligatory smart-contract agreements, a Turning complete programming language (able to process conditional loops) is required. A Turing complete machine such as the Ethereum Virtual Machine (EVM) also implements a taxation mechanism called 'Gas' to disincentivize programmers writing codes with a heavy looping algorithm.

Modern blockchain transaction platform featuring smart contract should implement some version of the EVM's taxation mechanism to provide incentives for developers to write efficient codes, resulting in faster execution time.

5) *Exponentially Weighted Moving Average of LMP to Account for Extreme Volatility*

Though relatively rare, real-time LMP may experience market volatility [34] triggered by factors such as fluctuations in fuel cost, short-term increase in peak load, and transmission line switching. Extreme volatility within a short time may interfere with the mining nodes' capacity to solve the hash puzzle. To prevent such interference, the node selection algorithm may choose to switch to an exponentially weighted moving average (EWMA) model of real-time LMP, as shown in (16), if high volatility is detected using typical statistical standard deviation tests.

$$LMP_t^{EWMA} = \begin{cases} LMP_1, \forall\ t = 1 \\ \alpha LMP_t +\ (1-\alpha)LMP_{t-1}^{EWMA}, \forall\ t > 1 \end{cases} \quad (16)$$

The first step of the hybrid consensus mechanism begins with the selection of mining and forging nodes. The proposed LMP based node selection method is outlined in Algorithm 1. LMP nodal pricing at a node (n) for a give time instance (t), LMP_n^t, are updated every five to ten minutes across all the major US ISOs. The upper and lower LMP cutoff values, C_{min} and C_{max}, may be established using the standard deviation of the distribution from its mean value.

```
Input: LMP nodal price at node n at time t ($LMP_n^t$), market-timer ($t_m$), upper LMP cutoff ($C_{max}$), lower LMP cutoff ($C_{min}$)
Output: Set of mining nodes ($l_n$), set of forging nodes ($u_n$)
LMP node selection:
Set $t_m$ to zero
Track market-timer for next set of nodal pricing output
while TRUE
        if $LMP_n^t$ != $LMP_n^{t-1}$
                c = 0
                $l_n$ = []
                $u_n$ = []
                if hist(sum of nodes($LMP_n^t$)) ≤ $C_{min}$
                        c = c+1
                        $l_n[c] = LMP_n^t$
                else if hist(sum of nodes($LMP_n^t$)) ≥ $C_{max}$
                        c = c+1
                        $u_n[c] = LMP_n^t$
        return $l_n[c]$, $u_n[c]$
end
```

V. Application of Hybrid Consensus in Energy Blockchain and Smart Contract Applications

The tokenization of energy can accomplish energy exchange in a blockchain ecosystem. As demonstrated in Fig. 4, an independent system operator of the electric grid may generate a certain number of tokens, 50,000 tokens in this case, as a part of an initial coin offering (similar to an initial public offering for stock markets). Some token may be reserved for research and development, while the remaining might be exchanged in a primary cryptocurrency-exchange market. These tokens' primary holders may use them for smart contract-based obligatory transactions or exchange them in a secondary cryptocurrency-exchange market, very similar to how stocks are trader in the primary and secondary market.

Other energy-specific applications are highlighted in this section in addition to energy tokenization. The most impressive of these applications involve smart contract executions in day-ahead, real-time, and financial transmission rights (FTR) based energy markets.

A. *Microgrids for Local Energy Trading*

Microgrids' importance has recently received much attention in the US due to the growing number of transmission grid induces wildfires in states like California, Oregon, and Washington [25]. In a local community, the exchange of power, backed by roof-top solar energy with a slim backbone transmission grid, is gaining traction. Microgrid users may record their transactions and execute obligatory smart contracts using a blockchain platform with the secured and energy-efficient hybrid PoW-PoS consensus algorithm.

B. *Tracking of Carbon Credits*

Carbon credits have been used for a long time to limit pollution by companies producing energy from conventional energy resources. Companies not using enough of their carbon credits often sell them to companies in need of those credits. A blockchain platform can provide a secured immutable platform between the regulatory authority and the utilities, enabling the regulatory body to enforce emission limits using smart contracts and allowing utilities to exchange carbon credits on a secured platform.

C. *Energy Trade Executions Using Smart-Contracts*

Significant portions of the US energy grid are operated by independent system operators (ISOs) to check systematic gaming and monopoly and ensure competitive energy pricing. To reduce price volatility, market participants often commit to buy or sell energy in a day-ahead market, whereas the differences are fulfilled in the real-time energy market. All market transactions and contract agreements of this nature can be transitioned to a safe and secured blockchain platform, allowing the grid operators to transact with commercial or private users using a standard token system.

US-based ISOs also have a market around FTRs, where market participants transact financial instruments to hedge congestion cost or arbitrage the price difference. Like stock exchanges, these transactions records are stored in centralized databases, posing a security vulnerability. Blockchain technology can provide a secured decentralization platform for the FTR markets while reducing overhead fees and helping with regulatory reporting requirements.

VI. Conclusion

Currently, existing popular consensus algorithms have several limitations preventing the widescale implementation of blockchain technology for energy applications. A secured and energy-efficient consensus algorithm such as the one proposed in this paper has tremendous potential to help the proliferation of blockchain technology specific to energy grid applications. Locational marginal price is an integral part of many restructured power markets and can be used to select a set of qualifying nodes for blockchain mining and validation. From an implementation standpoint, design considerations such as reward and difficulty adjustments, the choice of a suitable hashing algorithm, and nodal pricing volatility must be made to provide a stable and scalable platform.

Among its many potential applications, the blockchain technology may be used in day-ahead and real-time market-based transactions, microgrid contract obligations, and escrow payments from electric vehicle users. An underlying hybrid consensus algorithm that is secured, energy-efficient, and capable of handling high volumes of transactions can play a crucial role in modern electric smart grids.

***Abstract*—Multiplication is a key process in various applications. Consequently, the multiplier is a principal component in several hardware platforms. For multiplication of signed integers, radix-4 booth multipliers are widely used as they reduce the number of partial products to half. Several approximate multipliers for radix-4 booth multiplication have been presented in recent times to achieve energy efficiency. However, the errors displayed by these multipliers make them unsuitable for lossless applications. For these applications, accurate radix-4 booth multiplication is much needed. In this paper, we introduce an optimized algorithm and multiplier for accurate radix-4 booth multiplication. The algorithm reduces the number of bits that participate in the addition process during multiplication. At the same time, the algorithm has sufficient storage area for reduced design complexity in its multiplier. The multiplier gives promising results of 100% when tested for accuracy for a wide spectrum and all possible cases of multiplicand-multiplier pairs. Besides, the multiplier is shown to be cost-effective. Lastly, we compare our multiplier with the current radix-4 booth multipliers in terms of key error parameters to highlight its accuracy.**

***Index Terms*—Accurate, Cost-effective, Radix-4, Booth multiplier, Lossless applications.**

I. Introduction

Several machine learning and digital signal processing applications are highly influenced by the multiplication process. For instance, multiply-accumulate operations account for more than 90% of the computations in convolutional neural networks. Hence, the multiplier is a key component in various hardware platforms. Radix-4 booth multiplication is widely used for the multiplication of signed binary integers since it reduces the number of partial products by half compared to the conventional multiplication process.

Research in radix-4 booth multiplication made a shift from accurate to approximate computing design paradigm which constructs energy-efficient circuits at the cost of a little accuracy. Researchers have devised several radix-4 booth multipliers based on this emerging paradigm [1]–[10]. However, the errors featured by these multipliers are not tolerable by lossless applications. Besides, cost is another important parameter in the context of multiplier design. Therefore, there is a need for a cost-effective multiplier for accurate radix-4 booth multiplication.

In an attempt to address the above requirement, we introduce an accurate, cost-effective radix-4 booth multiplier in this paper. Initially, we devise an optimized algorithm for accurate radix-4 booth multiplication by reducing the number of bits that participate in the addition process during radix-4 booth multiplication while having sufficient storage area for reduced hardware design complexity. The accuracy of the multiplier is tested for a wide range and all possible cases of multiplicand-multiplier pairs. The cost of the multiplier circuit and its operations are critically analyzed. Besides, the proposed multiplier's accuracy is compared with the current radix-4 multipliers in key error parameters viz., Mean Relative Error Distance (MRE/MRED), Normalized Mean Error Distance (NMED), and Probability Relative Error Distance (PRED).

The remainder of the paper is organized in the following manner: The current radix-4 booth multipliers are discussed in Section II. The proposed algorithm and multiplier for accurate radix-4 booth multiplication are presented in Section III. Section IV critically analyzes the accuracy and cost-effectiveness of the multiplier. Besides, the proposed multiplier's accuracy is compared with the current radix-4 booth multipliers. Section V summarizes this work.

II. Literature Review

This section presents the summary of the current research work regarding radix-4 booth multiplication.

Liu *et al.* [1] presented ”two approximate radix-4 booth encoding algorithms” viz., ”R4ABE1 and R4ABE2”. They also designed ”two approximate booth multipliers: R4ABM1 and R4ABM2”, based on the algorithms with an approximate wallace tree structure in place. In this work, the energy efficiency of the multipliers is decided by a parameter called the approximation factor. Among the two multipliers, R4ABM2 produces relatively more error. For the approximation factor 2, it produces MRED, NMED, and PRED of 0.344×10^{-2}, 0.2543×10^{-5}, and 99.79% respectively. Whereas, for the approximation factor 32, it produces the highest error with MRED, NMED, and PRED of 2.52×10^{7}, 17879×10^{-5}, and 0.123% respectively.

In [2], the authors devised ”an approximate hybrid high radix encoding” to generate the partial products for signed multiplication. In this technique, ”accurate radix-4 encoding” is used to encode the Most Significant Bits (MSBs), and ”approximate higher radix encoding” is used to encode the Least Significant Bits (LSBs). ”Three approximate multipliers: RAD64, RAD256 and RAD1024”, are presented. Of the three multipliers, RAD1024 produces the highest error with an MRE of 0.93% and PRED of 93.26%. The authors did not consider evaluating NMED in this work.

Ansari *et al.* [3] presented "an improved, approximate 4:2 compressor", in which generate and propagate signals are used for encoding the inputs. This has resulted in the reduced number of flawed rows in the truth table of the compressor. Based on this compressor, the authors designed "an approximate multiplier called CABM". CABM produces MRED and NMED of 0.014 and 0.18 respectively.

"Three approximate radix-4 booth multipliers: ABM-M1, ABM-M2, and ABM-M3", are proposed in [4]. In each of the multipliers, a unique approximation technique is employed which encompasses reduction in the logic complexity of "booth partial product generator" and "partial product accumulation". Among the three multipliers, ABM-M2 generates the highest error with MRED and NMED of 2.689×10^{-2} and 1087.270×10^{-6} respectively.

The authors of [5] designed "two approximate multipliers: LOBO10 and LOBO12", using "radix-4 booth encoding" and "logarithmic product approximation". The multipliers encode the MSBs using accurate radix-4 booth encoding and approximate the higher radix partial products arising from the LSBs using logarithmic approximation. Of the two multipliers, LOBO12 generates the highest error with MRE, NMED, and PRED of 0.44-96.09%, 18.45×10^{-4}, and 90.99% respectively.

[6] introduces "two approximate multipliers: HLR-BM1 and HLR-BM2", based on hybrid low radix encoding. In this work, the odd multiples of radix-8 are approximated to their nearest powers of two to fix the low-performance issue of radix-8 booth encoding. Among the two multipliers, HLR-BM1 produces the highest error with MRE, NMED, and PRED of 0.03%, 0.79×10^{-5}, and 98.35% respectively.

The aforementioned approaches are inclined to approximate computing design paradigm which aims to construct energy-efficient circuits at the cost of a little accuracy. Not all applications are inherently resilient to accuracy loss. For instance, lossless applications such as medical image compression have zero tolerance to accuracy loss. Besides, the approximate encoding techniques discussed in the aforementioned approaches are based on accurate radix-4 encoding. This signifies the importance of accurate radix-4 encoding in the context of signed multiplication. We present a novel algorithm and cost-effective hardware design for accurate radix-4 booth multiplication in the next section.

III. Proposed Algorithm and Multiplier

In this section, we introduce our algorithm and multiplier for accurate radix-4 booth multiplication.

A. Algorithm

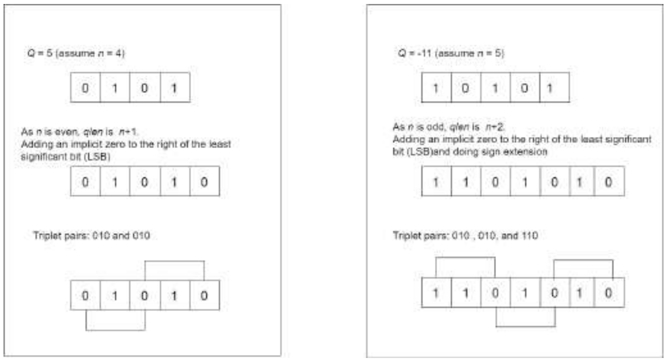
The proposed algorithm is illustrated in Algorithm 1. We have the input variables $'m'$ and $'q'$, two decimal integers converted into two's complement binary integers of length $'n'$ bits each, where $'n'$ is calculated as the maximum of the number of bits used to represent $'m'$ and $'q'$ as binary numbers.

Algorithm 1 Optimized radix-4 booth multiplication.

```
Input: Two integers $'m'$ and $'q'$ in decimal form.
Output: Product of $'m'$ and $'q'$.
1. Convert $'m'$ and $'q'$ into binary numbers of $'n'$ bits
2. if $(n\%2 = 0)$, then
      $qlen \leftarrow n + 1$
   else
      $qlen \leftarrow n + 2$
   end if
3. Declare arrays $M[n]$, $C[1]$, $A[n]$, $Q[qlen]$
4. $A \leftarrow 0$
5. $M \leftarrow$ binary equivalent of $'m'$
6. $L \leftarrow ceil(n/2)$
7. $C \leftarrow 0$
8. $Q[0 : qlen - 2] \leftarrow$ binary equivalent of $'q'$
9. $Q[qlen - 1] \leftarrow 0$
10. Check whether, in $Q$, groups of 3 bits are being
      formed or not. If not, do sign extension
11. Compute the values of $+2M$, $-2M$, $-M$ and store them
      in arrays $Plus2M[n + 1]$, $Minus2M[n + 1]$, and
      $MinusM[n]$
12. while $L > 0$, do
      if $Q[qlen - 3 : qlen - 1] = 000$ or $111$, then
         $c \leftarrow 0$
         $a \leftarrow A[0]$
      else if $Q[qlen - 3 : qlen - 1] = 001$ or $010$, then
         $c \leftarrow M[0]$
         $a \leftarrow A[0]$
         $A \leftarrow A + M$
      else if $Q[qlen - 3 : qlen - 1] = 011$, then
         $c \leftarrow Plus2M[0]$
         $a \leftarrow A[0]$
         $A \leftarrow A + Plus2M$
      else if $Q[qlen - 3 : qlen - 1] = 100$, then
         $c \leftarrow Minus2M[0]$
         $a \leftarrow A[0]$
         $A \leftarrow A + Minus2M$
      else if $Q[qlen - 3 : qlen - 1] = 101$ or $110$, then
         $c \leftarrow MinusM[0]$
         $a \leftarrow A[0]$
         $A \leftarrow A + MinusM$
      end if
      $Cout \leftarrow$ carry out after binary addition
      $C \leftarrow Cout \oplus a \oplus c$
      if $C = 0$, then
         $LRS(A\$Q)$ by 2 times
      else
         $ARS(C\$A\$Q)$ by 2 times
      end if
      $L \leftarrow L - 1$
    end while
13. $res \leftarrow (A\$Q[0 : qlen - 2])$
14. $prod \leftarrow$ decimal form of $res$
15. return $prod$
```

The following arrays are used: M ($'n'$ bits) to hold the binary representation of $'m'$, C (1 bit) to hold the carry, and A ($'n'$ bits) to hold the intermediate summation results of the partial products in binary representation. The array Q to hold the binary representation of multiplier $'q'$ has some additional components. After converting $'q'$ to a binary number, an implicit zero is added to the right of the LSB.

The crux of radix-4 booth multiplication is to convert the multiplier in its binary form into a recoded multiplier by checking whether successive triplets (groups of 3 bits) are being formed or not, starting from LSB. Therefore, after adding the implicit zero, the aforesaid condition is checked, and if it's not satisfied, sign extension is done to complete the triplet. The process of forming the triplets is shown in Fig. 1.



Q = 5 (assume n = 4)
0 1 0 1
As n is even, qlen is n+1.
Adding an implicit zero to the right of the least significant bit (LSB)
0 1 0 1 0
Triplet pairs: 010 and 010
0 1 0 1 0
Q = -11 (assume n = 5)
1 0 1 0 1
As n is odd, qlen is n+2.
Adding an implicit zero to the right of the least significant bit (LSB)and doing sign extension
1 1 0 1 0 1 0
Triplet pairs: 010 , 010, and 110
1 1 0 1 0 1 0

Fig. 1: Triplets formation.

Sign extension will be needed only when $'n'$ is odd. Thus, Q is $n+1$ bits long if $'n'$ is even, and $n+2$ bits long if $'n'$ is odd.

To save repeated computations, the values of $+2M$, $-2M$, $-M$ are computed beforehand as follows:

- $-M$ is the 2's complement of multiplicand $'m'$ and is stored as a binary number in array $MinusM$ ($'n'$ bits)
- $+2M$ is the binary representation of multiplicand $'m'$, with an added zero at the LSB, and is stored in array $Plus2M$ ($n+1$ bits)
- $-2M$ is the binary representation of the 2's complement of multiplicand $'m'$, with an added zero at the LSB, and is stored in the array $Minus2M$ ($n+1$ bits)

In each iteration, the last 3 digits of Q determine which operation will take place. The variable $Cout$ will have the carry-out value after the addition of A and $M/MinusM/Plus2M/Minus2M$. The variable C takes three intermediate variables and performs eXclusive-OR (XOR) operation on them, denoted by $\oplus$ operator in the algorithm. C determines whether to carry out Logical Right Shift (LRS) or Arithmetic Right Shift (ARS). The final product is the concatenation (denoted by \$ operator) of the values in arrays A and Q, where the higher-order half is stored in A and the lower-order half in Q, except for the last bit of Q.

B. Multiplier

Fig. 2 introduces the multiplier for the proposed radix-4 booth multiplication algorithm, for multiplication of two signed integers, both having $'n'$ bits in their binary representation.

The hardware mainly consists of an 8 × 1 Multiplexer (Mux), an n-bit adder, a carry logic, a control sequencer and registers C (1 bit), A ($'n'$ bits), M ($'n'$ bits), $Plus2M$ ($n+1$ bits), $Minus2M$ ($n+1$ bits), $MinusM$ ($'n'$ bits), q_{n+1} (1 bit) and Q ($n+1$ bits). A and Q are shift registers, concatenated as shown in Fig. 2. These registers are analogous to the arrays declared in the algorithm.

The register Q holds the binary representation of the multiplier, including the implicit zero to the right of LSB. If $'n'$ is odd, then the input and output lines to and from the register q_{n+1} are enabled, and the shift line from a_0 to q_n is disabled. In this case, q_{n+1} holds the sign extension bit for Q. If $'n'$ is even, then the input and output lines to and from q_{n+1} are disabled, and the shift line from a_0 to q_n is enabled.

The register M holds the binary representation of the multiplicand, register $MinusM$ the 2's complement representation of M, register $Plus2M$ the binary representation of M after logical left shift by one-bit position, and register $Minus2M$ the binary representation of $MinusM$ after logical left shift by one-bit position.

At the start, the multiplier and the implicit zero are loaded into register Q, the multiplicand into register M, and registers C and A are cleared to 0. The carry logic is essentially an XOR gate whose output is directed to C and the control sequencer.

The product is computed in L cycles (whose value is $ceil(n/2)$), for which the underlying logic is present in the control sequencer. At the beginning of each cycle, the last 3 bits (starting from q_0) of Q are sent to the control sequencer to determine which operation will take place.

A signal from the control sequencer to determine whether the addition of M, $Plus2M$, $MinusM$, $Minus2M$ or no addition takes place, is sent to the 8 × 1 Mux and accordingly M, $Plus2M$, $MinusM$, $Minus2M$ or 0 is sent as the output of the 8 × 1 Mux to the n-bit adder, and its MSB is sent to the carry logic. The MSB of the current value in register A is sent to the carry logic, and A is sent as input to the n-bit adder. The sum from the n-bit adder is sent to A, and the carry-out is sent to the carry logic. The output of the carry logic is sent to C.

Depending on the output of the carry logic, a signal is sent from the control sequencer to C, A, and Q. If the output of carry logic is "0", and if $'n'$ is even, then the logical right shift of A and Q takes place. If $'n'$ is odd, then the logical right shift of A, q_{n+1}, and Q by two-bit positions takes place. If the output is "1", and if $'n'$ is even, then the arithmetic right shift of C, A, and Q takes place. If $'n'$ is odd in this case, then the arithmetic right shift of C, A, q_{n+1}, and Q by two-bit positions takes place.

Together, registers A and Q hold the intermediate partial product while the last 3 bits of Q (starting from LSB) generate the add/no-add signal, which determines the next operation that will take place.

After L cycles, the higher-order half of the product is held in register A, and the lower-order half in register Q (q_n to q_1 bits) when $'n'$ is even, and in registers q_{n+1} and Q (q_n to q_1 bits) when $'n'$ is odd.

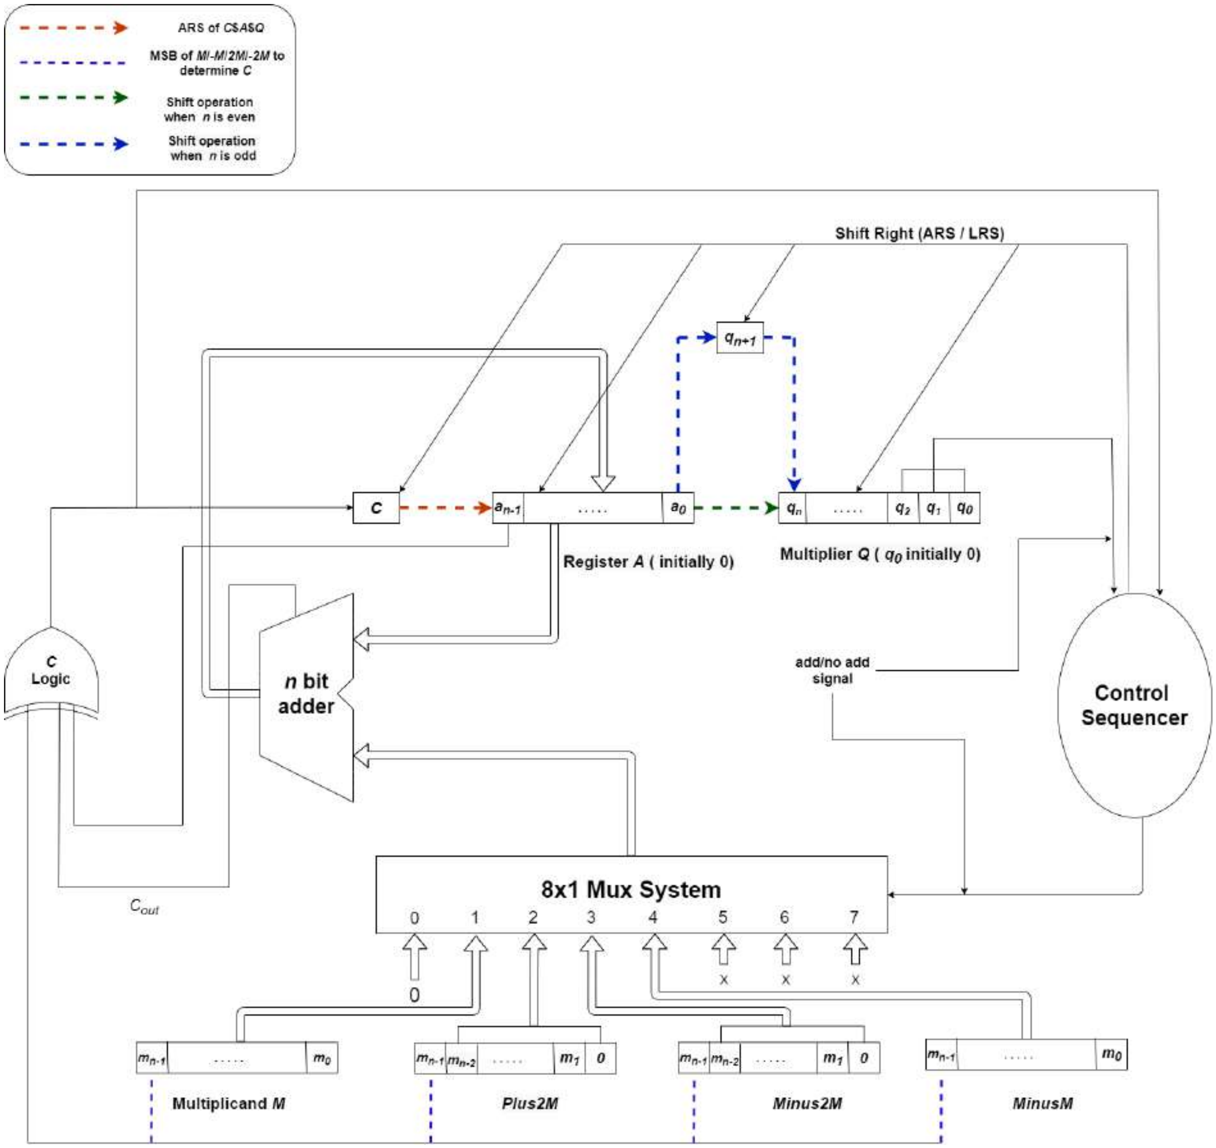


Fig. 2: Proposed radix-4 booth multiplier.

IV. Results and Discussions

The proposed algorithm and multiplier are evaluated for accuracy and cost-effectiveness in this section. Besides, the proposed multiplier's accuracy is compared with the current radix-4 booth multipliers.

A. Accuracy

Fig. 3 presents the code snippet where inputs over a range of integers are sent to the algorithm to check the algorithm's accuracy.

As shown in Fig. 4, the algorithm's accuracy is tested for 50 random integer pairs, each pair consisting of a multiplicand and a multiplier, in the range of -5000 to 5000.

At first, the product for each integer pair is calculated by the computer. Then, the integer pairs are sent to the algorithm to calculate their products. Finally, the products from the algorithm are compared with the actual products to test the accuracy of the algorithm.

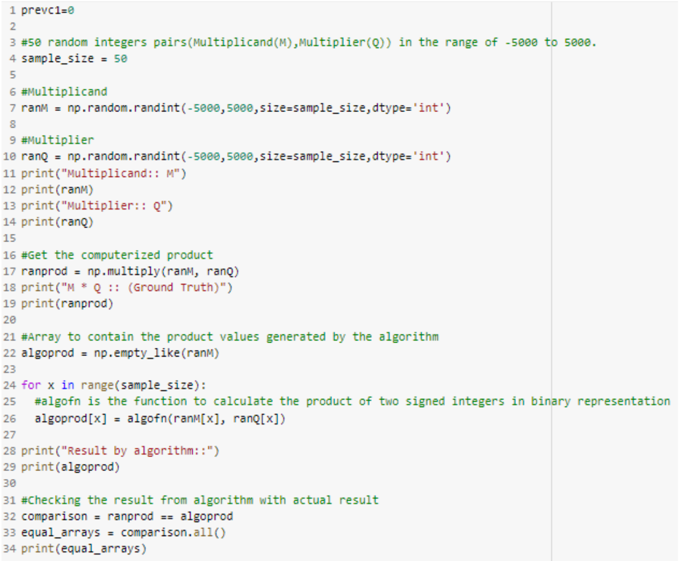
The accuracy of the algorithm is also tested for 4 different cases of multiplicand and multiplier values as presented in Figures 5, 6, 7, and 8 respectively.

To test the accuracy of the algorithm for a wide range of inputs, the sample size is increased to 10,000, for which the algorithm gave the correct results.

B. Cost of the circuit and operations

Our algorithm presents a cost-effective strategy for the implementation of radix-4 booth multiplication.

The original algorithm makes use of $n+1$ bits for the calculation of the subsequent partial products. In our algorithm, the C logic is a 3-input XOR gate, which reduces the size of registers A and M from $n+1$ to $'n'$ bits, thereby, reducing the number of flip flops by one in each of these registers.



```python
prevc1=0

#50 random integers pairs(Multiplicand(M),Multiplier(Q)) in the range of -5000 to 5000.
sample_size = 50

#Multiplicand
ranM = np.random.randint(-5000,5000,size=sample_size,dtype='int')

#Multiplier
ranQ = np.random.randint(-5000,5000,size=sample_size,dtype='int')
print("Multiplicand:: M")
print(ranM)
print("Multiplier:: Q")
print(ranQ)

#Get the computerized product
ranprod = np.multiply(ranM, ranQ)
print("M * Q :: (Ground Truth)")
print(ranprod)

#Array to contain the product values generated by the algorithm
algoprod = np.empty_like(ranM)

for x in range(sample_size):
  #algofn is the function to calculate the product of two signed integers in binary representation
  algoprod[x] = algofn(ranM[x], ranQ[x])

print("Result by algorithm::")
print(algoprod)

#Checking the result from algorithm with actual result
comparison = ranprod == algoprod
equal_arrays = comparison.all()
print(equal_arrays)
```

Consequently, we avoided the binary addition on that extra bit taking place in each iteration. Hence, the total number of binary additions avoided is equal to the total number of iterations in the multiplication process. This C logic is also the reason for the size of the adder to be $'n'$ bits. Thus, the proposed C logic reduces the cost of the circuit and operations.

Secondly, in contrast to the original algorithm, where the values $-M$, $+2M$, and $-2M$ are computed every time they are needed, in the proposed architecture, they are computed only once irrespective of the number of times they are required for the multiplication process because they are stored in the dedicated registers viz., $MinusM$, $Plus2M$, and $Minus2M$. The presence of these dedicated registers also reduces the design complexity of the architecture.

C. Comparison of different radix-4 booth multipliers

Table I compares the different radix-4 booth multipliers in terms of key error parameters namely MRE/MRED, NMED, and PRED. It is evident from the table that, the proposed multiplier is very accurate compared to the current multipliers.

V. Conclusion

In this work, we introduced an accurate, cost-effective radix-4 booth multiplier. We optimized the method to multiply two signed binary integers using radix-4 booth multiplication, by reducing the number of bits that participate in the addition process while having sufficient storage area for reduced hardware design complexity. We also designed a high-level architecture for the same. Using the proposed algorithm as the blueprint, we compiled a program to compute the product of two signed integers (in Python) and hence evaluate the algorithm's viability. We achieved promising results i.e 100% accuracy when we tested it against a sample size of 10,000 random integer pairs in the domain of (-5000,5000). We also compared it with the current radix-4 booth multipliers in specific key error parameters and showed that our algorithm performed better in terms of accuracy. We also showed how our algorithm is successful in being more cost-effective as compared to the original methodology by critically analyzing the cost of the multiplier circuit and its operations. The proposed algorithm can be used in several machine learning and digital signal processing applications like convolutional neural network computations. It can also be used in lossless applications which are highly intolerable of errors. Future work is to simulate the hardware architecture and evaluate the same in terms of energy efficiency.

Security Procedures for User-Centric Ultra-Dense 5G Networks

Mohammed Rajhi
Department of Computer Science and Networking
Jazan University
mrajei@jazanu.edu.sa

***Abstract*— The super-compressed network is a forthcoming 5G that can without difficulty attend to network system sufficiency concerns. To be able to attain the uncontrolled and diminutive base station placement, the need for UDN (Ultra-Dense Network) architecture can't be overemphasized. This paper takes the route of the UDN architecture plan, including the remonstrance's it comprises of with adding the security demands and procedure to deal with them. The new security procedure is fashioned after the implicit certificate or IC scheme, which decides the APS's security issues. The security process involvesthe APG (APs Group) security, network security domain, AP (Access Point) access security, UE (User Equipment) to UUDN (User-centric Ultra-Dense Network) access network security, dual authentication in addition to expanded keys.**

***Index Terms: Ultra-Dense network, User Centric, Security Challenges*, 5G.**

I. Introduction

Data traffic is about to witness great innovations in years not so distant away. End-users' device and wireless systems are growing rapidly, which will allow the introduction of new and better mobile applications. Due to this, a rising number of flexible organizations limit will be substantial for previous 2020 social orders, not particularly to achieve the excellent climb of client traffic acquired from these new compact broadband administrations most likely to also put intoconsideration the surplus supply of devices needed for their use [1]. To demonstrate the 5G network, the most suitable rundownis the ultra-dense networks (UDNs). UDNs works with the utmost traffic necessities through infrastructure densification. (9-1). Bestirred by the inability of new introductions to effectuate such requirements, the researched network has during the recent decade been working effectively towards establishing the understructure of the current Fifth Generation (5G) for the wireless networks. UDNs, in comparison to the latest traditional deployments, make use of denser arrangement for the access point [1]. The organizational disposition of more BSs or reception apparatuses per unit territory constitute the assets' spatial reuse. In the aftermath, more assets can be distributed toall client, bettering the previous information rates communicated to them. The last constituent remodels UDN into a doubtlessly suitable condition for the application of Millimeter-Wave, where a large percentage of data transfer capacity enables exceedingly high throughput under LOS situations [2][1]. To increase network adequacy, densification has been proven to be the most direct mechanism. Nevertheless, there are some factors that limit the dense network, as they tendto cause a high volume of inference. So, there is the need for further studies to figure out the limits by making use of new models. The application of DAS (Distributed Antenna Systems) is another technology that can maximize network capability. It is like a natural facilitator for the Millimeter-Wave for indoor placement.

Details	Traditional Cellular Network	Ultra-Dense Network
Access Point Density	Lower than user density	Comparable to the user density
Coverage	Hundred meters and more	Almost 10 m
Characteristics of Coverage	Regular cell, single layer	Heterogeneous, irregular
Backhaul	Wired, ideal	Ideal, non-ideal, wired, wireless
User Density	Low	High
Mobility	High	Low
Spectrum Bands	Low, limited	Higher, wider
Data Rate Requirement	Lower, Medium	High
Deployment	Wider coverage	Indoor, hotspot
Access point type	Macro, Macro Base Station	Small cell, relay, UErelay

Table 1.1 Comparison between Traditional Cellular Network and UDN.

A. *Ultra-Dense Network*

UDN is intent on giving a comparatively high data usage to every consumer indoor and in hotspot areas, including offices, packed residential places, arenas, and open-air-converging points, and many more [7]. Area spectrum efficiency becomes one of the key metrics to determine future mobile systems for extremely dense traffic demands [8], and then influences system capacity. A type of UDN consist of the static virtual cell that has quite the number of access points by which a small static cell can be created and can likewise accord the same coverage. User-centric is a different type of UDNs that can integrate with the local control center same as with the user, and relying on the unit of the single user, the virtual combined cell is elucidated. There are some standards and procedures that are illustrated simply reliant on architecture design. Localization and flatten is a practical way to handle 100 times excess traffic. Localization relies on backing from the flattened architecture and therefore reduces the expenses used in the transmission. METIS and NGMN put forward the localization of the data path [13] [14]. UDNs varies from the traditional cellular network which is why the user-centric principle is vital to apply. On the other hand, RAN (Radio access network) is the centralized access network, and the architecture of UDN is crucial here.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

It is able to give a preferable joint processing and thus deliver greater spectrum efficiency, but there is certainly still high potentiality. Apportioned architecture is far more adaptable for the placement process of the network. So the architecture that is farmore adaptable is usually preferred to connect with APS.

B. User-Centric Ultra-Dense Network

The 5G network faces more extensive and intricate security peril compared with the now 3G and 4G networks. It customary security dangers are remembered for it many UEs' diversity and the clarity of the remote channel. Additionally, it also makes use of new security instability from the upgraded usability in different designs that uses the merging between improved heterogeneous remote organizations, the open organization foundation is reliant on the IP system, and the enhanced business carrier with different trust-appraisals. In the UUDN, the system organizes a dynamic APs group (APG) that relies on each UE's condition. It delivers unnoticed and seamless service to the user all through the APG dynamic, reloading as an unobserved network coverage going together with user mobility [2]. Importantly, in user-centric UDNs (UC-UDNs), the user-centric collections are created by categorizing the more preferable number of APs collectively, therefore leading to a user-centric clustering architecture [9].

C. 5G Overview

The precise statement of meaning for 5G has always been argued. In a GSMA Intelligence report that was published recently, illustrated two aspects of the 5G technology that exist today: the hyper-connected vision and the next-generation radio access technology [10]. The latter which is the hyper-connected invention, is depicted as a recent technology in which all the advantageous features from the current generations like the 2G, 3G, and 4G are scratched out for the enablement of a better system that can provide users with wider implications than the 4G and LTE that exist now [10]. The UE dispatches a fundamental access demand. At that juncture, the AP gets the requisition and conveys it to the nearest organization framework. As per the requisition's initial situation, the nearest organization framework requires that the center organization framework compare network layer authentication vector and output. At that moment, based on the resulting network layer security boundary, the nearest organization framework begins the organization layer's standard authentication measure with the UE (like the 4G EPS-AKA measure).

II. SECURITY CHALLENGES OF UUDN

Soon as the organization layer's average verification of the UE is done, a static virtual cell or an APG is charged to the UE by the UDN. The framework of the network creates network access validation vectors to the UDN control layer which is reliant on the requisition boundary acquired from the UE. It coordinates the entrance layer (a particular virtual cell or APG) standard verification measure on the UE. When the UE does theshared validation measures toward both the organization layer and the entrance layer, the security access is refined [4]. APs are interlinked and arranged depending on many structural datalike it also relies on the static virtual cell. So, the UDN should actualize the access services irrespective of what the APS organization is. Like channel interference or any other type of interference, some factors can be erased within the UDN. Each network element requires to be generally verified, and the two-sided substance should make use of their different private keys. The security system needs to be used to ascertain that the two sides can receive essential information. Each comparable element need to have an alternative when acquiring the shared keys during information exchanges. The different correspondence comes together to make use of the uniquely shared keys. The security measures for encoded information is reliant on the shared keys and should uphold the dynamic collaboration or disengagement of correspondence elements. All entities should be bounded together by the command from the organization administrator. The longevity of divided keys among corresponding elements must be equal to the significant directions. The security implement must uphold the different legitimate channels amongst uniform sources or objections and keep a strategic distance from replicating the keystream. The security system must be dynamic to give an assurance of speedy reactions and adapt to the element's demonstration and data transfer capabilities in different corresponding capacity. When we make use of the traditional cellular network architecture, it can result to issues like too many functions being centralized in the core network. UDN wouldn't be efficient with high traffic throughput because it emanates from the overhead signaling and long data transmission between the network and APS [3]. Moreso, the highest layer functions of every allocated AP need to decline for a smoother support in interference management because the higher-layer procedures cannot in a long shot be appropriate for AP. When the coverage of AP is minimal, it can cause more handover. This will lead to ineffectiveness and less flexibility within both macro and UDN.

III. INTELLIGENT NETWORKING

Researches have been carried out on ultra-thin intelligent systems administration, which brought about change and allocates framework boundaries and techniques through the organization's clever perspective of remote climate andbusiness needs. Naturally developing the information data for each client and then using that data for the radio asset of the board, UUDN should maintain new perception in joining the executive's plane, client plane, and control plane.

	3GPP SCE	3GPP HeNB	UUDN
Flexible Backhauling	No	No	Yes
NFV & SDN base	No	No	Yes
U/C separation	Yes	No	Yes
User-centric	No	No	Yes
Localization and flatter	LIP & SIPTO	LIP & SIPTO	Localized (user plane)

Table 3.1 The differences between the networks

The main objective is to enhance the range productivity and consumer experience, achieve low energy or low force usage of the framework, lessen the network actions, and minimize standard upkeep costs. From the net-work and the board's perspective, to decrease the capital consumption and operating cost, UUDN should maintain self-systems organization and self-streamlining. To sustain the organization's adaptability, self-backhauling is also critical for UDN. The common cell network configuration places around isolating access, access configuration and the executives. In the UUDN scheme, the executives' plane of the network management is conducted to build up a universal point of view on the organization, to achieve the natural merging among the board control and user plane, and to recognize intelligent systems administration [6].

IV. Literature Review

More recently, user-centric UDNs have attracted substantial consideration. This is because of their capacity to satisfy each UE's TQoSin dense environs regardless of the location. In particular, some research efforts have focused on the user-centric assembling design issues [12]. In UUDN, the system can intelligently recognize the user's wireless interaction environments and then with flexibility organize the needed APG and abilities to help the user; subsequently, it becomes like a network is always following the user [11].

A. *Physical access security of entity APS*

The framework of UUDN is much flatter than the TCN, and the ultra - dense APs will be intensely launched to the clients [11]. The APS will be initiated by the users and then out of the joint launching by the operators. Consequently, it isn't easy to assure of a secure physical transmission environment [11]. The attacker can illegitimately acquire or make a copy of the digital certificate and the sensitive information stored in the APS. Because of this, the cloned APs may get into the UUDNnetwork and release security concerns into the network [11]. Malicious apps may attack CN entities and compromise the UE, such as spying on packages' operation.

B. *Dynamic network resources organization security*

Access point group is the key characteristic of the UUDN. Many APs in UUDN gets aptly organized into an APG to observe the user's movement and supply data transmission as required. The dynamic adjustment of APG will lead to some security concerns for UUDN [11]. The multiple numbers of APs connected to the network will have interacted with each other. It will make its security more difficult to realize self-configuration, self-optimization, and self-healing [11]. Together with the user movement, the APG will be entrenched and refreshed [11]. The security of the APG structure and refreshing is the key upset to UUDN [11].

C. *User information and privacy protection security*

The protection of user information and privacy is another vital concern for UUDN based on all IP networks linking the Internet [11]. Today and in the future of 5G, it is a common thing for individuals to keep their mobile devices physically around them. Assuming an UE's traffic is hijacked in a place of residence by an assailant [11]. If this is the case, it may be understood if a particular individual is present (or not) at one particular location, thus making an individual's privacy vulnerable to attacks [11]. The privacy data security contains the information prolateness and data wholeness of the user in question [11].

D. *Handover validation security*

Many handovers and verifications will often bring delays and a high probability of authentication failure. Thus, significantly reducing the user's experience [11]. Unmistakably, this traditional authentication mode cannot be supported entirely by UUDN [11]. To extenuate the lousy experience and adapt the APG mode, we find that a new authentication and key agreement (AKA) method, such as a group authentication procedure approach, should be adopted strongly in UUDN [11]. The group validation result should be easily inherited, recognized, and confidential among the group participants [11].

A different type of UDN is the user-centric UDN (UUDN), which has a local access center orchestrated with the user, and the virtually joined cell is created based on the unit of a single user [5] [2]. Moreover, more investigation of the spectral efficiency and energy efficiency and proposed energy-efficiency and user-centric cross-tier assembling solution can be subject to a minimum spectral efficiency constraint [11].

V. Proposed Methods

The structure of UDN and UUDN are flatter than common cellular networks. Furthermore, data communication between networking bodies is random and in a way not permanent. We will demonstrate some security domain procedures to achieve security. Those security domains are network domain security, AP access security, APG security, Dual authentication, UE to UUDN access network security and expanded key.

1) **Network Security domain**: APSs are interlinked and arranged according to various structural data like it also relies on the static virtual cell. So, the UDN has to actualize the access services irrespective of what the APS organization is. Some factors, like cochannel interference or an interference of any kind, can be erased within the UDN. Each network entityshould be generally verified, and the two-sided elements shouldmake use of their different private keys. The security system should be used to ensure that the two sides can get considerable information. Each correspondence entity should have the option to obtain the shared keys in information exchanges. Themany various correspondence joining's make use of distinctive shared keys. The security instruments for information encodedreliant on shared keys should maintain the dynamic joining or exit of correspondence elements. All entities should be bound together by the commands from the organization administrator.

2) **AP Access Security**: The APs are very close to the user and may even be launched by the user. The security concerns of AP deployment, which UUDN encounters, are same as that of Home eNB in the LTE network. To restrict the attacker from using HNB as an advantage to penetrate into the LTE network, the HeNB supports a device verification approach with certification-based or USIM-based consensual authentication. Same as the APS also requires mutual validations among the APs and UUDN network when the APs access the UUDN [3]. When the validation is successful, the APs can then access the operational status.

3) **APG Security**: At the point when the organization layer usual authentication of the UE is done, a static virtual cell or an APG is attached to the UE by the UDN. Currently, the network framework creates network access confirmation vectors to the UDN control layer reliant on the requisition boundary obtained from the UE. It directs the entrance layer (a particular virtual cell or APG) common validation measure on the UE.

During the period when the mutual validation leans toward both the organization layer and the entrance layer are concluded by the UE, the security access is refined [3]. In respect to the security policy, when the APG is unable to ascertain the member's AP or the AP shuts down and reports to APG, the key of the AP acquired in LSC will be eliminated. LSC will erase the AP from the APG index list. Simultaneously, the LSC will transfer some configuration adjustment commands to the APG and its members. If the AP rejoins APG, the validation procedure is required.

Fig 2 The APG-AKA in UUD

4) **Dual authentication**: The duration of divided keys amongst correspondence entities should be as per the cogent directions. The security implements should maintain different legitimate channels within similar sources or objections and sustain a strategic distance from replicating the keystream. The security system should be dynamic to assure of speedy reactions and adapt to the entity's demonstration and data transference capability in different correspondence undertakings. The network architecture design also becomes affected because of the new ways of the SDN and NFV for the 5G network architecture can predetermine the primary functionswith the aid of decoupling and transmission.

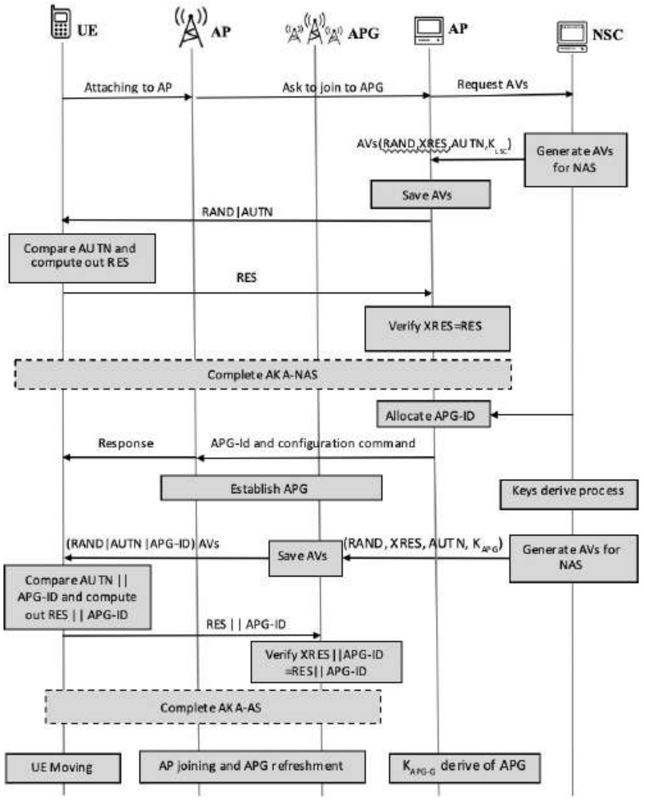

fig 3 Process of APG-AKA

It makes the architecture far more flexible toward the 5G dual connections and user plan is an efficient way to give higher user data rate by dense mini-cells with no mobility or any connectivity experience [4].

5) **UE to UUDN Access Network Security:** Due to the restoring of APG, many security concerns have arisen. APG members will be replaced, and attackers may latch onto the AP wireless connections. For example, when a data transference between the UE and APs (APG), the signaling and user data can be accessed illegitimately or can be exploited by the attackers. The user's movement between the APs may also be tracked or acquired at the actual user's locations. These can pose serious concerns for user's privacy. It efficiently shields the user's private data with the keys based on specific encryption algorithms.

6) **Expanded key:** To ensure network safety, the user data are linked to an encryption algorithm. Each process requires a different key. Without a doubt, the key for integrity procedures or ciphering shouldn't include transmitting data over the network directly. On the other hand, there is a risk that the key can be accessed illegitimately or even upstaged. A a more reliable approach is to ensure that the temporary key derives the keys for ciphering or integrity, and then the keys never exit the security elements. The key that is derived by hierarchy should be designed to adapt to the network architecture. It illustrates the different keys and the other keys in the key hierarchy system in LTE from which they are obtained. Characteristically, the design of an expanded key obtained from the hierarchy of UUEN and it has its own similarities. There may be multiple APGs in UUDN, even in similar network area, that operates in accordance to different UEs. An AP may serve various UEs at the same time, and an AP may also originate from different APGs. Even then, there are still concerns that the APG may be abused or misused by malicious APs.

VI. Conclusion

Meeting the high traffic maximum necessary of the 5G, UDN is a very impressive innovative bearing. In this work, a UUDN is the proposed idea. For this reason, we gave a network design for the UUDN idea. An architecture is structured with the probability of limitation, compliment, U/C partition, keenness, client-driven and adjustable systems administration. Due to the new structure, challenges and observations, many key innovations are familiar with giving high QoE, high region capability, productivity, minimal cost, and green correspondence. Four different practical cutting-edge subtitles are discussed in headings which includes; intelligent networking, interference management, and security.

VII. Future Work

For further studies, there is a massive range of areas to explore in relation to DAPGing, high level interference management, and many security clarifications, along with their disadvantages. In order to make UUDN a reality in the foreseeable future for deployment, a lot of areas needs to be covered for further studies. Another issue that needs to be appropriately addressed is the cooperative networking and heterogeneous networking. To support UUDN which is full of various complicated scenarios and inconsistent coverage will surely prove to be a big challenge.

***Abstract*—This work presents the implementation of analytical transport model of MoS_2 tunnel field effect transistor (TFET) using Verilog-A in Cadence/Spectre. The parameters of the model are extracted, and most notable is its high I_{ON}/I_{OFF} ratio, which makes it suitable for low power design, and IoT applications. Subsequently, we employ the TFET model in the design of ultra-low power phase locked loop (PLL). Various components of PLL are examined in terms of their structures and functions. The results show that the voltage controlled oscillator (VCO) operates from 0.5 GHz to 2.9 GHz with a tuning range of 82.8%. It also consumes 1.91 µW power at 2 GHz carrier and has a phase noise of -117.3 dBc/Hz at 1 MHz offset frequency. The average power consumed by phase locked loop is 0.021 mW. In addition, the operation of the PLL is not sensitive to temperature variations.**

Keyword—phase locked loop (PLL), phase noise, tuning range, tunnel field effect transistor (TFET), voltage controlled oscillator (VCO)

I. INTRODUCTION

It is already established that tunneling field effect transistor (TFET) is a good choice for designing low power circuits. This is because of its ability to operate with low supply voltage (sub-0.5 V), which drastically reduces the static power consumption. The miniaturization of MOS transistor has reached the limit where we experience short channel effect (SCE) such as drain induced barrier lowering. In this case, the OFF-state current (I_{OFF}) increases as a result of lowered potential barrier for electrons from source to drain. This makes short channel MOSFET unsuitable for digital logic applications because of its low I_{ON}/I_{OFF} ratio. The maximum sub-threshold slope (SS) achievable by a typical MOS transistor is 60 mV/decade at room temperature. Tunneling field effect transistor has shown much better performance in terms of SS, leakage current, power consumption etc. Applying an appropriate bias voltage to the gate-source region of TFET causes the valence band to align with the conduction band and injecting the charge carriers. Similarly, under reverse bias, the two bands are misaligned and there is no injection of carriers. This effect is referred to as band-to-band tunneling [1 - 3]. Unlike thermionic-based MOSFET, the principle of operation of TFET is less dependent on temperature. Thus, process, voltage, and temperature (PVT) variations are not serious concerns in TFET-based circuits. Although the dynamic power decreases linearly in CMOS technology, the static power continues to increase because the threshold voltage cannot be scaled proportionally with the supply voltage. This causes the leakage current to increase, which consequently increases the leakage power. In order to achieve ultra-low power or energy-efficient design in analog, digital or mixed signal circuits, it is desirable to employ a transistor with different mechanisms of injecting charge carriers other than thermionic or temperature dependent. Some other benefits of TFET is good compatibility CMOS transistor and can also be integrated with the current FinFET device. Nevertheless, it does not show a better performance than CMOS when operated beyond a certain voltage. So, it cannot completely replace CMOS transistor in high performance applications [4]. In addition, it does not have a symmetrical structure like MOSFET because the source and drain are made of and doped with different materials.

There are various choices of material that are suitable for TFET design. Some of the factors considered are low band gap and low effective mass that aids the tunneling probabilities of electrons and holes carriers. It ensures that TFET produces high I_{DS} even at low voltage supply. Graphene is a promising candidate and it satisfies most of the requirements in material choice selection. It is regarded as zero band-gap material because there's no band gap between conduction and valence bands. At Dirac's point, graphene is considered massless because its effective mass is zero. However, studies have shown that transistor made of graphene, in its pristine form, has high I_{OFF} current. One of the ways to overcome this challenge is by creating nanoribbon with the graphene, which eventually opens up the band gap and lowers I_{OFF} current. The graphene nanoribbon (GNR) TFET provides the required I_{ON}/I_{OFF} ratio

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

for digital applications [5]. Transition metal dichalcogenide (TMDC) are 2-D materials that have also been employed in the fabrication of TFET. Unlike graphene, TMDCs have infinite band gaps, which usually ranges from 1 to 2 eV. Although transistor made of TMDCs has a low I_{ON} current when compared with graphene-based transistor, it has better I_{ON}/I_{OFF} ratio because of its low OFF-state leakage current. This makes it more suitable for logic design. Phase locked loop operates based on feedback control mechanism whereby the external reference is expected to track the feedback signal from frequency divider. It has various applications such as data clock recovery, frequency synthesizer etc. PLL also has been widely used in the field of power electronics and communication. In this work, we have designed a novel low power phase locked loop with tunneling field effect transistor. Its performances in terms of tuning range, center frequency, power consumption, and phase noise are also presented and compared with related work in other transistor technologies.

This paper is organized as follows; we present the brief description of transistor model in Section II, Section III examines the design of each component of PLL and discusses the results, and Section IV is the conclusion.

II. MODEL DESCRIPTION

The model shown in Fig. 1(b) is an heterostructure, which consists of source, drain, and double gates. The source is made of heavily doped Ge and the drain is silicon. The transistor channel is 0.65 nm thick MOS_2 with a band gap of 1.79 eV. For the gate oxide, HfO_2 is chosen because of its high dielectric. The source and drain are doped to ensure proper band tunneling and silicon is chosen as drain material because of its higher band gap, which lowers the flow of ambipolar current.

(d)

Fig. 1. (a) nTFET structure (b) $I_D - V_{GS}$ logarithmic plot for nTFET (c) $I_D - V_{DS}$ plot for n-type TFET (d) $I_D - V_{DS}$ plot for p-type TFET.

Similarly, the p-type TFET also has the same structure, but with reverse doping for the source and drain. The polarity of V_{GS} is also reversed for appropriate bias of gate-source junction. We will not go into the details of our TFET model because it is already presented in [6].

The behavior of both n and p-type transistors are summarized in Figs. 1(b) – 1(d). As shown in Fig. 1(b) , $I_D - V_{GS}$ logarithmic plot shows that the n-type TFET has high I_{ON}/I_{OFF} ratio of 5.27×10^7 for $V_{GS} = V_{DS} = 0.5$V. The output characteristics of nTFET is presented in Fig. 1(c) with $V_{DS} =$ 0.5V and V_{GS} ranges from 0.1 to 0.5V with a step size of 0.1 V. Similarly, $I_D - V_{DS}$ plot for p-type is shown in Fig. 1(d). In this case, V_{DS} = -0.5V and the values of V_{GS} ranges from -0.1V to -0.5V with a step size of -0.1V. In addition, the transistor model achieves SS as low as 10 mV/decade, which is six order of magnitude better than MOSFET. We can conclude that the TFET is suitable for low power design, such as internet of things (IoT) applications.

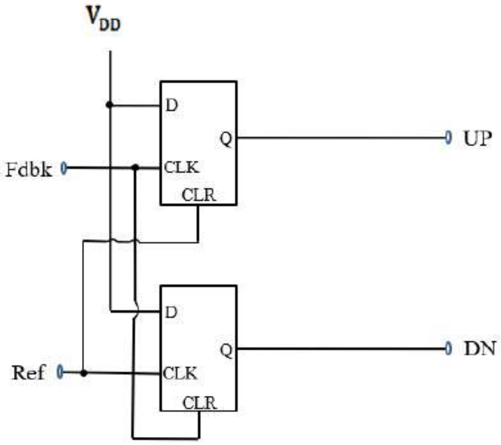
III. TFET-BASED PHASE LOCKED LOOP DESIGN

Phase locked loop consists of different building blocks that are used to generate a stable output frequency, which is a multiple of the input reference. The usual components of PLL are voltage controlled oscillator (VCO), phase frequency detector (PFD), charge pump, loop filter (LF), and frequency divider. PFD produces an error signal from the differential phase and frequency of both input reference and feedback signals. Depending on which of the two signals is leading, the frequency of VCO is increased or decreased by the error signal. The loop capacitors are charged and discharged through charge pump output current. The loop passive filter is responsible for eliminating high frequency components and reference spurs. LF also determines the bandwidth and stability of phase locked loop. It generates the control voltage, which alters the output of voltage-controlled oscillator. The frequency divider takes in the output of VCO, samples it, and convert it to a fractional output, which is fed back to PFD. The phase detector we used in this work has quite similar structure with the conventional tri-state PFD. It employs two D flip flops, but without NAND gate. The reset path is modified to reduce dead zone and power consumption. Figures 2(a) and 2(b), respectively, show the structure and output of PFD when the reference and feedback signals are in phase. It is shown in Fig. 2(b) that the UP and DN outputs have low glitches, which makes it more energy efficient and useful for IoT devices (e.g. IoT sensor nodes).

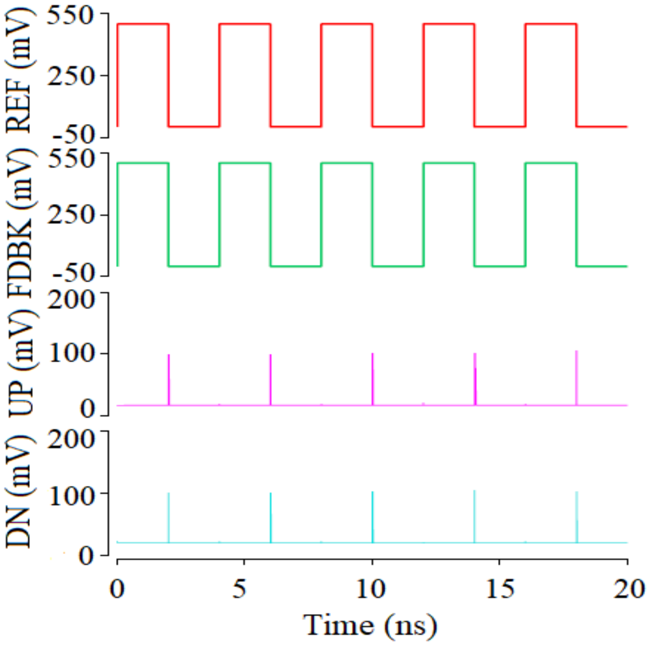
The charge pump (CP) takes the two outputs (UP and DN signals) from PFD and convert to charge pump current that charges and discharges the capacitors of the loop filter. LF is a second order low pass filter and it controls the dynamics and transient response of PLL. The CP/LF configuration in [7] provides the needed control signal, V_{ctrl}, for voltage controlled oscillator. More so, the loop filter prevents instability of the loop in lock condition from slight variations in the input. This is achieved by blocking higher order harmonics from PFD. The transfer function of LPF is given as:

$$F(s) = \frac{Vctrl(s)}{I_{cp}(s)} = \frac{1+sRC_1}{s(C_1+C_2)+s^2RC_1C_2} \qquad (1)$$

where R, C_1, C_2 are the loop filter resistance and capacitors, respectively.



(a)



(b)

Fig. 2. (a) PFD (b) UP and DOWN outputs.

The current starved voltage-controlled oscillator (CSVCO) is preferred to LC VCO because of its wide tuning range, low cost, small silicon area, and low power consumption. However, LC voltage controlled oscillator can achieve a better phase noise than CSVCO through high Q inductor. Furthermore, it is widely used in high frequency applications such as RF. The control voltage from CP/LF provides bias current for each inverter stage, which charges their load capacitances. The biasing transistors control the amount of current flowing through the inverter. The charging time of the capacitance varies depending on the amount of current., which then results in changes in frequency of the oscillator. The oscillation frequency is expressed as:

$$f_{osc} = \frac{I_D}{NC_L V_{DD}} \qquad (2)$$

where I_D is drain current, V_{DD} is the supply voltage, N is the number of delay stage, and C_L is the cumulative capacitance of the delay stages.

It is evident that ultra-low power design is mainly achieved by keeping I_D low and maintaining the desired oscillation. This is one of the major reasons we have employed TFET in our design because it can easily be operated with low V_{DD} . So, the downward scaling of bias current does not affect the oscillation frequency. Power analysis is a very important aspect of analog or digital circuits, and it can be categorized into two; static and dynamic. Although there is also short circuit power, which occurs whenever the pull-up and pull-down transistors are both conducting. It is considered infinitesimally small, so it is ignored in this study. According to (3), the dynamic power reduces greatly by scaling down V_{DD} , minimizing the parasitic capacitance of the transistor, or decreasing frequency. Since we want the PLL to be suitable for high frequency applications, we have employed the model because of its inherent low capacitance. This reduces the delay and invariably increases its speed of operation. TFET has also solved the problem of high leakage current in CMOS device, thus, the static power is drastically reduced. The power of current starved voltage controlled oscillator is estimated as 1.91 μW at oscillation frequency of 2 GHz, which is quite low when compared to the oscillator in [8]. This implies that the TFET-based VCO has a wide tuning range of 82.8% and the estimated phase noise is -117.3 dBc/Hz measured at 1 MHz offset frequency.

$$P_{dyn} = \alpha \times f \times V_{DD}^{2} \times C_L \qquad (3)$$

where f is the frequency, α is the activity constant, and C_L is the load capacitance.

We equally performed temperature analysis between -55 ˚C to 125 ˚C. The results show that the output of voltage controlled oscillator does not vary with temperature and there is no degradation in its performance. The final block of PLL is frequency divider, and it is implemented with D flip flop divide by two circuit.

The VCO performance comparison is presented in Table 1. The designed oscillator operates between from 500 MHz to 2.9 GHz with a tuning range higher than the ring oscillators presented in [9, 10]. Furthermore, our designed oscillator consumes ultra-low power of 0.0019 mW, which is much smaller than the power consumed by CMOS, FINFET, and graphene nanoribbon (GNR) TFET-based oscillators [11 - 13].

IV. CONCLUSION

Since the Internet-of-Things (IoT) is gaining more interests and phase locked loop is one of its most widely employed circuits, it is desirable to design ultra-low power PLL. This work presents ultra-low power phase locked loop design for IoT and biomedical applications. The design of each functional block of PLL is examined, and we have employed MoS_2 TFET because of its low sub-threshold and propensity for low power analog and digital electronics. We characterized the current starved VCO and compared it with the related work. The results show that the PLL operates in the range of 0.5 GHz to 2.90 GHz with a wide tuning range of 82.8%. The VCO has a phase noise of -117.3 dBc/Hz at 1 MHz offset frequency and consumes a very low power of 1.91 µW. The total power consumed by phase locked loop is 0.021 mW. In addition, the output of PLL shows resistance to temperature variations, which make it suitable for Internet of Things (IoT), medical, industrial, and military applications.

***Abstract*—Many approaches based on the improvement of ad hoc routing protocols are proposed due to the issue of the mobile node in VANET (Vehicular Ad Hoc Networks). Indeed, before a source node transfers data, it sends a request message RREQ to all other neighbor nodes in the network where all nodes participate in transmitting the packet. After the message RREQ (route request) comes to the destination, it is replied to by a message RREP (route reply). If an intermediate nodes' energy went out due to the battery, it drops a data packet RREP message after a new recovery must be started, and it can affect the performance of the protocol. This paper proposed two news protocols E-AODV and RE_AODV, with an energy threshold and a new "minimum residual energy" for VANET. The E-AODV approach improves network performance because of node battery depletion and RE_AODV because of the RREP messages' broadcasting and filtering it by the energy threshold.**

Keywords—AODV, energy threshold, RAODV, VANET, E-AODV.

I. Introduction

With intelligent traffic management systems, the streets are much safer, and the energy consumption for vehicle mobility can be significantly reduced. Further pedestrian traffic with a battery-powered device like smartphones or smartwatches can be incorporated in the future. Much information data is necessary to realize these traffic control systems. VANET routing protocols are Ad hoc self-organizing routing protocols without using access points or pre-existing network infrastructure. Proactive routing protocols establish routing paths between all nodes periodically and continuously, affecting high data transfer of control messages, also called overhead. So, much energy and network resources are wasted with an often-changing network topology. Reactive protocols are on-demand routing protocols, in which the routing path from the source to the destination is established when the source needs to send data.

Nevertheless, the established route can have a link breakage caused by the battery run out of a node. It can be avoided by enhancing the RREQ message with an energy threshold and a variable to record the nodes' minimum residual energy, which forms the route for sending the data packet. Additionally, the RE_AODV protocol proposes to replace the RREP message with an enhanced R-RREQ message to face the problem when a node moves out of transmission range while sending the RREP message. The enhanced R-RREQ message is also broadcasted like the RREQ message to find the source node by multi-hop. This work is performed to know the impact of modifying the RREP packet delivery mechanism to a broadcast mechanism and adding an energy threshold to the RREQ packet delivery mechanism in the route discovery stage on the overall data packet delivery performance of the VANET network. The paper is continuous as follows: section 2 in Previous literature study, section 3 Methodology, section 4 Implementation, section 5 Result, and the last section conclusion and future work.

II. Previous Literature Study

The ad hoc networks' dynamic change conducts many problems like loss of packet data during transmission. Many types of research are proposed to overcome the issue so that the paper introduces one solution against the issue mentioned. Chonggun Kim, Elmurod Talipov, and Byoungchul Ahn proposed a new approach, "a Reverse AODV Routing Protocol in Ad Hoc Mobile Networks," [2] where it improves the AODV protocol named reverse AODV or R-AODV, and it is a reactive protocol, too. This new protocol increases the output of data transmissions. It is providing a new path for better performance, throughput, end-to-end delay, etc. To skip the loss, the route reply message. Indeed, the Ad hoc AODV protocol requires the successful delivery of the RREP message. The routing performance retrogrades due to the RREP packets' loss due to the nodes' high mobility. They found out that the performance of AODV is improving by R-AODV for packet delivery, End to end delay, and energy consumption.

The modified AODV, introduced by Landge and Nigavekar, is also motivated by increasing data throughput and energy consumption. To achieve these goals [1], they integrate a pre-calculated energy parameter into the RREQ packet. The pre-calculated energy is for a specific event for sending to the destination. With this new energy field, a connection break can

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

be avoided by ensuring that the intermediate nodes have sufficient residual energy. After the reception of the RREQ message by the intermediate node, it compares its recent energy with the value inside the energy field. If the remnant energy is lower than the pre-calculated energy, then it discards the RREQ message. Otherwise, to the next neighbor, the message is forwarded. It guarantees that the intermediate nodes will be alive as long as needed for the data transfer. Data package loss due to this reason is avoided. After the reception of the RREQ messages by the destination node, it will choose the route with the lowest hop number and thus with the lowest energy consumption. The procedure for route reply is the same as in the AODV protocol specified.

III. Methodology

A. *Vehicular Ad Hoc Networks*

The biggest obstacle in VANETs than MANETs is the nodes' movement, resulting in highly dynamic network topology changes. Routing protocols in VANETs face this problem using Ad hoc networks, which means a route will be found after a source demands a data transmission and the maintenance of temporarily stored routes in the routing table. The routing maintains the routing and the protection of the communication of 2 nodes with them routing messages. That means the reliability of the transmission of the messages depends on the technique of the protocol. Routing protocols in VANETs also take into account the lack of infrastructure.

B. *Ad hoc On-demand Distance Vector*

The AODV-protocol (Ad hoc On-demand Distance Vector) is a reactive routing protocol that further develops DSDV. This protocol does not create a routing table in advance, but it reacts if a node demands a data transfer and start a route discovery. An established routing path will be stored for a specific time in a routing table. The RREQ (route request message) and the RREP (route reply message) are used to establish a routing path for the data transfer. To maintain and repair a route inside the routing table, the RERR (route error message) and periodically "HELLO"-messages are transmitted.

Causing by a data transfer demand of a source node, the RREQ message is transmitted by flooding into the network, and it is forwarded until it arrives at the destination or an intermediate node that has a valid path to the destination in the routing table, see Fig. 1.

Following an RREP message is forwarded back through the chosen data transfer route by unicast transmission, according to Fig. 2. A data transfer is started when the RREP message arrives back at the source node. The discovered route will be stored for a limited time in the routing table of the nodes.

C. *Reverse- AODV*

In R-AODV(Reverse- AODV), the route request is the same as in AODV, but the reverse route request is not unicast to find the source node. After receiving the RREQ by the destination node, an R-RREQ (reverse route request) is prepared. It reduces a failing data transfer because of link breakage by being also broadcasted by flooding into the network. The possibility of finding a routing path is increased.

Preparation of RREQ message with energy threshold and minimum residual energy
Step A
Starting route discovery, forwarding RREQ message to nodes
RREQ message is discarded
yes
RREQ ID and originator sequence number is already processed
Forwarding to next nodes
no
Comparison if the node is the destination
yes
Preparation of RREP message and forwarding back
no
Step B
Comparision energy threshold
(a)
RREQ message is discarded
(b)
Step C
Comparision minimum residual energy
(c)
Updating routing table and RREQ-message

Fig. 4 Flowchart of the proposed algorithms E-AODV

This last discovered route is used to transfer the data package. If a discovered route via node 1-2-3 (see Fig.3) fails because node one is moving out from the route, then the R-RREQ can discover another route, too. The structure of the R-RREQ message can be seen in Table 1, containing the following information.

D. *The proposed approach*

The RREP and R-RREQ message are used like in the AODV and R-AODV protocol for the E-AODV protocol. The RREQ message is enhanced by an energy threshold and a value for the "minimum residual energy" of an intermediate node taking part inside the data packet delivering route. A percentage of the initial energy provides the energy threshold. The minimum residual energy is the initial energy at starting the route discovery process and will be updated during route discovery. When the energy of the RREQ reception node is greater than the threshold, then the RREQ message will be forwarded, and when the residual energy is lower than the "minimum residual energy" value, then this value is updated in the RREQ message and the routing table of the node.

TABLE 1 MODIFIED RREQ-MESSAGE STRUCTURE

Packet type	Reserved	Hop Count
Broadcast ID		
Destination IP Address		
Destination Sequence Number		
Source IP Address		
Source Sequence Number		
Threshold Energy		
Minimum Residual Energy		
Timestamp		

Fig. 4 shows the process for the enhanced RREQ message. In general, the process follows the AODV approach. The enhancements are marked inside the dashed boxes with the next explained Steps.

Step A) The RREQ-message is prepared by adding the energy threshold and a "minimum residual energy." The energy can be chosen by a specific percentage of the initial energy. Further, at the preparation of the RREQ-message by the source node, the value of the minimum residual energy is filled with the initial energy of the source node. The changes of the RREQ message structure can be depicted in Table 1.

Step B) The receiving intermediate node compares the own residual energy with the energy threshold specified by the RREQ-message. If the own energy of the receiving intermediate node is lower than the threshold, then the RREQ message will be (a) dropped. In this case this intermediate will not be part of the data transmission route. However, when the own energy is higher than the energy threshold, it continues (b), see Fig. 4 with forwarding the modified RREQ message to the next nodes.

Step C) After the intermediate nodes' energy is compared to the value of "minimum residual energy." If the intermediate nodes' energy is lower than the value inside the RREQ-message, then the routing table information of the node and the RREQ message will be updated (c) with the new residual energy and hop count. Otherwise, the routing table and the RREQ-message will not be updated with residual energy of the node, and the process continues.

When the destination node receives more than one route. The change is made by adding the minimum residual energy, affects the selection of the main route. If there is another route with a minimum energy value on that route greater than the minimum residual energy value in the routing table, that route will be selected as the main data transmission route.

The RE_AODV protocol combines the E-AODV approach, with the enhanced RREQ message, by the energy threshold and the "minimum residual energy" and the R-RREQ message of the R-AODV protocol, developed by Chonggun Kim, Elmurod Talipov, and Byoungchul Ahn, X. Zhou et al.[2] . The R-RREQ message is forwarded back to the source by broadcast transmission.

IV. Implementation

This section describes the simulation environment and simulation parameters to compare the performance between the original AODV, the modified AODV -> E-AODV, R-AODV, and the hybrid E-AODV -> RE_AODV.

A. Simulation Environment

Three types of environments will be used in the simulation, namely 50 nodes for sparse environments, 100 and 150 nodes for medium environments, and 200 nodes for dense environments.

B. Simulation parameters

The NS-2.35 network simulator is used with the different protocols protocol to perform the simulation. The simulation area is determined by 1000m × 1000m in size with two types of geometrical topologies, see Fig. 5.

Each plot has an edge length of 125m x 125m. First is a grid map with a 9 x 9 intersection and 64 plots, the cutout from the real map around Jl. Soetomo in Surabaya is the second map. This map is converted from OpenStreetMap.

Ten random mobility route-sets for the nodes are created and converted into mobility files for both geometric topologies. These mobility files are used for the simulation in NS2. Complete information can be seen in Table 2

C. Simulation and evaluation

At first, a set of simulations is carried out to determine the suitable value for the energy threshold. The values 50%, 25%, 20%, 15%, 10%, and 5% were tested on the manual created grid map with 50 nodes. The packet delivery ratio results with ten random mobility scenarios can be depicted in Table 3, which are visualized in Fig. 5. The packet delivery ratio between 5%, 10%, and 15% are stable, and the decrease is minimal.

TABLE 2 SIMULATION PARAMETERS

No.	Parameter	Specification
1	Network simulator	NS-2.35
2	Routing protocol	AODV E-AODV R-AODV RE_AODV
3	Simulation time	200 seconds
4	Simulation area	1000 m × 1000 m
5	Number of nodes	50, 100, 150, 200
6	Transmission radius	400m
7	Default speed of nodes	50 m/s

TABLE 3 RESULTS OF THRESHOLD DETERMINATION

Test results						
Thres-hold	50%	25%	20%	15%	10%	5%
PDR	0.361	0.613	0.629	0.710	0.731	0.741

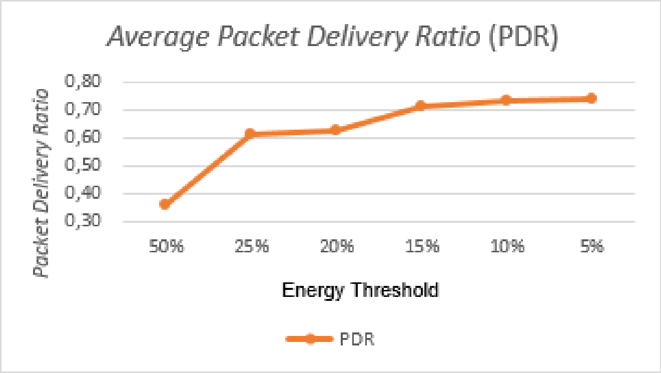

Fig. 5 PDR Graph in Threshold Determination

The drop of the PDR increases significantly for larger values. For 50%, 25%, and 20%, the number of control messages is vastly limited, so the threshold of 15% is considered suitable.

V. Results

At first, the simulations are carried out by comparing the protocols RE_AODV, R-AODV, and E-AODV to determine the AODV routing protocols' competitors.

The results are based on the grid map with 200 nodes and ten sets of the nodes' mobility. Fig. 6, 7, 8, 9, 10 are visualizations of Packet Delivery Ratio PDR, End-to-End delay E2E, Routing Overhead RO, Energy Consumption CE, Throughput, and Table 4 contains a summary of the average results.

The PDR values in Fig. 6 showing very high stability of R-AODV compared to E-AODV and RE_AODV. Otherwise, E-AODV has very fluctuating results for different mobility scenarios. However, on average, RE_AODV has the highest PDR. The stability of E-AODV is very low compared to RE_AODV and R-AODV, but the changes in the curves are similar between RE_AODV and R-AODV. The lowest End to End delays are achieved by the RE_AODV, followed by R-AODV and the last E-AODV protocol, as shown in Fig. 7.

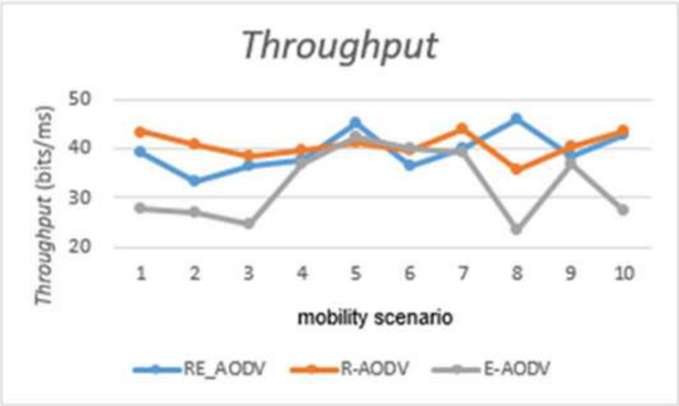

Fig. 10 Throughput for RE_AODV, R-AODV, E-AODV

TABLE 4 RESULTS OF RE_AODV, R-AODV, E AODV

	RE_AODV	R-AODV	E-AODV
PDR	0.63	0.61	0.57
E2E in ms	384	759	2,113
RO in %	66,080	88,620	10,640
CE in J	35,058	39,805	34,405
Throughput	39.54	40.63	32.54

TABLE 5 QUALITATIVE RESULTS OF R-AODV, RE_AODV, AND E-AODV

Metric	RE_AODV	R-AODV	E-AODV
PDR	Stable	Stable	Unstable
E2E	low, Stable	low, Stable	high, unstable
RO	Intermediate	high	low
CE	low, Stable	high, Stable	low, unstable
Throughput	high, Stable	high, Stable	low, unstable

The routing overhead for RE_AODV is decreased compared to R-AODV but vastly higher than E-AODV, see Fig. 8. E-AODV also shows the highest stability for the overhead routing values. The lowest energy consumption is achieved by the E-AODV protocol, in which RE_AODV is only slightly higher but much more stable, as showed Fig. 9. R-AODV consumed the most energy in the simulation. Overall the energy consumption is at the same level.

R-AODV accomplishes the highest throughput and is negligibly followed by RE_AODV, see Fig. 10. The Throughput for E-AODV is significantly lower, between the scenarios is much more fluctuating.

Qualitatively the results can be summarized according to Table 5. Based on the high throughput, packet delivery, and lowest End to end delay, along with the stable results, the RE_AODV is determined as the competitor of AODV.

The simulation of AODV and RE_AODV is executed in the before mentioned real scenario and grid scenario. The comparison between the standard AODV protocol and modified-AODV (RE_AODV) are shown as short summarization in Table 5 and Table 6. Both scenario tests are executed with sparse (50 nodes), medium (100, 150 nodes), and high (200 nodes) density environments. For the movement of the nodes, also ten sets of random mobility scenarios are applied. By use of an AWK script, the results of the Packet Delivery Ratio (PDR), End-to-end Delay (E2E), Routing Overhead (RO), Consumed Energy (CE), and Throughput are acquired. The energy threshold is determined as 15%, as discussed before.

In Table 6, a summary of the real scenario simulation results is presented, followed by the grid scenario simulations' summarized results; see Table 7. On average, the RE_AODV protocol obtains better results than the AODV protocol, except for the vastly higher Routing Overhead. In the real scenario, the Packet Delivery Ratio of RE_AODV is 2.42% higher, the end-to-end delay is 56.1% lower, the Routing overhead is 314.59% higher, the energy consumption is 2.68% lower, and the throughput is 8.66% higher. For the grid scenario, RE_AODV acquired a 7.59 higher PDR, a 68.64% lower E2E, a 336.5% higher RO, a 7.27% lower CE, and an increased throughput by 14.96%.

When analyzing the results, it can not be determined in which environment the RE_AODV protocol performs better. The results for energy consumption, throughput and end to end delay differs between the real and grid scenario, as well as for the node density. In the real scenario with a node density of 50, the RE_AODV protocol performs best with less energy consumption, but the throughput and end to end delay is best at 150 nodes. In the grid scenario the energy consumption, end to end delay and throughput is best at 200 nodes, but with 50 nodes the throughput is even lower, than AODV. This shows that it can not be generalized in which environment the RE_AODV protocol perferms best, but in average it obtain better results than AODV. It can be assumed, that the random mobility and thus the distribution of the nodes have a significant effect on the performance results, which have to considered for further studies or applications.

VI. CONCLUSION AND FUTURE WORK

The impact that occurs when implementing modifications to the RREP packet delivery mechanism on the network is a more stable Packet Delivery Ratio (PDR), low End-to-End Delay (E2E) with a high level of stability, very high Routing Overhead (RO). high, Consumed Energy (CE), which tends to be high with a reasonably good level of stability, as well as high and stable network throughput so that these modifications function to increase PDR stability, reduce E2E values, increase CE stability, and increase network throughput values in combined modifications (RE_AODV)

Meanwhile for the addition of energy filters in the RREQ delivery process is an unstable PDR, a high enough E2E with a low level of stability, a very low RO, a very low CE, and a network throughput that tends to be low so that these modifications play a role in reducing the RO and CE values in the network on combined modification (RE_AODV).

The number of Routing Overhead (RO) or the number of control packet deliveries that significantly increased on the modified AODV with the hybrid method (RE_AODV) increased RO by up to 336.51% in the simulation grid and 314.59% in real simulation. It is caused by the modification in the RREP sending mechanism from unicast to broadcast, causing massive RREP packet delivery.

A. *Analysis*

In PDR, E2E and throughput can be seen, that the results of RE_AODV and R-AODV are significantly better than AODV but quite similar to each other. The effect of the energy threshold is low, and the slightly better performance of RE_AODV compared to R-AODV is probably based on the lower number of control messages.

The forwarding of the control messages by broadcasting ensures that the control messages arrive at the source and destination. Which effect that data transmission can be started, and the robustness of the network is increased. Otherwise, it can be concluded that a too high number of control messages can decrease the network performance because of traffic congestion. The intermediate nodes' queue will overflow, and packets will be dropped, resulting in reduced PDR, E2E, RO, and Throughput performance. The broadcast delivery mechanism has an increased performance impact on the network if enough intermediate nodes to forward the control messages are available. If the number of control messages is too high in relation to the number of nodes, then the performance decreases, which can be seen, when the number of nodes reducing, especially for the 50 nodes scenario.

In conclusion, the number of control messages must be adjusted according to the number of nodes inside the network. The goal for future work has to be to find an optimal number of control messages by finding suitable filters for broadcasted request and reply messages. The optimal solution would be an adjusted filter according to the density of nodes, in which the energy consumption can also be reduced.

B. Suggestions and future work

As a result of the investigation and analysis of this project, the following ideas can be suggested the use of dynamic filter of intermediate nodes by using "HELLO"-messages relating to the density of nodes in the network. The target is to ensure that the source and destination receive the control messages but simultaneously adjust the number of control messages to prevent an overflow of the nodes' queue. Moreover, Adding a node forwarding limitation not only when sending RREQ packets but also when sending R-RREQ packets to reduce the routing overhead and to select the route for the data packet, also for the hybrid RE_AODV protocol.

***Abstract*— The implementation of automated micro-irrigation in urban gardens using wireless sensor and actuator networks (WSAN) is being more popular. However, the use of WSAN in automated irrigation brings various technical challenges, for example, achieving low cost, long life battery, adequate communication range and compactness. In this paper, a WSAN is designed and implemented for controlling drip irrigation of urban garden that can achieve long battery life, low cost, compactness with the sufficient range of communication. The designed WSAN consists of end-devices and a coordinator, each of which is fitted with single-chip microcontroller along with wireless transceiver. Each end-device is equipped with a microcontroller, a water valve, a soil moisture sensor, a temperature sensor, a rain sensor, battery charger through solar panel and a ZigBee transceiver. The end-device reads the garden temperature, soil moisture level, battery charge status and rain presence and controls the water valve based on these data values. At the same time, the read data is transmitted to the coordinator station through ZigBee ad-hoc network. The coordinator receives the data from each end-device and presents to the interfaced user application. Due to being powered up by an energy limited resource, special techniques and algorithms are developed and only low-power electronic components are selected carefully. This paper includes implemented hardware and software results for the wireless nodes.**

Keywords*— *ZigBee; WSAN; low power; drip irrigation

I. Introduction

Control of Drip Irrigation

As a type of micro-irrigation, drip irrigation is being used widely owing to its excellence to save water and increase yields. In drip irrigation, water is delivered by the network of pipes, tubings and emitters and dripped directly to the root zone of the plant. Generally, control of water dripping to plants works in on-off mode and controlled by from the starting point of the pipes network. Gardener can switch on the water flow and after certain period of time switches of the irrigation. Furthermore, this process can be controlled by time-based automation. This type of control is acceptable if all the irrigated plants are in the same type and having the same root zone area and shape. However, different plants require different amount of time to be irrigated. In that case, manual control of drip irrigation or time-based automation cannot satisfy the precision requirements. The most appropriate solution is to build fully automated irrigation system in which dripping emitters are controlled separately, based on the moisture level of each irrigated plant. Establishment of this control requires installation of particular sensors at plant root zones and special actuators as dripping emitters. Each actuator drips water according to the collected data of the respective sensors.

The most suitable approach to build the intended irrigation control is applying WSAN (Wireless Sensor and Actuator Network) to the system. However, there are some issues related to power consumption and control algorithms of actuators should be figured out.

A. Related Works

Many systems have been proposed to control drip irrigation using wireless technologies so far. For instance, in this paper [1], low power valve controller for drip irrigation is implemented based on JN5139 low power wireless module. The JN5139 module integrates microcontroller and radio transceiver inside itself and therefore the designed valve controller achieved low cost and compact size. It was designed to run for three months on two alkaline batteries, under different periods of sleep. The frequency of activation was assumed to be 4-5 times per week. The valve controller was designed to precisely control the solenoid valve, collect information on the status of the solenoid valve, and provide real-time feedback. The implemented controller was tested in field and the results showed that it can operate continuously at least 3 months with two alkaline batteries.

In this paper [2], authors proposed smart irrigation system based on wireless sensor nodes and coordinator hub. The whole system is solar powered and each sensor node was a part of a ZigBee network in a Star topology around a hub concentrator.

The designed wireless sensor nodes powered up by 9V rechargeable batteries and connected to 1 Watt solar panels. The communication between wireless nodes and coordinator

978-1-6654-4067-7/21/$31.00 ©2021 European Union

hub is realized by XBee modules in the range of 28 square meters. Arduino boards are used in sensor nodes and hub coordinator because of the easy interface to standard Wi-Fi shields, USB, I2C and power regulation. Sensor nodes read moisture, temperature and humidity by SHT1x sensors and send the collected data to coordinator hub wirelessly. The battery life-time of wireless nodes was calculated 6 to 9 months by putting them into sleep modes frequently.

Similarly, this irrigation system [3] was proposed utilizing ZigBee wireless technology in master-slave architecture. Each slave node includes temperature sensor, soil moisture sensor, water valve, microcontroller and ZigBee module. The microcontroller of the slave node reads and frames the air temperature and soil moisture of the garden. After that, the frame is transmitted to the master station through the ZigBee module. The master station employs an embedded fuzzy logic irrigation algorithm in order to provide the grass and trees with water based on a set of rules. Furthermore, the master station is interfaced with a home web server to access remote monitoring and operation. The detailed characteristics of power consumption were not highlighted. Because, the main objective of the proposed system was allowing the operation by the use of internet and smartphone.

In this experimental study [4], authors developed energy efficient wireless sensor mote for low-data-rate applications such as, control of drip irrigation systems. The designed platform is called DZ50. It consists of ATmega328P microcontroller and RFM12b wireless transceiver. Due to being in sleep mode for long period of time and operating with low power, this platform achieved very high energy efficiency. The experimental results demonstrated that the mote life-time can be extended more than 7 years.

Furthermore, several techniques have been implemented through scheduling [5],[6], and adaptive radio-frequency in wireless nodes and selecting a network configuration [7] in order to achieve higher energy efficiency.

One of the major power consuming component in a wireless node is a radio module. So, various wireless standards have been built with medium access control protocols that provide multitask support, data transmission and also energy performance [8], in particular the wireless local area network standards, IEEE 802.11b - Wi-Fi [9] and wireless personal area network, IEEE 802.15.1 – Bluetooth [10] and IEEE 802.15.4 – ZigBee [11].

B. *Objectives*

In this paper, the design and implementation of a ZigBee based low power wireless sensor and actuator network (WSAN) for the control of drip irrigation is presented. The main objective is to achieve low-cost, compactness and high energy efficiency.

Main tasks have been:

- To design and implement hardware for wireless sensor control nodes that capable to control actuator and monitor air temperature, soil moisture level, rain presence and battery status;
- To develop firmware for the wireless nodes;

The designed WSAN should satisfy following main specifications:

- A minimum of two years battery life with single AA type battery, supposing that each end-device reads every sensors and actuates solenoid valve maximum ten times per day;
- A minimum 100 meters of communication range between end-devices and central coordinator;
- A low cost and compact volume
- No actuation in rainy time

II. System Design and Implementation

A simple and low cost network architecture can be applied to build WSAN for the control of drip irrigation system. That’s why, typical master-slave approach is chosen, in which central control unit is master node and end-devices are slave nodes, respectively (Fig. 1.). Master node exchanges data with slave nodes only one-by-one through ZigBee modules and only slave nodes can initiate the communication. Master node is in receive mode continuously, since it is powered up by robust and unlimited power supply being in receive mode constantly does not make a problem from energy point of view. The slave nodes are not required to enter receive mode continuously or periodically, and this dramatically increases their battery-life.

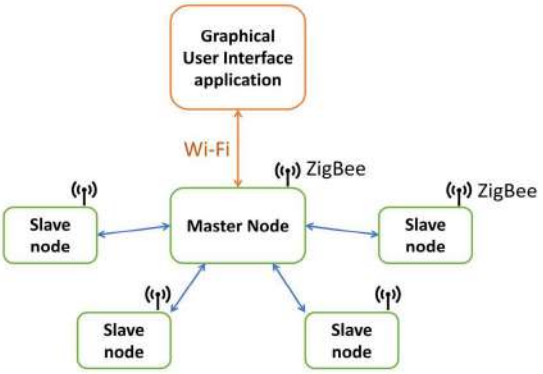

Fig. 1. Proposed architecture of the designing WSAN

A. *Main Components*

The specifications and requirements mentioned above demands to choose components very carefully.

As the wireless transceiver, XBee S2C ZigBee Standard module (from Digi) has been chosen due to its low power consumption and sufficient-range of communication. XBee S2C operates based on ZigBee protocol and direct-sequence spread spectrum modulation method. This module works on one of the 16 channels (channels from 11 to 26) in the 2.4GHz frequency band. It can reach up to 1200 meters of communication range in the line-of-sight and 250 kbps data rate. XBee S2C module works at 3.3V with the current consumption of 33mA (45 mA in boost mode) in transmission mode and 28mA in receive mode and less than 1 µA in sleep mode [12].

As a main controller unit for all the electronic components in a wireless node, Atmega328P microcontroller has been chosen. It is proposed to put microcontroller and XBee module into sleep mode in order to extend battery life. In Atmega328P microcontroller, built-in watchdog timer is available and we use it to wake-up from the deep sleep mode. But, the maximum predefined watchdog timer value is 8 seconds. Therefore, the duration of sleep period can be multiplication of 8 seconds, e.g. 450*8seconds=3600 seconds. What it means that microcontroller wakes up after every 8 seconds and counts one more, than enters into sleep mode immediately. When the count reaches 450, microcontroller begins to work in wake-up mode. In sleep mode, the microcontroller consumes 44µA at 3.3V at average.

The most power consuming element of the designing WSAN is the actuator which is used to open and close water flow. Generally, solenoid valves are employed to do this function. Our project requirements and specifications demands very low-power solenoid valve in order to save energy and reach longer battery-life. So, it is decided to choose latching solenoid valve as actuator due to its controllability with very low amount of energy spending. Latching solenoid valve, sometimes called bistable solenoid valve, does not require constant application of power to keep its close or open state. The state can be changed by applying very short electrical pulse to the coil of the bistable solenoid. In this project, it is decided to choose the latching solenoid valve with the following parameters (Table 1).

TABLE I. ELECTRICAL CHARACTERISTICS OF THE DEPLOYED VALVE

Nominal voltage of the pulse	Pulse duration	Coil resistance
3.3 V	30 ms	9 Ω

B. Coordinator (Master Node)

Master node integrates a Wi-Fi module in order to link the designing WSAN with gardener's user application. Therefore ESP-01 Wi-Fi module is integrated into master node owing to its very low cost, small size and ease of use. ESP-01 is configured to work in Access Mode for enabling gardener's devices to connect to the Wi-Fi access point of the module.

Master node performs following main functions:

- Receiving information of slave nodes wirelessly via XBee modules
- Sending the received information to user application using Wi-Fi module
- Controlling a water pump according to the signals of water level sensors in order to provide water tank with water in time

The program flow of the coordinator is illustrated in Fig. 2.

The master node integrates microcontroller, Wi-Fi module, XBee module, water tank level sensors and water pump. The initial input voltage of master node PCB is 12V. Among the main components of master node, microcontroller, water level sensors and water pump operate at 5V. These parts are powered up by one voltage regulator L7805 which has a wide input range between 7 – 35V [13]. Besides, the output current of this voltage regulator is sufficient to provide microcontroller and water pump.

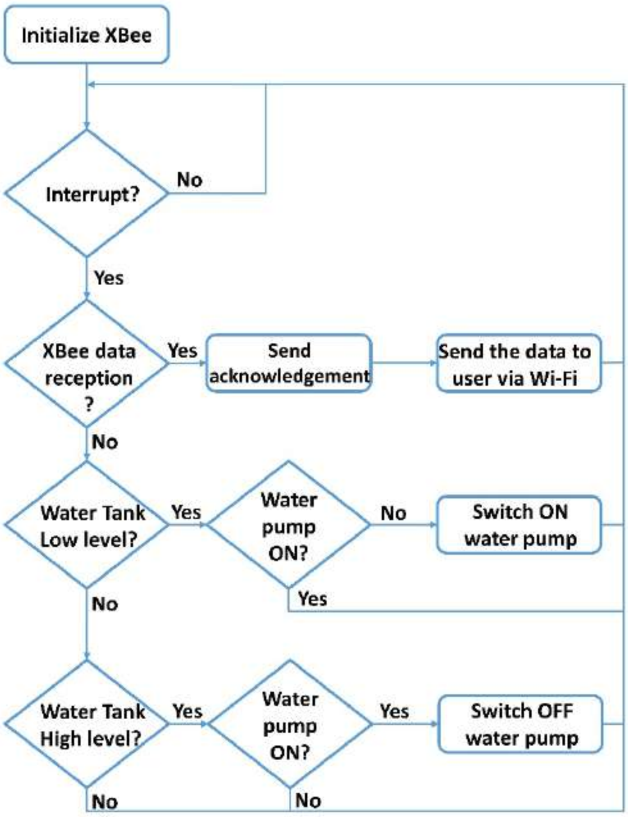

Fig. 2. Program flow of master node

MCP1700 low dropout voltage regulator is chosen to power up the components which work at 3.3V. This voltage regulator is very low cost (few cents) and consumes very low quiescent current (1.6 µA) [14]. Wi-Fi module and XBee module operate at 3.3V, but they cannot be supplied from one MCP1700. Because, ESP-01 module consumes 215mA and XBee modules consumes up to 33mA, and if both modules operate simultaneously the total current consumption is 248mA which almost equal to the maximum output current of the voltage regulator. Therefore, it is decided to dedicate separate voltage regulators for both modules in order to avoid overload on MCP1700. Figure 3 presents the implemented PCB of the master node.

C. End Device (Slave Node)

The end-device is designed to be capable to perform following main functions:

- Carrying out measurements of temperature, soil moisture level, rain presence and battery charge status
- Sending the measured values to coordinator wirelessly
- Resending the measured values to coordinator in case of not receiving acknowledgement from the coordinator device
- Automatically controlling actuator according to the measured values

- Automatically charging back-up battery from solar panel

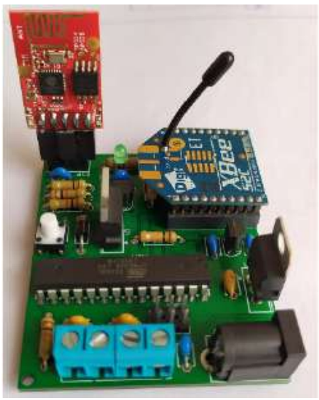

Fig. 3. Implemented PCB for the master node

The most significant parameters which must be under control are battery charge status and soil moisture level. Because, the back-up battery may be damaged due to overcharging or irrigating plant may die from draught owing to low level of soil moisture. Therefore, these parameters need to be measured frequently through the corresponding sensors and control actions should be performed. In this project, it is decided to measure them in every 8 minutes, but this period of time can be changed based on the type of irrigating plants. During 8 minutes, the microcontroller and radio module are put into sleep mode and all the sensors are disabled. In this time, only watchdog timer of microcontroller operates in active by consuming 10µA current at average. When the battery state is full of charge microcontroller terminates charging process, if not full, charging operation continues. If the soil moisture level increases up to the value that equals to the upper-threshold plus some hysteresis microcontroller closes solenoid valve and if the soil moisture level decreases down to the threshold microcontroller opens the solenoid valve. Besides that, in every hour end-device measures and transmits temperature, soil moisture level, battery charge status and rain presence values to the coordinator device. Fig. 4 presents the operation flow of the slave node.

The power section of the end-device is designed differently from the coordinator device. It is decided to involve all the electronic components that operate at the same voltage level in order to minimize number of voltage level conversions from one level into another. Considering the specification of being low-power of this work, it is proposed that all the electronic components of the end-device operate at the fixed 3.3Volts. Whole the circuit is powered up by the rechargeable battery with 3.7Volts and MCP1700 voltage regulator is employed to convert the input voltage into 3.3V. This voltage regulator is chosen due to its very low quiescent current of 1.6µA and maximum output current of 250mA [14]. However, the actuator of the end-device consumes 367mA, so it is decided to use separate voltage regulator for it. AP7366-33W5-7 fast transient low dropout regulator is chosen to power up actuator. Its maximum output current is 600mA at the fixed output voltage of 3.3V. But this regulator's quiescent current is 60µA that means it consumes 60µA current always whether it is used or not. This problem is solved that microcontroller disables AP7366-33W5-7 when the solenoid valve is not operating. In disabled mode the voltage regulator consumes only 0.05µA which is acceptable. When the solenoid valve needs to operate, microcontroller enables it by sending active high signal to its EN port.

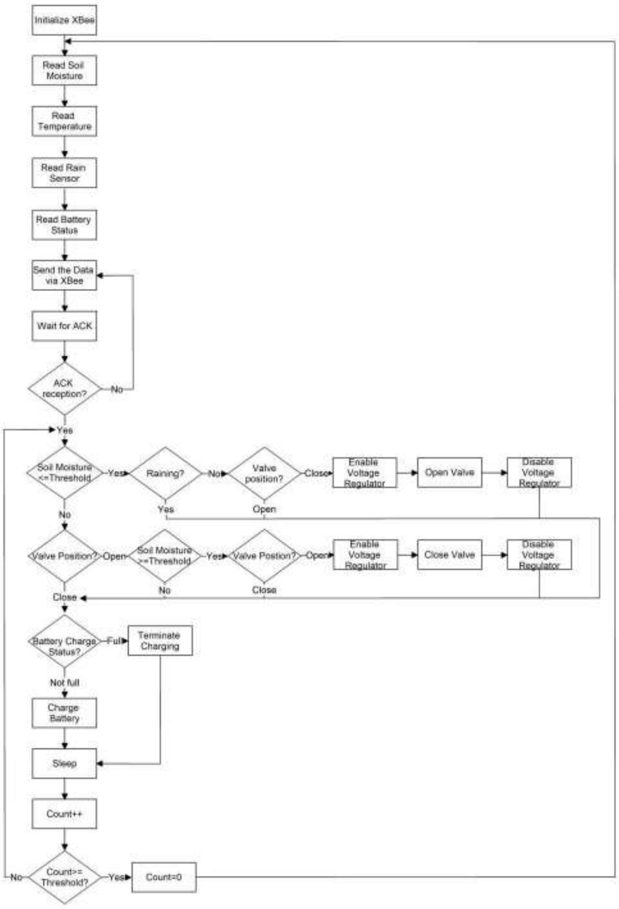

Fig. 4. The program flow of the end devices

In order to open and close the latching solenoid valve, the sign of control signal should be reversible. It can be executed by H-bridge drivers. TC78H651FNG bridge driver integrated circuit from Toshiba is chosen for the valve driver in this work. This IC operates at 3.3V and can output up to 1.5A of current at 3.3V [15]. Furthermore, this driver integrates two H-bridge circuits that means with TC78H651FNG the end-device is capable to control two actuators independently. Another advantage of this driver is its 0µA current consumption in standby mode. Because all the circuits in this integrated circuit configure with complementary metal oxide semiconductor elements that decrease intensely the standby current [16]. Besides, its small outline package (TSSOP) with the dimensions of 5mm X 4.4mm contributes overall PCB size to be compact. Fig. 5 shows the picture of the implemented PCB.

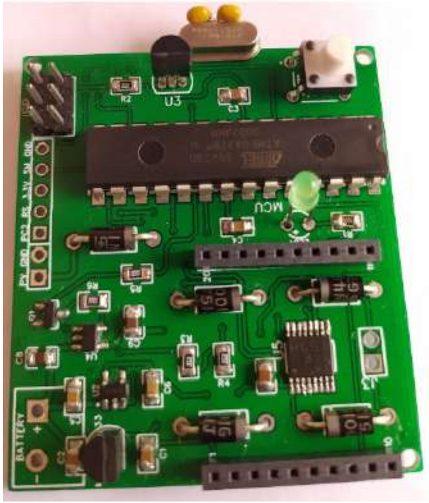

Fig. 5. End device PCB

The open-close states of the latching solenoid valve is executed according to the input and output functions of the H-bridge driver presented in the Table 2.

TABLE II. INPUT/OUTPUT FUNCTIONS OF H-BRIDGE DRIVER

Channel control inputs		**Channel outputs**		**Mode**
IN1	***IN2***	***OUT1***	***OUT2***	
HIGH	LOW	HIGH	LOW	Channel opening
LOW	HIGH	LOW	HIGH	Channel closing

The designed driver circuit for controlling the actuator is presented in Fig. 6.

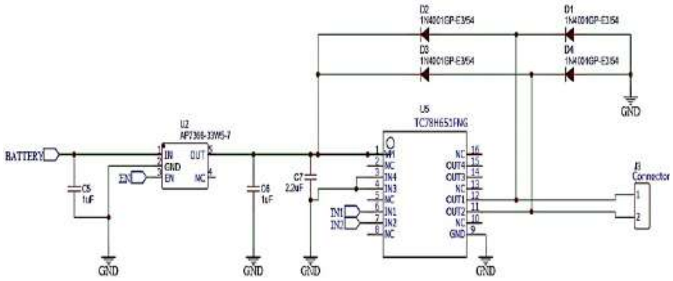

Fig. 6. Designed driver to control solenoid actuator

According to the requirements, the implemented end-device of WSAN should operate 2 years with the only one battery. Therefore, it is decided to design battery charging section by solar panel. Battery charging section should have following requirements:

- Over charge protection
- Reverse discharge protection
- Controllability by microcontroller
- Faster charge current regulation
- Compact dimension

Those requirements can be met by the use of MCP73831 charge management controller IC for Lithium-Ion and Lithium-Polymer batteries. This controller is very suitable to use in cost sensitive and space limited applications. It has fast charge constant-current mode and in this mode battery is charged at the programmed value of the current. The charge current value is formed inserting one external program resistor between PROG pin and V_{SS} pin. The programmed charge current is calculated using (1) [17]:

$$I_{reg} = \frac{1000}{R_{prog}} \tag{1}$$

where, R_{prog} is program resistor (in kΩ) and I_{reg} is programmed charge current (in mA). In this work, the charge controller is programmed to charge battery at 100mA constant current at 4.2V. In order to program it for 100mA charge current, 10kΩ program resistor is connected to the PROG pin. Besides, MCP73831 integrates the input overvoltage protection and reverse discharge protection.

TABLE III. STATE OF THE OUTPUT STATUS DURING CHARGING CYCLE [19]

Charge cycle state	**STAT1**	
	MCP73831	***MCP73832***
Shutdown	High Z	High Z
No Battery Present	High Z	High Z
Preconditioning	L	L
Constant-Current Fast Charge	L	L
Constant Voltage	L	L
Charge Complete-Standby	H	High Z

The charge status of battery can be read from STAT pin of MCP73831 by microcontroller. Table 3 shows the output signal on STAT pin of charge controller corresponding the state of charge cycle. The microcontroller reads STAT pin and makes decision to terminate or start the charging process by sending signal to PROG pin of MCP73831 through a transistor as depicted in Fig. 7, below.

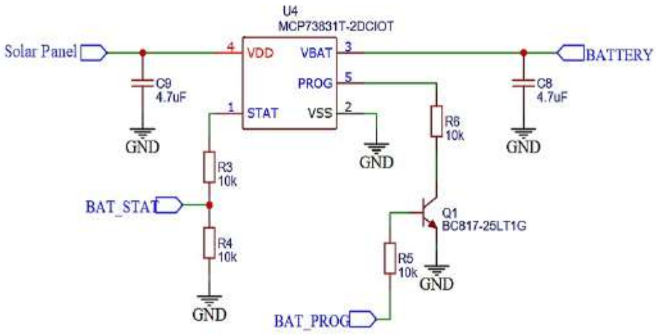

Fig. 7. Battery charging section of the end device

III. RESULTS AND DISCUSSION

The WSAN was tested in a rooftop garden and performed successful operation. Each end-device is powered up by single Li-Ion LIR14500 rechargeable battery. This battery has 3.7V nominal voltage and 800mAh nominal capacity. The end of discharge voltage of this battery is 2.8V [20]. In order to estimate the initial available energy amount of single battery following simple calculation can be used (2):

$$E_{init} = V \bullet I \bullet t \qquad (2)$$

$$E_{init} = 3.7V \bullet 800mA \bullet 3600\sec = 10656 Joules$$

Now, we can calculate total energy consumption by all the parts of an end-device.

One state change of latching solenoid valve spends 36.3mJ energy that is calculated from (3).

$$E_{state\_change} = \frac{V^2}{R_{coil}} \bullet T_{pulse} = \frac{3.3^2}{9} \bullet 0.03 = 36.3mJ \; (3)$$

Assuming the number of daily actuations is 10, and 60% of efficiency in power conversion, the total energy consumed to control one actuator per day is calculated as:

$$E_{daily\_actuator} = 10 \bullet E_{state\_change} \bullet \frac{100}{60} = 0.605 Joules$$

The maximum energy consumption values of the radio module in one cycle of wireless communication are presented in Table IV. One communication cycle is executed in every hour and spends 18.31*10^{-3} Joules from the back-up battery. In one day, the wireless communication cycle occurs 24 times and total energy consumption by XBee module is estimated as:

$$E_{daily\_XBee} = 24 \bullet 18.31 \bullet 10^3 = 0.44 Joules$$

TABLE IV. XBEE MODULE ENERGY CONSUMPTION OF SINGLE CYCLE ACTIVE COMMUNICATION

Action	**Duration (max)**	**Average current**	**Energy (Joules)**
Device is in sleep	≈ 1 hour	1µA	$11.88*10^{-3}$
Transition to active mode	10 ms	50 µA	$1.7*10^{-6}$
Data transmission and re-transmissions	50 ms (max)	33 mA	$5.5*10^{-3}$
Waiting and receiving acknowledgement	10 ms (max)	28 mA	$0.93*10^{-3}$
Device goes back to sleep			
Total energy for one hour activities:			$18.31*10^{-3}$

In one hour, microcontroller operates maximum $T_{hourly\_operation} \approx 78.5ms$ (1ms for reading sensors, 70ms for XBee active communication time, 1ms for 8-minute cyclic checking of soil moisture level and battery charge status) and sleeps almost $T_{hourly\_sleep} \approx 3600\sec$. Besides that, microcontroller is in active mode while the solenoid valve is actuating. In one day, solenoid valve actuates maximum 10 times and it lasts $T_{daily\_solenoid} \approx 10 \bullet 30ms = 300ms.$ That means, microcontroller also spends 300ms time per day in active mode. So, daily operation time of microcontroller is calculated as shown in (5).

$$T_{daily\_operation} = 24 \bullet T_{hourly\_operation} + T_{daily\_solenoid} \quad (5)$$

In active mode, the daily maximum energy consumption of microcontroller is

$$E_{daily\_active} = 3.3V \bullet 10mA \bullet 2.184\sec \approx 72.1 \bullet 10^{-3} Joules$$

In sleep mode, the daily maximum energy consumption of microcontroller is

$$E_{daily\_sleep} = 3.3V \bullet 44\mu A \bullet 24 \bullet 3600\sec = 12.55 Joules$$

The total daily energy consumption of microcontroller is sum of them:

$$E_{daily\_MCU} = E_{daily\_active} + E_{daily\_sleep} \approx 12.62 Joules$$

Moreover, voltage regulators also consume some energy consumption. The MCP1700 voltage regulator spends energy with the quiescent current of 1.6 µA during 24 hours in a day. Another voltage regulator AP7366 consumes energy with the quiescent current of 60µA only when the solenoid valve actuates (30ms). The total daily energy consumption of voltage regulators is

$$E_{daily\_VR} \approx 512.5 \bullet 10^{-3} Joules$$

In addition, all the sensors and H-bridge driver integrated circuit consume less than 1 Joule of energy in a day. Because, they are powered up only when microcontroller should measure the parameters or change the state of the actuator.

All in all, the total daily energy consumption of an end-device is calculated as:

$$E_{daily\_total} \approx E_{daily\_actuator} + E_{daily\_XBee} + \\ + E_{daily\_MCU} + E_{daily\_VR} + 1 = 14.5 Joules$$

As a result, the initial available energy of 10656 Joules a battery lasts approximately 734 days, which means more than 2 years of battery-life. However, it is crucial to take into consideration that there are some factors, e.g. temperature fluctuations and self-discharging phenomenon decrease the overall battery life time. That’s why, battery charging section is designed in the end-device PCB, and the charging can at least compensate those effects of discharging or increases the battery-life. Consequently, the requirement of 2 years battery life time is satisfied. Furthermore, the size of end-device’s PCB is 50mm to 45mm, so another requirement of being compactness is also satisfied.

IV. Conclusion

The solution to design and implement of low-power, low-cost and compact wireless sensor and actuator network to build automated irrigation systems in urban gardens has been presented in this paper. It utilizes ZigBee wireless technology to establish radio link between wireless nodes. In general, this work can have great impact for the automation of urban garden irrigation systems.

***Abstract*— Long-range radio technologies can ensure Low Power Wide Area Network deployment at a very low-cost intended for a huge range of Internet of Things applications. Recently, there are some attempts to implement Long-range cloud connection in this field. Nevertheless, several issues must be considered when setting up Long-range Internet of Things solutions. The paper proposes a novel solution based on Long-range Cloud implementation on The Things Network platform for the Water Pipeline monitoring application. This solution helps the researchers in terms of preparing their test-bed environment. For validation purposes, an experimental Long-range Cloud system has been established by the means of low-power and low-cost electronics using accessible open sources to deploy Long-range nodes, Long-range gateway, and The Things Network. The system proves its efficiency through its harmonic and synchronized operation mode.**

Keywords—IoT; LoRa; Low power; Cloud; The Things Network; Water Pipelines Monitoring application

I. Introduction

Network connectivity is provided on small edge devices by the Internet of Things (IoT) and new services are offered at reasonable prices. The major defy in the IoT applications and systems conception is the reduction of the implementation and maintenance costs of edge nodes having an increasing number concerning hand-held devices number.

By the dint of the wireless communication protocols specified for IoT applications, hardware complexity and power consumption of edge nodes can be decreased. In a similar context, Thanks to the cloud technology providing the common service frameworks, costs of IoT systems maintenance can be minimized. There are two important types of wireless communication protocols conceived for IoT: short- and long-range communication protocols. The first type includes Bluetooth, Zigbee, and WiFi as short-range communication protocols. These IoT protocols are appropriate for the indoor environment. These IoT systems are founded on application servers and wired networks excluding the short wireless link connecting edge nodes and wireless gateways. The second type integrates long-range wireless communication protocols for IoT like Sigfox [1] and LoRa [2]. The edge nodes related to this kind of systems do not necessitate battery change for many years. Additionally, these nodes have a communication range of tens of kilometers. These protocols are suitable for the outdoors permitting agricultural data sensing or civil infrastructure monitoring. However, adding network servers is essential to supervise the radio resource connecting wireless gateways and application servers taking into consideration the channel states of multiple wireless gateways. This fact creates the difference between long and short-range IoT systems. There are some low-power, long-range, operator-based technologies such as Sigfox^{TM} which cannot be utilized in an ad-hoc manner. Nevertheless, other technologies such as LoRa^{TM} proposed by Semtech radio manufacturers can be used in private. Deploying such technology according to the newly proposed LoRaWAN^{TM} specifications [2] is possible for large-scale interoperability or based completely on ad hoc solutions. These solutions enable us to perform customization toward specific application profiles.

In accordance with a previous survey on IoT cloud platforms [3], there are no less than 49 IoT cloud platforms on the market to satisfy the requirements of various individual users and groups such as enterprises, governments, farmers, healthcare providers, transport operators, manufacturing services and communications, etc. [4]. The best used IoT cloud platform [5] in LoRa Cloud projects is The Things Network (TTN) [6].

This paper focuses on the water pipeline monitoring as an IoT application, and more particularly, it presents a novel test-

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

bed LoRa Cloud platform based on the TTN which serves to detect the leaks in these pipelines since water is a vital raw material for the human being. It guarantees low-power and long-range communication with the cloud. Also, our proposed system is conceived with LoRa nodes and gateway, connected to the cloud via TTN.

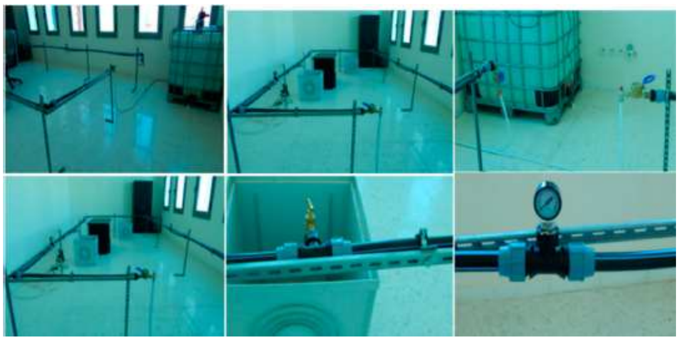

Fig 1. Water Pipeline Monitoring application [7]

The remainder of this paper is arranged as follows: Section II introduces the LoRaWAN, cloud computing, and TTN concepts. It treats different key issues with three notions. Section III presents the literature works related to the IoT cloud platforms suitable for the LoRa protocol and highlights some works in the water monitoring field. The realized test-bed structure is described deeply in section IV. Finally, section V concludes the paper.

II. PREREQUISITES

We define, in this section, three important concepts used throughout the paper, that is LoRaWAN, cloud computing, and The Things Network. First, we will identify the basics of the notion LoRaWAN by focusing on the principle characteristics that justify the LoRa protocol choice. Secondly, we present the cloud computing notion by emphasizing on its proven efficiency.

A. *LoRAWAN*

LoRa defines a low-power, long-range wireless communication platform designed as an efficient platform for small, low-powered devices. It is not only appropriate for battery-operated devices but also for IoT deployment [8].

The LoRaWAN system parts are illustrated in Figure 2. These parts are terminal, gateway, network server, and application server.

- **The terminal** is considered as an edge device deployed on remote sites.
- **The gateway** permits the transfer of packets coming from the LoRa terminals to the LoRa network servers and vice versa. Additionally, the gateway permits the transmission from the LoRa physical layer protocol to the protocols of the backhaul network.
- **The network server** operates with protocols of the upper-layer for IoT systems. Furthermore, control signaling messages of the MAC/L2/L3 layers are exchanged between this server and the terminals.

As a final point, **the application server** is responsible to handle the data collected from IoT terminals. Generally, different organizations work with the application server. Hence, it is independent of the IoT network protocols.

B. *Cloud computing*

Cloud computing presents the on-demand computer system resourcesavailability, especially computing power and data storage, with no active and direct managing of the user [9]. Broadly speaking, this term defines the data centers availability to numerous users through the Internet. Actually, huge clouds, having functions distributed throughout several emplacements from central servers, preponderate. If the connection to the user is completely closed, it can be considered an edge server.

There are three types of cloud[10]. Enterprise clouds are limited to a particular organization. Public clouds are available to various organizations. The hybrid cloud combines the first two types, i.e. enterprise and public clouds.

The cloud computing concept is based on resource sharing to reach scale economies and a high degree of coherence. Avoiding (or only minimizing) up-front IT infrastructure costs are permitted to companies by advocates of public or hybrid clouds. Furthermore, cloud computing allows enterprises to get their applications and run them faster, with ameliorated manageability and diminished maintenance costs. That demands from IT teams to rapidly regulate resources to accommodate unpredictable and fluctuating requirements. The “pay-as-you-go” is a model, typically used by cloud providers. Once administrators are not familiarized with cloud-pricing models [11], these models can bring unexpected operating expenses.

The pervasive availability of high-capacity networks induces the remarkable growth in cloud computing. The autonomic and efficient computing, as well as the low-cost computers and the ubiquity of high-storage devices,are considered another contributing factor in this growth.

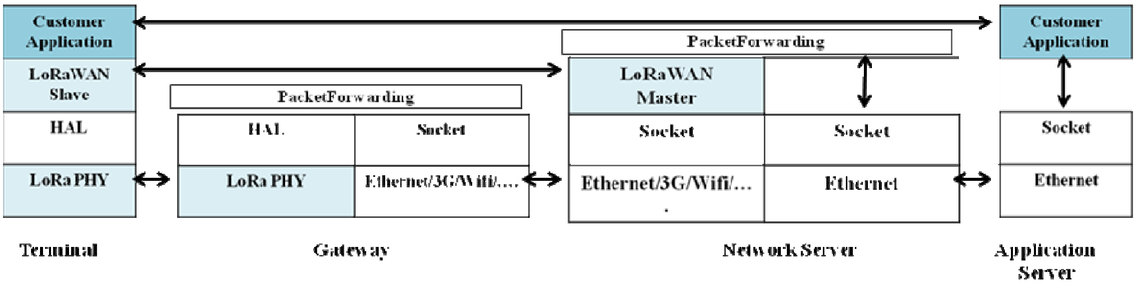

Fig 2. LoRaWAN system structure

Besides, hardware virtualization and the widespread implementation of service-oriented architectures are counted as a third factor that helped to improve cloud computing growth.

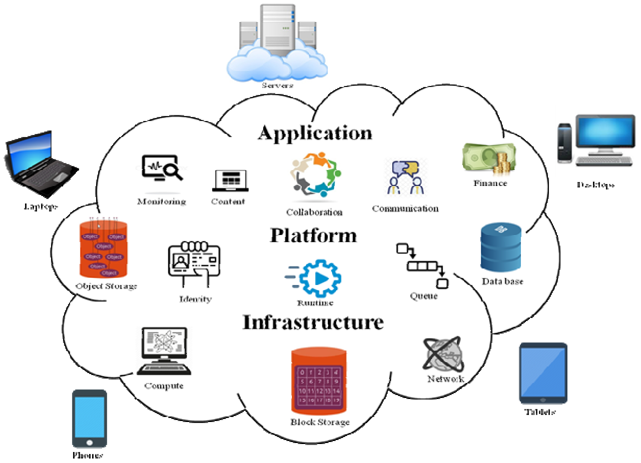

Fig 3. A general cloud computing model

C. *The Things Network*

The Things Network (TTN)[6] defines an IoT cloud platform suitable for the LoRa protocol. It allows low power devices to utilize long-range gateways for connecting to a decentralized network to exchange data with applications.

III. Related works

In the literature, several related works are developed using the LoRa Cloud Platform. The authors in [12] proposed a solution based on the LoRa platform. They deploy ad hoc IoT test-beds using Thingspeak [13] platform account for implementing the different sensors and the gateway. The data, also, is visualized in real-time.

ThingSpeak is an open-source API and application for the "Internet of Things", allowing storing and collecting data from connected objects using the HTTP protocol over the Internet or a local network. With ThingSpeak, we can create sensor data logging applications, location tracking applications and a social network for connected objects, with status updates. Moreover, it operates with several IoT platforms like Arduino, ioBridge, Twitter, Twilio, MATLAB, and ThingHTTP.

Pham et al. [14] explained how these applications are being utilized in the African rural and the sub-Saharan context. They detailed the deployment of sensors and gateway which can be made by small farms based on the free account created on the ThingSpeak platform. They explained a low-cost, long-range IoT framework that takes into account the cost of hardware and services, rapid ownership, flexibility, and customization by third parties.

WAZIUP project was proposed by Dupont et al. [15] to remote, largely isolated and rural, areas in the developing countries, particularly those located south of the Sahara Desert. The main objective is to deploy an open innovation IoT platform capable of bridging the North/South technological divide with Big Data capabilities.Three different cloud layers are used by WAZIUP IoT, these are the Infrastructure as a Service (IaaS), the Container as a Service (CaaS), and the Platform as a Service (PaaS). The first layer is provided by OpenStack [16] to provide virtual machines (VMs) running the full platform. The second layer is used to serve containers (e.g. Docker containers) to WAZIUP services and applications and provided by Kubernetes [17]. The compilation and deployment of an application are ensured by the third Cloud layer which is provided by Deis [18]. Indeed, Deis allows us to compile all the applications pushed by the users and to host them in containers on Kubernetes.

In addition to that, OpenStack is among the best known open source cloud platforms [16]. It provides essential functions for creating application services in any cloud environment. OpenStack provides a collection of interfaces for a service application program. It also ensures the automation of management operations.

The system services offered by OpenStack was used by So and his colleagues [19] in the real restructuring of the operations of the LoRa network server to make it scalable and flexible.Indeed, Four Virtual Machines are used on the function of the LoRa network server on the OpenStack platform. First, the gateway agent VM defines the protocol of communication between the LoRa network server and the LoRa gateway. The second is the LoRa data VM which ensures the operations of the data plane. The third VM is the application server which makes the LoRa network server connects with the application server using the efficient transport protocol. And the last one is the LoRa control that ensures the control plane.

The authors in [20] detail the implementation of the Thethings.io which is an industrial IoT cloud platform. By using a simple API, developers can have a whole back-end solution using the Thethings.io. It is considered hardware agnostic and permits to connect any device able to use WebSockets, HTTP, CoAP, or MQTT protocols. It supports supervision, monitoring, and analysis functions.

The project in [21] was based on TTN and develop a single channel LoRa gateway using Raspberry Pi 2 and other shields [22] open sources [23]. In this same type, the authors in [24] present a project that used the ESP8266 module [25] and the Radio RFM95/96. To test the developed single-channel LoRa gateway three nodes have been used. The first one is tested with an ESP8266-based LoRa node with RFM95 transceivers. The second one is with an ArduinoPro Mini. Then, the third one is based on a TeensyLC connected to HopeRF RFM 95 radio.

Saravanan et al. [26] proposed a solution formonitoring water level related to storage reservoirs in Water Distribution Networks (WDN). This solution is based on LoRa IoT enabled devices to remote actuation of valves. A gateway based on Raspberry Pi gathers the level data from all LoRa nodes. Then, it submits the data to the local server and control signals to the actuator. Grafana platform is utilized for data visualization and offers a human-machine interface serving to manipulate the valve remotely.

Another solution conceived for Smart Village Projects is proposed by Manoharan et al. [27]. Thanks to LoRa devices with sensors placed in water tanks at villages,the realized system supervises the level and quality of water in all tanks. The whole water distribution system is displayed and controlled from one place.

IV. LoRa IoT Cloud Platfrorm for water monitoring application

Our contribution consists in deploying a cloud-based platform for LoRa Internet of Things in Water Pipelines Monitoring Application (Fig. 4).

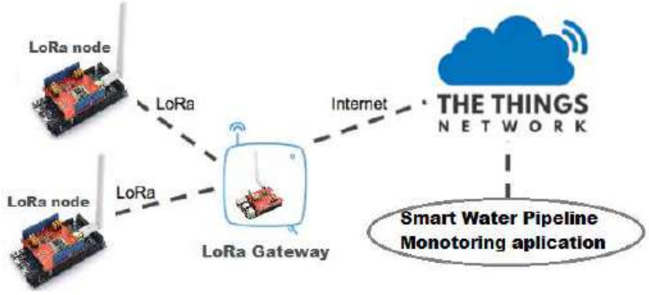

Fig 4. LoRa Cloud-based platform

On the one hand, we use two LoRa end-devices to collect water flow monitoring data based on YF-S201 Water Flow Sensor. We use the LoRa/ GPS HAT for RPI v1.4 [28] as the LoRa Radio module to deploy nodes. The first LoRa node is realized by the means of Arduino UNO R3 [29] and the second one is based on Arduino Mega 2560 [30] as shown in Fig.5.

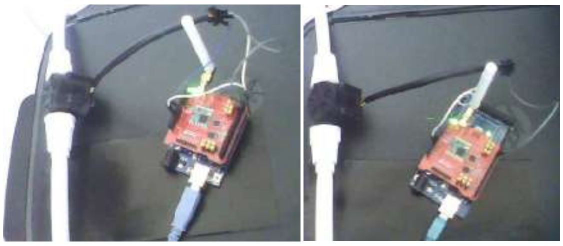

Fig 5. LoRa end-devices

On the other hand, we use a Raspberry Pi 2 model 3 [31] plugged into the LoRa/ GPS HAT for RPI v1.4 (Fig. 6). We program this component to be a LoRa gateway which receives data from LoRa nodes and sends it to the cloud. The realized component, having an identifier “eui-b827ebffff4f8ed9”, is characterized by its low-cost and low-power comparing with other electronic components. The whole platform is illustrated in Fig. 7.

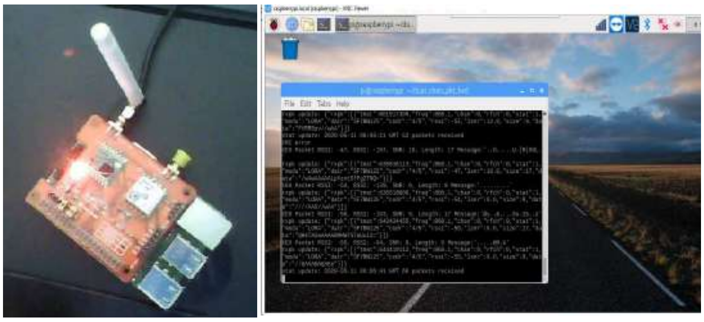

Fig 6. LoRa gateway

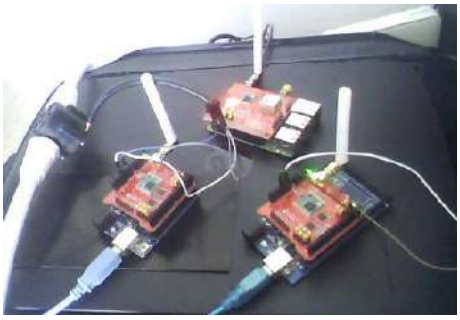

Fig 7. LoRa deployment

After ensuring the right function of our LoRa network (LoRa end-device sand gateway), we will register the gateway device in The Things Network (TTN) platform to connect to the Cloud. We add the LoRa component to TTN devices, that gives it active status (green color) as portrayed in Figure 8.This figure illustrates an overview of the added gateway. A specified ID is associated with the new component giving a detailed description. The connected status proves the successful connection of the created gateway.

Fig 9. Creation of Water Pipeline Monitoring application in the TTN

It is essential now to add application devices to define its nodes correctly. For this, we add the two realized LoRa end-devices to the created application as shown in Figure 10. Therefore, every end-device is characterized by its device address. In our case, LoRa node based Arduino UNO has an address equal to “26 01 15 8F” and the node based on Arduino MEGA 2560 has an address equal to “26 01 13 79”.

Fig 10. Adding LoRa end-devices to the Water Pipeline Monitoring application in the TTN

After finalizing the conception of our proposed LoRa cloud platform on the TTN, it is important to validate its operating mode. We circulate a water flow in the pipeline and the sensors start sends LoRa data to the gateway so we can observe uplink packets in the TTN Gateway Data. These packets are coming from nodes having addresses “26 01 15 8F” and “26 01 13 79” as illustrated in Fig. 11.

Fig 11. LoRa gateway data in the TTN

After receiving packets, LoRa gateway sends data to the Water Pipeline Monitoring application in TTN. We concentrate in this paper on monitoring the parameter water flow value since any degradation of its variation under a fixed threshold (a constant fixed experimentally) means leakage detection. In Fig. 12 and Fig. 14, we can perceive water flow values (L/hour) in hexadecimal form in the TTN application data of the first and the second end-devices.

Fig 15. Detailed information on water flow value related to the second LoRa end-device

We confirm from these results the well operating mode of our realized platform. To conclude, we achieve to conceive a successful LoRa cloud test-bed composed of two end-devices and a gateway connected to The Things Network for Water Pipeline Monitoring application.

V. Conclusion

The number of Internet of Things (IoT) applications has increased significantly in recent years. Thus, these require low-power operation and long-range communication which are provided by the application of LoRa/LoRaWAN. The connected devices generate big data that are processed by system architectures based on the cloud server. In this paper, we deploy a real LoRa Cloud platform on The Things Network for the Water Pipeline Monitoring application. Our platform is realized with materials guarantying low-cost, low-power, and low-consumption characteristics. Our contribution is very essential for researchers in terms of preparing their test-bed environment for any contribution related to the LoRa cloud communication in different IoT applications. As future work, we will develop a new version of the proposed platform based on several connected devices and that can be deployed in a large scale application.

***Abstract*—The occurrence of imbalanced datasets in medical imaging has proven to be a challenge for the development of models to analyze and evaluate the underlying condition. In this paper, the bias of the chest CT scan dataset is handled by taking discrete splits and employing ResNets to detect COVID-19 in each split. The scraped images were pre-processed using CLAHE histogram for comparison with low contrast images. Multiple ResNets were extended to form an ensemble neural network model using ANNs which handles the class imbalance. The system has an overall accuracy of 87.23% and the performance is assessed for each class. The image features identified are visualized using the GradCAM algorithm and some of the commonly found clinical features in the CT scan images of the patients suffering from this disease are summarized for better understanding the working of the model.**

Keywords—Imbalanced Data, COVID-19 detection, Ensemble ResNets, Chest CT-scans

I. Introduction

Deep neural network architectures have been widely used in the classification of medical images for the detection of the underlying condition [1]. These systems have the ability to identify and learn extensive features from the image datasets for discerning the clinical features detected in them.

COVID-19 [2] is a disease caused by the Severe Acute Respiratory Syndrome Coronavirus 2 or (SARS-CoV-2). It is a highly communicable disease with people experiencing respiratory illness and recovery expected with effective and appropriate treatment methods. The most commonly used test for the disease is the RT-PCR (Reverse Transcription Polymerase Chain Reaction) [3]. The identification of this disease can also be done by analyzing the chest CT scans of the patients for some of the widely observed clinical features given below [4]:

1) Ground Glass Opacities (or GGOs)

One of the most common findings in chest CT scans of people diagnosed with COVID-19 infections is GGOs [5]. Usually multifocal, bilateral and peripheral but in the early phase of this disease. They initially start developing from the inferior lobe of the right lung as a unifocal lesion.

2) Air space consolidation or opacification

This refers to the condition in which there is replacement of the usually present gas by fluids or solids in the lung parenchyma (small airways present in the lungs) [6].

3) Crazy paving appearance

This occurs in the more later stages of the infection. Here, thickened interlobular and intralobular lines in combination with a ground glass pattern are visible in the CT scans of the patients [7].

4) Bronchovascular thickening in the lesion

This refers to the widened vessels observed through the chest CT scans. The bronchial walls become thicker due to inflammation owing to the accumulation of liquid or mucus [8].

5) Traction bronchiectasis

This is a common condition observed in patients that arises when the airways to lungs may get damaged around GGOs [9]. Due to this, there will be accumulation of the mucus in the lungs, leading to a variety of complications including buildup of bacteria causing other infections.

6) Formation of subpleural bands

This is a comparatively rare condition found in patients where there is a formation of thin curvilinear opacities between the surface of the lungs and the chest walls [10].

The need for a model to handle highly imbalanced dataset would help in the identification of the disease with its estimated severity for timely treatment. With the spread of the disease to over 214 countries [11] of the world with widely varying severity and the low detection rates of the disease due to its asymptomatic nature, the identification of the disease is proving to be a challenge.

Residual deep neural networks or ResNets [12] follow the architecture of Convolutional Neural Networks (or CNNs) [13]. They exhibit high control over the information that flows from one cell to the next in the cell using a parameterized forget gate. These networks have a more refined residual block, a pre-activation variant of residual block for simplifying the flow of learned gradients in the network.

In the field of auxiliary medical diagnosis technology, ensembled deep neural networks [14] have performed extremely

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

capably for the detection of clinical features in the medial images. Ensemble network architectures [15] use the activations and the feature weights learned from the individual deep neural models and their learnings are enhanced for increasing the efficiency of their performance.

Images available for training may not be of uniform contrast or brightness for the neural network to identify features within them [16]. To improve the contrast improvement index, entropy and measure of enhancement [17], Contrast Limited Adaptive Histogram Equalization (CLAHE) is used for their normalization. The images are split into regions and histograms are calculated for each region which are then interpolated in between.

Gradient-weighted Class Activation Mapping (or GradCAM) [18] algorithms are a generalization of the Class Activation Mapping [19] algorithms used for producing visual explanations for trained deep neural models. The better localization and clear class discriminative saliency maps allow the understanding of the gradient weights built up at the final layer in the deep neural architecture [20]. They are combined with existing pixel-shaped visualizations to create high-resolution class-discriminative visualization.

In this paper, class imbalance is handled by creating splits of equal ratios of images across both COVID-19 and non-COVID-19 images. Each split is trained using a ResNet model and the outputs of the individual models are ensembled using a feed forward neural network. The effect of increasing contrast within the image by using CLAHE enhancement is analyzed. The features identified by the trained network are visualized using the GradCAM algorithm.

The rest of the paper is organized as follows. Section II gives the summary of some of the best deep neural networks used for medical image classification. The system design of the developed deep neural network is given in Section III, followed by the implementation details in Section IV. Results obtained from the model along with their analysis is presented in Section V. Section VI presents the conclusion of the paper with Section VII summarizing the proposed future works with improvements for the paper.

II. Related Works

The summary of some of the state-of-the-art work done in the field of classification of medical images, ensemble networks and imbalanced datasets is given below with a detailed discussion on its advantages and comparison with our developed model.

Ensemble deep neural network architectures are generally applied for the optimization of the performance of a single constructed network. Mporas and Naronglerdrit [21] evaluated the existing well-known pretrained models identification of COVID-19 in X-Ray images with publicly available datasets. Rafi [22] implemented an ensemble system for the detection of COVID-19 in X-Ray images. This network aimed to combine two state-of-the-art models, ResNet and Deep CNN, that used transfer learning techniques to achieve more accurate results. A SoftMax optimization function was used to further optimize over the trained models with pre-trained weights for faster concurrence.

In our model, the dataset contained highly imbalanced chest CT scans which were normalized using CLAHE algorithms for enhancing their features. These images were resampled and fed to a cluster of ResNet models for creating an ensemble architecture for improving the efficiency of the system and to balance the dataset by eliminating the high bias between the classes.

Liu et al [23] developed an ensemble architecture for highly imbalanced data using under sampling methods giving high performance with highly overlapped and skewed distributions. The use of classification hardness distribution concept helped to overcome the difficulties even with the presence of noise and missing values in the chosen dataset. Cahyana et al [24] expanded their minority class by oversampling to fix the size of the majority class for increasing the number of its instances for training the model for classification.

In our model, the dataset contained imbalance distribution of images in the binary classes and this was studied to improve the performance of our model by combining the attribute weights of each model trained with proportional images distributed in the classes and combined using an ensemble method. This has helped to avoid the oversampling of the minor class and ensure the high performance of the model for classification.

Deep neural architectures that implement supervised learning algorithms suffer from high prediction bias due to an imbalanced dataset resulting in poor performance and low computation efficiency. Aggarwal et al [25] used Active Learning (AL) algorithm to increase the effectiveness of labelling using an acquisition function. This function trains on the labelled dataset before picking more from the unlabeled dataset until the entire budget is spent.

Our model handles the imbalanced dataset by splitting the class with the higher images into multiple sets and training each set of the images with the images from the minor class. The performance of each deep neural model with a set of the images paired with the minor class is then saved with its learnt feature weights after training. The activations from each of the models is then used to build an ensemble network with high performance over the individual models.

Wang et al [26] performed the detection of COVID-19 in X-ray images dataset with data enhancement to 17 times the size for classification into COVID-19 positive, normal and viral pneumonia labels. They used transfer learning to fusion multiple trained models for dynamically improving their weight ratio during the training process.

In our paper, the enhancement of the dataset images were performed using CLAHE histogram for the ensemble ResNet-ANN model to extract the features for the classification of COVID-19 chest X-Ray images into COVID-19 positive and negative. This method would be applicable to study the imbalanced dataset with no oversampling to improve the quality of the training classification model. The learning of the model was visualized by using the Grad-CAM algorithm for observation.

In summary, an imbalanced COVID-19 dataset with chest CT-scans was chosen for binary classification. To improve the performance of the model, an ensemble architecture with multiple ResNets was developed with the major label split into sub-datasets for training with the minor dataset individually and the trained weights were fed into various meta classifiers for categorization. The visualizations of the trained attributes was done using the Grad-CAM algorithm and the analysis presented.

III. System Design

This section gives the details of the ensemble ResNet system for the binary classification of the COVID19 dataset with imbalanced classes.

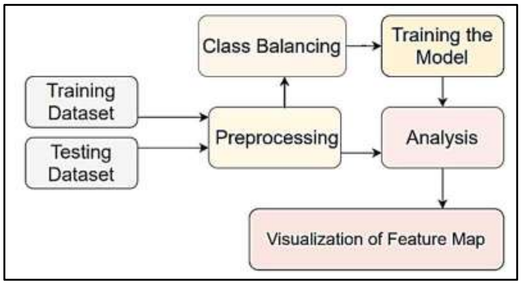

Fig. 1. Overall Architecture Diagram

Figure 1 describes the overall design which is adopted to handle class imbalance in the number of scans and to detect COVID-19 without bias towards any one class. The training and testing sets are preprocessed by using Contrast Limited Adaptive Histogram Equalization (CLAHE) to equalize the images. The training set is then balanced by splitting the set into equal parts and an ensemble of classifiers is trained. The testing set is analyzed against the trained model and the features identified by the model are visualized using GradCAM algorithm.

A. *Dataset Description*

The dataset contains chest CT-scans scraped from the Web [27] with the distribution given in Table I. Class 0 refers to the images that are obtained from those who have not tested positive for COVID-19 and Class-1 images are collected from those tested COVID-19 positive. The dataset has a high imbalance of positive images.

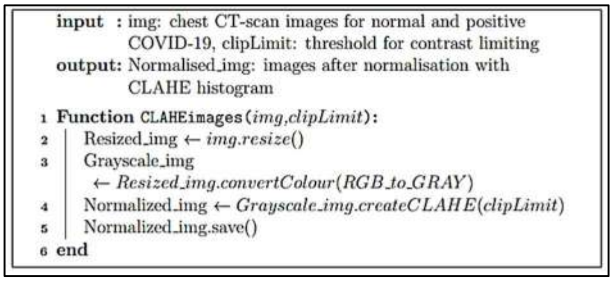
TABLE I. Images Per Class Distribution

Severity	Class 0	Class 1
Training set	566	5810
Testing set	50	100

B. *Preprocessing*

The CT Scan images are preprocessed by applying the CLAHE filter [28] which is a variant of Adaptive Histogram Equalization (AHE) [29]. AHE works on the principle of contrast amplification [30] and has a disadvantage of over amplifying noise when there are near-constant regions. This is overcome by using CLAHE which clips the histogram at a clip limit thereby limiting amplification to a value between 3 and 4. CLAHE performs histogram equalization locally, pixel by pixel. Algorithm 1 is used for applying CLAHE normalization on the collected CT-scans and to improve the contrast of the images.

Algorithm 1: CLAHE Normalization for pre-processing the images

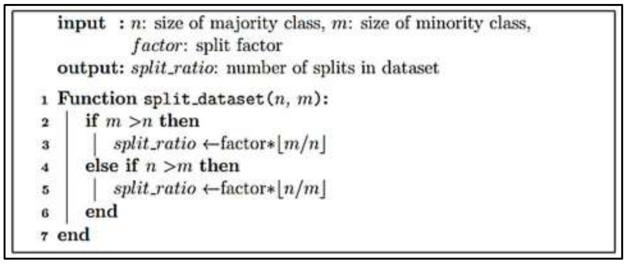


```
input  : img: chest CT-scan images for normal and positive
         COVID-19, clipLimit: threshold for contrast limiting
output: Normalised_img: images after normalisation with
         CLAHE histogram
Function CLAHEimages(img,clipLimit):
    Resized_img ← img.resize()
    Grayscale_img
      ← Resized_img.convertColour(RGB_to_GRAY)
    Normalized_img ← Grayscale_img.createCLAHE(clipLimit)
    Normalized_img.save()
end
```

C. *Class Balancing*

Imbalance in dataset [31] classes can result in the model overfitting the data of the major class and not being able to predict the minor class effectively. To resolve this, resampling [32] of the dataset using replication of minority classes is performed by calculating the ratio with which the dataset should be split as seen in Algorithm 2. This ensures the majority class is balanced with the minority class as in each split, all the samples of the minority class are present and the same number of differing samples of majority class are present. The split factor determines the balance of major and minor classes.

Algorithm 2: Determining Dataset Split Ratio



```
input  : n: size of majority class, m: size of minority class,
         factor: split factor
output: split_ratio: number of splits in dataset
Function split_dataset(n, m):
    if m > n then
        split_ratio ←factor∗$\lfloor m/n \rfloor$
    else if n > m then
        split_ratio ←factor∗$\lfloor n/m \rfloor$
    end
end
```

D. *Modelling Each Data Split*

Once the dataset is split into divisions with equal ratios of major and minor classes, each division is modelled using the ResNet model. ResNets [33] are a deep neural model that solve the vanishing gradient problem by using “Residual blocks” which are seen in Figure 2.

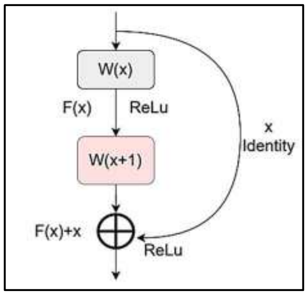


Fig. 2. Structure of ResNet Block

The core aspect of residual blocks are “skip connections” [34]. Using skip connections the output $H(x)$ can be defined as,

$$H(x) = F(x) + x \tag{1}$$

ResNets resolve the vanishing gradient problem by creating many small networks that are ensembled together to create a deeper network. The output of a previous layer is added to a deeper layer and this process is repeated throughout the network ensuring that there is a continuous propagation of values.

E. Ensemble ResNet Architecture

Once ResNets are built for each dataset split, an ensemble network is created. Ensembling [35] involves modelling the predictions of individually trained models in order to improve the performance of detection. Each individual ResNet is trained on a particular dataset split and then the entire training set is run against the trained ResNets as seen in Figure 3. The output predictions of the ResNet models are then trained using a Level-1 classifier achieving a two-step optimization in learning. The Level-1 classifier is chosen as an ANN based on the overall performance of the classification model.

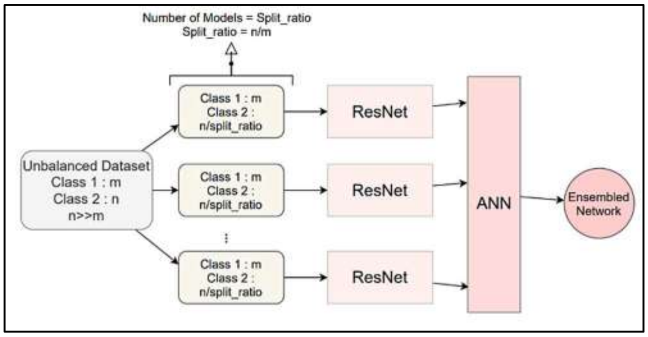

Fig. 3. Ensemble Network to Resolve Class Imbalance

IV. System Implementation

The neural models are implemented using Google Colab with Intel(R) Xeon(R) CPU @ 2.20GHz Processor, 13 GB RAM and 12GB NVIDIA Tesla K80 graphics processor.

A. Dataset Preprocessing

The images from the dataset contain chest CT-scans from both patients tested positive for COVID-19 and those who tested negative. These images undergo normalization using Contrast Limited Adaptive Histogram Equalization (CLAHE) [36] normalization for over-amplification of the contrast. This procedure is applied on the luminance channel of the images and the results are after equalizing only the luminance channel [37] of an Hue Saturation Value (HSV) image. The clip limit [38] which acts as the threshold for contrast limiting is taken as 5. Figure 4 a) and b) show how CLAHE histogram equalization increases the contrast within the image and shows how the features within the image get highlighted with better equalization. Once CLAHE histogram equalization is applied, the CT scan images are augmented using Keras's Image Data Generator [39]. Augmentation parameters used are specified in Table II.

B. Balancing the Dataset

The processed data set is then resampled to avoid class imbalance. In this dataset collected, positive COVID-19 images are the major class and negative COVID-19 images are the minor class. The split factor of the dataset is taken as 2 i.e. the number of positive COVID-19 images in each dataset split is twice the number of negative COVID-19 images in that split.

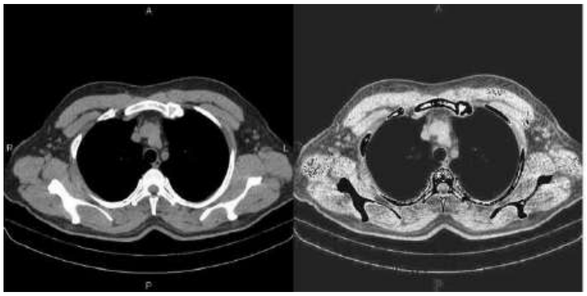

Fig. 4. CT Scan Image of COVID-19 Positive Patient a) Original Image b) with CLAHE Histogram Equalization

TABLE II. Image Data Generator Parameters

Parameter	Value
Rotation Range	40 degrees
Width_shift_range	0.2
Height_shift_range	0.2
Rescale	1/255
Shear_range	0.2
Zoom_range	0.2
Horizontal_flip	True

TABLE III. Training Parameters of Individual ResNet Models

Parameter	Value
ResNet Version	1
Number of Layers	20
Loss	Categorical Cross Entropy
Optimizer	Adam
Learning Rate	0.01
Batch Size	64
Epochs	10

The number of dataset splits is calculated to be 5 according to Algorithm 2. Each of the 5 dataset splits has 566 non COVID-19 images and 1162 positive COVID-19 images.

C. ResNet Model

The ResNet model was built using Keras and TensorFlow [40]. The model has an initial convolutional layer with 16 filters of 32 x 32 dimensions applied. The outputs of the initial convolutional layer are fed to a batch normalization layer followed by an activation layer. Next, 64 filters of 32 x 32 dimensions are applied followed by layers of batch normalization, activation and convolution. This process is repeated by reducing the dimensions of the filters by half and doubling the number of the filters until the number of filters reaches 256 and the dimensions are 8 x 8.

At each stage of the ResNet there are residual blocks that concatenate the output of the previous block with the output of the current block using a concatenation layer. The activation function used in these hidden layers is ReLu [41]. The final stage of the ResNet involves average pooling and flattening the vectors to form a 1D tensor. The output layer has 2 nodes which are activated using SoftMax activation [41]. The ResNet models are trained using the parameters described in Table III.

D. Ensemble Neural Network

Once the ResNet models are trained, each image of the training set is run through each of the 5 models and the output activations are noted and then fed into a Level-1 meta classifier. The Level-1 classifier learns the features from the already optimized activations and tries to determine if the CT scan images have COVID-19 or not.

Different machine learning algorithms are implemented as a part of determining the best meta classifier. It is observed from Figure 5 that the Artificial Neural Network (ANN) performed as the best Level-1 classifier with the accuracy of the predicted images at 87.13%. This can be attributed to the size of the dataset being smaller along with the presence of imbalanced data classes enabling the deep neural model to execute its own feature engineering to search for features and converge faster during the training of the model.

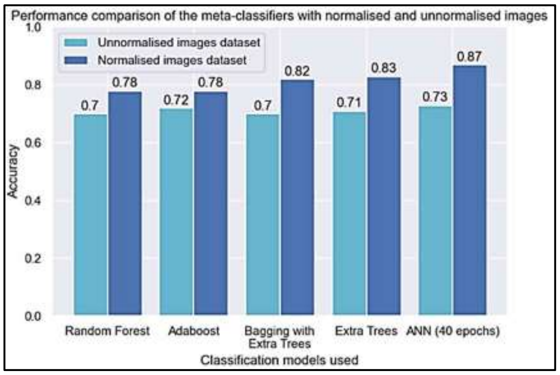

Fig. 5. Performance Comparison of Meta-Classifiers with Normalized and Unnormalized Images

The Level-1 ANN model has 10 input nodes corresponding to the output probabilities of 5 level-0 models. It is followed by 7 hidden layers with 8,16,32,64,64,32,16 and 8 nodes each activated by ReLu activation function. The output layer has 1 node activated by Sigmoid [41] activation function. The Level-1 ANN classifier is trained using the parameters given in Table IV.

TABLE IV. TRAINING PARAMETERS OF LEVEL-1 ANN CLASSIFIER

Parameter	Value
Loss	Binary Cross Entropy
Optimizer	Adam
Learning Rate	0.01
Batch Size	32
Epochs	50

V. RESULTS AND ANALYSIS

This section presented the results obtained from the classification of COVID-19 CT-scan images using the ensembled ResNet model developed.

A. Training plot of the ensemble ResNet for the classification of COVID-19 CT scans with and without CLAHE histogram

The training plot of the ensemble ResNet-ANN model using the ANN as meta-classifier is given in Figure 6 along with the variation of accuracy and loss. This helps to identify the learnings of the model to stop the training before overfitting the data but with enough time to avoid underfitting the data.

The accuracy is observed to have reached a peak at about 92.34% with the loss at 17.49%.

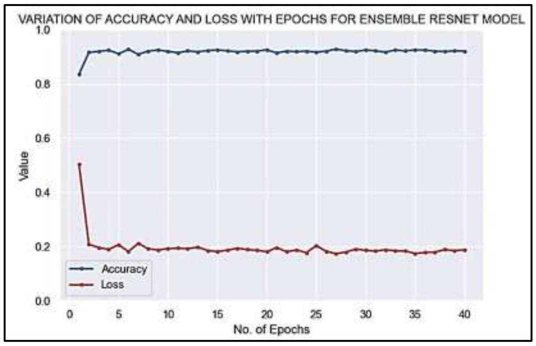

Fig. 6. Variation of Accuracy and Loss with Epochs for Ensemble ResNet Model

B. Confusion matrix of the ensemble ResNet model trained with images normalised with CLAHE histogram

The confusion matrix of the ensemble ResNet-ANN network in Figure 7 is observed to understand the performance of the network for the binary classification of images. The identification of the classes by the developed architecture proves the ability of the model to handle imbalanced datasets.

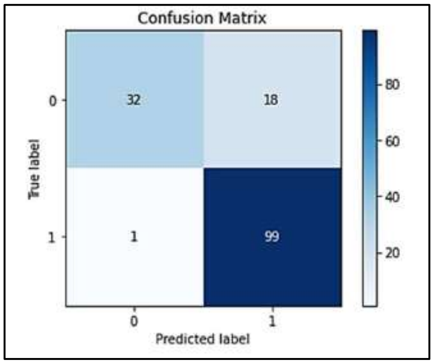

Fig. 7. Confusion Matrix for the Ensembled ResNet Performance Model

C. Performance comparison of the ensemble deep neural model for normalised and unnormalised images

The performance of the trained ensemble model for binary classification is analyzed with accuracy, precision recall and F1-score values.

Accuracy [42] gives the ratio of the correctly classified instances to the total number of instances.

$$Accuracy = (TP + TN)/(TP + TN + FP + FN) \qquad (2)$$

Recall [42] value gives the proportion of actual positive instances to the total number of predicted positive instances.

$$Recall = TP/TP + FN \tag{3}$$

Precision [42] gives the proportion of predicted positive values that are actually positive and its variance with no. of dense layers.

$$Precision = TP/TP + FP \tag{4}$$

F1 score [42] combines the precision and recall value of the trained deep neural model using a harmonic mean.

$$F1\,Score = 2 * Precion * Recall/(Precision + Recall) \tag{5}$$

F1 Score is a better measure to seek a balance between Precision and Recall. This is highly useful in cases such as here where there is an uneven class distribution (large number of Actual Negatives).

TABLE V. PERFORMANCE OF THE ENSEMBLED RESNET MODEL

Trained over CLAHE normalized images				
Class	**Precision**	**Recall**	**F1-Score**	**Accuracy**
0	0.97	0.64	0.77	0.87
1	0.85	0.99	0.91	
Avg.	0.91	0.81	0.84	
Trained over Unnormalized images				
Class	**Precision**	**Recall**	**F1-Score**	**Accuracy**
0	0.99	0.23	0.33	0.73
1	0.71	0.99	0.83	
Avg.	0.86	0.73	0.67	

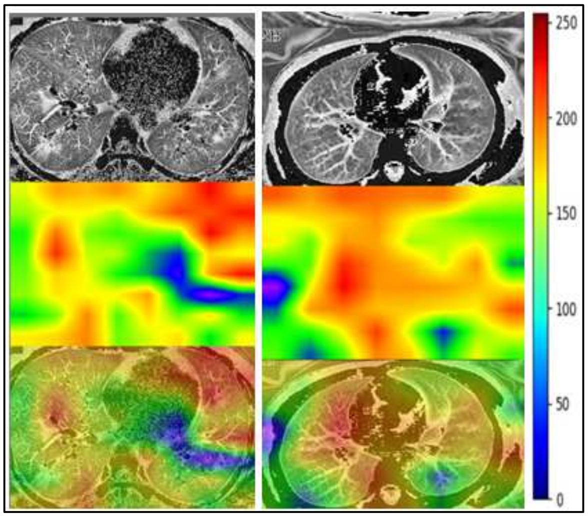

Fig. 8. GradCAM Visualization of CT Scan Images of Patient Tested Positive for COVID-19 with the Prediction Score at a) 0.51 and b) 0.79

From Table V, it is observed that the images that the model performed better when the input images were normalized with the CLAHE than the unnormalized images. The identification of the Class 0 images was performed inadequately when the model was trained with unnormalized images. An accuracy of 0.87 was obtained when the ensemble model was trained with images pre-processed with CLAHE histogram.

D. *Visualisation if the activations of the trained Ensemble ResNet model over normalised images using GradCAM*

GradCAM visualisation of the trained weights of the ensembled ResNet model on the CT scans dataset for Class-1 images is done here. This helps to provide a visual explanation for the trained deep neural model on the input dataset. From Figure 8 a) and b), the GradCAM visualization of the image is observed to possibly identify the areas of clinical features such as Ground Glass Opacities, air space opacification in the CT scan images for their classification as belonging to Class-1 or COVID-19 positive.

VI. CONCLUSION

An ensemble method is introduced to deal with class imbalance while dealing with identification of positive COVID-19 CT scans. The normalization of the images is achieved by applying CLAHE histogram over the images for enhancing their features before splitting the dataset into equally balanced parts and feeding the images to the Level-0 ResNet models for training. The output containing the activations with feature weights learned by these multiple ResNet models are used to create an ensemble network architecture for enhancing their performance and improving the existing bias in the binary classes of the images. The model performed with an accuracy of 87.23% with CLAHE enhanced images and the learning of the trained models are visually represented using GradCAM algorithm.

VII. FUTURE WORKS

The application of augmentation in the deep neural networks for the localization of the symptoms found in the visualization on CT scan images can be explored further for the diagnosis any disease. This would enhance the results presented for proper diagnosis and treatment of the patients for their recovery at the earliest.

ACKNOWLEDGEMENT

We thank Dr. Manjula Jayakumar, M.B.B.S, D.O., D.N.B, F.I.C.O. (UK), Chief Pediatric Ophthalmologist, Dr. Agarwal’s Eye Hospital and Research Centre, Chennai for her invaluable insights for the completion of the project.

***Abstract*— Quadcopter, also known as quadrotor, is an unmanned Ariel vehicle (UAV). This paper presents the dynamic analysis of a quadcopter for propulsion and flight control with system noise. The quadcopter is maneuvered by adjusting the angular velocities of the rotors which are controlled by the DC motors. In this paper, a novel controller is proposed that uses the properties of four-element viscoelastic material. To make the system robust some random noise is generated which is absorbed by the controller. The performance of the novel controller is compared with the conventional PID controller by making both the controller optimum. The robustness of the novel controller is compared with the PID controller by using the force-displacement hysteresis curve.**

***Keywords*— unmanned aerial vehicles; UAVs; Quadcopters; PID controller; vertical takeoff and landing; VTOL**

I. INTRODUCTION

There are many types of multicopters which use different platforms such as Tricopter, Quadcopter, Hexacopter etc. Quadcopter has received significant attention of researchers as it gives rise to several areas of interest, which are very complex in nature. The Quadcopter has evolved into more complex system [1] [2]. The design requirements for various usage of UAVs have given various problems in the field of stability. Hence researchers have developed various control techniques to achieve stable system. There are different control systems applied for robust control of a Quadcopter, including PID controllers [3] [4] [5], LQR controllers [6], the backstepping control [7] and other nonlinear controllers [8]. The Quadcopters are used for various applications such as civilian applications, including remote sensing, aerial imaging, firefighting, environmental measurement, disaster relief and emergency management, situational awareness, infrastructure surveys, and several other military and commercial applications. While in operation the Quadcopters experience various forces, which can destabilize it. One of the main problems with the linear control system is adaptability with random forcing functions that come into action when a Quadcopter is flying. Most of the linear controllers fail when these forcing functions dominates. In this paper we tried to develop a novel control technique that will take care of the above problem. The controller is based on the response of a four-element (FE) viscoelastic material.

This is achieved by developing a mathematical model for a Quadcopter and then the controller is optimized and applied to the system. The results are compared with a conventional PID system.

Mathematical Model of Quadcopter:

THE FIGURE BELOW SHOWS THE BODY FRAME OF A QUADCOPTER MODEL.

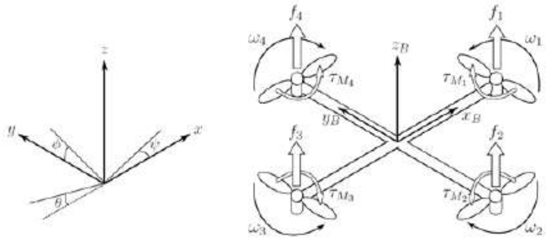

Figure 1Inertia and Body frame of a Quadcopter

In inertial frame the absolute position of the Quadcopter is defined as ζ. Similarly, the angular positions in inertial frame is defined as η. Pitch angle θ determines the rotation of the quadcopter around the y-axis. Roll angle Φ determines the rotation around the x-axis and yaw angle Ψ around the z-axis. The variable q contains both the linear and angular positions.

$$\zeta = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

$$\eta = \begin{bmatrix} \phi \\ \theta \\ \psi \end{bmatrix}$$

$$q = \begin{bmatrix} \zeta \\ \eta \end{bmatrix}$$

The Centre of mass of the Quadcopter is considered as the origin of the body frame. Vb and are considered as the linear velocities and the angular velocities respectively in body frames.

$$V_b = \begin{bmatrix} v_{xb} \\ v_{yb} \\ v_{zb} \end{bmatrix}$$

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$$w_b{}^b = \begin{bmatrix} p \\ q \\ r \end{bmatrix}$$

The rotation matrix is given by Q as follows:

$$Q = \begin{bmatrix} C\psi C\theta & C\psi S\theta S\phi - S\psi C\phi & C\psi S\theta C\phi + S\psi S\phi \\ S\psi C\theta & S\psi S\theta S\phi + C\psi C\phi & S\psi S\theta C\phi - C\psi S\phi \\ -S\theta & C\theta S\phi & C\theta C\phi \end{bmatrix}$$

Where Sx=Sin(x) and Cx=Cos(x). Here Q is an Orthogonal matrix, Hence $Q^{-1} = Q^T$.

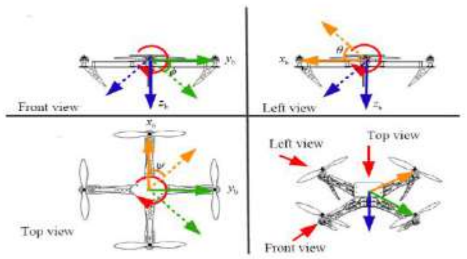

Figure 2Representation of Euler angles

Suppose W is the transformation matrix for angular velocities from Inertial frame to the body frame. Then W is given by:

$$W = \begin{bmatrix} 1 & 0 & -S\theta \\ 0 & C\phi & C\theta S\phi \\ 0 & -S\phi & C\theta S\phi \end{bmatrix}$$

$$w_b{}^b = \begin{bmatrix} p \\ q \\ r \end{bmatrix} = W \begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{bmatrix}$$

Here the Quadcopter is assumed to be symmetric about X and Y axes. Hence the inertia matrix is a diagonal matrix, which is given by:

$$I = \begin{bmatrix} I_{xx} & 0 & 0 \\ 0 & I_{yy} & 0 \\ 0 & 0 & I_{zz} \end{bmatrix}$$

The angular velocity of the rotor n, denoted as ω_n gives force F_n which is given by:

$$F_n = k\omega_n{}^2$$

Similarly, the torque due to the above rotor n is given by:

$$\tau_n = b\omega_n{}^2$$

Where k and b are lift and drag coefficient respectively. The combined force generated is in Z direction and is given by:

$$\text{F=} \sum_{n=1}^{4} F_n$$

Now the torque is given by:

$$\tau = \begin{bmatrix} \tau_\phi \\ \tau_\theta \\ \tau_\psi \end{bmatrix} = \begin{bmatrix} lk(-\omega_2{}^2 + \omega_4{}^2) \\ lk(-\omega_1{}^2 + \omega_3{}^2) \\ b\sum_{n=1}^{4} \omega_n{}^2 \end{bmatrix}$$

Where l is the distance between center of mass and the rotor.

Newton-Euler equations:

In the body frame the body is moving with an acceleration $\dot{V}_b{}^b$ for which the force required is m$\dot{V}_b{}^b$. The centrifugal force is given by ($w_b{}^b \times (mV_b{}^b)$). Now these two forces will be equal to the gravity force and thrust force created due to the rotors. Hence the equation is given as follows:

$$m\dot{V}_b{}^b + w_b{}^b \times (mV_b{}^b) = Q^T G + F^b \text{ ....(I)}$$

The centrifugal force is nullified in the inertial frame hence the above equation is reduced to:

$$m\ddot{\zeta} = mG + QF^b$$

$$\begin{bmatrix} \ddot{x} \\ \ddot{y} \\ \ddot{z} \end{bmatrix} = -g \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} + \frac{F}{m} \begin{bmatrix} C\psi S\theta C\phi + S\psi S\phi \\ S\psi S\theta C\phi - C\psi S\phi \\ C\theta C\phi \end{bmatrix} \text{ ....(II)}$$

In the body fixed frame, the angular acceleration of the inertia is $I\dot{\omega}_b{}^b$ and the centripetal force is $\omega_b{}^b \times (I\omega_b{}^b)$. Now these two forces are equal to external torque τ . Hence the equation is given by:

$$I\dot{\omega}_b{}^b + \omega_b{}^b \times (I_b\omega_b{}^b) = \tau \text{ ....(III)}$$

$$\begin{bmatrix} \dot{p} \\ \dot{q} \\ \dot{r} \end{bmatrix} = I_b{}^{-1} \begin{bmatrix} \tau_\phi \\ \tau_\theta \\ \tau_\psi \end{bmatrix} - I_b{}^{-1}(\omega_b{}^b \times (I_b\omega_b{}^b)) \text{ ....(IV)}$$

The various parameters used for the quadcopter are given below:

Parameters	Value	Unit
g	9.81	m/s2
m	2	Kg
l	0.2	M
k	1.32E-5	
Ix	1.25E-2	Kgm2
Iy	1.25E-2	Kgm2
Iz	2.5E-2	Kgm2
b	5.17E-7	

Table 1parameters of the Quadcopter

1. **Control Design:** A PID controller for the above Quadcopter ca=n be designed as follows:

Suppose we have four inputs (i.e. three Euler angles and altitude), then the error dynamics equation is given by:

$$\ddot{e}+K_I\int e+K_d\dot{e}+K_pe=0 \text{ ....(V)}$$

Where, e=desired state-real state and K_I , K_d & K_p are gains.

Now the equation for the controller is:

$$\ddot{\zeta}_c=\ddot{\zeta}_{des}+K_I\int e+K_d\dot{e}+K_pe \text{ ....(VI)}$$

This gives the thrust force as:

$$F=m(g+\ddot{\zeta}_c)/(\cos(\theta)\cos(\phi)) \text{ ....(VII)}$$

1.1. Novel Control Law:

The proposed novel control law is based on the behavior of a viscoelastic material. The relationship between the force and displacement of a viscoelastic material can be represented by multielement models. A model consisting of four elements (two spring and two dampers) is shown below. This type of materials finds there use in vibration reduction [9] [10].

The relation between the force and displacement is derived below:

$$F_m(t)=k_1\delta(t)+c_1\dot{\delta}(t)+k_2(\delta(t)-\vartheta(t))$$

................(VIII)

Where, $\delta(t)$ is the resulting displacement of the four-element (FE) viscoelastic material model. $F_m(t)$ is applied force on the model. $\vartheta(t)$ is displacement in second damper

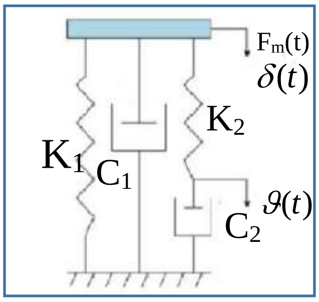

Figure 3Four-element viscoelastic material

as shown in the figure. Now using force balance equation:

$$k_2(\delta(t)-\vartheta(t))=c_2D\vartheta(t) \text{ ....(IX)}$$

Eliminating $\vartheta(t)$ from equation (VIII) we get:

$$F_m(t)=\left(\frac{k_1k_2+(c_2(k_1+k_2)+c_1k_2)D+c_1c_2D^2}{k_2+c_2D}\right)\delta(t) \text{ .(X)}$$

The above equation represents the constitutive equation of a FE viscoelastic model. The novel control law i.e. the four-element control law is based on the above equation. The equation can be rewritten as:

$$F_m(t)=G*\delta(t) \text{ ....(XI)}$$

Where, G is the equivalent transfer function of FE controller. Now the control law for the quadcopter is given as follows:

$$\ddot{\zeta}_c=\ddot{\zeta}_{des}+\left(\frac{k_1k_2+(c_2(k_1+k_2)+c_1k_2)D+c_1c_2D^2}{k_2+c_2D}\right)*e(t)$$

4. RESULT AND DISCUSSION :

The Quadcopter is simulated for the parameters as given in the table. Both the controller is designed as given above. The results are compared for both optimized controllers. The block diagram for the PID/FE controller is given below.

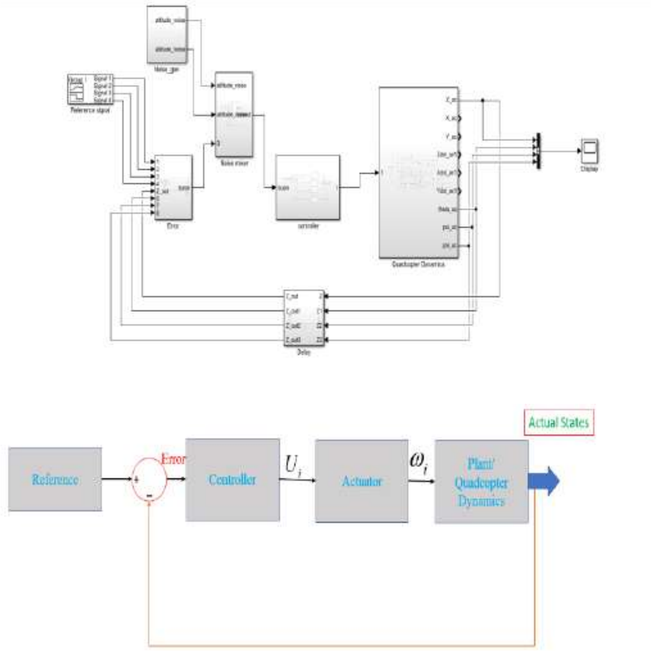

Figure 4Control architecture of Quadcopter FE controller

A basic input signal is given where for the first 1 sec, the altitude increases steadily to 1m then remains stable for 2 sec. After 3 sec it again rises steadily to 2m in 3 sec, then the altitude decreases steadily to 1m in 2 more sec. after this the altitude remain stable until 10 sec. The other inputs are kept constant as shown below.

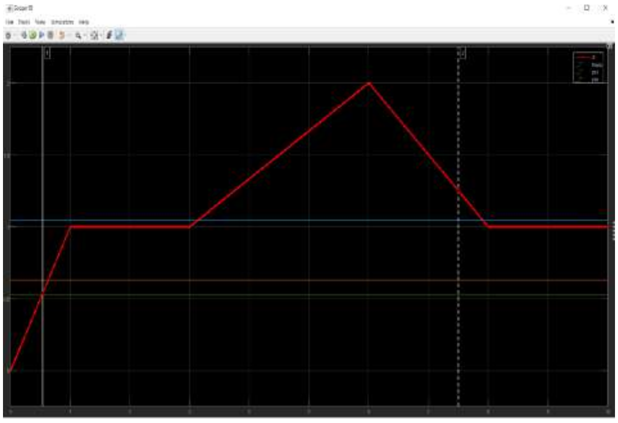

Figure 5Reference signal for both the controller

Both the controllers are optimized by minimizing the mean error and maximum peak. But the two won’t happen simultaneously. Hence, we took the minimum value of the multiplication of the above two.

Altitude variation:

The altitude variation of the quadcopter for the given reference as shown in the figure 5 is given below.

The result for both the controller i.e. PID and FE is shows that in PID controller the error variation is much more compared to the FE controller. The PID controller takes more time to settle and when there is an abrupt change in the input signal the peak overshoot of the PID controller is more. Hence the FE controller is more stable in all situation in the given reference signal. This can be further verified later, when we will see the hysteresis curve for both the controller. Here it is to be noted that for both the controller there is continuous mixing of noise in the input signal, this is why there is a continuous variation in the output state even after settling.

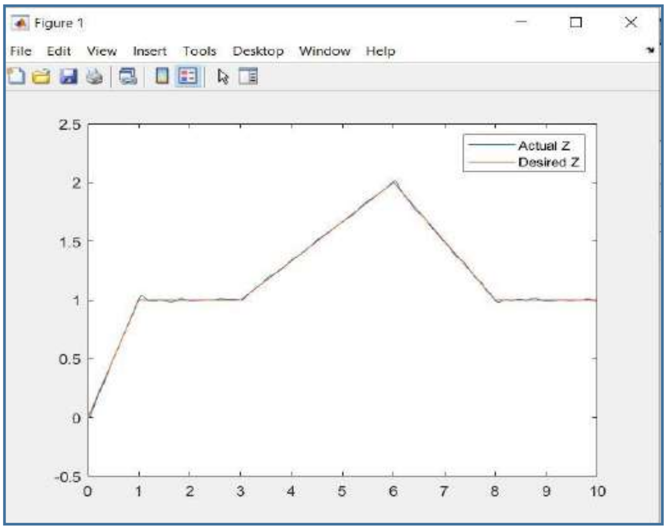

Figure 6PID controller altitude variation

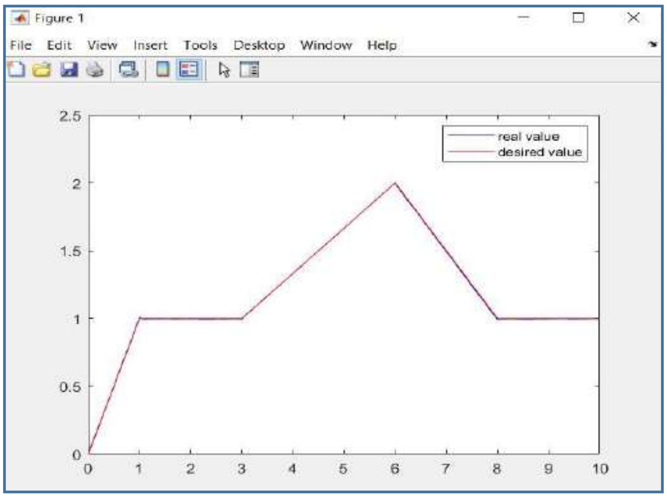

Figure 8FE controller altitude variation

Attitude Variation:

Similarly, the attitude variation is shown for both the controller below. Here as we can see the attitude state is more sensitive to the input noise unlike altitude, Hence the variation in output state is much more compared to the reference signal. But still the FE controller manages to give better result compared to PID controller.

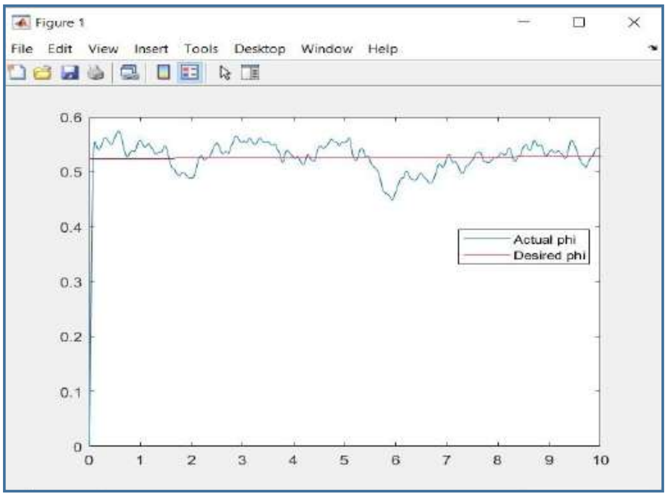

Figure 7Phi variation in PID controller

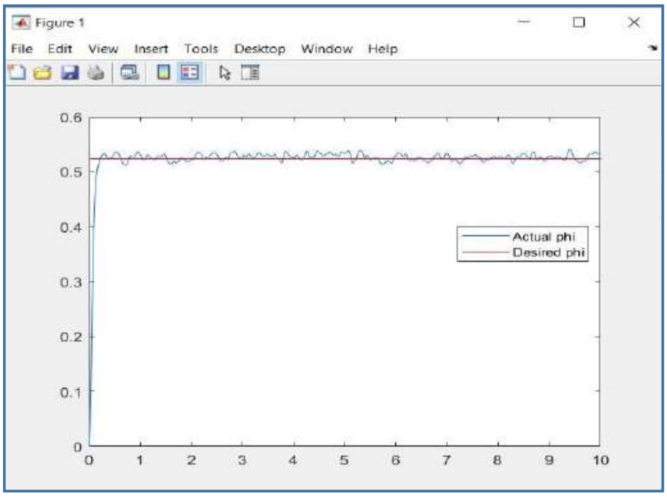

Figure 9Phi Variation in FE controller

It is to be noted that, the above response of both the controller are obtained with continuous noise input (Both for altitude and attitude). The error variation will be consistent due to the continuous noise input which is given below.

Error Variation:

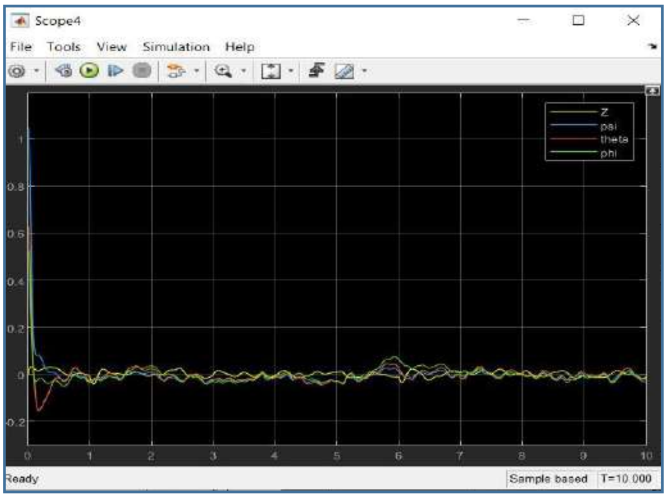

Figure 10Error variation of output states in PID controller

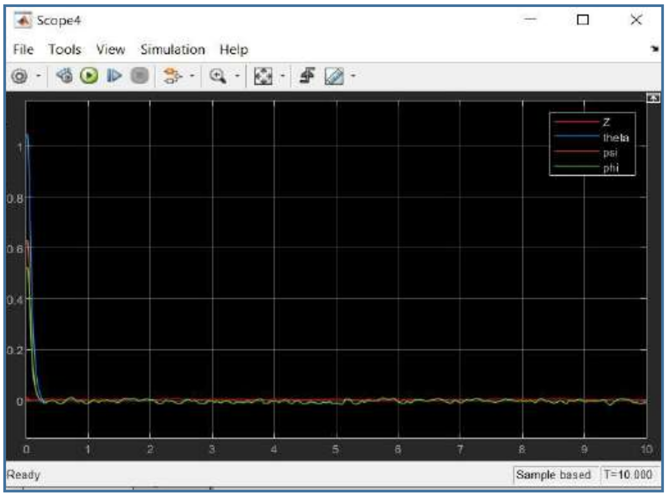

Figure 11Error variation of output states in FE controller

Here, the input force produced in FE controller is way higher than the PID controller. Hence it is saturated to the peak value of PID controller.

Conclusion: In this paper we have presented a dynamic analysis of quadcopter. The quadcopter is controlled by a novel controller which is based on the behavior of four element (FE) viscoelastic material. The numerical simulation was done to show the robustness and accuracy of FE controller. The controller is optimized and compared with PID controllerThe results are found to be satisfactory. The future work is dedicated to applying the controller in more generalist system of Multicopters and the control of manipulator on a drone.

***Abstract*— Software Defined Networks (SDNs) are adapted for their high programmability and security offered by them for use in enterprise networks. The SDN Controller present in these networks have the function to route the packets in the network to enable communication between the end-point devices connected to the network. In this paper, we created an SDN environment in Mininet using Ryu Controller to collect the communication data to build a topology-based system that could perform dynamic deep neural routing in the network. The neural routing model implemented here is a multitask learning model hosted on top of the SDN Controller that will perform network routing. The trained neural network had given a high-performance accuracy of 99.73% and the proposed system is compared and measured with the existing network routing algorithm in SDNs.**

Keywords*— *Software Defined Networks, SDN routing, Deep neural network routing, Multitask learning

I. Introduction

The widespread use of multi-functional networks requires the optimization of traffic and the distribution in the management of a large number of devices within these networks [1]. The need for intellectualization [2] of the networks to make them inherently secure with mechanisms to defend themselves against attacks and to detect anomalies is required to be performed. Providing activation and customization of networks like the Intent Based Networks (IBNs) [3] along with Network Function Virtualization [4] with high scalability has driven to meet the needs of users and enterprises to adapt these networks for transmission of large amounts of data across the world.

Software Defined Networks (SDNs) have a three-tier architecture[5] : the Application Plane, the Control Plane and the Data Plane. These networks provide flexibility to control traffic in the network by decoupling the control plane from the data plane for simplifying the network operation and management for network innovation. The open and dynamically controlled network environment opens up possibilities to programmatically control the network with intelligent route planning, traffic prediction and classification [6].

SDNs are a new paradigm that has a centralized architecture, compared to the traditional networking architecture, where the SDN Controller [7] present in the Control Layer has the complete knowledge of the network, including the topology of the switches formed by the network, network traffic pattern and handling traffic engineering management function. Hence it performs the function of routing in the system to establish communication across the various hosts in the network. The Controller uses a communication protocol such as OpenFlow [8] that allows it to host the Control Plane and Data Plane by giving the orders for the switches for their activation and to write rules into their Flow tables [9].

SDNs help to create affordable networks with high security since the need for intelligent switches is replaced by the Controller that uses Dynamic Routing Algorithm [10] to perform routing operations in the network. The SDN Controller controls the operations spanned out in the entire network due to its centralized architecture [11] and implements firewalls in the network for hosting an Intrusion Prevention System [12]. Routing of packets in the network is handled by the SDN controller since it is aware of the SDN schema, referring to the network topology and structure. The controller learns the configuration of the switches in the network topology by flooding the Address Resolution Protocol (ARP) packets to the switches to establish the data routes [13].

A disadvantage presented by the ARP flooding is that it takes a significant amount of time during which the switches could be vulnerable to a wide range of attacks such as Denial-Of-Service (DOS) attacks [14] due to the temporary escalated traffic in the network. To avoid this, a neural network model can be trained to dynamically determine routes that a packet can take based on the instantaneous network parameters without increasing the traffic in the network.

Multitask learning [15] is used to learn inter-dependencies between the various traffic parameters in the network for multi-output neural modelling. The multitask model consists of a number of subtasks that could be used to solve multiple parts of the same problem. This can be used to predict the activation of switches to write rules for SDN routing.

In this paper, a multitask model is set up based on the topology of the SDN network under study. Topology [16] of the SDN network helps determine the number and the level of switches present. The inputs of the multitask model are network parameters and each switch in the topology can be modelled as a subtask and the outputs will be used to determine which of the switches should be active for the given inputs. The trained neural model is used to implement the routing to avoid flooding at each instance of running the network. The routes predicted by the neural model are added into the flow table of switches via REST APIs in the SDN.

The rest of the paper is organized as follows. Section II gives the summary of some of the best works done in SDN and Deep

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Neural network routing. The system design of the developed model is given in Section III, followed by the implementation details in Section IV. The analysis of the multitask learning model and the evaluation of integration of the model with the SDN controller are given in Section V and VI. Section VII presents the conclusion of the paper and Section VIII summarizes the proposed future works for the paper.

II. Related Works

The summary of some of the state-of-the-art work done in the field of Deep Neural Network Routing is given below.

Mohammed et al [17] explored machine learning and deep learning techniques for the classification and prediction of traffic in SDNs. They had studied the usage of Convolutional Neural Networks (CNN), Autoencoder networks and (Recurrent Neural Networks) RNN along with (Long Short-Term Memory) LSTMs for the non-linear transformation of data to extract useful features of classification.

Mestres et al [18] worked with knowledge defined networking that uses deep learning techniques to gather knowledge about the network, and exploit that knowledge to control the network using logically centralized control facilities provided by SDNs. The designed system used an artificial network with traffic as input and average delays as output features to prevent potential bottlenecks, packet losses or performance drops.

In our paper, three types of network parameters are extracted: traffic, structure and path parameters. The traffic and structure serve as inputs and the path parameters serve as outputs to our neural model. The number of outputs for the model is determined by the number of switches in the network which is in turn dependent on the topology of the SDN network.

Wu et al [19] developed an Artificial Intelligence Enabled Routing (AIER) mechanism with congestion avoidance in SDNs to alleviate the impact of monitoring periods with dynamic routing. The AIER mechanism adds an Artificial Neural Network (ANN) hosted in the Control plane to select a suitable path to avoid congestion in the network. The dataset for the AIER model is collected from generating all data flows in the network with a congestion flag.

In our paper, we develop a neural network model that determines the routing path based on network parameters at that instant. The outputs of the neural model are translated into routing paths that are used to write rules from the SDN Controller into the flow table of the switches.

Zhang et al [20] developed a model using multitask learning for short term traffic state forecasting using Gated Recurrent Units for intelligent transportation systems. They used residual mappings and extracted informative features of the model to study the impact of the size of the training data on model performance to prevent bottlenecks in the networks due to scaling up of the training dataset.

The multitask learning architecture we have used in predicting routes for our SDN consists of a number of sub-tasks each of them have the activation of a switch present in the network depending on the hosts communicating in the network at that instance.

Zuo et al [21] had proposed traffic engineering with a learning-based network path planning using GEANT topology and grid networks in SDN. They formed a sequence-to-sequence model to learn forwarding paths of nodes in the network to capture their essential sequential features.

In our paper, multitask learning has been implemented to generate subtasks to predict the activation of the switches in the topology-based SDN. To take into account the effect of data size to train the model, the dataset has been collected over a variety of congestion windows and its effects are studied in the results in a clos topology for its high scalability.

Mao et al [22] used a CNN for intelligent routing at real-time for the changing traffic patterns in the SDN. to compute the path combinations with high accuracy. The data used for training the proposed CNN was collected from running each path in combination using conventional routing protocols.

In our implementation, we have extended the ANN to a multitask learning deep neural network where the path prediction is divided into a number of subtasks to predict the path for the activation of switches and the dataset used comprises of the flows collected by simulating traffic with various congestion windows in the SDN.

In summary, the system implemented in our paper uses a Multitask learning deep neural network architecture to predict the routes through the activation of the switches in the constructed Clos topology network for the SDN. The dataset for the training of this model was collected by using the network traffic parameters obtained from simulating varying congestion and traffic flowing in the network to increase the efficiency of the performance of the model. This neural model is integrated with the SDN Controller using the REST APIs provided in the SDN Mininet interface.

III. System Design

This section gives a brief description of the design of the SDN system with the deep neural routing model for network routing.

A. Dataset Description

The dataset that was used to train the Multitask Learning deep neural network comprises three types of parameters [23].

1) Traffic Parameters

These parameters given in Table I contain information about the traffic flow in the network to avoid possible bottlenecks in the network and to increase the efficiency of performance of SDNs.

TABLE I. Traffic Parameters Collected from the iPerf Command

No.	Name	Description
1	Interval	Time Taken between successive packets
2	Ct	TCP connect time
3	Transfer	Amount of data transferred
4	Bandwidth	Bandwisth of the link
5	Write	Total number of socket writes
6	Err	Total number of non-fatal socket write errors
7	Rtry	Number of TCP Retries
8	Cwnd	TCP Congestion Window
9	RTT	Round Trip Time
10	NetPwr	Network Power as Throughput/RTT

2) *Structure Parameters*

These represent the hosts which are involved in the active communication in a particular data exchange between two end-point devices. The communication between hosts could take place between hosts connected to the same switch or any other switch in the SDN.

3) *Path parameters*

The first layer of switches in the network refer to the switches connected directly to the end-point devices or the hosts in the network. The higher layer of switches that are involved in the routing are traced using a Packet Tracer tool such as sflow-rt [24] used on the Mininet [25] interface of the constructed SDN. The path followed by the data packet through the switches is fed into as binary values to train the deep neural network model.

B. *Dataset Preprocessing*

The dataset consisting of the traffic, structure and path parameters are normalized before using them to train the multitask learning model. Normalization [26] is performed to scale the data to a value between 0 and 1. Input values can be of a wide range which decreases the speed of learning as the time taken for the neural model to converge to local minima during gradient descent is high. Normalization ensures that the learning time is reduced and more features are learnt from the data. Min-Max normalization ensures that the inputs are within a range of (0,1).

C. *Multitask Learning*

The implemented Deep Neural architecture is based on multitask learning.

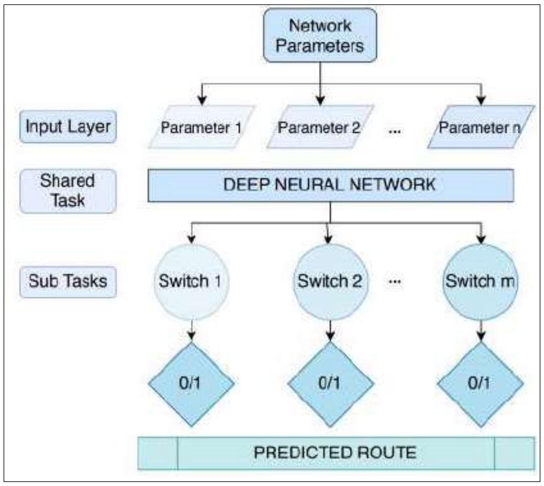

Fig. 1. Multitask Learning Model for Route Prediction

Figure 1 shows the overall design for the multitask learning model. Multitask learning [27] helps the neural network model learn the overall network parameters and decide which switches will be active for the given parameters. If a single task learning model is used, then the neural network would be able to predict if a switch is active or not but the prediction would have been an independent decision without taking into consideration the activation conditions of the other switches. In a multitask learning model, the model can predict which all switches are activated at the given instant of time. The activation of higher level switches depends on which lower level switches are active.

In the given design, the network parameters are given as input. The neural network learns the variations in the network conditions as the shared task. The prediction of which switches will be active for the given network conditions is carried out by the sub tasks. Each sub task is the activation condition of each switch. The number of subtasks in the model is dependent on the topology of the SDN network and the number of switches present in the network.

D. *Modelling of the Multitask Neural Network*

The Multitask Learning Architecture consists of a shared Neural Network and then independent Neural networks that predict the outputs at each switch. The shared neural model is also known as a shared representation.

1) *Forward propagation:*

The network parameters are given as inputs to the shared representation. The forward propagation is given by

$$Z^l = W^l A^{l-1} + b^l \tag{1}$$

Where, W^l and b^l are the weight and bias at layer l and A^{l-1} is the activation at layer $l-1$. When the value of l is 0 i.e., it is the initial layer, then A^{l-1} takes the values of the input X given to the network.

$$A^{l-1} = \begin{cases} X \; for \; l = 0 \\ A^{l-1} \; for \; l > 0 \end{cases}$$

The output of the forward propagation i.e. Z^l is passed through an activation function f^l.

$$A^l = f^l(Z^l) \tag{2}$$

The activated output of layer l is passed as input to the next hidden layer. Once the inputs are propagated through all the hidden layers in the shared representation, the output of the shared representation is given as input to each of the sub tasks. Each subtask has their own set of weights and biases and the output of the shared representation is propagated through these layers. At the final output layer of each subtask, a cost function evaluates the predicted output and the actual output.

When there are i sub tasks, the cost function for each sub task J_i is given by,

$$J_i = cost(\hat{y}_i, y_i) \tag{3}$$

where $\hat{y}_i$ is the predicted output and y_i is the actual output for the subtask i.

The overall cost for the shared representation J is the weighted sum of the costs of each individual sub task.

$$J = \sum \propto_i J_i \tag{4}$$

where $\propto_i$ is the weighting factor that determines the contribution of each sub task to the overall cost of the shared representation. $\propto_i$ is determined during the hyperparameter tuning stage of the neural model.

2) *Backpropagation:*

Backpropagation is done to reduce the overall cost of the neural model by optimizing the weights and biases. In a multitask learning model, backpropagation is applied to each sub task by using the cost function J_i of each sub task i and then the backpropagation is applied to shared representation by using the aggregated cost J.To perform backpropagation the gradients of cost are calculated with respect to weights and biases. For each sub task i, the gradients are calculated for each hidden layer l of the sub task.

$$\frac{\partial J_i}{\partial w_i^l} = \frac{\delta J_i}{\delta z_i^l} A^{l-1} \quad (5)$$

$$\frac{\partial J_i}{\partial b_i^l} = \frac{\delta J_i}{\delta z_i^l} \quad (6)$$

The weights and biases are optimized by using the gradients.

$$W_i^l = W_i^l - \rho \frac{\partial J_i}{\partial w_i^l} \quad (7)$$

$$b_i^l = b_i^l - \rho \frac{\partial J_i}{\partial b_i^l} \quad (8)$$

Where, ρ is the learning rate of the model.

Once the backpropagation is applied to the sub tasks, the loss is propagated through the shared representation. The aggregated cost J is used to calculate the gradients for each hidden layer l of the shared representation. The weights and biases are optimized by using the gradients.

$$\frac{\partial J}{\partial w^l} = \frac{\delta J}{\delta z^l} A^{l-1} \quad (9)$$

$$\frac{\partial J}{\partial b^l} = \frac{\delta J}{\delta z^l} \quad (10)$$

$$W^l = W^l - \rho \frac{\partial J}{\partial w^l} \quad (11)$$

$$b^l = b^l - \rho \frac{\partial J}{\partial b^l} \quad (12)$$

Where, ρ is the learning rate of the model.

E. Configuring REST APIs in the SDN

Representational State Transfer or REST APIs [28] are used to communicate between the SDN Controller and the applications or services that would be running in the network to facilitate automation with network programming. OFCTL_REST API [29] is used for retrieving and updating the switch stats to help debug and update the flow table of the switches for network routing.

IV. System Implementation

This section gives the implementation details of the Deep Neural network along with its integration with the SDN.

A. SDN Setup

The SDN was set up in a Windows 10 with Intel i7 7th Gen Processor with NVidia GeForce 940MX with Oracle VM Virtual Box with 4GB RAM allocation to host the Mininet version 2.2.1 with OpenFlow 1.3 on Ubuntu 18.04. RYU controller 4.34 is established in the SDN as the central coordinator of the network making up the Control Plane with OpenVSwitch 2.14. The network follows a clos topology [30] that uses double-layered switches. The network constructed here consists of 8 hosts connected to 7 switches with a Ryu Controller.

This network can be extended as per the requirement in the constructed SDN. Clos topology is the most common topology used in the cloud networks and is a multi-layer switching network where the number of switching layers determines the structure of the clos network. The clos topology has three stages- the ingress stage, middle stage and egress stage. Each packet entering the ingress stage can be routed through any of the middle stage switches to the relevant egress stage switch. The advantages of using a clos network is that it can be scaled horizontally and also has low latency in accessing data. In case any switch in the middle stage of the clos network fails, then the packets can be routed through any of the other remaining middle stage switches thereby guaranteeing fault tolerance.

B. Dataset collection using the iPerf command

1) Network parameters

The traffic parameters are collected by the iPerf command in the XTerm terminal of the hosts in the SDN. iPerf tool [31] is used to measure the bandwidth and the quality of a network link by implementing a client-server architecture between the source host and destination host which are communicating across the network. The parameters that the iPerf command uses is given in Table II.

TABLE II. IPERF COMMANDS ON THE SERVER AND THE CLIENT SIDE

Server side	
Command	**Description**
-s -server	Starts iPerf in server model and waits for an iPerf client to contact it
Client side	
Command	**Description**
-c -client <Host>	Starts iPerf in client mode and connects with the iPerf server <Host> (IP address or DNS name)
-t time <Time> (default: 10 seconds)	Sets the duration of the connection in seconds
-I -interval	Seconds between periodic bandwidth reports
-b -bandwidth <BW>	Sets the bandwidth for data transfer
-e -enhanced output	Display enhanced output reports
-w -window size <Size>	TCP window size
-f -format	Format to report: Kbits, Mbits, Kbytes, Mbytes
-h -help	Outputs the help text
-v -version	Outputs the version

2) Structure Parameters

The communication between the source and destination host is established by using simple ping commands. The commands for transferring data from the source host are done by using the XTerm terminal [32] for that particular host.

3) Path Parameters

A packet tracer tool such as sflow-rt is used in the SDN to find the path used by the data packets to travel across in the network. This tool captures all the data packets being currency transmitted across the network. The packets using the OpenFlow protocol are traced and the switches that transfer the data packets in the data transfer are recorded in the dataset. During any data transfer between two hosts, the first layer switches connected to the host are always active. The second layer switches, connected only to the first-layer switches, are chosen based on the present state of traffic in the system.

In Figure 2 a), we observe that the second-layer switch S5 is actively used for the data transfer between the hosts connected to the first layer switches. In Figure 2 b), S7 is the second layer switch chosen by the constructed clos topology in the SDN.

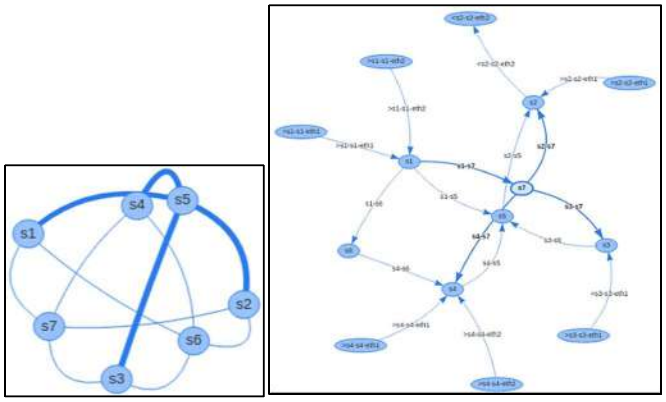

Fig. 2. a) Tracing of the OpenFlow packets using sflow-rt to identify the active Layer-2 switch(S5), b) The switch S7 is chosen as the Layer-2 active switch for data transfer

C. Preprocessing the Dataset

The dataset collected has a total of 1,048,575 samples. The dataset is cleaned to remove null instances. The dataset was split into a training and testing set with a ratio of 80:20. Normalization is done by using Keras' MinMaxScaler [33] for each input field. The minimum value of the field is subtracted from each instance of the field and this is divided by the maximum value in that field.

D. Structure of the Deep Neural model for network routing

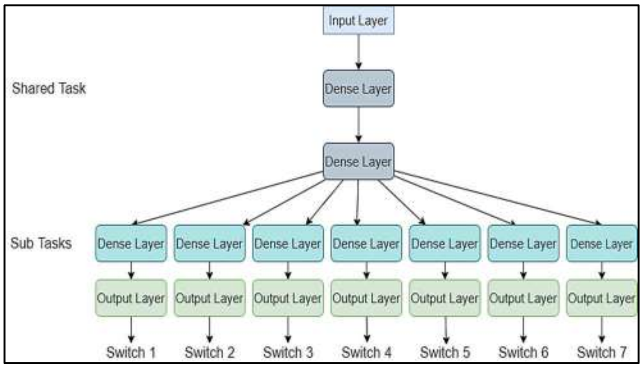

Fig. 3. Implementation of Multitask Learning Neural Model

Figure 3 shows the overall implementation of the multitask learning neural model. The input layer has 23 nodes corresponding to 23 network parameters extracted in the dataset. The shared task of neural tries to identify variation of features within the input dataset. The shared model comprises 1 hidden layer with 16 nodes activated using ReLu Activation function [34]. ReLu increases the speed of convergence as it does not activate for any negative input values. The output of the shared representation is fed to 7 sub tasks. Each sub task represents the activation of a corresponding switch. The number of subtasks is based on the topology and structure of the network chosen. The outputs of the subtasks are passed through the output layer which has one neuron activated by Sigmoid function [34]. Sigmoid function is used as it is a binary classification problem where if the output probability is greater than 0.5, then the switch is activated.

E. Parameters for Training

The parameters of training can be observed in Table III. Adam Optimizer [35] is used. Adam optimizer combines Momentum and Root Mean Square Propagation (RMSP) to control gradient descent such that the step-size can pass local minima but the training stops at the global minima. Binary cross entropy [36] is the loss function used.

TABLE III. TRAINING PARAMETERS OF THE MODEL

Parameter	Value
Optimiser	Adam
Loss Function	Binary Cross Entropy
Batch Size	128

F. Training

The training of the neural model is done on Google Colab with Intel(R) Xeon(R) CPU @ 2.20GHz Processor, 13 GB RAM and 12GB NVIDIA Tesla K80 graphics processor.

TABLE IV. ACCURACY AND LOSS VARIATION WITH NUMBER OF ITERATIONS

Iterations	Accuracy	Change in accuracy (in %)	Loss	Change in loss (in %)
4	97.32	-	6.0	-
8	98.65	1.36	4.67	22.16
12	99.73	0.08	4.0	14.34
16	99.82	0.09	3.2	20

The accuracy of the deep neural model is calculated with increasing number of iterations as shown in Table IV. It is interpreted that by increasing the number of iterations the values of accuracy increase linearly. Loss is calculated using the binary cross entropy function for each epoch. Table IV shows that the loss in the model decreases with increasing the number of iterations of the training dataset.

The training is stopped before the model overfits to learn noise and irrelevant data but undertraining the model will decrease its ability to generalize.

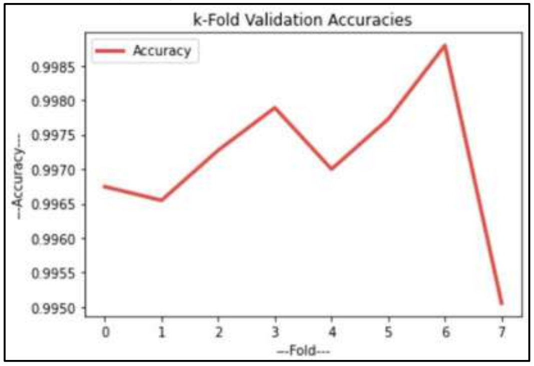

Fig. 4. k-Fold Cross Validation performed with the variation of Accuracy across 8-folds

When the accuracy increases steeply then the model may be overfit and if the number of iterations is too low then the model may be underfit. Based on the change in accuracy and loss, the model is trained for 12 iterations. In order to ensure that the model does not overfit, Stratified k-Fold Cross Validation [37] is performed with the number of folds taken as 8. This is implemented for cross-verification of the developed model to train over the collected dataset before testing. Figure 4 shows the variation of accuracy score for the 8 folds of cross validation. The average accuracy score is found to be 0.9973.

G. *Integration of the Deep Neural model with the SDN Controller*

The SDN Controller uses a standard dynamic routing algorithm for updating the flow tables. This approach incurs overhead due to flooding and over-writing of rules, making it harder and slower for the expansion of the network, decreasing the efficiency of SDN's performance. The integration of the deep neural model with the SDN was done by hosting the trained model on the Controller to predict the path between two hosts for data transfer. The output of the neural model is translated to feed into the OFCTL_REST API that is used to write the rules into the flow tables of the switches to accept the data packets from the corresponding switches or hosts.

V. Evaluation of Multitask Learning Model

This section talks about the results and analysis of the multitask model designed to perform the network routing.

A. *Variation of accuracy on the size of dataset*

Accuracy per batch of dataset is measured with increasing size of the dataset collected for training the deep neural network as seen in Table V. The accuracy is observed to increase with data size being used. The increase in the size of data being used will help the neural model to train with a variety of data that has varying levels of traffic simulations and paths. The loss incurred by the model with increasing dataset size and its variance is given in Table V. The loss decreases with the increase in data size linearly due to higher number of available cases for the model to train and generalize before testing of the model is performed.

TABLE V. Accuracy and Loss Variation with the Dataset Size

Dataset size	**Accuracy**	**Change in accuracy (in %)**	**Loss**	**Change in loss (in %)**
0.25	88.63	-	88.42	-
0.5	93.45	5.43	52.98	40.08
0.75	96.61	3.38	6.39	87.93
1.0	99.73	3.22	3.13	51.01

B. *Variation of True Positive Rate and True Negative Rate with Dataset Size for multilayer switches*

True Positive Rate (TPR) or Sensitivity [38] is defined as the number of times the deep neural model categorizes a positive value correctly. The trained model should be able to identify the switches to be activated in the actual path during network routing.

True Negative Rate (TNR) or Specificity [38] is defined as the number of times the negative values are correctly identified. In this case, the true negative rate should be high enough to predict which switches needn't be active in the network for a particular flow of communication between the hosts.

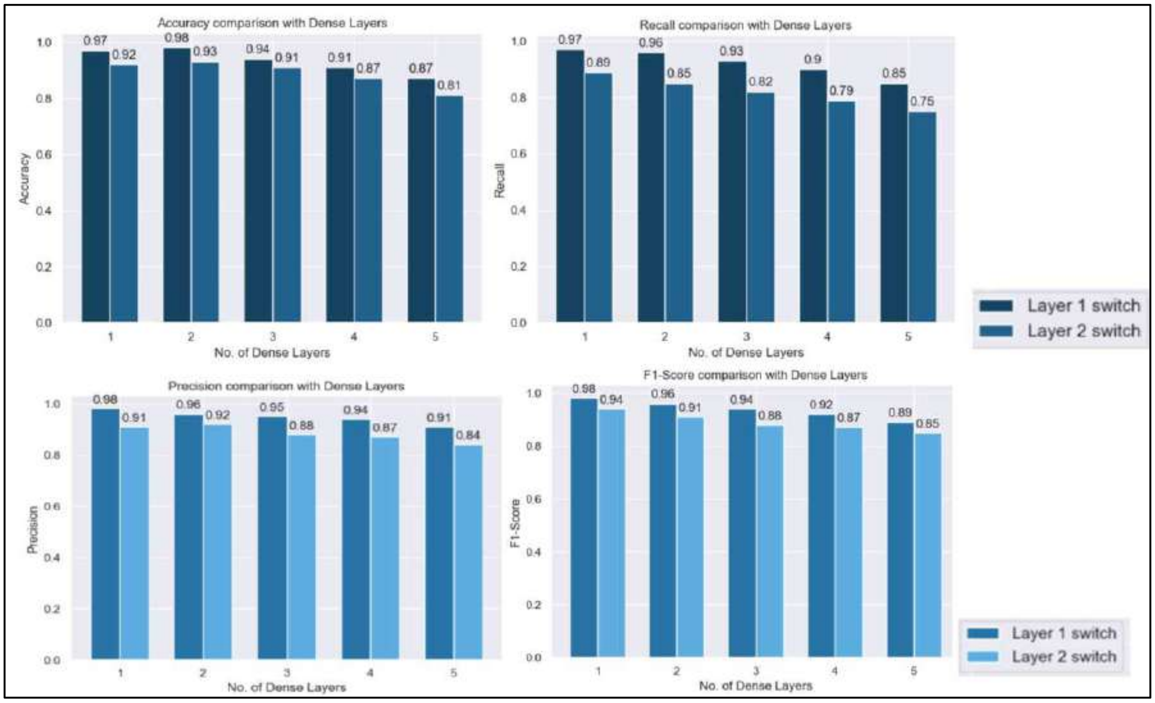

Fig. 5. a) Accuracy on Number of Dense Layers with Layer-1 and Layer-2 switches b) Recall on Number of Dense Layers with Layer-1 and Layer-2 switches c) Precision on Number of Dense Layers with Layer-1 and Layer-2 switches d) F1-Score on Number of Dense Layers with Layer-1 and Layer-2 switches

As it can be observed from Table VI, the ability of the neural model to predict the positive values correctly increases linearly with larger dataset. The prediction of Layer-2 switches varies with the traffic present in the system, which changes dynamically. The size of the dataset should be sufficiently high to prevent the false negatives and false positives in the network to increase the model's performance.

TABLE VI. TPR AND TNR VARIATION WITH THE DATASET SIZE

Dataset size	Layer chosen	TPR	Change in TPR (in %)	TNR	Change in TNR (in %)
0.25	Layer-1	94.14	-	96.73	-
	Layer-2	89.46	-	84.56	-
0.5	Layer-1	95.03	0.94	97.49	0.78
	Layer-2	92.56	3.46	86.37	2.14
0.75	Layer-1	97.21	2.29	97.88	0.4
	Layer-2	94.42	2.0	89.21	3.28
1.0	Layer-1	99.35	2.2	98.46	0.59
	Layer-2	97.65	3.42	90.21	1.12

C. *Accuracy, Recall, Precision and F1-Score on Number of Dense Layers with Layer-1 and Layer-2 switches*

Accuracy [39] gives the measure of how close the predicted values are to the actual value. Recall [39] value gives the proportion of true positive values out of all the positive values predicted by the network. Precision [39] gives the proportion of predicted positive values that are actually positive and its variance with number of dense layers. F1- score [39] combines the precision and recall value of the trained deep neural model using a harmonic mean. This is highly useful in cases such as here where there is an uneven class distribution.

The variation of Accuracy, Precision, Recall and F1-Scores of Layer-1 and Layer-2 switches in the clos network constructed here are plotted against the varying number of dense layers in Figures 5 a), b), c), d). The accuracy indicates how well the model has trained on the dataset.

It is observed from Figures 5 a), b), c) and d) that the accuracy, precision, recall and F1-Score does not seem to increase with increasing the number of dense layers. This is due to the over-fitting of the data by increasing the number of trainable layers in the model. The complexity of the model would also increase leading to poorer performance with increasing number of dense layers.

D. *ROC Curve and AUC Value*

An ROC curve or Receiver Operating Characteristic curve [40] is a graph showing the performance of a classification model at all classification thresholds. The AUC or the area under the ROC curve [40] gives the aggregate measure of performance across all possible classification thresholds. For the developed Deep Neural network model, the AUC area is at 0.987 as seen in Figure 6.

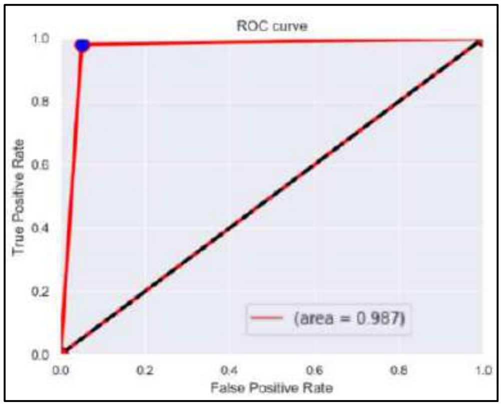

Fig. 6. ROC Curve of the Neural Model

VI. EVALUATION OF INTEGRATION OF NEURAL ROUTING WITH THE SDN CONTROLLER

In this section, the integration of the neural routing model with the SDN Controller is analyzed.

A. *Retry value in network- existing system vs proposed system*

The performance of the SDN system with the Deep Neural network for routing integrated and without the neural network is done by using the number of retry values [42] required when sending the data packets across the network.

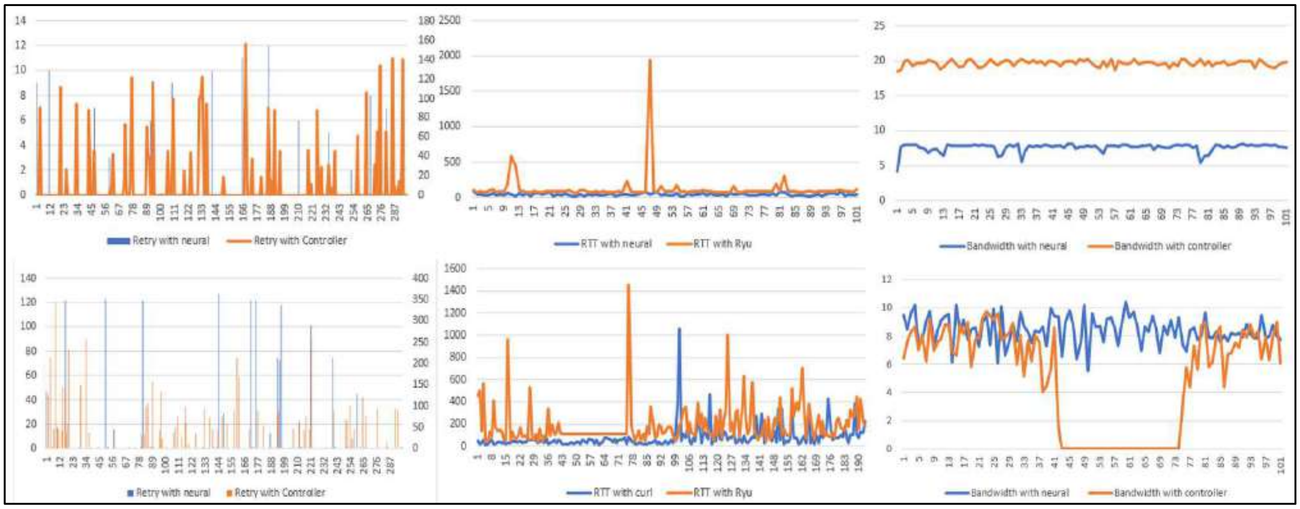

Fig. 7. Comparison of SDN with Ryu Controller and Deep Neural Routing a) Retry, b) Round Trip Time and c) Bandwidth in Layer-1 Switches (above) and d) Retry e) Round Trip Time and f) Bandwidth in the Layer-2 Switches (below)

The Retry value in the neural network integrated system for Layer-1 switches is plotted in Figure 7 a) and for Layer-2 switches in Figure 7 d). It can be seen that the number of retry values for the neural routing model is significantly lower as compared to the traditional SDN routing model for both Layer-1 and Layer-2 switches.

B. *Round Trip Time value in network- existing system vs proposed system*

The Round-Trip Time or RTT [41] is another measure of the performance of the SDN system as it determines the speed of transfer of data packets in the network. The performance of the system with Deep Neural routing model integrated and without neural is observed by the low RTT values in Figure 7 b) and Figure 7 e) for Layer-1 and Layer-2 switches respectively.

C. *Bandwidth Value in network- existing system vs proposed system*

The bandwidth [42] of the network is observed to drop to zero in the existing system as in Figure 7 f) that the proposed system handles better by limiting the overhead in the system especially with higher layers of switches. The low congestion of the data flowing in the network will enable the system to maintain a steady bandwidth as observed in Figures 7 c) and f).

VII. Conclusion

A deep neural network based on multitask learning architecture was implemented using the path, network and traffic parameters collected from the SDN. These parameters were collected dynamically from the network using packet tracer tools deployed on the Application Layer of the SDN. Clos topology containing multilayer switches was constructed in the network where the data flow between the hosts occurred through first and higher layer switches. The constructed neural routing model will dynamically determine the higher-layer switches in the network by analyzing the collected traffic parameters present in the network and activating the switches by writing rules. The activation rules for switches present in the data path during active communication between the hosts are written into the flow table of the switches using OFCTL_REST API. The trained deep neural model was evaluated on various parameters to determine the efficiency of its performance and the model performed switch activations in the network with an accuracy of 99.73%. The performance of the SDN using the dynamic routing model in the existing system is compared with the deep neural routing model using the values of Retry, Round Trip Time and Bandwidth values collected during the data flows when the SDN Controller performed routing on the data with the deep neural model performing the route prediction.

VIII. Future Works

The implemented deep neural routing model using multitask learning architecture is topology based and the dependence of this model on the constructed architecture could be explored by using LSTM architecture for dynamic expansion of the network. The scalability of the network can be extended by the employment of more hosts in the network and across multiple networks in a SDWAN. Further, the prediction of dynamic traffic in the network could be implemented with the route prediction of the data collected from the traffic and congestion forecasts from the future communication between the hosts in the network.

A Light-based Interpretation of Schrodinger's Wave Equation and Heisenberg's Uncertainty Principle with Implications on Quantum Computation

Dr Pravir Malik
Deep Order Technologies, USA
pravir.malik@deepordertechnologies.com

Abstract— **Quantum computation as currently conceived is based on the largely unproven Copenhagen Interpretation of Quantum Mechanics. By viewing light as a multi-layered, symmetrical construct though, it is possible to interpret quantum-level dynamics assumed as fundamental, differently. Hence, looking at Schrodinger's Wave Equation and Heisenberg's Uncertainty Principle from the point of view of light, it becomes possible to understand quantum-level dynamics as an outcome of a multi-layered, symmetry-based model of light. Such a different view of quantum-level dynamics suggests a different way to conceive of quantum computation. As such, Schrodinger's Wave Equation can be viewed as an arbitration to take information from behind the quantum-veil that may exist in antecedent layers of light, and through such arbitration or rate of change of the wave-function, compute it into material existence. Heisenberg's Uncertainty Principle suggests that meta-level function seeking to precipitate or to be arbitrated into material existence may take different form while still fulfilling the intent of the meta-level function. Quantum computation, therefore, can be conceived as a creative as opposed to a solely constructive process. The object of quantum computation in such an interpretation of quantum phenomena is nothing other than to continue to create something new, or to continue to enhance materialization of meta-level function, rather than to simply construct based on regurgitating programming-based instruction.**

Keywords— ***Quantum Computation, Schrodinger's Wave Equation, Heisenberg's Uncertainty Principle, Symmetrical-Model of Light, Planck's Constant, Speed of Light, Copenhagen Interpretation of Quantum Mechanics***

I. INTRODUCTION

The jury is still out on the dynamics that animate the quantum level.

It is assumed, based on the Copenhagen Interpretation of Quantum Mechanics, that a quantum-object will exist in a number of superposed states until measured. The act of measurement will cause the quantum-object to collapse into an observable state, and therefore it will be impossible, given today's science and technology, to know what is happening behind the quantum-veil.

Yet quantum computation assumes knowledge of phenomena behind the quantum-veil, and subsequently that an n-qubit quantum computer can exist in 2^n (2 to the power n) states simultaneously. Further, it is assumed that if these qubits can be entangled, then the combination of the dual properties of superposition and entanglement, will confer quantum computers with extraordinary processing power.

If, however, an alternative light-based view of quantum phenomena were to be adopted (Malik, 2018b), there are different implications for quantum computation (Malik, 2020). Such implications can be teased out by interpreting cornerstone quantum-level equations, such as Schrodinger's Wave Equation and Heisenberg's Uncertainty Principle.

Schrodinger's equation, which seeks to model how a quantum state of a quantum system changes with time, or in other words seeks to model matter as a wave rather than as a particle (Stewart, 2012), is depicted in the following, Equation (1):

$$i\frac{h}{2\pi}\frac{\partial}{\partial x}\psi = \hat{H}\psi$$

Eq. 1: Schrodinger's Wave Equation

ψ depicts a wave form and can be thought of as a probable cloud of possible states. $\hat{H}$ is the Hamiltonian operator, which acts as a focusing function. In its essence what the equation is likely suggesting is that the way a wave form changes over time is equivalent to some expressible state of the possibilities inherent in the cloud of possible states.

Heisenberg's uncertainty principle, that calls out the difficulty in measuring any two properties of a quantum-object

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

at the same time, and in the following, Equation 2, focusing on momentum (p) and positions (x) of a quantum-object, is depicted as:

$$\Delta p \; X \; \Delta x \; \geq \; \frac{h}{4\pi}$$

Eq. 2: Heisenberg's Uncertainty Principle

This paper will first summarize a multi-layered, symmetry-based model of light that will be associated with the "cloud of possible states" (Section II). It will then suggest an interplay (Section III) between Planck's Constant, h, and the speed of light, c, to offer interpretations and some quantum computation implications of the Schrodinger equation (Section IV) and Heisenberg's uncertainty principle (Section V) based on the proposed model of light (Malik, 2018a). The model of light, interpretations of the fundamental quantum-level equations, and some implications for quantum computation will then be summarized (Section VI).

II. LIGHT-BASED MODEL

Light has a significant impact on the experienced nature of reality. Fundamentals such as space, time, and the possibilities of the movement of objects are all tied to the reality of light traveling at speed c, 186,000 miles per second in a vacuum (Einstein, 1995). By extrapolating on the necessity for light to move at a constant speed of c it is possible to construct a multi-layered light-based model (Malik et al 2019; Malik 2020) which can provide significant insight into the nature of quanta, and subsequently on the interpretations of the Schrodinger equation and the Heisenberg principle.

In this model the infinite information conceived were light to travel infinitely fast depicted by the row $c_\infty\colon [Pr, Po, K, H]$ in Equation 3, below, precipitates into material reality, c_U - where light travels at speed c, via intermediate realities where light is envisioned to exist at speeds slower than infinity, but faster than c. These intermediate realities are specified by rows c_K and c_N respectively, such that $c_U < c_N < c_K < c_\infty$. Note that Einstein's Theory of Relativity does not disallow speeds of light greater than c: it is the acceleration to speed c from a slower speed that is not possible (Perkowitz, 2011). Further, spaces with light speeds greater than c should be viewed as conceptual spaces made to vary were light to travel at different speeds, or property spaces, being separate from but influencing physical space as explored by Nobel Physicist Frank Wilczek (Wilczek, 2016).

Referring to the matrix-equation, Equation 3, that follows, precipitation itself takes place via a series of quantization functions. The first quantization (↓) is specified by $(\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{K}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\infty}))$ and suggests that reality (R) at $\mathrm{c}_\mathrm{K}, \mathrm{R}_{\mathrm{C}_\mathrm{K}}$, is a function (f) of reality at c_∞, $\mathrm{R}_{\mathrm{C}_\infty}$.

The states of all-presence (Pr) formed because light is instantaneously present in whatever volume is being considered, all-power (Po) formed by the ability of light to overpower any other emergence, all-knowledge (K) formed by the fabric of light being able to record any appearance or disappearance of event, and all-harmony (H) formed by everything being connected in the nature of the all-present light, are mathematically transformed into large sets as specified by $\mathrm{c}_\mathrm{K}\colon [\mathrm{S}_{\mathrm{Pr}}, \mathrm{S}_{\mathrm{Po}}, \mathrm{S}_\mathrm{K}, \mathrm{S}_\mathrm{H}]$, where S_{Pr} is the set of all-presence, S_{Po} is the set of all-power, S_K is the set of all-knowledge, and S_H is the set of all-harmony, respectively.

A further quantization takes place via $(\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{N}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\mathrm{K}}))$, and suggests that reality (R) at $\mathrm{c}_\mathrm{N}, \mathrm{R}_{\mathrm{C}_\mathrm{N}}$, is a function (f) of reality at c_K, $\mathrm{R}_{\mathrm{C}_\mathrm{K}}$.

Hence, elements from each of the four sets combine in unique combinations, specified by $\mathrm{c}_{\mathrm{N}:}\ \mathrm{f}(\mathrm{S}_{\mathrm{Pr}} \ \mathrm{x}\ \mathrm{S}_{\mathrm{Po}} \ \mathrm{x}\ \mathrm{S}_\mathrm{K} \ \mathrm{x}\ \mathrm{S}_\mathrm{H})$, to create a bases for a practically infinite number of unique seeds or functions.

A final quantization, specified by $(\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{U}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\mathrm{N}}))$, suggests that reality (R) at $\mathrm{c}_\mathrm{U}, \mathrm{R}_{\mathrm{C}_\mathrm{U}}$, is a function (f) of reality at c_N, $\mathrm{R}_{\mathrm{C}_\mathrm{N}}$. This quantization results in material reality, specified by $\mathrm{c}_\mathrm{U}\colon\ [\mathrm{S}, \mathrm{T}, \mathrm{E}, \mathrm{G}]$, where S refers to Space, T refers to Time, E refers to Energy, and G refers to Gravity. Specifically, "Space" – envisioned to be the arena for all the subtle-seeds to exist and subsequently leading to the creation of material possibility; "Time" – ensuring that the possibilities in the seeds are worked out; "Energy" – associated with seeds and their conversion into matter; and "Gravity" – specifying relationships between seed and seed and seeds and seeds. Further, Space, being a repository of archetypes represents light's property of knowledge (K); Time, assuring maturity regardless of opposition represents light's property of power (Po); Energy, allowing seeds to have presence, represents light's property of presence (Pr); and Gravity, allowing relationship between seed and seed, represents light's property of harmony (H).

Hence the multi-layered fourfold light-based model is summarized as (3):

$$\begin{bmatrix} \mathrm{c}_\infty\colon [\mathrm{Pr}, \mathrm{Po}, \mathrm{K}, \mathrm{H}] \\ (\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{K}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\infty})) \\ \mathrm{c}_\mathrm{K}\colon [\mathrm{S}_{\mathrm{Pr}}, \mathrm{S}_{\mathrm{Po}}, \mathrm{S}_\mathrm{K}, \mathrm{S}_\mathrm{H}] \\ (\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{N}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\mathrm{K}})) \\ \mathrm{c}_{\mathrm{N}:}\ \mathrm{f}(\mathrm{S}_{\mathrm{Pr}} \ \mathrm{x}\ \mathrm{S}_{\mathrm{Po}} \ \mathrm{x}\ \mathrm{S}_\mathrm{K} \ \mathrm{x}\ \mathrm{S}_\mathrm{H}) \\ (\downarrow\ \mathrm{R}_{\mathrm{C}_\mathrm{U}} = \mathrm{f}(\mathrm{R}_{\mathrm{C}_\mathrm{N}})) \\ \mathrm{c}_\mathrm{U}\colon\ [\mathrm{S}, \mathrm{T}, \mathrm{E}, \mathrm{G}] \end{bmatrix}_{\mathrm{Light}}$$

Eq. 3: Multi-Layered Fourfold Light-Based Model

Note that because space-time-energy-gravity appears to come into existence when light precipitates to speed c, it is fair to assume that the deeper nature and activity at the quantum veil before matter is formed, is of the substance of space-time-energy-gravity. As proposed in The Origins and Possibilities of Genetics (Malik, 2019), space-time-energy-gravity can also be thought of as the script used to write a "law" about any specific emergence, which get aggregated into the overall dynamics of Space, Time, Energy, and Gravity as experienced at the macro level.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

III. The Interplay Between Planck's Constant and Speed of Light

In this model of Light, quanta are perceived as a bridge mechanism that allows subtle information in a conceptual space determined by a faster moving speed of light, to quantize or materialize some of that information, more concretely, in a conceptual space determined by a relatively slower moving speed of light.

This implies that emergence in the layer where light exists at c, has to take place via the device of quanta. Planck's discovery that energy at the subatomic level requires a minimum threshold 'quantum' to express itself perhaps relates to this. Einstein postulated quanta as a fundamental property of light itself, rather than as something that arose in the interaction of light with matter as Planck thought. Note that Planck's treatment of quanta was more as a mathematical convenience that allowed the derivation of an equation that explained the curve of radiation wavelengths at varying temperatures of a heated black body (Isaacson, 2008). Einstein's theory produced a law of the photoelectric effect where the energy of emitted electrons would depend on the frequency of light. Einstein received the Nobel Prize for this discovery (Isaacson, 2008).

Summarizing, if c is the upper limit of the layer associated with c_U, then it makes sense that the lower limit h (Planck's constant) should be inversely proportional to c. Hence, Equation 4:

$$h \propto \frac{1}{c}$$

Eq. 4: Relationship Between Planck's Constant and Speed of Light

This relationship is substantiated by combining two well-known equations: the first is Einstein's photoelectric equation connecting energy with frequency of light as depicted by Equation 5, and the second is the electromagnetic equation connecting speed of light with wavelength and frequency as depicted by Equation 6:

$$E = h\nu$$

Eq. 5: Einstein's Photoelectric Equation

$$c = \nu\lambda$$

Eq. 6: Relationship Between Speed of Light, Wavelength, and Frequency

To yield Equation 7:

$$h = \frac{E\lambda}{c}$$

Eq. 7: Connecting h and c

About h, H.A. Lorentz the Dutch scientist has commented in The Science of Nature (Lorentz, 1925): "We have now advanced so far that this constant not only furnishes the basis for explaining the intensity of radiation and the wavelength for which it represents a maximum, but also for interpreting the quantitative relations existing in several other cases among the many physical quantities it determines. I shall mention a few only, namely the specific heat of solids, the photo-chemical effects of light, the orbits of electrons in the atom, the wavelengths of the lines of the spectrum, the frequency of the Roentgen rays which are produced by the impact of electrons of given velocity, the velocity with which gas molecules can rotate, and also the distances between the particles which make up a crystal. It is no exaggeration to say that in our picture of nature nowadays it is the quantum conditions that hold matter together and prevent it from completely losing its energy by radiation."

Elaborating on the interplay between c and h:

- When light slows down, then the binding factor of matter, h, can change. Hence, at light speeds greater than c, the resulting 'h' would become smaller than h since there is an inverse proportionality between c and h.
- h in this physical realm is such that matter forms in the way that it does. At faster than c speeds of light, this binding factor, h, would be smaller in value, and hence result in a materialization where matter would not be bound in the way it is when light travels at c.
- In Light's state of traveling infinitely fast, 'h' would be zero, implying that the essential properties of Light will pervade existence. As light slows down, to create vast sets of properties anchored in each of the four essential properties of Light as depicted in (3), 'h' must be such that it allows the essential properties to splinter into a vast number of variations of itself. Further, 'h' must be such that it allows these variations to be accessed in any subsequent layer of Light. This may suggest that each element could exist in a relatively materialized 'field-like' form.
- With the second quantization function or mathematical transformation, light would be slower than in the first quantization or transformation, and yet faster than c. The resulting 'h' would hence be such that the material form would be something between being 'field-like' and 'particle-like', the latter being the basis of matter as it begins to manifest in the physical realm where light travels at c.
- Perhaps such an 'h' that accompanies the second transformation will allow form to materialize to be 'wave-like', which would also have the needed characteristic of linking various elements from their individual 'fields', to create a unique though subtle wave-form seed.
- It is such a unique wave-form seed that with the existence of the h corresponding to c, then becomes the basis of the quantum-bridge that allows matter in its known form to arise.

IV. Interpretation of Schrodinger Wave Equation Based on Model of Light & Implication for Quantum Computation

Restating Schrodinger's equation (1):

$$i\frac{h}{2\pi}\frac{\partial}{\partial x}\psi = \hat{H}\psi \qquad (1)$$

ψ depicts a wave form and can be thought of as a probable cloud of possible states. $\hat{H}$ is the Hamiltonian operator, which is a focusing function, and in its essence what the equation may be suggesting is that the way a wave form changes over time is equivalent to some expressible state of the possibilities inherent in the cloud of possible states.

But in reference to the multi-layered model of Light depicted in (3), the cloud of possible states is another way of saying that behind physical form, "form" is represented in another way than physically. Schrodinger's equation, a cornerstone in quantum theory, alludes to the mystery that accompanies the lifting of the material veil. Different interpretations of the quantum world have arisen to suggest the meaning of potentiality implicit in this equation. As summarized by Kleinman in his book "The Four Faces of the Universe" (Kleinman, 2006), at one end are theories to do with 'hidden variables' that bring into focus our ignorance of the deeper aspects of the system being studied, to David Bohm's notion of the 'implicate order' in which any element contains enfolded within it the totality of the universe (Bohm, 1983), to a 'many-worlds' interpretation asserting that every observation of a quantum system splits the universe into parallel and disconnected worlds.

It is interesting to note that in his lectures on Schrodinger's equation Feynman (Gottlieb, 2013) has stated: "Where did he get that [equation] from? Nowhere. It is not possible to derive it from anything you know. It came out of the mind of Schrödinger".

The Copenhagen Interpretation of Quantum Mechanics in fact does away with the real questions about what reality is altogether, by simply focusing on the observed universe. This orientation perhaps stems from one of its founders, Neils Bohr, who claimed that it was not the purpose of physics to answer questions about the nature of reality (Kleinman, 2006).

Considering Schrodinger's equation therefore, 'i' is a complex number and suggests the interplay of two dimensions, one being real, and one being 'imaginary'. But the 'imaginary' dimension could be thought of as none other than the meta-levels implicit in the mathematical model in this treatise. Further, $\frac{h}{2\pi}$ is in line with the suggestion that h will have to become a fraction of itself as c increases. Hence, the change in the wave function, $\frac{\partial}{\partial x}\psi$, is intimately related to i and $\frac{h}{2\pi}$, and perhaps more fully makes sense when considered in the context of i x $\frac{h}{2\pi}$ x $\frac{\partial}{\partial x}\psi$ - which has to be the case when dealing with the integration of dynamics of multiple levels of light.

Further, the change in the wave function, $\frac{\partial}{\partial x}\psi$, is related to $\hat{H}\psi$, and suggests that there is some system "energy", represented by the Hamiltonian, $\hat{H}$, that when applied to the existing wave, ψ, will indicate how the wave will be expressed going forward.

Therefore, 'form' can be seen to exist as Light, and in this point of view Schrodinger's equation becomes an arbitration to take information from behind the quantum-veil that may exist in antecedent layers of light, and through such arbitration or rate of change, compute them into material existence. Quantum computation, therefore, becomes a predominantly creative as opposed to a solely constructive function. The object of quantum computation in such an interpretation of quantum phenomena is nothing other than to create something new, rather than to construct, based on regurgitating programming-based instruction. That which is created as 'new' is nothing other than enhanced or even unique function that is proposed to exist in antecedent layers of light.

V. Interpretation of Heisenberg's Uncertainty Principle Based on Model of Light & Implication for Quantum Computation

In his book, The Little Book of String Theory, Princeton University's Gubser (Gubser, 2010) describes the effect on approaching absolute zero temperature on molecules. He takes the example of water molecules and relates that one cannot make the water molecules colder than absolute zero, -273.15 Celsius. This is so because there is no more thermal energy to suck out at that temperature. However, quantum uncertainty, the phenomenon which relates the momentum and location of electrons in atoms necessitates that the water molecules will still vibrate. Gubser suggests this by considering Heisenberg's uncertainty relation depicted previously by (2) and reproduced here for convenience:

$$\Delta p\ X\ \Delta x\ \geq \frac{h}{4\pi} \qquad (2)$$

In (2) Δp is the uncertainty in a particle's momentum, Δx is the uncertainty in the particle's location, and h is the Planck's constant. In frozen water crystals it is precisely known where the water molecules are, and therefore Δx is fairly small. This means that Δp has to be considerably larger, and therefore that the water molecules are still vibrating even though they are at absolute zero. This innate vibration, known as 'quantum zero-point' energy, expresses the phenomenon of quantum fluctuations.

The Planck's constant order of magnitude (10^{-34}) though, suggests that the boundary between the layer so created when light travels at 'c' and the antecedent layers of light, manifests as the phenomenon of quantum fluctuations, or the uncertainty relation, or the quantum zero-point energy. In reality this phenomenon is nothing other than an expression of the essential play of unique seeds or functions that is posited as a key formative force behind any organization occurring in the layer so created when light travels at speed c.

In this interpretation the thermal energy describes the essential energy of movement of molecules, while the uncertainty relation suggests the phenomenon of function-precipitation from other layers of Light, "physically" linking layers of light. This also casts a different interpretation on the cosmological phenomenon of quantum vacuum, reinforcing in line with this treatise, that the “emptiness” of space is in fact a veil to infinitely more information seeking precipitation at the material level.

But further, it may also be suggested that the uncertainty principle itself is only valid at the layer so created when light travels at speed c, and that too, because of the finiteness of c. This finiteness as already suggested implies h, which implies that if the position of a particle is going to be observed by shining light on it, the light has to have at least a quantum of energy. But to determine the position of a particle accurately, light of a shorter wavelength would have to be used (Hawking, 1988) which would necessarily have relatively higher energy as compared with higher wavelength light, which in turn would interfere with the velocity and hence momentum of the particle. The uncertainty in measuring the momentum could also therefore be thought of as a consequence of the finiteness of the speed of light, c.

If the speed of light were to approach ∞ miles per second, as suggested in Section III, the quantum would be smaller and the uncertainty in measuring position or momentum would be reduced. At the layer where light is proposed to travel infinitely fast there would therefore be no uncertainty since light would accurately tell both position and momentum definitively.

Hence, the uncertainty principle may be further qualified, as in Equations 8 - 10:

$$\Delta p \; X \; \Delta x \; \geq \frac{h}{4\pi}$$

Eq 8: Uncertainty Principle when Light at 186,000 miles per second

$$@\mathrm{C_Q}\!: \; \Delta p \; X \; \Delta x \; \rightarrow \; 0$$

Eq 9: Uncertainty Principle at when Light >> 186,000 miles per second

$$@\mathrm{C}_{M_3}\!: \; \Delta p \; X \; \Delta x = 0$$

Eq 10: Uncertainty Principle when Light traveling infinitely fast

The notion of position and momentum becoming finite when light travels at c, also may imply that space, time, and quanta are emergent rather than absolute properties, as also suggested in Section II. This is also the conclusion of Arkani-Hamed of the Institute of Advanced Studies in the following thought experiment (Wolchover, 2013):

‘Locality says that particles interact at points in space-time. But suppose you want to inspect space-time very closely. Probing smaller and smaller distance scales requires ever higher energies, but at a certain scale, called the Planck length, the picture gets blurry: So much energy must be concentrated into such a small region that the energy collapses the region into a black hole, making it impossible to inspect. “There’s no way of measuring space and time separations once they are smaller than the Planck length,” said Arkani-Hamed. “So we imagine space-time is a continuous thing, but because it’s impossible to talk sharply about that thing, then that suggests it must not be fundamental — it must be emergent.”

Unitarity says the quantum mechanical probabilities of all possible outcomes of a particle interaction must sum to one. To prove it, one would have to observe the same interaction over and over and count the frequencies of the different outcomes. Doing this to perfect accuracy would require an infinite number of observations using an infinitely large measuring apparatus, but the latter would again cause gravitational collapse into a black hole. In finite regions of the universe unitarity can therefore only be approximately known.’

The notion of emergence of fundamentals such as space, time, and quanta, further reinforce the idea that quantum computation is a fundamentally creative as opposed to a constructive act. What Heisenberg’s uncertainty principle is suggesting is that while a meta-function will fulfil its purpose, it may manifest in a variable process due to the different sets of dynamics existing in the different conceptual layers of layers. If a hypothetical quantum computer were to be constructed in a layer of light closer to light traveling at infinite speed, the uncertainty would be less, as also suggested by the preceding equations. This would be because there would be fewer influences arbitrating possibility.

VI. SUMMARY AND CONCLUSION

The jury is still out on the dynamics that animate the quantum level.

It is assumed, based on the Copenhagen Interpretation of Quantum Mechanics, that a quantum-object will exist in a number of superposed states until measured. The act of measurement will cause the quantum-object to collapse into an observable state, and therefore it will be impossible, given today’s science and technology, to know what is happening behind the quantum-veil.

Yet quantum computation assumes knowledge of phenomena behind the quantum-veil, and subsequently that an n-qubit quantum computer can exist in 2^n (2 to the power n) states simultaneously. Further, it is assumed that if these qubits can be entangled, then the combination of the dual properties of superposition and entanglement, will confer quantum computers with extraordinary processing power.

The alternative light-based model leveraged in this paper is predicated on the infinite information conceived were light to travel infinitely fast depicted by the row c_∞: $[Pr, Po, K, H]$ in the (3). Information from this layer precipitates into material reality, c_U - where light travels at speed c, via intermediate realities where light is envisioned to exist at speeds slower than infinity, but faster than c. These intermediate realities are specified by rows c_K and c_N respectively, such that $c_U < c_N < c_K < c_\infty$.

Such a model gives rise to an alternative view of quantum-level phenomena as suggested by the alternative interpretation of foundational quantum-level equations such as Schrodinger’s wave equation and Heisenberg’s uncertainty principle. Leveraging the alternative interpretation of Schrodinger’s equation, quantum computation can be seen to be a creative act arbitrating information or function from information-rich conceptual spaces created by light travelling at faster than speed

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

c. Heisenberg's uncertainty principle reinforces such a model of light suggesting that meta-level function has leeway in the way at it manifests but will manifest to fulfil the function it is intended to.

Leveraging such interpretations suggests an alternative to view the field of quantum computation, to be creative rather than solely constructive.

***Abstract*—This paper describes an optimal bio-inspired PID controller for accurate steering management of the Autonomous Underwater Vehicle system (AUV). To achieve precise control performance, a PID controller is designed, and its gain parameters K_p, K_i, K_d are tuned by applying Simulated Annealing (SA), Genetic Algorithm (GA) and Moth-Flame Optimization Algorithm (MFO). The experimental response corresponding to the unit step and square input waveform for these proposed nature-inspired optimization algorithms were obtained. The response characteristics like overshoot, rise time, settling time and performances index ITAE were calculated and compared. The experimental results show that MFO-PID is highly efficient, followed by GA and SA, respectively.**

Keywords—Moth-flame, GA, SA, AUV, PID, Optimization

I. Introduction

AUV, which stands for an autonomous underwater vehicle, can perform several operations in shallow and deep-sea environments. They have been successfully applied in various fields including military operations, commercial and research purposes etc. Fitted with electronic subsystems, they allow the robot to steer efficiently in harsh surroundings while undergoing the assigned tasks without any human input. This coherent nature of the AUV is due to its six degrees of freedom (DoF). The device's robust interconnection is shown in Fig.1. and the symbolic notations of position and velocity terms of AUV [1] are shown in Table. I. Despite these adroit networks of subsystems, due to the presence of natural and environmental disturbances such as tidal waves and ocean currents, etc., control of such vehicles becomes an arduous task.

For achieving a more potent control, researchers have utilised several intelligent control methods for AUV control [2], [3]. However, controllers like PD, PID have proved to showcase a more straightforward controlling approach. Moreover, such schemes possess more uncomplicated application in implementation from the linear regime's computational point of view [4]. In contrast, however, PID controllers are suffering from tedious computations during the changes in system parameters because of the occurrence of natural perturbations. Many papers are also available in the literature that erudite a controller's application and design, synthesized using a PID control process for the robust steering control of the AUV system [5], [6]. Such controllers are also in demand to control multiple other systems like the trajectory tracking and control of TRMS and Ball beam systems [7], [8].

This paper implements a PID based controller, which is optimally tuned by a bio-inspired meta-heuristic optimization approach referred to as the Moth-Flame Optimization (MFO), Genetic Algorithm (GA) and Simulated Annealing (SA) for the robust control of an AUV. It is found that the performance MFO-PID is better as compared to GA-PID and SA-PID.

This paper is arranged as mathematical modelling of AUV system is explained in section II, followed by section III &IV, which include synthesis of PID based controller applying MFO. Section V gives the experimental responses of the AUV. Eventually, section VI provides the conclusion.

II. AUV MODELLING

To formulate a PID controller for the steering management of an autonomous underwater system, we would first require its general transfer function which gives information regarding the yaw angle, and its relation with the deflection parameter. For this, the mathematical modelling of an AUV [9] is done. This is carried out by considering two different frames of reference, namely earth-fixed and body-fixed frame. System coordinates of this prototype are expounded using three mutually perpendicular axes starting from a random point. North and East correspond to x and y-axis, respectively. Increasing depth conform with the z-axis. The position vector η and velocity vector v can be described by the equations (1) and (2) respectively.

$$v = [u\, v\, w\, p\, q\, r]^T \qquad (1)$$
$$\eta = [x\, y\, z\, \phi\, \theta\, \Psi]^{\mathrm{T}} \qquad (2)$$

In pure steering plane, simplification of these equations is carried out by considering the origin of the body-fixed frame[10] to concur to the center of gravity:

$$m(\dot{v} + u_o r) = \sum Y \qquad (3)$$
$$I_Z \dot{r} = \sum N \qquad (4)$$

Surge speed (u_o), is fixed at 0.75 m/s. Assuming the pitch angle and roll to be small:

$$\Psi = \frac{\sin\phi}{\cos\theta} q + \frac{\cos\phi}{\cos\theta} r \approx r \qquad (5)$$

In matrix form, the equations (1) to (5) are rewritten as (6):

$$\begin{bmatrix} m - Y_{\dot{v}} & -Y_{\dot{r}} & 0 \\ -N_{\dot{v}} & I_{zz} - N_{\dot{r}} & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \dot{v} \\ \dot{r} \\ \dot{\Psi} \end{bmatrix} + \begin{bmatrix} -Y_v & -Y_r + mv_o & 0 \\ -N_v & -N_r & 0 \\ 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} v \\ r \\ \Psi \end{bmatrix} = \begin{bmatrix} Y_{\delta i} \\ N_{\delta i} \\ 0 \end{bmatrix} \delta_r \qquad (6)$$

By substituting the values of vehicle parameter of AUV[11], [12] dimensions, the hydrodynamic coefficient for u_o at 0.75 m/s and by applying the state space approach to get equations (7) to (9)

$$\dot{x}(t) = Cx(t) + Du(t) \qquad (7)$$
$$C = \begin{bmatrix} -0.114 & -0.2647 & 0 \\ 0.0225 & -0.2331 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$
$$D = [0.0211 \text{ -0.0258 } 0]^{\mathrm{T}}$$
$$U = \delta_r \qquad (8)$$

The relation between yaw (ψ) and rudder deflection (δ_r) in terms of the transfer function is acquired as:

$$\frac{\Psi(s)}{\delta_r(s)} = \frac{-0.0258s - 0.0024}{s^3 + 0.3445s^2 + 0.319s} \qquad (9)$$

Now that the system's requisite transfer function has been derived, we can synthesize the proposed compensator.

III. DESIGN OF PID CONTROLLER FOR AUV

PID controller, is a conventional control scheme, is applied extensively for precise control of various systems. Controllers based on PID have been successfully implemented in the design and control of multiple systems[13]–[15]. The PID displays sufficient stability margins, optimum time responses, better system characteristic properties such as low overshoot, and lesser settling time. It consists of proportional, integral and derivative gain parameters which are functions of error between the desired set point and actual system output. The general unity feedback characteristic equation of AUV with PID control laws are written as equations (10), (11) and (12).

$$c(t) = k_p e(t) + k_i D^{-1} e(t) + k_d D e(t) \qquad (10)$$
$$U(s) = \frac{c(s)}{e(s)} = k_p + k_i s^{-1} + k_d s \qquad (11)$$
$$1 + G(s)U(s) = 0 \qquad (12)$$

Now for finding the accurate values of the operational gains(k_p, k_i, k_d), the characteristic equation is optimized based on the Integral Time Absolute Error (ITAE) performance index, i.e., integral of time multiplied by absolute error to minimize the error signal.

$$\text{ITAE} = \int_0^t t|e(t)|dt \qquad (13)$$

PID controller gains are then tuned using MFO, GA and SA to observe their performances for comparison. The block diagram of PID Controller based optimization of AUV using MFO/GA/SA by taking ITAE as the cost function is shown in Fig.2.

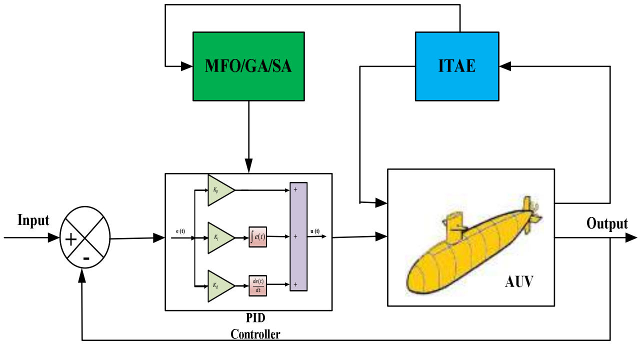

Fig.2. Block Diagram of unity feedback optimal PID control

IV. TUNING OF PID CONTROLLER USING SA, GA AND MFO

PID controllers are commonly used in all dynamical systems, but it requires a monotonous tuning of control actions to avoid sluggishness of the system response. Nature and bio-inspired optimization algorithms can diminish the computational difficulties in the monotonous tuning of PID controllers, thereby the AUV's steering control is with minimum human interventions. Here, the PID controller in AUV's steering loop is tuned by Simulated Annealing, Genetic Algorithm and Moths Flame Optimizer methods.

A. Simulated Annealing Tuned PID Controller

Simulated Annealing is one of the most widely used methods for optimizing control problems of dynamical systems. This algorithmic technique is inspired by the relationship of combinational optimization and quantum and classical or statistical mechanics laws. A simple mechanism of cooling of material is applied in steps till the lowest energy is reached. The state at this lowest energy is the optimized state. Pseudocode for the SA algorithm applied for tuning the gain parameters of the proposed PID controller is given as:

```
Step 1: The ranges for the 3 gain coefficients of a PID control are fixed in the form of an objective function $f(x) = [K_p, K_i, K_d]^t$
Step 2: Set $t_o$ as the temperature at the beginning of the process
Step 3: Take $s_i$ as the initial stage of the system
Step 4: Take $s_{opt}$ as the desired optimized state of the system
Step 5: Initially, assign t as $t_o$ and $s_{opt}$ as $s_i$
Step 6: **for** $t = 1$ to $t_{max}$ **do**
        Assign $s_{opt+1}$ to adjacent/nearest $(s_{opt})$
        Change $\Delta E$ to $(f(s_{opt+1})$-$f(s_{opt}))$
        **if** $min\ (1, e^{-\Delta E/t}) \geq$ random (0,1) **then**
                Update $s_{opt}$ to $s_{opt+1}$
        **end if**
        Assign t as the temperature-schedule(t)
**end for**
Step 7: Output the final solution of the optimized function
```

The values for the 3 gain coefficients Kp, Ki and Kd obtained using SA method are -19.9298, -4.9419 and -41.25 respectively. However, the simulated annealing technique poses a critical drawback while working on minimization problems. For instance, any change in the system values that decrease the cost function 'f ' will be accepted as desired, but sometimes, changes that increase 'f' might also get counted. This happens with a probability p, known as the transition probability. Due to this disadvantage offered by SA, we use GA to stabilize the system.

B. Genetic Algorithm Tuned PID Controller

Genetic algorithm (GA) is a nature-based optimization technique applied to solve computational problems. It is used on a chromosome population where every chromosome represents a solution that has an associated fitness value to it. This value defines how optimal a solution is. Some arbitrarily generated population is initially taken, followed by the selection process, which is fitness based. The next step involves recombination to develop the next generation. For the above step, parent genes are used to obtain child chromosomes. Several iterative processes continue till the stopping criteria is achieved. Pseudocode for the genetic algorithm is:

```
Step 1: Designate the ranges for the control parameters of the PID controller to model an objective function as- $f(x) = [K_p, K_i, K_d]^t$
Step 2: Generation of initial source population of $M$ chromosomes randomly.
Step 3: Calculation of the fitness $F$ using Eq. (14)
Step 4: **for** $i = 1: n$
        Take two chromosomes from the current population.
        Crossover is applied to chromosomes with crossover rate $x$.
        Mutation is applied to the chromosome with mutation rate $m$ to generate a new chromosome.
        Add the above generated chromosome to next generation population.
        Current Population is replaced with next generation population.
    **end for**
Step 5: Finally, output the solution of the optimized global best.
```

One practical step for applying GA is to evaluate the fitness value for all the chromosomes to reduce the error signal $e(s)$. PID controller is applied to minimize this error. As this fitness value is inversely proportional to the value of the performance index, we can define the chromosomes' fitness as (14).

$$F = \frac{1}{Performance\ Index} \tag{14}$$

The tuned optimized parametersK_p, K_i and K_d, using GA are - 17.4092, -1.8497 and -38.4368, respectively. The response obtained using GA shows an overshoot of more than 10%. This result also shows that GA does not have a high speed of convergence that is why an alternative algorithm, designed using evolutionary strategies can be deployed to obtain a faster and more efficient performance of the system. The moth flame optimization algorithm (MFO) is one such technique.

C. Moths Flame Optimization Algorithm tuned PID

MFO is a newly developed nature-based solution finding mechanism made from the algorithms inspired by the population search strategy. This bio-inspired optimization algorithm is very flexible, and can easily be implemented in finding the optimal solution of real-world problems. Some applications of MFO are available in literature ranging from the tuning of controllers such as fuzzy-PID, fuzzy-PI, PID, PI. Moth–flame optimization (MFO) technique was introduced by Mirjalili[16]. It initiates by creating moths arbitrarily inside the solution region by a transverse orientation shown in Fig.3.

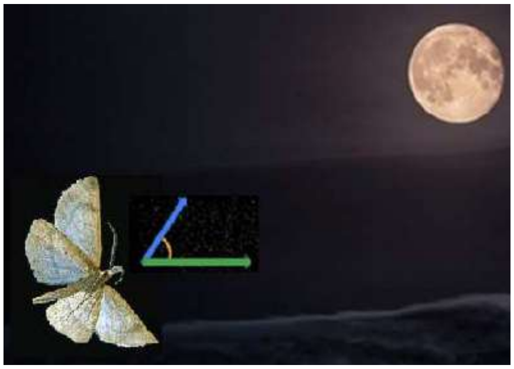

Fig.3 Moth's Transverse Orientation

After this, the fitness function values for every moth are calculated and tagged the most optimum position by flame. Then, depending on the spiral movement function, the moths' positions are modified to attain more acceptable positions sorted by a flame, the new most acceptable positions of individuals are upgraded, and replicating the previous operations.

This process takes place until the total number of iterations have been completed. The MFO algorithm has three main postulates. These are given below:

1.Initializing Population:

It is taken that all moths can fly in all the dimensions. The moth set can be represented as:

$$B = \begin{bmatrix} b_{1,1} & b_{1,2} & \cdots & \cdots & b_{1,d} \\ b_{2,1} & \cdots & \cdots & \cdots & b_{2,d} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{x,1} & b_{x,2} & \cdots & \cdots & b_{x,d} \end{bmatrix} \qquad (15)$$

Where x stands for the number of moths and d gives the number of dimensions in the solution region.

Array to store the values of the fitness function is as follows:

$$OB = \begin{bmatrix} OB_1 \\ OB_2 \\ \vdots \\ OB_x \end{bmatrix} \qquad (16)$$

The given matrix defines the flames in the d-dimensional region, and their fitness value vector follows it.

$$F = \begin{bmatrix} F_{1,1} & F_{1,2} & \cdots & \cdots & F_{1,d} \\ F_{2,1} & \cdots & \cdots & \cdots & F_{2,d} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ F_{x,1} & F_{x,2} & \cdots & \cdots & F_{x,d} \end{bmatrix} \qquad (17)$$

$$OF = \begin{bmatrix} OF_1 \\ OF_2 \\ \vdots \\ OF_x \end{bmatrix} \qquad (18)$$

The solutions are moths and flames. What distinguishes them is how we treat and update them after every iterative step. Actual searching agents which move throughout the search area are moths. Flames are optimal positions of moths which have been derived until now.

2.Updating Moths' Position:

The optimal global value can be obtained for the optimization problem; this algorithm employs three steps. These are given below:

$$MFO = (I, P, T) \qquad (19)$$

where I describe the function, which gives the first moth population randomly

$I: \phi \rightarrow \{B, OB\}$

P signifies the moths' movement in the search area

$P: B \rightarrow B$

T is the condition for termination

$T: B \rightarrow true, false$

The equation below, explains the function I, which applies random distribution.

$$\mathrm{M(p,q)} = \big(\mathrm{ub(p)} - \mathrm{lb(q)}\big) * \mathrm{rand(\,)} + lb(p) \qquad (20)$$

Where lb and ub represent the lower and the upper bounds, respectively.

Three conditions which should be followed while applying a logarithmic spiral are:

- The starting point of the spiral should begin from the moth.
- The ending point of the spiral should be in the flame position.
- Spiral's range fluctuation is not supposed to surpass the search space.

$$S\big(B_p, F_q\big) = D_p \cdot e^{bt} \cdot \cos(2\Pi t) + F_q \qquad (21)$$

Where D_p represents the region within p^{th} moth and q^{th} flame.

$$Dp = |Fq - Bp| \qquad (22)$$

Bp describes the logarithmic spiral's shape, and t stands for any arbitrary value within $[r, 1]$. The spiral motion guarantees the balance between exploitation and exploration close to the flame. Where r changes from [-1,2] in the whole process of iteration, which is called as the convergence constant. The logarithmic spiral shape, as described above, is shown in Fig.4.

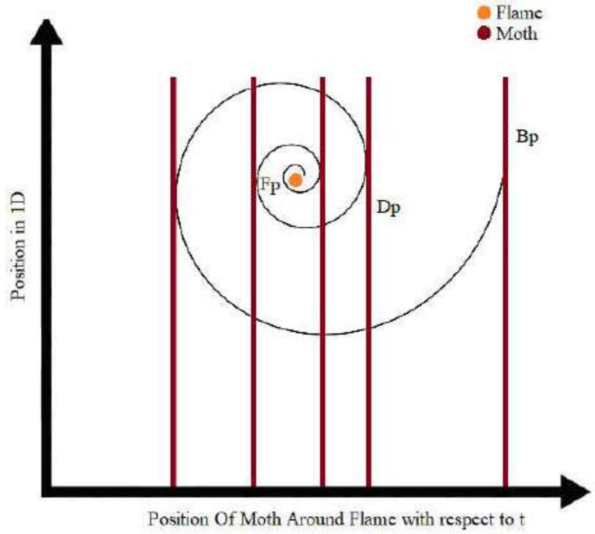

Fig.4. Logarithmic spiral shape

3.Mistakes Update in Flames

Moth positions are updated in n different locations inside the search region, which might reduce the exploitation of the most optimized solutions. Thus, minimizing the flames solves the conflict using an equation given below:

$$flame\ no. = round\left(N - l * \frac{N-1}{T}\right) \quad (23)$$

N represents the total flames
l represents the present iteration
T represents the total iterations
Pseudocode for the MFO algorithm is described as:

```
Step 1: Assign the fixed ranges for each control parameter of the proposed PID controller in the form of a cost function as- $f(x) = [K_p, K_i, K_d]^t$
Step 2: Initialize the Moth-Flame population
Step 3: Initialize position of moth $B$ arbitrarily
Step 4: for $p = 1\ to\ n$ do
            Calculate the value of fitness function F
        end for
Step 5: While iterations<=total iterations do
            Update flame no by using Eq. (23)
            $OB$ = Fitness Func($B$);
            if iteration == 1
            $F$ = sort($B$);
            $OF$ = sort ($OB$);
            else
            $F$ = sort ($B_{t-1}$, $B_t$);
            $OF$ = sort ($B_{t-1}$, $B_t$);
            end
Step 6: for $p = 1:n$
            for $q = 1:d$
            Update the values of $r$ and $t$
            Calculate the value $D$ using Eq. (22)
            Update $S(p,q)$ using Eq. (21)
            end
end
Step 7: Consequently, the precisely tuned solution of the optimized cost function is output.
```

The tuned optimally calculated parametersK_p, K_i and K_d, by using MFO are -15.5343, --0.025 and -38.93, respectively.

V. Simulation and Results

For comparison of the optimization performances of Moth-Flame Optimization (MFO), Genetic Algorithm (GA) and Simulated Annealing (SA) method, the output response of AUV, controlled by tuned PID controllers are observed for unit step and unit square wave input. In the square wave input case, the chosen frequency for simulation was fixed at 15 mHz.

The tuned PID controller's step and square wave responses for MFO-PID, GA-PID and SA-PID controllers for AUV steering control are shown in Fig.5. and Fig.6 respectively.

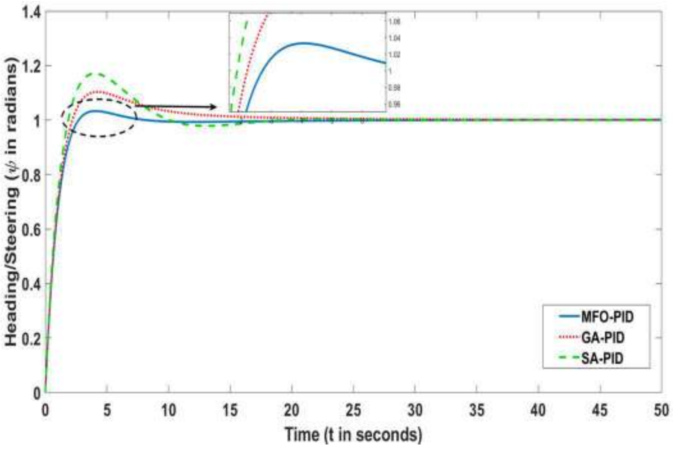

Fig.5. Unit Step Responses by the respective tuned controllers

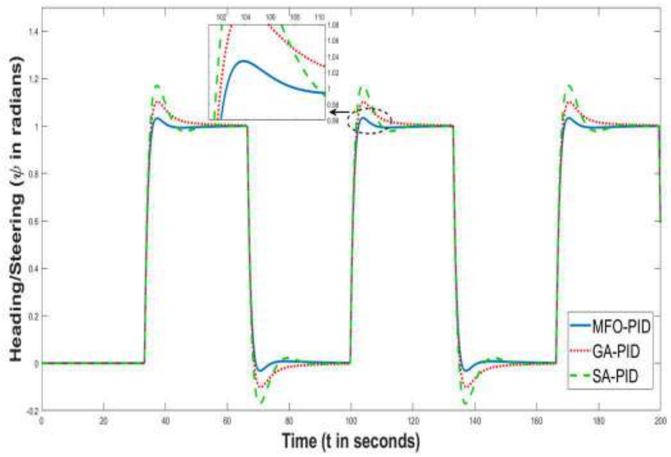

Fig.6. Square Responses by the respective tuned controllers

The precisely optimized solutions of the gain parameters are given in Table II.

TABLE II. GAIN PARAMETERS OF TUNED PID CONTROLLER

Gain Parameters			
PID Parameters	***SA***	***GA***	***MFO***
K_p	-19.9298	-17.4092	-15.5343
K_i	-4.9419	-1.8497	-0.025
K_d	-41.25	-38.4368	-38.93

The PID transient performance characteristics using MFO, GA and SA are given in Table III.

TABLE III. TRANSIENT PERFORMANCE OF TUNED PID CONTROLLER

ITAE			
Tuning Algorithm	***SA***	***GA***	***MFO***
Rise Time (Sec)	1.37	1.56	1.72
%Overshoot	17.1	10.3	3.3
Settling Time (Sec)	14.1	12.4	5.7

The cost comparison amongst MFO, GA and SA are given in Table IV.

TABLE IV. COST COMPARISON

ITAE ERROR			
Tuning Algorithm	***SA***	***GA***	***MFO***
Error(J)	0.6396	0.4371	0.2066

It is observed from Table III that the MFO tuned PID controller has remarkable performance as compared to GA tuned PID and SA tuned PID in terms of lesser overshoot and settling time. It proves that the MFO tuned PID for AUV steering control is optimally and accurately meeting the design objectives. It is also noted from Table IV that the cost and error are drastically reduced in contrast to GA tuned PID and SA tuned PID controllers.

VI. CONCLUSION

To obtain the robust control for an autonomous underwater vehicle, this paper presents the application of a bio-inspired optimization algorithm called Moth-Flame Optimization to optimally tune the gain parameters of a PID based controller for efficient motion stabilization of the AUV system. Tuning of the proposed PID controller is done for an error-based performance index ITAE. Genetic Algorithm and Simulated Annealing Method are also used to compare the system's step and square responses. The response obtained for MFO-PID is clearly, better than GA-PID, followed by SA-PID in case of overshoot, settling time and rise time. The scope of future work can be the application of this algorithm to design more complex controllers for advanced systems.

***Abstract*— In In-Band Full Duplex (IBFD) transceivers, Electrical Balance Duplexers (EBDs) provide Transmit (TX)-Receive (RX) isolation to implement a form of self-interference (SI) cancellation to facilitates simultaneous transmission and reception from a single antenna. EBD works by coupling transmitter, receiver, antenna, and balancing impedance using a hybrid coupler. The balancing impedance in the EBD needs to be equal as much as possible to the antenna impedance to achieve a high isolation while the antenna impedance variations limit the isolation bandwidth. Hybrid couplers are also not ideal elements, and their S parameters are variable in frequency domain. An antenna with a stable impedance, designed by authors, has been connected in this work to two different hybrid couplers in the EBD stages. One coupler is a commercial coupler and the other one, designed by the authors, has more S parameter stability in the frequency domain than the commercial one. It is shown that by using the designed coupler in the front-end EBD stage more stable isolation bandwidth and 45% better isolation value at ultra-wideband range of 1.5-3.5GHz are obtained, in comparison when using the commercial one.**

Keywords—duplexers, in-band full duplex, self-interference cancellation, couplers, antennas

I. Introduction

In-band full-duplex (IBFD) systems can theoretically double link capacity of Time Division Duplex (TDD) and Frequency Division Duplex (FDD) systems thus allowing simultaneous transmission and reception on the same frequency and reduce wireless latency [1], [2]. Transmitting and receiving on the same time-frequency resource results in strong co-channel Self-Interference (SI), which can be more powerful than the desired receive signal [2]. Any residual SI, due to unsuitable transmit (Tx) to receive (Rx) isolation, will effectively increase the receiver noise floor therefore reduces the capacity of the receive channel [3].

Existing IBFD designs [4], [5] involve various combinations of analog cancellation, digital cancellation, and antenna based suppression to provide the required isolation. Digital cancellation [6] cannot properly prevent SI from overloading the receiver. Analog cancellation [5], [6], can provide significant isolation and prevents receiver overloading in most cases [5]. Antenna based suppression and separation methods can provide significant isolation also, however these designs require additional antennas [6]. Single antenna full duplex systems in [5] use circulators to provide some level of Tx-Rx isolation but these are unattractive options due to their cost, size, and limited bandwidth. New duplexers based on SI Cancellation (SIC) at the receiver have received substantial interest to enable IBFD operation [1], [5]–[8].

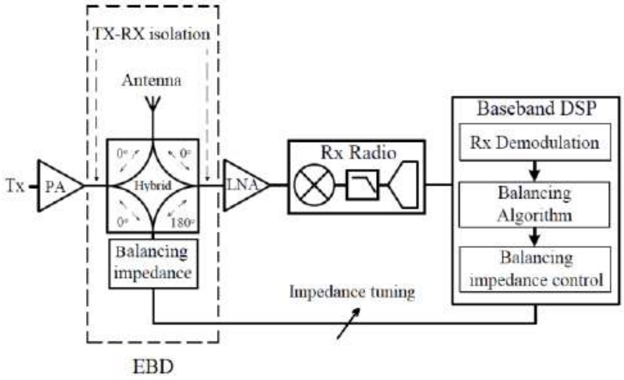

Fig. 1. EBD stage of IBFD system with adaptive balancing impedance

Recent results [3], [7], [9]–[11] have demonstrated that Electrical Balance Duplexers (EBDs), which is of interest as the first stage of passive Radio Frequency (RF) front-end cancellation in IBFD transceivers, implement a form of SIC in order to provide high transmit to receive isolation whilst facilitating simultaneous transmission and reception from a single antenna. EBD could potentially be combined with analog cancellation, digital cancellation, and full duplex MIMO technology [4]. The analog circuit technique of EBD works by coupling the transmitter, receiver and antenna using a four-port hybrid junction, along with a balancing impedance connected to the fourth port, Fig. 1. Using a suitable hybrid coupler, a high transmit-to-receive isolation is expected in the EBD stage when the balancing impedance is equal to the antenna impedance at all frequencies within the aimed bandwidth. However, in practice, the antenna impedance is not an ideal 50 Ω resistor but has a complex impedance having real and imaginary parts. This exhibits variations with respect to frequency so the bandwidth and value of the Tx-Rx isolation will be limited by the impedance mismatching between the antenna and balancing impedance.

Measured real antenna data in [3], [8], and results for a prototype EDB in [12], demonstrate that the variation in antenna impedance significantly reduces the isolation bandwidth. Evaluations that include measured antenna data in the EBD in [7], [9], [11] shows a mean isolation of 35 dB over a 20-MHz bandwidth at 1.9 GHz but poor performance of wider bandwidths, again said because of antenna impedance variations. A Micro- ElectroMechanical Systems (MEMS) implementation of tuneable balancing impedance of the EBD is presented in [13], balancing at 800 MHz and 1900 MHz to provide 43 dB isolation over a 20 MHz bandwidth at each frequency but introduce non-linear distortion into the system. Consequently, to maintain Tx-Rx isolation, the balancing

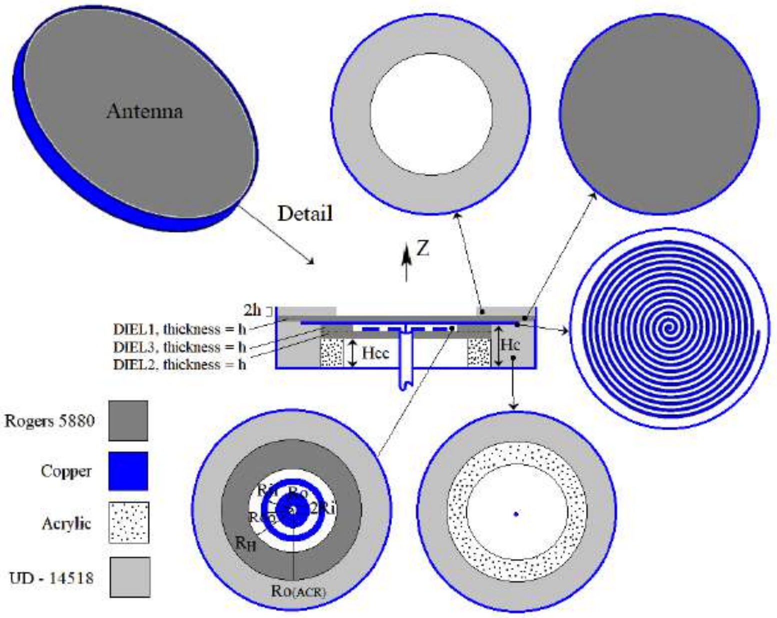

Fig. 2. Designed antenna with stable impedance, Section III.A (whole and cross-section views),

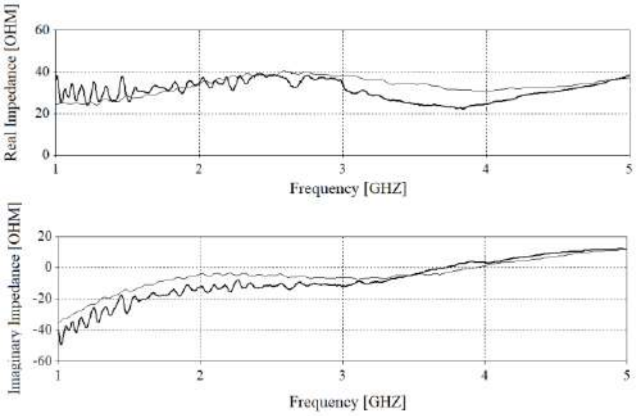

Fig. 3. Measured and simulated impedance of the antenna in Fig. 2.

impedance must be tuneable as it tracks and mimics the antenna impedance as it changes. This requires an adaptive architecture [9], [11], Fig. 1, using a balancing algorithm which extremely limits both the mimic and the isolation bandwidths.

In all above scenarios in the literature, analyses consider the antenna impedance variations as the main factor limiting the SIC when the antenna is connected to a hybrid coupler. The main aim in this work is to investigate how the EBD isolation is affected by stability of coupler S parameters in the frequency domain. In the rest of this paper, in Section II, Tx-Rx gain function of EBD circuitry is briefly reviewed to assess EBD isolation in generic form. Used devices in the experiments of this work (stable impedance antenna, stable S parameter coupler, commercial coupler, and balancing load) are introduced in Section III. Stable impedance antenna and stable S parameter coupler are designed by authors. In Section IV, EBD isolations are measured when the two couplers are connected to the stable impedance antenna in two separate experiments. In comparison when using the commercial coupler in the EBD, it is shown that the EBD isolation bandwidth is increased, and the isolation value is optimized when using the designed coupler with higher S parameter stability. Finally, a conclusion is given in Section V.

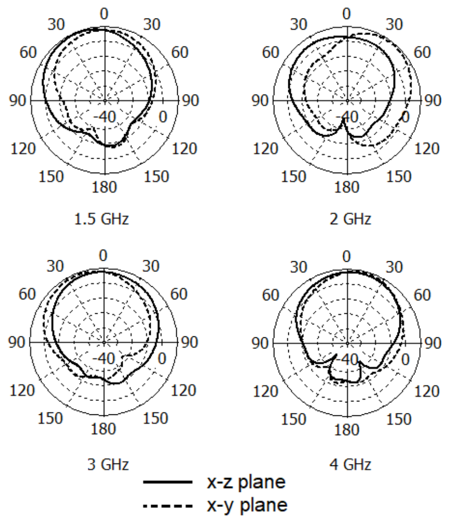

Fig. 4. Measured directivity pattern of the antenna in Fig.2.

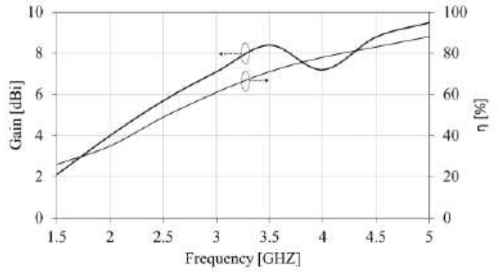

Fig. 5. Measured gain and radiation efficiency of the antenna in Fig. 2.

II. Tx-Rx Gain of Electrical Balance Duplexers

Tx-Rx gain of an symmetrical EBD is given [10] by:

$$G_{Tx-Rx}(\omega) = L\,|\Gamma_{BAL}(\omega) - \Gamma_{ANT}(\omega)|^2. \qquad (1)$$

where Γ_{BAL} and Γ_{ANT} are the complex reflection coefficients of the balancing impedance and antenna impedance,

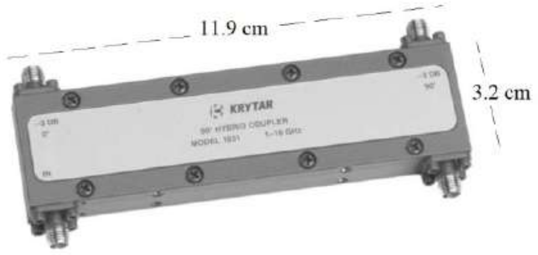

Fig. 6. Commercial 3-dB coupler, Model Krytar1831 [18] (Section III. B)

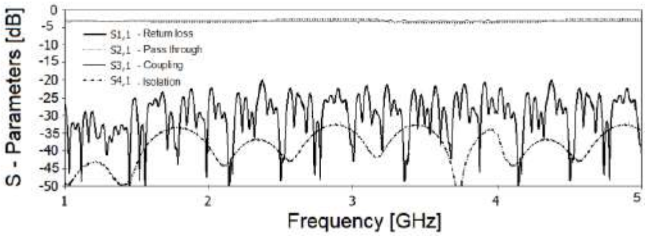

Fig. 7. Measured S parameters of the 3- dB Krytar1831 coupler in Fig. 6 (Section III. B).

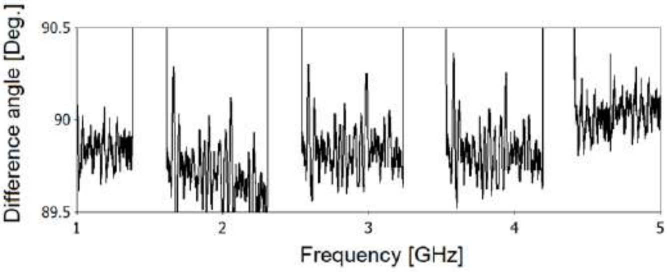

Fig. 8. Measured phase characteristic of the 3-dB Krytar1831 coupler in Fig. 6 (Section III. B), Zoomed view

respectively (see Fig.1), and for an ideal (lossless) hybrid L = ¼. As we can see from (1), the Tx-Rx gain is theoretically zero when the balancing reflection coefficient and antenna reflection coefficient are equal at the carrier frequency. To obtain maximum (theoretically infinite) Tx-Rx isolation over a given frequency band, the balancing impedance must be equal to the antenna impedance at all frequencies within that band such that $\Gamma_{BAL}(\omega) = \Gamma_{ANT}(\omega)$ for $\omega_l<\omega<\omega_h$ where ω_l and ω_h are the lower and upper limits of the band of interest, respectively. Also, coupler characteristics is a determining parameter to calculate the Tx-Rx gain. Results in [10] demonstrate that (1) remains valid for non-ideal circuit.

III. Devices

In this section, four RF elements used in the paper experiments are introduced. First device is an antenna with a stable impedance. More details about the antenna design are given in the authors other papers in [14] and [15]. Also, two couplers are introduced here, first one is a commercial coupler, and the second coupler is designed by the authors. The second coupler has more S parameter stability in the frequency domain than the first one. More details about design procedure of the second coupler are given in author’s separate paper. Also, a wide band 50-ohm RF load is used as the balancing impedance.

A. Antenna with Stable Impedance - Designed

A single arm Archimedean Spiral (AS) is backed by a cavity, Fig. 2, to have an antenna with a unidirectional beam. The AS is formed as a conducting spiral strip arm of width w =2 mm on bottom of a disc shaped Rogers RT 5880 substrate - so called DIEL1- of radius A_C = 62 mm with a dielectric constant of ε_r = 2.2, loss tangent of 0.0009, h=0.79-mm thickness plus a 9 μm copper coating. DIEL1 has no copper on the top. The centerline of the spiral arm is defined by the function of $r = K\,\Phi$, where K is a constant and Φ is the winding angle, ranging from starting angle $\Phi_S = 0.07\pi$ Rad to ending angle $\Phi_E = 28\pi$ Rad. The antenna circumference C is defined by $C = 2\pi\, R_{max}$ with $R_{max} = K\, \Phi_E$ where K = 0.64 mm/rad, R_{max}= 56 mm. The cavity radius, A_C, has 6 mm distance from the arm end to the cavity wall as A_C = 62 mm= 0.31 λ_L whilst λ_L is the wavelength at the lowest design frequency of 1.5 GHz. The distance between the bottom of the cavity and the spiral on the bottom of DIEL1 substrate is considered as H_C = 6.9 mm = 0.035 λ_L. The height of the copper case wall is chosen as H_C + 2h to surround the DIEL1 disc substrate while the case has a 1 mm uniform thickness of copper.

Reflected fields from bottom of the case are attenuated in the designed antenna using electromagnetic absorbers (EMAs) made up of model UD-14518 of ARC Technology to make the antenna impedance more stable in an UWB frequency range. The UD-14518 specified by relative permittivity of ε_r=ε’-jε” ~ 22+3j and relative permeability of μ_r=μ’-jμ”~ 4.5+2j at aimed the bandwidth [16]. As shown in Fig. 2, a ring-shaped Electromagnetic Absorber (EMA) strip - so called EMA1- of optimized width 11mm and with the same height of copper case H_c = 6.9 mm is placed under the antenna arms. Also, second EMA, so called EMA2, is added to above the DIEL1 substrate to more improve impedance stability. EMA2 has an optimized thickness of 2h = 1.6 mm while its outer radius is equal to the cavity diameter of A_C and its inner radius is A_C -17mm = 45mm.

A capacitive impedance matching using two cocentric planar copper rings, Fig. 2, is also used to improve impedance stability. Maximum bandwidth for a stable impedance is achieved when air with dielectric constant of ε_r =1 is considered between the copper rings and the spiral. As seen, the two cocentric planar copper rings are considered on the top surface of a disc shape dielectric material, so called DIEL2, with a distance of h = 0.79 mm between the copper rings and the spiral body. DIEL2 with a thickness of h is made up of the same material of Rogers RT 5880. DIEL2 has a small hole with R_i = 1.7mm radius in the centre for passing the coaxial cable whilst the outer radius of DIEL2 is 41mm. Also, a planar dielectric ring, so called DIEL3, with the same thickness and the same material with DIEL2 is used as a spacer between DIEL2 and DIEL1. DIEL3 has a hole with radius of R_H = 35mm in the centre whilst its outer radius is equal with the outer radius of DIEL2. The internal copper ring has inner radius of R_i=1.7mm and outer radius of R_O= 5.5 mm while the external ring has inner radius of R_{ii} = 8mm and outer radius of R_{OO} =11 mm. To hold the substrates and spiral a cylindrical ring is 3D printed on Acrylic material with a dielectric constant of $\varepsilon_{r(ACR)}$ = 3.5, internal radius of R_{iA} = of 41 mm, outer radius of R_{oA} = 51 mm and height of $H_{CC} = H_C$ -2h = 5.3mm. The antenna is fed by a 50 Ω coaxial cable whereas the inner conductor of the cable is connected to the AS at its starting angle and outer ground conductor of the cable is connected to the inner radius of internal capacitive ring at the top surface of DIEL3.

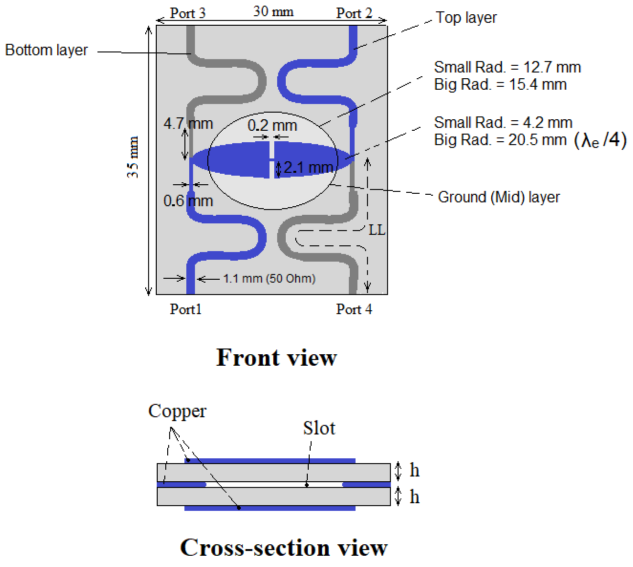

Fig. 9. Designed 3-dB coupler with stable S parameter (Section III. C)

The Finite Integration Technique (FIT) with high meshing in CST MICROWAVE STUDIO [17] software is used for simulations. Measured and simulated antenna impedances with a stable impedance at 1.5 GHz to 3.5 GHz range are shown in Fig. 3, with an average variation of about 15 Ω for the measured imaginary and real impedance. Also, measured directivity pattern of the antenna and its measured gain/efficiency vs frequency plots are shown respectively in Fig. 4 and Fig. 5. The antenna has a measured Axial Ratio (AR) below 3 dB indicating a circular polarization over 1.6 GHz (AR plot is not shown here). These results indicate good impedance stability at 1.5 - 3.5 GHz range for the designed antenna while the antenna also has a suitable radiation performance at this Ultra-wide Band (UWB) bandwidth. The fabricated antenna is shown in Section IV.

B. *Commercial 3-dB Coupler (Krytar Model 1831)*

Krytar coupler model 1831 is an UWB commercially available coupler [18], Fig. 6. Measurement results of the coupler by Vector Network Analyzer (VNA) are given in Fig. 7 and Fig. 8. As seen, this commercial coupler features UWB characteristics with the coupling of 3 ± 1 dB at 1-5 GHz bandwidth. Also, isolation in the order of better than 30 dB and return loss in the order of better than 20 dB are measured. It is seen that the measured S parameters are not very stable in the frequency domain as there are dense variations around 15 dB for isolation and 25 dB for return loss at 1-3.5 GHz range. In Fig. 8, it is observed that the measured phase difference between output ports is dominantly around 90^o over the bandwidth, needed for a suitable quadrature hybrid coupler.

C. *3-dB coupler with Stable S Parameter - Designed*

Proposed miniaturized coupler capable of providing tight coupling over an UWB band, is shown in Fig. 9 where its coupling mechanism is similar to [19] and [20]. The differences for the proposed model concern the shaping factor of the broadside coupled strips, the slot, electrical size and most importantly the operation frequency which is in the ultra-high frequency band. This coupler consists of three conductor copper layers which are interleaved by two dielectric substrates. The top copper layer includes ports 1 and 2. The bottom copper layer is similar to the top layer, but the ports here are ports 3 and 4. Ports 3 and 4 are on opposite sides of the substrate compared to ports 1 and 2. The two layers are coupled via a slot, which is made in the copper layer supporting the top and bottom dielectrics. As seen in Fig. 9, the two microstrip conductors and the slot are of an elliptical shape. The 50 Ω microstrip lines are included to make connections to SMA ports. The structure features double symmetry with respect to both horizontal and vertical plans.

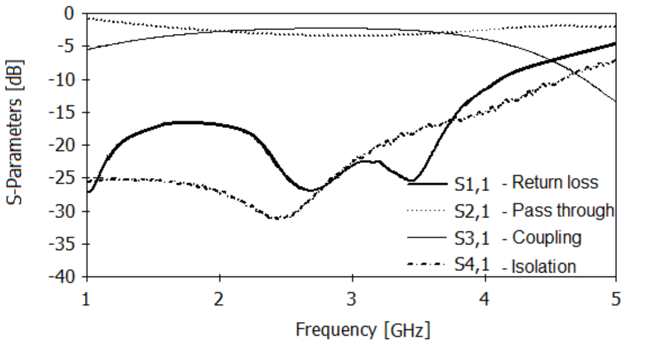

Fig. 10. Fig. 7. Measured S parameters of the designed 3-dB coupler with stable S parameter in Fig. 9 (Section III. C).

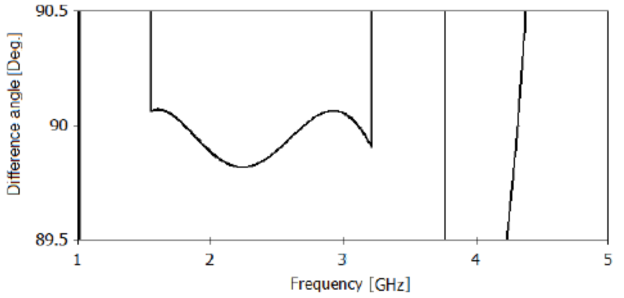

Fig. 11. Measured phase characteristic of the designed 3-dB coupler with stable S parameter in Fig. 9 (Section III. C), Zoomed view

Fig. 12. Wideband 50-ohm RF Load (Section III. D)

Analysis starts in a similar way to the ones described in [21] for the equivalent rectangular shaped microstrips. If characteristic impedance of the microstrip ports of the coupler is $Z_0 = 50\,\Omega$ and the coupling factor is $C_{\text{dB}} = 3$ dB, the values of even mode characteristic impedance Z_{ev} and odd mode characteristic impedance Z_{od} are calculated as 175.5 Ω and 14.2 Ω, respectively.

The validity of the presented design is tested in the 1.5–3.2 GHz frequency band where the centre frequency of operation is 2.35 GHz. A Rogers RO4350B substrate with a dielectric constant of 3.48 and a loss tangent of 0.0037, h = 0.51mm thickness, plus 35- μm-thick conductive copper is used for the coupler development. The elliptical body length is chosen as 20.5 mm ~ λ/6 ~ $\lambda_e/4$ where λ_e is effective wavelength and λ is free space wavelength at the central frequency of 2.35 GHz. The return loss, coupling, and isolation of the designed coupler are first verified by running high mesh FIT in the CST software and the final obtained dimensions are shown in Fig. 9.

Four phase shifters each having length of LL = 33 mm= $0.4\ \lambda_e$ are added to the terminals of elliptical bodies to adjust output phase difference to 90^o, needed for a suitable quadrature hybrid coupler, Fig. 9. To maintain a compact size, phase shifters are formed as curved microstrip lines. Simulations do not show considerable differences in results when the curves angle are not smaller than 75 degree. A combination of impedance matching technique and structural modifications also have been employed to optimize the coupler results. The impedance matching is carried out in a similar way for all four ports by narrowing the width of tracks which connect the ports to the elliptical body as shown in Fig. 9. Also, two narrow slots have been etched on each elliptical body as shown in the same figure. Measurement results by VNA are given in Fig. 10 and Fig. 11. The coupler features measured UWB characteristics with coupling of 3 ± 1 dB at the aimed 1.5-3.2 GHz band. Also, smooth isolation in the order of better than 25 dB and return loss in the order of better than 17 dB is achieved as there are non-dense variations around 10 dB for isolation and 9 dB for return loss at 1-3.5 GHz range. It is seen that the S parameters for the designed coupler have less variation density and more stability in the frequency domain in comparison with the commercial Krytar 1831 in Section III.B. It is observed in Fig. 11 that the measured phase difference between ports 2 and 3 is about 90^o over the target band. The fabricated coupler is shown in Section IV. These results indicate that this compact coupler with 35 mm × 30 mm × 1.1 mm $(0.27\ \lambda\times 23\ \lambda\times 0.009\lambda)$ dimension operates as a backward wave quadrature coupler.

D. *Wideband 50-ohm RF Load*

A wideband commercial 50-ohm RF load (Fig. 12) - which has the nearest commercially available impedance to the antenna impedance - is used in the experiments.

IV. Tx-Rx Isolation in EBD Stage and Comparisons

In this section Tx-Rx isolations of EBD are investigated when the devices introduced in Section III are used and the obtained results are compared together. The designed stable impedance antenna (Section III.A) is connected to the commercial Krytar 1831 hybrid coupler (Section III.B) and stable S parameter coupler (Section III.C) in two separate experiments to from EBD, Fig. 13. For the Krytar 1831 coupler from Fig. 7 it is seen that the measured S parameters are not stable in the frequency domain at 1-3.5 GHz range as there are dense isolation variations around 15 dB and return loss variations around 25 dB while for the designed coupler (Fig. 10) there are less dense variations with the isolation variations around 10 dB and return loss variations around 9 dB. A 50 Ω wideband 50-ohm RF load (Section III.D) is also connected as balancing impedance to both couplers. The experiment setups are shown in Fig. 14.

Average isolation of 20 dB and 29dB are measured by VNA at 1.5GHz-3.5GHz bandwidth respectively for EBD with the Krytar 1831 coupler and EBD with the designed stable S parameter coupler, Fig. 13. While both EBDs use the same antenna and the same 50 Ω RF load, it is seen that when using the designed coupler more stable UWB bandwidth and 45% better isolation value are obtained in comparison when using the Krytar 1831 coupler.

First reason of variations and limitations still seen in the obtained optimized UWB isolation could be the small inherent impedance variations of the designed coupler and the antenna.

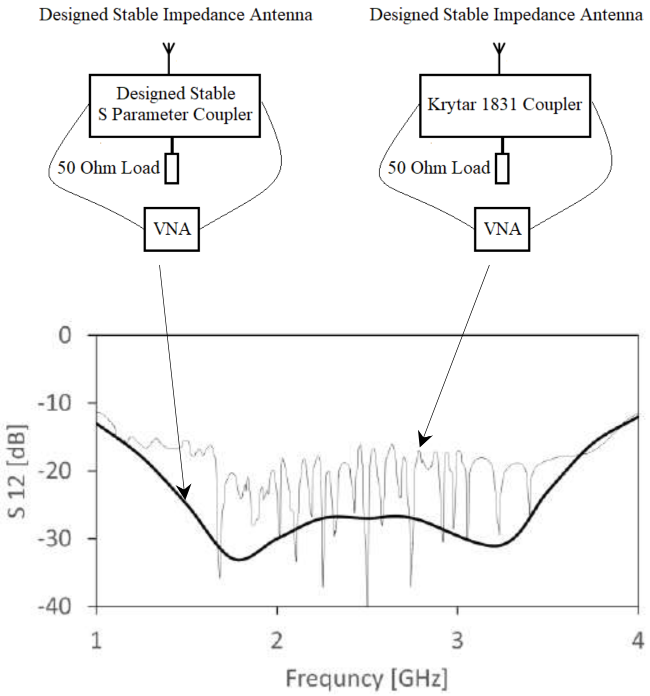

Fig. 13. Measured Tx-Rx EBD isolation when using designed stable impedance antenna with the commercial Krytar 1831 coupler and the designed stable S parameter coupler

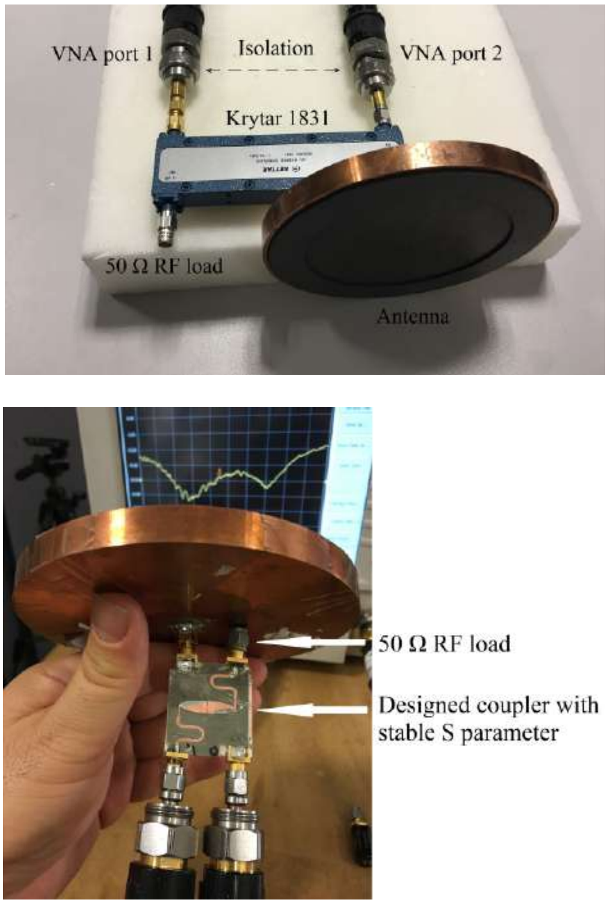

Fig. 14. EBD Setup to measure Tx-Rx isolation when the designed stable impedance antenna is connected to: (Top) Krytar 1831 hybrid coupler (Below) Designed stable S parameter coupler.

The second reason could be impedance mismatch between antenna and 50 Ω balancing load.

V. Conclusion

Electrical Balance Duplexers (EBDs) in In-Band Full Duplex (IBFD) transceivers, isolates transmit and receive signals to implement a form of self-interference cancellation to facilitates simultaneous communication from single antenna. EBD works by coupling transmitter, receiver, antenna, and balancing impedance using a hybrid coupler. The balancing impedance in the EBD needs to be equal as much as possible to the antenna impedance to achieve a high isolation where the antenna impedance variations limit the isolation bandwidth. Hybrid couplers are also not ideal elements, and their S parameters are variable in the frequency domain. An antenna with a stable impedance, designed by authors, has been connected to two different hybrid couplers in the EBD stages. One coupler is commercial Krytar model 1831 and the other one, designed by authors, has more S parameter stability in the frequency domain. It is shown that using hybrid coupler with more stable isolations results to higher isolation bandwidth and better isolation value in the EBD stage at an UWB frequency range from 1.5 GHz to 3.5 GHz.

***Abstract*— Noise has been used as a way of protecting privacy of users in public datasets for many decades now. Differential privacy is a new standard to add noise, so that user privacy is protected. When this technique is applied for a single end user data, it's called local differential privacy. In this study, we evaluate the effects of adding noise to generate randomized responses on machine learning models. We generate randomized responses using Gaussian, Laplacian noise on singular end user data as well as correlated end user data. Finally, we provide results that we have observed on a few data sets for various machine learning use cases.**

Keywords—Differential Privacy, Randomization, Privacy

I. Introduction

Data is being collected in large amounts from a web browser to purchasing of data for applying machine learning algorithms to engage with customers. Machine learning algorithms work by studying a lot of data and updating their parameters to encode the relationships between features and the output in that data. If Machine learning is used to solve important tasks, like making a cancer diagnosis model, credit card eligibility, customer engagement, customer lifetime value, then features need to be developed using personally private information leading to invasion of privacy. In a study by PWC more than 83% of participants did not want to share their due to fear of privacy loss. [1]

In the 1990s, the American state of Massachusetts made medical data publicly available which included minimal demographic information: birth date, zip code and gender, in addition to the diagnosis. A computer scientist Latanya Sweeney purchased a voter list with 54,000 names. Sweeney was able to link the demographic information in the medical records released by the government to the demographic information in the voter database and in many cases, she was able to match an unlabelled medical record to the patient's name using the voter list she had bought earlier. She tried this data-matching technique for the then-governor William Weld. Just six people in the city of Cambridge shared his birthday. Out of the six, only three of them were men. Weld was the only one who lived in the correct zip code. Cynthia Dwork came up with a new way to define privacy as a quantifiable measure, also giving a formal guarantee that information is not leaked, called "differential privacy". [2]

"Differential privacy" describes a promise, made by a data holder, or curator, to a data subject: "You will not be affected, adversely or otherwise, by allowing your data to be used in any study or analysis, no matter what other studies, data sets, or information sources, are available." [3]

Differentially private algorithms are able to answer a large number of aggregates, statistical queries approximately, so that the approximate answers can draw roughly the same conclusions as if the original data. Local differential privacy is a model of differential privacy with the added restriction that approximates personal responses of an individual such that we do not reveal too much about the user's personal data. Some of the methods in Differential privacy methods are:

Randomization
Laplace Method
Exponential Mechanism

In this paper we explore methods for local differential privacy by adding noise to generate randomized responses for features in Machine learning models.

II. DEFINITIONS

Our idea is to explore methods adding noise and generate randomized responses to be used in features. Here are few ways noise can be expressed mathematically:

1. Noise limitations expressed mathematically:

Gaussian noise

x: Gaussian random variable
The probability density function, p of a Gaussian random function, x is:

$$p(x) = \frac{1}{\sigma\left(\sqrt{2\pi}\right)} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where μ is the mean and σ is the standard deviation.

Laplacian mechanism

The Laplace Distribution (centred at 0) with scale b is the distribution with probability density function:

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$$L(x|b) = \frac{1}{2b} e^{-\left(\frac{|x|}{b}\right)}$$

where b is a scale parameter.

2. Pearson Correlation

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 (y_i - \bar{y})^2}}$$

where:
r = correlation coefficient
x_i = values of the x-variable in a sample
$\bar{x}$ = mean of the values of the x-variable
y_i = values of the y-variable in a sample
$\bar{y}$ = mean of the values of the y-sample

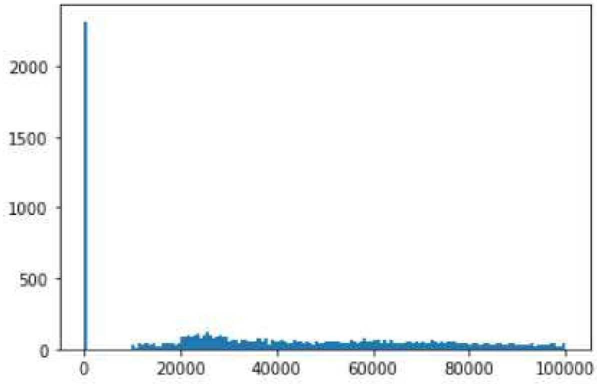
III. METHODOLOGY

A sample dataset with a selected subset of features is shown below. ‘Engaged’ is the output of the dataset.

Engaged	Income	Number of Open Complaints	Number of Policies	Total Claim Amount
0	71941	0	2	198.23
1	21604	0	1	379.20

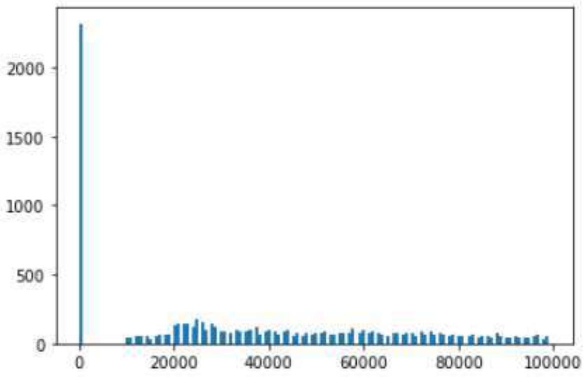
Before noise was added to Income:

Shown below is a histogram plot of ‘Income’ before noise addition to ‘Income’.

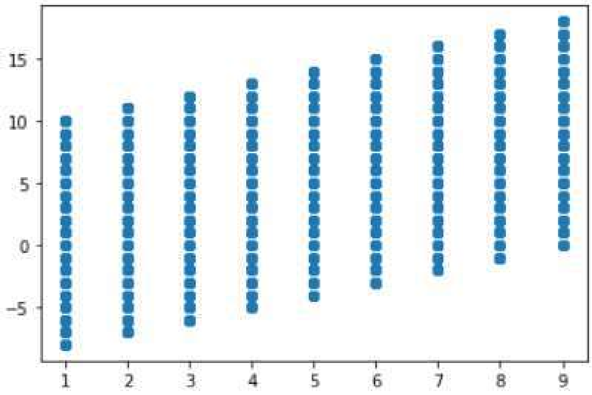


After noise is added to Income:

Shown below is a histogram plot of ‘Income’ after noise addition to ‘Income’.



Shown below is a scatter plot which shows how ‘Number of Policies’ values’ change as noise is added.
The horizontal axis corresponds to ‘Number of Policies’ variable before noise addition.
The vertical axis corresponds to ‘Number of Policies’ variable after noise addition.



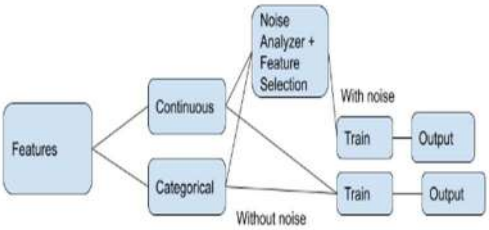
Pseudo Code	
Input	f(x) = {f1, f2, ..., fn}: features of x G(x): Gaussian noise function
Function	Repeat for all features f in {f1, f2, ..., fn}: Take a random feature column, fx ∈ f For each M in {Logistic Regression, Random Forest Classifier}: if fx is categorical: call pseudoCodefunction1 else call pseudoCodefunction2

Pseudo Code -- Function 1	
Input	Example data x1, x2, …, xn in X Random sample percentage for selecting values to add noise
Function	For x ∈ X:

	Take random sample x with sampling probability L/N Compute For each value compute the noise g(x): Clip noise g(x) to g(x)’ Add Noise x’ = x + g(x)’ within a bound Fx’ append x’ where Fx’ is the new noise feature

Pseudo Code -- Function 2	
Input	Input: Example data x1, x2, ..., xn Random sample percentage for selecting values to add noise.
Pre-process	If Categorical introduce a new random value based on data: Method 1: Increase a max bound Method 2: Introduce a categorical value in range Bounds changed and gaussian function updated
Function	For x ∈ X: Take random sample x with sampling probability L/N Compute For each value compute the noise g(x): Add Noise x’ = x + g(x) within a bound Fx’ append x’ where Fx’ is the new noise feature

IV. RESULTS



The results were determined using the above workflow for ML training. The Noise Analyzer and Feature Selection module were used to add noise to the features. This was done using Python and scikit-learn in Jupyter notebooks. Finally, the ML models were trained with noise and without noise as expressed in the flow.

The IBM-Watson Customer Marketing Value data set was selected. 'Engaged' is the output column. 'Yes' and 'No' in 'Response' feature were converted into 1 and 0 respectively and made the output column. Categorical variables were factorized and added to the dataset.

Eleven features were chosen for randomization, namely, ‘Customer Lifetime Value’, ‘Education’, ‘Gender’, ‘Income’, ‘Location Code’, ‘Marital Status’, ‘Months Since Last Claim’, ‘Months Since Policy Inception’, ‘Number of Open Complaints’, ‘Number of Policies’ and ‘Sales Channel’ from the data set.

Model: Logistic Regression

1. Before Gaussian noise and randomized responses were added to the features, a logistic regression model was trained on the data set. The training accuracy was 86.41%.

Feature chosen	Trained on noisy dataset; Tested on original dataset	Trained on original dataset; tested on noisy dataset
Customer Lifetime Value	86.41%	86.39%
Education	86.40%	86.32%
Gender	86.40%	86.40%
Income	86.39%	86.45%
Location Code	86.40%	86.30%
Marital Status	86.40%	86.41%
Months Since Last Claim	86.36%	86.19%
Months Since Policy Inception	86.42%	86.26%
Number of Open Complaints	86.40%	86.22%
Number of Policies	86.35%	86.11%
Sales Channel	86.45%	86.38%

Model: Random Forest Classifier

2. Before Gaussian noise and randomized responses were added to the features, a random forest classifier was trained on the data set. The training accuracy was 100%.

Feature chosen	Trained on noisy dataset; tested on original dataset	Trained on original dataset; tested on noisy dataset
Customer Lifetime Value	100%	100%
Education	100%	99.26%
Gender	100%	100%
Income	100%	100%
Location Code	100%	99.37%
Marital Status	100%	99.75%

Months Since Last Claim	100%	98.9%
Months Since Policy Inception	99.99%	97.89%
Number of Open Complaints	100%	99.98%
Number of Policies	99.99%	100%
Sales Channel	100%	99.77%

3. In contrast to the previous results, here three features are considered instead of one for randomization.

'Customer Lifetime Value', 'Income' and 'Marital Status' are chosen for randomization.

Model	Trained on noisy dataset; tested on original dataset	Trained on original dataset; tested on noisy dataset
KNN	100%	100%
SVM	85.68%	85.68%

'Months Since Last Claim', 'Months Since Policy Inception', 'Number of Open Complaints' are chosen for randomization.

Model	Trained on noisy dataset; tested on original dataset	Trained on original dataset; tested on noisy dataset
KNN	96.66%	94.70%
SVM	85.68%	85.68%

4. 'LocationCode' was found to have the highest Pearson Correlation value, which meant that 'LocationCode' was the feature which had the closest to a linear relationship with the output 'Engaged'.

Model	Trained and tested on original dataset	Trained on noisy dataset; tested on original dataset	Trained on original dataset; tested on noisy dataset
KNN	100%	99.9%	99.68%
SVM	85.68%	85.68%	85.68%
Logistic Regression	86.41%	86.38%	86.30%
RF	100%	100%	99.42%

V. CONCLUSION

From our experiments we can safely conclude machine learning applications will not be affected by differential privacy preserving mechanisms and in fact can become allies. If proper care is taken to add noise to the data, we have seen the models are almost alike with noise and without noise. We could easily extend the methodology to build features using SQL join, distributed joins as well as advanced data aggregation methods. There are several real world machine learning applications like targeting customers, marketing funnels, segmentation, churn prediction in ecommerce, communication, retail as well as health care applications where differential privacy and local differential privacy techniques could be applied in order to protect the privacy of the end user data. Personalization while preserving end user privacy is something that we all want and we hope we were able to present a strong case for it in our study.

***Abstract*—The possible fields of application for small sensor nodes are tremendous and still growing fast. Concepts like the *Internet of Things* (IoT), *Smart City* or *Industry 4.0* adopt wireless sensor networks for environmental interaction or metering purposes. As they commonly operate in license-exempt frequency bands, telemetry transmissions of sensors are subject to strong interferences and possible shadowing. Especially in the scope of Low Power Wide Area (LPWA) communications, this scenario results in high computational effort and complexity for the receiver side to perceive the signals of interest. Therefore, this paper investigates means to an adequate segmentation of receive spectra for a partial spectrum exchange between base stations of telemetry-based IoT sensor networks. The distinct interchange of in-phase and quadrature (IQ) data could facilitate stream combining techniques to mask out interferences amongst other approaches. This shall improve decoding rates even under severe operation conditions and simultaneously limit the required data volume. We refer to this approach of a reception network as Edge-RAN (Random Access Network). To cope with the high data rates and still enable a base station collaboration, especially in wirelessly connected receiver mesh networks, different filter bank techniques and block transforms are examined, to divide telemetry spectra into distinct frequency sub-channels. Operational constraints for the spectral decomposition are given and different filter methodologies are introduced. Finally, suitable metrics are established. These metrics shall assess the performance of the presented spectrum segmentation schemes for the purpose of a selective partial interchange between sensor network receivers.**

***Index Terms*—Wireless sensor network, IoT, spectrum segmentation, Low Power Wide Area (LPWA) communications, long range telemetry, Edge-RAN decoding**

I. Introduction

Over the last recent years, the *Internet of Things* (IoT) is one of the most driving forces for developments and research interest in the area of wireless sensor networks. The conception comprises the communication between numerous different sensor nodes with the aim of environmental interaction or data aggregation, for example in infrastructure monitoring [1]. For many applications, the mobility of nodes must be preserved, putting harsh constraints on weight and energy consumption when powered by battery. The layout of these nodes is therefore targeted on an extremely energy efficient minimalist design. This in turn shifts complexity towards the receiver side for detection and decoding, which can be considered a general characteristic of Low Power Wide Area (LPWA) sensor networks [2]. Often, license-exempt frequency bands are utilized, inevitably exposing signals to strong interferences. Given also the nodes' restricted transmit power, the signal-to-noise-ratio (SNR) at receiving stations can be quite unfavorable, particularly for high path losses in distances of several kilometers and severe shadowing by obstacles like trees or buildings. While a station may detect the presence of a burst, the signal strength might not be sufficient for an overall successful decoding. In Figure 1, such a typical scenario is depicted with several receiving stations spanning a network and continuously monitoring the spectrum for transmissions of sensors within range. Especially for highly mobile transmitter nodes, for example attached on bats for the purpose of wildlife tracking [3], that are frequently changing their position relative to the reception grid, the receive spectra can differ notably between stations. At this point, the idea arises to further improve the system decoding rate via an interchange of inphase and quadrature (IQ) data among different base stations. This approach is then in compliance with the schemes of *Cooperative Multi-Point* (CoMP) [4] or *Distributed Base Station Cooperation* [5] discussed in the context of the fifth mobile communication standards (*5G*). Within the scope of telemetry-based IoT sensor networks, we refer to this conception as *Edge-RAN* (*Random Access Network*) decoding, in allusion to *Centralized-RAN* (also *Cloud Radio Access Network*, C-RAN) in 5G. Contrary to the central approach of C-RAN, a distributed demand-based pre-processing of IQ streams within the edge of the receive network among the collaborating base stations is performed. By providing

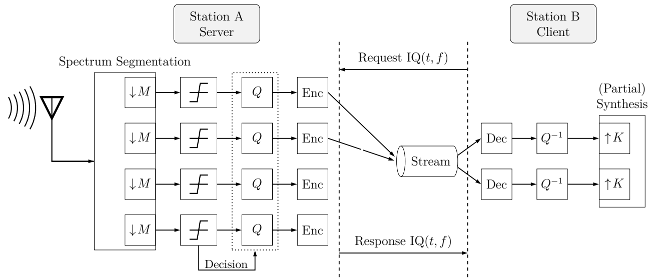

Fig. 2. Proposed telemetry-dedicated IQ compression scheme.

several spectra synchronized in time and obtained by various receivers, the combination of those streams or a fragmentary exchange between them, may compensate for distinct sample sections, that would otherwise be affected by interferences or suppressed by shadowing. A server (*cf.* Figure 1) might then request a specific fraction of manipulated interference-cleared spectral recordings, in order to provide the resulting streams to several connected users for an individual final decoding. A wirelessly linked and rate restricted base station system, however, renders this collaboration quite challenging. While we do not address stream combining techniques here, we focus on means to provide the desired IQ interchange over a rate-limited channel and thus facilitate those subsequent algorithms. We propose to divide the receive spectra into sub-channels, that exploit the small bandwidth of telemetry signals. This shall enable a partial spectral exchange to cope with the rate limitations of links in an IoT base station network. In Figure 2, the overall IQ compression scheme is shown. It comprises the frequency segmentation as its key feature, followed by in-band signal detection providing a decision about the presence of user signals to a content-adapted quantization (Q) stage and later encoding (Enc) of requested sub-bands. The decoding side may only reconstruct a fraction of the entire spectrum.

The paper is structured as follows. At first, state of the art IQ compression schemes are addressed in Section II. Section III introduces spectrum segmentation for a distinct exchange and combination of sub-streams in telemetry-based IoT networks. Constraints on possible approaches are given and suitable filter bank techniques and block transforms are illustrated. In Section IV, the metrics of coding gain, basis restriction and complexity measures are established and the performance of presented filtering procedures, regarding their eligibility for telemetry data, is discussed. Section V finally summarizes the findings and concludes this paper.

II. State of the Art IQ Compression

As has been stated in Section I, IQ compression is especially tackled in the scope of 5G. To reduce the rate requirements within the backhaul, Guo et al. [6] proposed a scheme that directly acts on time domain data. A stream is divided into groups, that are processed via *block floating point encoding*. Vosoughi et al. [7] apply a similar method, yet operate on difference symbols and an adapted Arithmetic coder. A lossy extension is given by *least significant bit removal*. While these approaches are simple and applicable to generic signals of any shape, they are reported to achieve only a minor compression factor of about 3.5 [7]. Samardzija et al. [8] exploit the specific signal characteristics in mobile communications, applying a deliberate downsampling, block scaling and non-linear quantization. Nieman et al. [9] follow the same idea. They remove the signal's cyclic prefix, perform decimation and a spectrum-adapted quantization via noise shaping. Contrary to those time domain approaches, Grieger et al. [10] conduct the compression in frequency domain. Via a Fast Fourier Transform (FFT), a subset of carriers is quantized and Huffman encoded. Although these proposals promise higher compression rates, they are specifically designed for orthogonal frequency division multiplex (OFDM) signals. The algorithms make use of particular signal properties and require a-priori knowledge. Hence, they are not directly transferable to streams in case of IoT networks. Here, a generic compression scheme is required, easily adaptable to unknown narrowband transmissions, that are heavily fluctuating over time. Another approach that operates on transform coefficients is the scheme denoted as *Compressive Sampling* or *Compressed Sensing* [11]. This conception is based upon the assumption, that a signal's representation can be sparse, thus exhibiting only few non-zero coefficients within the frequency domain. The Nyquist sampling theorem presumes a rather fully occupied spectrum. In this way, it is deemed to be too pessimistic. These considerations give rise to a quasi sub-Nyquist rate reduction, implicitly compressing any input signal in the process of sampling. While in [12] and [13] corresponding telecommunication compression frameworks, referred to as *Random Demodulator* and *Modulated Wideband Carrier*, have been presented, a large-scale adoption is still impeded by the system's susceptibility to noise aggregation. The inverse transform comprises the extensive search for a sparse solution of an under-determined system. However, an IoT spectrum is inherently exposed to rather harsh noise (*cf.* Figure 3). Furthermore, possible short time interferences counteract the sparsity assumption, leaving a successful reconstruction impossible [14], [15].

Existing generic compression approaches can not provide sufficient performance, whereas schemes proposed in the context of 5G are based upon OFDM-related signal characteristics. The conception of *Compressive Sampling* suffers from noise, which is the prevailing process in IoT spectra. To overcome these limitations, the scheme in Figure 2 shall be adopted. The division of spectra in distinct sub-bands is a crucial component. Therefore, this paper investigates proper means of spectrum segmentation, in order to exploit the narrow bandwidth characteristic of low rate telemetry transmissions. This shall be a building block for an efficient compression of reception spectra in IoT sensor networks.

III. Band Segmentation Approach for the Interchange of Telemetry Spectra

The interchange of spectra among telemetry base stations shall exploit the inherent macro diversity of the reception

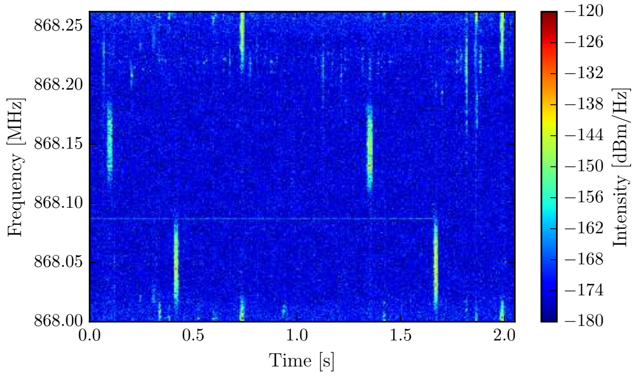

Fig. 3. Spectogram of a typical telemetry stream in the SRD frequency band.

network. IQ streams of different stations might be combined to mask out interferences or compensate for notches in the channel transfer characteristic, as observed by one receiver but not the other. The spectral segmentation might also limit the overall noise bandwidth and thus increase the relative in-band SNR. This can alleviate decoding by concealing possible strong disruptive frequency components nearby, that would otherwise dominate the signal as seen by the receiver. In a practical setup, this network must meet the requirements concerning ease of installation, maintenance and cost. Wired connections and high speed fiber-based solutions are therefore not a viable option. Wireless approaches like WiFi or radio link systems are both flexible and economical, but are limited in rate. This issue gets apparent, when considering an actual large scale telemetry network as presented in [1]. Here, a common exposed receiver records the frequency-scattered signals being broadcast by a distributed network of numerous sensor nodes for the purpose of infrastructure monitoring. Scanning the complete *Short Range Devices* (SRD) band from $863\,\mathrm{MHz}$ to $870\,\mathrm{MHz}$ and gathering complex samples with 24 bit resolution in a configuration with up to four antennas, easily results in a necessary rate of $1.34\,\mathrm{Gbit/s}$. Even with the latest standards of WiFi, this high rate can not be provided. The rate problem appears even more acute for a fully meshed receiver network or in a hierarchical network structure that aggregates several streams in the backbone. As elaborated before, in order to alleviate this challenge, we propose a partial exchange by means of a spectrum segmentation.

Figure 3 exemplarily depicts an excerpt of a typical actually recorded telemetry spectrum with approximately $2\,\mathrm{MHz}$ bandwidth centered around the frequency of $868.13\,\mathrm{MHz}$, acquired by the reception system presented in [1]. As this range corresponds to the license free SRD radio bands (equivalent to the frequency bands around $915\,\mathrm{MHz}$ in the United States), numerous transmissions are present. Besides persistent or temporary carriers, also momentary bursts are perceivable. One has to note, that common to all of the signals shown, is their comparatively low bandwidth in relation to the sampling range. Often rates of only a few kHz or even less are sufficient for IoT use cases with low overall data throughput. An example is the *LoRa*[1] protocol with a typical bandwidth of $125\,\mathrm{kHz}$, gaining increased research interest in the scope of low power and long range sensor applications. This is in contrast to mobile communication with a constantly high channel occupancy. Besides, only a minor fraction of the stream is actually populated with user data, while the rest is dominated by noise. It is this characteristic of momentary narrowband transmissions that gives rise to the segmentation of telemetry spectra into a frequency-time grid. With knowledge about the transmit hopping pattern, a base station for which the connected decoder indicated a failed decoding, might then state a request for a specific frequency band and time span to all receivers within the network (*cf.* Figure 3). Rather than an exchange of the complete spectrum, a partial and selective streaming of data with minimal rate can be performed, still adhering to the limited rate of each wireless link within the wireless receiver mesh network. Also, by this separation, each of the resulting frequency bands within the addressable frequency-time grid can be compressed individually depending on its actual content (presence of signals or prevailing channel noise).

This raises the question which spectral segmentation method at server side is advantageous for the purpose of partial telemetry IQ exchange and related Edge-RAN decoding at the client side. Considering the context of spectrum compression in sensor network applications, corresponding constraints have to be imposed on potential techniques for partitioning:

- *Handling of complex values*: As the sample stream is composed of IQ samples, the algorithm must be suitable for complex data. Furthermore, the phase of the representing complex rotator must be preserved, as actual payload information might be encoded into this parameter by modulation.
- *Critical sampling*: Considering an overall compression, critical sampling is a favorable feature for the filtering procedure. This implies that the total number of samples over all resulting filter sub-channels remains constant compared to the input [16]. Even moderate oversampling structures would increase the data volume. This would force a possible subsequent compression scheme to settle for the loss that the preceding analysis stage provoked.
- *Aliasing cancellation* (AC): Adherence to critical sampling denotes an operation at the Nyquist rate. This inevitably leads to Aliasing, that has to be canceled when recomposing the sub-channels or at least suppressed as best as possible, to not corrupt the payload signal within the frequency range of interest. One refers to those methods providing perfect reconstruction (PR) or near perfect reconstruction (NPR), respectively [16].
- *Relation to time-frequency pattern*: For a selective interchange of partial spectra, a relation to the actual physical parameters of frequency and time must be given for the obtained general transform coefficients. This would for example also preclude the previously mentioned methodology of *compressive sampling* [11], often cited

[1] *https://lora-alliance.org/ last accessed 10 June 2020*

in relation to compression in wireless sensor networks, but not abiding by this restraint.

- *Scalability*: A partitioning technique must support various numbers of sub-bands, thus implementing a scalable sub-channel bandwidth to properly adopt to the signal characteristics.

In the following, we briefly introduce the spectral segmentation algorithms that, at least partially, adhere to the given constraints. Basically, the approaches can be grouped into two fundamental categories.

Filter Bank Techniques

Spectral decomposition based on filter bank structures can be considered as the more classical approach. As there is no priority to different sub-bands in the application at hand, a uniform filter bank with equal spectral spacing and bandwidth can be targeted. It is thereby common to design a single *prototype* filter with a relative bandwidth according to the desired number of sub-channels. This prototype is then modulated to form the overall filter bank structure [16]. The *Discrete Fourier Transform* (DFT) [17] is among the most utilized approaches and will be considered for the evaluation. Besides, the so-called *Modified Discrete Fourier Transform* (MDFT) proposed by Fliege et al. [18] fulfills the stated constraints above and will be issued in the following analysis. In [19], Viholainen et al. presented the *Exponentially Modulated Filter Bank* (EMFB) as an alternative complex modulated critically sampled filter approach. It will be considered as the third filter bank representative. It is characterized by an odd channel stacking, as opposed to the DFT and MDFT with even stacking.

Block Transforms

While for the filter bank techniques the common sub-filter characteristic is designed in frequency domain, the block transforms operate in the equivalent time domain. Here, the prototype is considered a *window* function, weighting the input sample sequence organized in successive blocks [20]. Detached from the domain of filtering and referring to the notation of transforms, the sub-channel filters are also identified as *basis vectors*. Requirements for Aliasing cancellation and perfect reconstruction for the case of a full assembly of the spectrum are expressed in terms of those windows and summarized in the phrase of *Time Domain Aliasing Cancellation* (TDAC) [21]. As representatives for block transforms, the *Modulated Complex Lapped Transform* (MCLT), *Extended Complex Modulated Lapped Transform* (ECLT) [20] and the *Karhunen-Loève Transform* (KLT) [22] are considered. While the latter can be deemed critically sampled, the MCLT and ECLT do actually state PR structures with inherent two-fold oversampling. However, they provide exponential modulation, processing of complex streams and efficient implementations. Therefore, they are also incorporated into analysis.

Selection of proper PR and NPR prototypes

Due to the various filter structures and modulation approaches, there are different constraints for Aliasing cancellation and (near-)perfect reconstruction. These constraints are mapped to certain restrictions on the prototypes. The only prototype that allows for PR in the case of a DFT is rectangular in time [23]. With a length of L samples, the corresponding number of channels M is equal to L and the DFT structure is thereby fully determined. A popular solution for the prototype of the MCLT is a sine window [24]

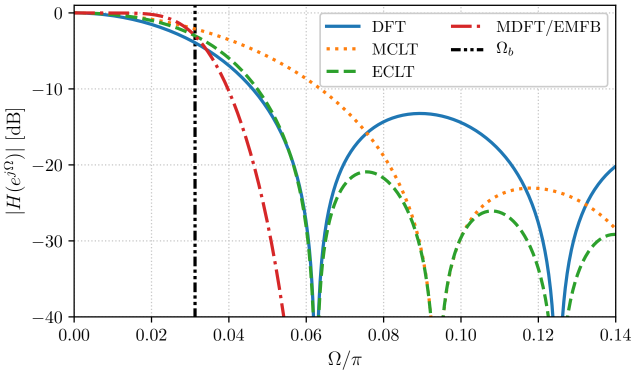

Fig. 4. Prototype transfer functions. Sub-channel border is indicated by Ω_b.

$$p[n] = -\sin\left[\frac{\pi}{2M}(n+0.5)\right], \qquad n = 0,\ldots,2M-1 \quad (1)$$

where the length L of the window $p[n]$ is restricted to $2M$ samples. The ECLT can be considered a generalization of MCLTs, extending the basis function to arbitrary length $L = 2KM$, with K a positive integer. The filter retrieval process for PR includes a highly non-linear and rather sensitive complex optimization, for which a global optimum is not guaranteed [25]. For $K = 2$, however, a possible closed-form solution is given by [24]

$$p[n] = 0.5\cos\left[\frac{\pi}{2M}(n+0.5)\right] - \frac{1}{2\sqrt{2}}. \quad n = 0,\ldots,4M-1 \quad (2)$$

With the MDFT and EMFB as classical filter bank approaches, their prototype is designed utilizing the *Quadrature Mirror Filter* (QMF) property [24]. The filter structure assures for a direct Aliasing cancellation of adjacent sub-channels, while other aliasing components are supposed to be sufficiently suppressed by the filter's stopband attenuation [18]. Various filter design methods for this purpose do exist, whereas we resort to the iterative optimization process that was proposed by Doblinger et al. in [26], with $L = 16M$ and a desired stopband attenuation of $100\,\mathrm{dB}$. The KLT can be considered a special case of a varying block transform, depending on the actual signal itself. Rather than a fixed set of basis vectors or equivalently sub-channel filters, the basis vectors are dynamically computed as the eigenvectors of the estimated autocorrelation matrix within the current block. The transform is thus constantly changing, trying to decorrelate its output coefficients, so no fixed filter structure can be stated in advance. Figure 4 illustrates the one-sided transfer functions $\left|H(e^{j\Omega})\right|$ of the discussed prototypes in decibel scale for a sub-channel number of $M = 32$. All curves have been normalized for DC gain, where again no prototype can be given for the KLT due to its non-static structure. The entity Ω_b represents the channel border. Distinctive differences in the filters' frequency responses are evident. While the prototypes of the MCLT and ECLT can provide perfect reconstruction, their progression in frequency exhibits rather large side lobes. In contrast, the common MDFT and EMFB prototype features a much smoother progression within the passband and a harsh decay in the stopband. Yet, these approaches can generally only allow for a near perfect reconstruction. The perfect reconstruction constraint is thus not bounded to the classical filter optimization goals. It is therefore of scientific interest to investigate the feasibility of the presented transforms for spectrum segmentation in a telemetry-dedicated IQ compression scheme.

IV. Filter Bank Evaluation

A fundamental relation of source coding is the so-called rate-distortion function. Without restriction to a specific signal source distribution, it can be expressed by [27]

$$R(D) \cong 0.5 \log_2 \left(\frac{\varepsilon^2 \sigma^2}{D} \right), \tag{3}$$

where ε^2 is a factor depending on the actual signal distribution and σ^2 is the corresponding variance. Equation (3) thus relates the minimal rate $R(D)$ needed to preserve the signal information under the maximal allowed distortion metric D. Regarding (3) with a direct dependence to σ^2, in the context of a sub-band coding system for IQ compression, it is favorable for a segmentation to concentrate stream information in as few sub-bands as possible. This in turn gives room for a harsh compression and less rate for the low variance channels, while only a minor number of channels need higher rates.

A. Coding Gain

As this feature is also desired in the context of audio and video applications [28], [29], one can adopt metrics commonly known in multimedia processing for the purpose of IQ segmentation evaluation. A transform's ability to focus the signal energy in just a few sub-bands is therefore desirable, denoted as the *energy compaction* characteristic. This can be measured by the metric of *transform coding gain* G_{TC} [28]

$$G_{TC} = \frac{\frac{1}{M} \sum_{i=0}^{M-1} \sigma_i^2}{\left(\prod_{i=0}^{M-1} \sigma_i^2 \right)^{\frac{1}{M}}}. \tag{4}$$

The coding gain relates the arithmetic mean of the transform sub-channel variances σ_i^2 to the geometric mean. A more irregular variance distribution yields higher gains and indicates a better energy compaction. Figure 5 depicts the metric of coding gain in decibel scale for the presented transforms. The signal shown in Figure 3 serves as an input and the gain is calculated along (4) in dependence of the sub-channel number M.

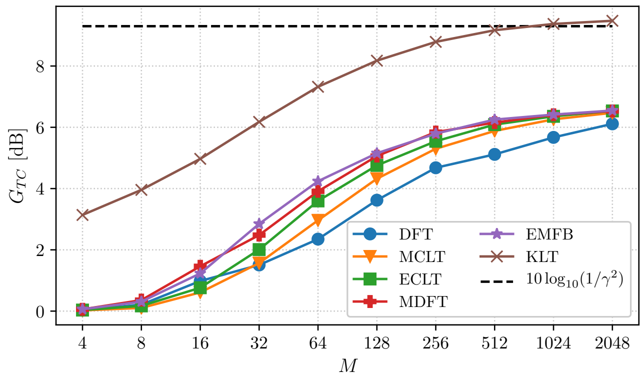

Fig. 5. Coding gain in dependence of the sub-channel number M.

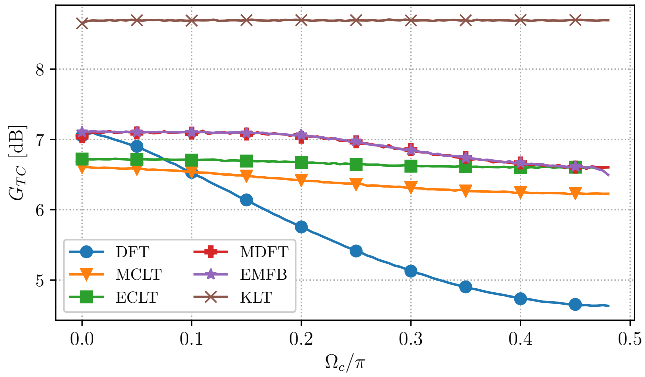

Fig. 6. Coding gain in dependence of carrier frequency relative to the frequency resolution grid.

For all segmentation techniques the coding gain increases with an increasing number of sub-channels M. The relative channel bandwidth is reduced, approaching the narrowband signal bandwidth, such that a separation of distinct telemetry transmissions becomes feasible. Among the fixed filter structures, the EMFB and MDFT indicate the best compaction compared to the DFT and the presented lapped transforms. This advantage of the EMFB over the MDFT might yet be related to the channel stacking, so also to the relative position of signal carriers within the test signal to the transform grid. The KLT, however, shows an overall superior performance with an offset of about 3 dB to the EMFB curve. With its adaptivity to the current signal autocorrelation, it decorrelates the channel coefficients. It maximizes the coding gain and gives an upper bound for a given block length, under the assumption of a prevailing quasi-Gaussian overall source [30]. For a very high sub-band number M, all curves show a saturation behavior. The KLT reaches the maximal possible gain for the spectrum in Figure 3 determined by the the spectral flatness measure γ^2 [28], the inverse of (4) for $M \to \infty$, as indicated by the black dashed line. A slight exceedance is seen, due to computation inaccuracies and spectral smoothing via windowing (a *von-Hann* window was used). Figure 6 shows the coding gain evaluations in dependence of a varying normalized carrier frequency Ω_c.

The position of a carrier in frequency domain, relative to the transform grid, that equally subdivides the spectrum, is decisive for the containment of energy within the corresponding sub-channel. Here, $M = 32$ is set and an unmodulated carrier $e^{j\Omega_c t}$ superimposed by complex Gaussian noise $n(t) \sim \mathcal{CN}(0, \sigma_n^2)$ is simulated for a SNR of 5 dB. The carrier frequency Ω_c is swept from the relative location 0.0 coinciding with the sub-channel center frequency up to 0.5 being positioned right between the actual transform grid. Again, the KLT exhibits the best performance, unaffected by the carrier position. It is followed by the MDFT and EMFB, whose curves almost perfectly coincide. For all fixed filter bank structures, a drop in gain is notable when the deviation from the transform grid increases. While this loss is rather moderate for the filter bank techniques as well as for the lapped transforms MCLT and ECLT, especially the DFT suffers from this effect. The finding for the coding gain simulations gets apparent, when considering the prototype characteristics in Figure 4. The blue curve for the DFT not only exhibits the most decreasing progress in the passband region left to the sub-channel border $\Omega_b = \frac{\pi}{M}$, but also shows the highest out-of-band ripples. This not only makes it susceptible to signal carriers off the ideal transform grid as shown in Figure 6, but also leads to an undesired spreading of signal energy across neighboring channels, notable by the inferior coding gain in Figure 5. The prototype for the MDFT was the same as for the EMFB and shows a flat passband progression, but then drastically drops before the channel border Ω_b, confirming the behavior for both coding gain results presented.

B. Basis Restriction Error

When only a partial subset of the whole IQ stream is exchanged, also only a fraction of the spectrum's energy is contained. A metric that reflects the ability of a segmentation technique to preserve the overall energy under elimination of certain sub-channels is the *basis restriction error* [29] or equivalently the *compaction efficiency* [22]

$$\eta_E(l) = \frac{\sum_{r=0}^{l-1} \sigma_r^2}{\sum_{r=0}^{M-1} \sigma_r^2}. \tag{5}$$

Here, only a subset of $l = 0, \ldots, M-1$ sub-channels are used to re-transform the spectral coefficients to the time domain reconstruction signal. The sub-channel variances σ_r^2 are thereby sorted in decreasing order and all corresponding sub-band coefficients addressed by an index $r \geq l$ are set to 0. Evaluating (5) for the input spectrum in Figure 3 yields the result shown in Figure 7.

Again, $M = 32$ channels have been simulated and only the first l sub-bands, exhibiting the highest variance, have been used for reconstruction. Larger values of $\eta_E(l)$ closer to 1 indicate better efficiency. As before, the KLT expectedly outperforms the other techniques. Given the configuration of prototypes as in Section III, the EMFB shows also here a superior result among the fixed structure approaches, revealing a better channel segmentation than the ECLT and MCLT following. Interpreting the basis restriction in (5) in the sense of Aliasing distortion, the EMFB also exhibits a slight advantage over the MDFT, with its internal downsampling factor being half of that of the MDFT [19].

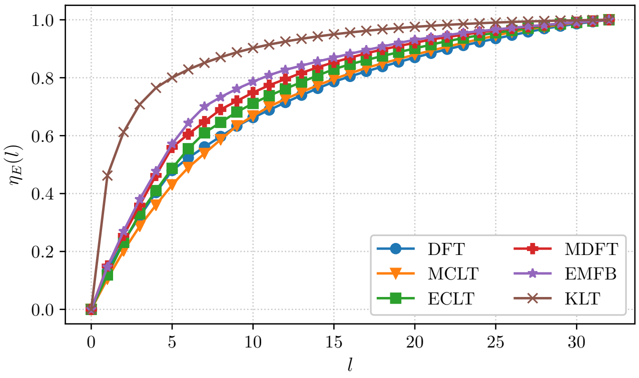

Fig. 7. Basis restriction error for the presented segmentation techniques.

C. Measures of Complexity

Besides the characteristics of PR or NPR and the energy compaction for later compression or partial spectrum transfer, the aspects of design complexity, computational effort, overhead and signal delay are decisive for practical usage. For the transforms as described in Section III, these factors are listed in Table I. The implementation aspect of complexity for the evaluated techniques is addressed in terms of the number of multiplications $\mu(M)$ and additions $\alpha(M)$ (real valued) for the calculation of the next M complex sub-channel samples in the process of segmentation. While there are various computationally efficient approaches in literature, we rely on the *Cooley-Tukey* algorithm [31] in the case of the DFT. For the MCLT and ECLT the setup presented in [32] is employed, based upon lattice structures and butterfly operations. The polyphase and crossover scheme applied in [33] serves as a reference for the MDFT, while the EMFB is assumed to be implemented by a fast lapped transform structure for a pair of cosine/sine modulated filter banks [32]. The KLT is considered a complex matrix multiplication. In order to get also a visual impression of the transforms' complexity, Figure 8 depicts the computational effort in terms of multiplications $\mu(M)$, in dependence of the number of sub-channel samples M to be calculated. When comparing $\mu(M)$ and $\alpha(M)$, an asymptotic effort can be noticed for all filter bank approaches, with the MDFT and EMFB showing a slightly higher cost due to the larger prototype length used (*cf.* Section III). The KLT, however, reveals a quadratic increase of $\mu(M)$ for increasing M, which is manifested by the harshly rising progression in logarithmic scale, seen in Figure 8. It appears to be feasible for minor sub-channel numbers M. Though, for higher and more practical values of M, its complexity is not manageable any more. Furthermore, the calculation of the eigenvectors and the related matrix inversion are not even taken into account here. While it may be the quasi-optimal transform with regard to energy compaction and basis restriction, its computational

TABLE I
IMPLEMENTATION RELATED ASPECTS OF FILTER TECHNIQUES FOR IQ STREAM SEGMENTATION. THE COMPUTATIONAL EFFORT IS COMPARED IN TERMS OF THE NUMBER OF MULTIPLICATIONS $\mu(M)$ AND ADDITIONS $\alpha(M)$ TO COMPUTE THE NEXT M COMPLEX SUB-CHANNEL SAMPLES.

Transform	$\mu\,(M)$	$\alpha\,(M)$	Overhead	Design Complexity	$d\,[T_s]$
DFT	$2M\log_2 M$	$3M\log_2 M$	none	none	$M-1$
MCLT	$M\,(\log_2 M+5)$	$M\,(3\log_2 M+5)$	none	none	$2M-1$
ECLT	$M\,(\log_2 M+7)$	$M\,(3\log_2 M+7)$	little/moderate	none/extensive	$4M-1$
MDFT	$M\,(\log_2 M+30)+4$	$M\,(3\log_2 M+34)-4$	moderate	extensive	$16M+\frac{M}{2}-1$
EMFB	$M\,(\log_2 M+19)$	$M\,(3\log_2 M+19)$	moderate	extensive	$16M-1$
KLT	$4M^2$	$4M^2-2M$	extensive	none	$M-1$

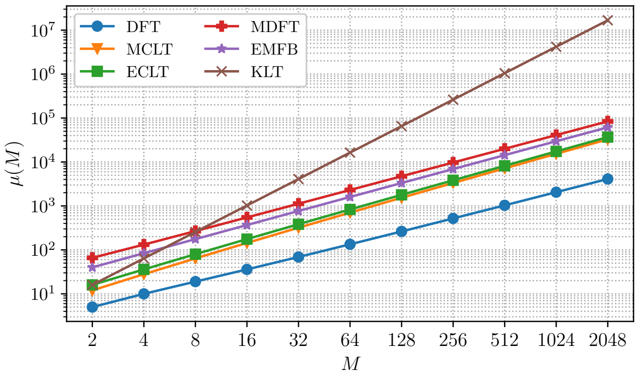

Fig. 8. Quantity of multiplication operations $\mu(M)$, dependent on the number M of new sub-channel samples to be obtained in each transform.

complexity renders it rather impractical for the scenario of an Edge-RAN telemetry reception network. The complexity of the remaining transforms correlates with their respective channel selectivity, where the EMFB structure seems to offer a reasonable balance between those aspects. The qualitative overhead given in Table I also supports these findings, as it is quite extensive for the KLT having to transmit the eigenvectors for each single stream segment, while the filter bank and lapped transforms only rely on a single transmission of prototype coefficients. Under the presented configuration, the MCLT, ECLT and DFT use fixed windows deemed known to the remote site. Therefore, they do not contributing to the overhead. Nevertheless, it has to be noted again, that the ECLT, MCLT introduce two-fold oversampling, reducing the effective comparable compression ratio. The prototype design complexity coheres to the energy compaction ability, showing higher effort for ECLT, EMFB and MDFT, but in exchange also offering a more desirable channel separation performance. The last column represents the overall transient delay $d\,[T_s]$ in terms of sampling periods T_s. It is of interest for a proper layout of buffer storage in the process of stream synchronization. Considering the block transforms as filter banks, their corresponding delay conforms to the filter order $L-1$ [34], with L the prototype length, respectively. The MDFT and EMFB exhibit also here a higher cost. Again, this is related to the longer prototype length and their PR structure. Nevertheless, these schemes bring the benefit of improved frequency selectivity, which is deemed to be of more practical relevance.

V. CONCLUSIONS

This paper investigated means for spectrum decomposition, taking advantage of the narrowband characteristic of telemetry transmissions. A partial IQ exchange between base stations in an Edge-RAN IoT network shall exploit the inherent macro diversity. Partial spectrum combining may mask interferers and shadowing effects seen at various stations and improve the overall decoding success rate. The selective transmission of sub-bands shall also limit the overall data volume, as only a minor spectrum portion is actually populated with low-rate telemetry signals. Utilization of this characteristic is inevitably required for a multi-station collaboration over wireless rate-limited links. With the spectrum division as the most essential building block, this publication gave a holistic view on spectrum decomposition methods. Thereby, the operation conditions and spectral features in narrowband IoT sensor networks have been accounted for, not having been issued by literature so far. The eligibility of the presented approaches has been supported by both, theoretical analysis and simulation on actually recorded real-word data. Constraints, such as critical sampling and Aliasing containment have been given, upon which eligible filter and block transform approaches have been presented. Among those, the Karhunen-Loève Transform (KLT) was found optimal regarding the employed metrics of coding gain and basis restriction error. Despite its performance, the usage of the KLT for spectrum decomposition can be considered critical. The prerequisite of scalability for larger sub-channel numbers M can not be satisfied, because the computational effort and related overhead drastically increases to a non bearable extent. For the given prototype configuration, the Exponentially Modulated Filter Bank (EMFB) performed best among the static approaches, yet at the cost of a higher design and computational effort. While it might be sub-optimal, the fixed structure allows for reduced overhead and shows a robust behavior against deviations of carrier frequencies relative to the transformation grid. In general, it transpires that the transfer function of the prototype is decisive with regard to the metrics of coding gain and basis restriction. With the Modulated Complex Lapped Transform (MCLT) and Discrete Fourier Transform (DFT) being restricted in their prototype length L, that meet the preassigned perfect reconstruction (PR) conditions, they exhibit a notable decay in passband. Furthermore, they and can not provide sufficient stopband attenuation for an adequate energy containment and minimal spectral leakage. The Modified Discrete Fourier Transform (MDFT), Exponentially Modulated Filter Bank (EMFB) and Extended Complex Lapped Transform (ECLT) do not suffer from this limitation. They can be implemented efficiently, yet the design process is deemed simpler and more stable for the case of MDFT and EMFB. While they involve more computational complexity, these near-perfectly reconstructing approaches appear superior over the perfect reconstruction transfoms with respect to selectivity. This aspect is deemed most important for a partial sub-band exchange. Given their high selectivity capability while still exhibiting feasible computational complexity and overhead, the EMFB and MDFT are deemed the best choices for band segmentation within a spectral sub-band compression system for telemetry IQ data.

***Abstract*—Flex Sensor and Gyroscope based hand gloves are being used widely to detect gesture-based sign language patterns to provide aid for speech-impaired people. However, detecting dynamic gestures is not an easy task due to the variability and redundant implementation precautions. This article approaches a dynamic hand gesture recognition system by using Probabilistic Neural Network (PNN) deliberately focused on practical usage of dynamic gestures on day-to-day life. In this experiment, 10 gesture patterns have generated by using a data glove. For each gesture, 360 training input vectors are generated to train the PNN model, and the output has provided via a speaker.**

Keywords—flex sensor, gyroscope, dynamic gesture, PNN

I. Introduction

There are approximately 360 million people around the world who are deaf and mute [1]. Due to speech and hearing impairment, these people have to communicate by using sign language. By using a convenient Man-Machine Interface (MMI), it is possible to generate the record and validate such sign language gestures to mediate a communication system between mute and unmute people. Kinect sensor-based works are proposed in previous years to design gesture recognition prototype [2]–[6]. Kinect is a depth sensor that has designed by Microsoft. However, these systems are not portable and cheap. User needs stationary Kinect sensor on board to work with it. Authors have used Convolutional Neural Network (CNN) to detect static gestures from the user on [7], [8]. Static sensor-based work also has done using Time-of-flight (ToF) camera [9] and Dynamic Time Wrapping algorithm [10]. As these works are based on the camera sensor, they are highly dependent on the image quality, lighting condition, camera angle and many more factors. There is much approach to detecting various versions of sign language as well. Authors approached to detect Vietnamese, Indian and American Sign Language [11], [12]. Most of these approaches are not capable of detecting dynamic gestures.

This proposed system will approach a dynamic gesture recognition system to eliminate these problems at a much affordable solution as well as portability. This system also consists of a speaker module to generate Bangla speech as output for each corresponding gesture.

II. Methodology

A. Hand Gloves Design

The hand glove has designed using flex sensors attached with the fingers.

- Three flex sensors have used for gesture recognition.
- These three sensors have mounted in index, middle and ring finger.
- An MPU-6050 which is a three-axis and accelerometer and three-axis gyroscope has used. This device uses I2C protocol for communication and has 16-bit built-in ADC channel for high accuracy.
- A Raspberry Pi 3B has used for interfacing the flex sensors and the MPU-6050.
- An MCP-3008 ADC has used to interface the flex sensors with Raspberry Pi as Pi does not have inbuilt analog pins.

B. Mathematical Model

The mathematical models are used to process raw data from sensors and using them for gesture recognition purpose. The first 20 reading of sensors at the time *t* for generating a training set, can be expressed as:

$$\{x_{g,k,1}^{n}(t),\ x_{g,k,2}^{n}(t), x_{g,k,3}^{n}(t), \dots x_{g,k,20}^{n}(t)\} \qquad (1)$$

Where *x* is the signal value, *n* is the user index, *k* is the replicate index, and *t* is the time.

A replicate of a gesture by a person can be expressed as:

$$\Pi_{n,g,k} = \{x_{g,k,1}^{n}(i.dt), x_{g,k,2}^{n}(i.dt), x_{g,k,3}^{n}(i.dt) \dots x_{g,k,20}^{n}(i.dt) : i \in \{0, 1, \dots D_{n,g,k}\}\} \qquad (2)$$

Where *dt* is the interval between sampling of sensors data and $D_{n,g,k}$ is the last reading from sensor by n^{th} user for g^{th} gesture.

C. Overall Framework

The proposed gesture recognition system consists of three stages of processing. The framework consists of three main procedures where the value of gyroscope is preprocessed first. In the next stage, the raw data from flex is retrieved. After gathering these data, the sensors data have trained and tested by PNN further to analyze the recorded gesture. The PNN has specifically chosen to solve the classification problem for each dynamic gestures. The overall system has demonstrated in Fig 1.

D. Reading MPU-6050

The MPU-6050 is consists of a three-axis gyroscope and accelerometer integrated on a single chip. This sensor is also called 6 Degree of Freedom (DoF) device because of its six outputs. It measures the rotational velocity of the rate of change of the angular position over time in X, Y, and Z-axis.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Micro-Electro-Mechanical Systems (MEMS) technology has used inside this sensor.

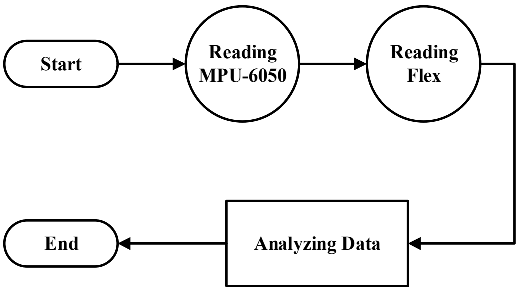

Fig. 1. Overall demonstration of the system

The outputs of the gyroscope are measured in degrees per second. The unit for measuring acceleration is meter per second squared. To read the sensor, we have used the wire library after that the by resetting the power management register; the sensor was reset. The register address is as follows:

TABLE I. MPU-6050 REGISTER ADDRESS

Register	B7	B6	B5	B4	B3	B2	B1	B0
0x6B	DEVICE_RESET	SLEEP	CYCLE		TEMP_DIS	CLKSEL[2:0]		

As the datasheet says, the data of each axis is stockpiled in two registers. The addresses of these registers are shown in Table 2.

TABLE II. MPU-6050 ACCELEROMETER DATA REGISTERS

Register	B7	B6	B5	B4	B3	B2	B1	B0
0x3B	ACCEL_XOUT[15:8]							
0x3C	ACCEL_XOUT[7:0]							
0x3D	ACCEL_YOUT[15:8]							
0x3E	ACCEL_YOUT[7:0]							
0x3F	ACCEL_ZOUT[15:8]							
0x40	ACCEL_ZOUT[7:0]							

To read all the registers value correctly, at first the value of X, Y and Z-axis for first six register are requested. After that, we read the second register, perform 2's complement and combine them appropriately to generate the actual values. Here, the roll φ and pitch θ angles are calculated for normalized accelerometer reading G_p.

$$\frac{G_p}{\left\|G_p\right\|} = \begin{pmatrix} -sin\theta \\ cos\theta sin\varphi \\ cos\theta cos\varphi \end{pmatrix} \Rightarrow \frac{1}{\sqrt{G_{px}^2 + G_{py}^2 + G_{pz}^2}} \begin{pmatrix} G_{px} \\ G_{py} \\ G_{pz} \end{pmatrix} = \begin{pmatrix} -sin\theta \\ cos\theta sin\varphi \\ cos\theta cos\varphi \end{pmatrix} \qquad (3)$$

$$tan\varphi_{xyz} = \left(\frac{G_{py}}{G_{pz}}\right) \qquad (4)$$

$$tan\theta_{xyz} = \frac{-G_{px}}{\sqrt{G_{px}^2 + G_{pz}^2}} \qquad (5)$$

Similarly, the register values of Gyroscope are:

TABLE III. MPU-6050 GYROSCOPE DATA REGISTERS

Register	B7	B6	B5	B4	B3	B2	B1	B0
0x43	GYRO_XOUT[15:8]							
0x44	GYRO _XOUT[7:0]							
0x45	GYRO _YOUT[15:8]							
0x46	GYRO _YOUT[7:0]							
0x47	GYRO _ZOUT[15:8]							
0x48	GYRO _ZOUT[7:0]							

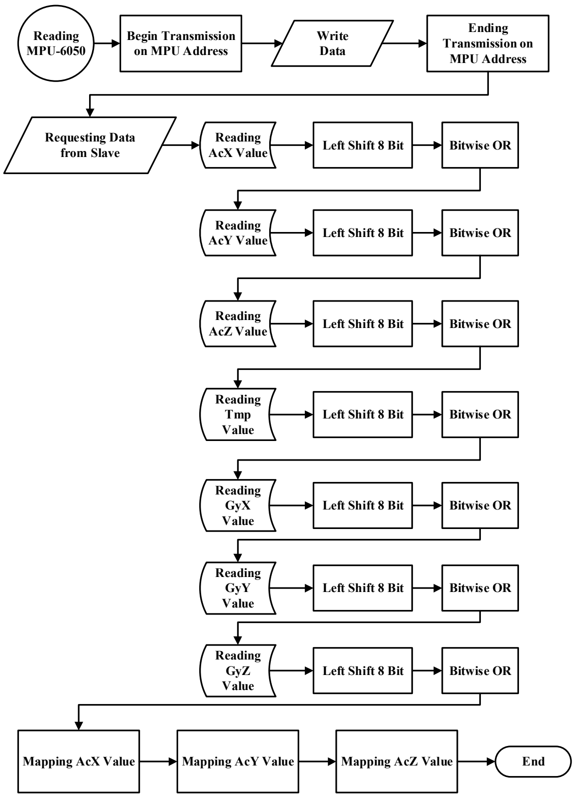

Fig. 2. MPU-6050 Data Reading Procedural

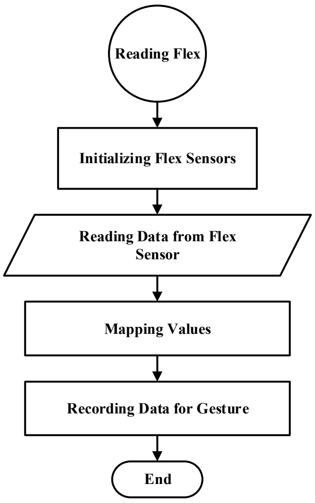
E. *Reading Flex Sensors*

Flex sensors are ideal for measuring the amount of deflection. Generally, these sensors can be capacitive, fiber optic or conductive ink-based.



Reading Flex
Initializing Flex Sensors
Reading Data from Flex Sensor
Mapping Values
Recording Data for Gesture
End

Fig. 3. Flex Sensor Data Reading Procedural

We have used conductive ink-based flex sensors here. Flex sensor works as a variable pin resistor. The output from a flex sensor can be determined from the following equation.

$$V_{out} = V_{in}\left(\frac{R_1}{R_1 + R_2}\right) \tag{6}$$

F. Building Gestures

Gestures have a changeable property, which changes dynamically every time we execute a particular gesture. Therefore, it is necessary to record a gesture for more than once to identify it correctly. The gesture properties are plotted below.

We noted the parameters by recording the values for flex sensors and gyroscope from 88 volunteers for 20 times. We have trained each gesture for 1760 times using a Probabilistic Neural Network algorithm. The algorithm implemented in TensorFlow 1.15 with Python 3.5 GPU support on Nvidia 720m card. The learning rate was 0.1 at 180 epochs.

No	Bangla Speech	Flex Sensor Data
1	আসসালামুয়ালাইকুম (Greetings!)	2	আমার নাম অপু (My name is Opu.)	3	আমি চট্টগ্রাম থা□ি । (I live in Chittagong.)	4	আপনার নাম □ি ? (What's your name?)	5	আমি ভালো আছি। (I'm fine.)	6	আপনি □ে মন আছেন? (How are you?)	7	এই দি□ে আসুন। (Please come here.)	8	এখানে বসুন। (Please Sit down.)	9	আমি এ□ দম ভালো নেই। (I am not well.)	10	বিদায়। (Goodbye!)	
III. Result

To evaluate the performance, the system was tasted with 23 disabled people. Every person has repeated each gesture for 20 times. Therefore, each gesture was tested for 460 times. In the case of gestures 7 and 10, the gesture recognition algorithm was having a problem to detect them accurately. The values of gyroscope are considered at this position to resurrect the detection issue, which was successful for both gestures.

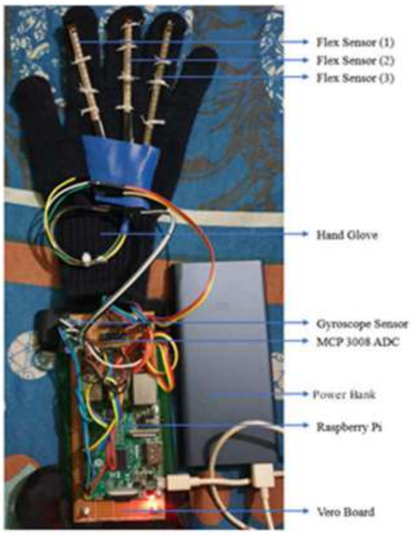

Fig. 4. System Implementation

The Gyroscope data has plotted in Fig 5 to discriminate between the gesture 7 and 10.

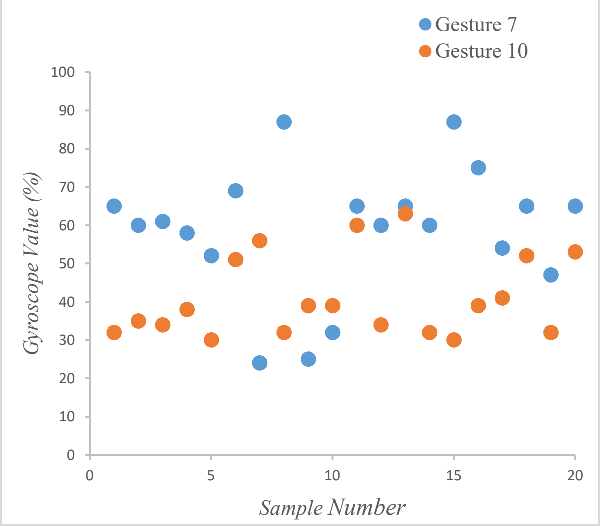

Fig. 5. Gyroscope Datapoints for Gesture 7 and 10

The system has performed overall 92.7% accuracy. The performance can be improved by adding more training datasets.

IV. Conclusion

Our proposed hand gloves have made using three flex sensors. Primarily, that limits our capability to track finger gesture for the remaining two fingers. However, due to this purpose, the device's overall cost is less, which is a tremendous advantage from a consumer perspective. On the other hand, the dynamic gesture that has been used here is entirely chosen by us. As these are not universally recognized patterns, the user may need to adapt to the patterns on the first hand. But the output generated using dynamic gestures are considerably faster than static gesture patterns like American Sign Language (ASL).

Mainly we have proposed a method to recognize dynamic gesture patterns using flex sensor and gyroscope which can be used not only in speech but also in drone control, haptics, augmented reality etc. We have converted the data generated from gloves into a two-dimension matrix where in x-axis sampling time and in y-axis flex sensor's resistances are plot. Thus, it will give us a visual idea about the data. This proposed method helped to identify gestures from different user even though the user response wasn't the same as the training data because we have used a form of pattern recognition.

***Abstract*— Prediction of energy consumption is useful in energy budgeting of smart grids, expenditure budgeting by consumers, and comfort management of smart buildings. Essentially, building management systems of smart buildings need to manage energy, efficiently. In order to do this, energy prediction plays an important role. The energy consumption, in general, is predicted using machine learning algorithms. However, machine learning algorithms demand massive amounts of data for performing well. Acquisition of this data from data owners can lead to privacy breaches. Federated learning is a framework of distributed systems which can mitigate privacy breaches to certain extent. Federated learning has as such been developed for mobile edge devices like vehicles, phones etc. In this paper, a novel application of federated learning framework focused on the smart building energy prediction scenario is presented. The architectural details on how the federated learning framework is applied is presented. Also, the performance of this prediction model as compared to centralized method of machine learning is discussed. Deep neural networks are used with the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) dataset to realize and evaluate this architecture.**

Keywords—Smart building, Federated learning, Deep Neural Network, Energy prediction.

I. Introduction

Smart buildings comprise of lighting, surveillance, Heating, Ventilation and Air Conditioning (HVAC), water supply etc. subsystems along with the inhouse kitchen appliances. These subsystems are automatically controlled to provide user comfort energy efficiently. Prediction of energy consumption of such smart buildings is crucial because of the involved energy efficiency related decision making. The predicted energy can help the smart buildings in optimizing their energy consumption. In other words, by using energy prediction, the building management system can automatically minimize the expenditure towards energy, without compromising on the user comfort [1]. Energy predictions can also help energy budgeting by smart grids. Peak demands in certain periods affect the stability of the grid. Hence, the smart grid technology, needs to predict and schedule the load in real-time, and thus achieve the energy demand-supply balance [2] & [3]. The prediction techniques used need to forecast the energy consumption accurately for a specific time interval, under varying environmental conditions, using the past data.

With the advances in the artificial intelligence and data analytics, several Machine Learning (ML) based building energy consumption prediction techniques have been discussed in literature. For example, [4] proposes a novel hybrid prediction approach based on the evolutionary deep learning method combining genetic algorithm with long short-term memory. [5] discusses ML approaches like artificial neural network, Support Vector Machines (SVMs), Gaussian-based regressions, and clustering applied in forecasting and improving building energy performance. [6] presents a deep learning-based model to predict cooling energy consumption of a building based on outdoor weather conditions. A composite model of power prediction based on fuzzy C-means clustering and grey wolf optimized back propagation neural network is proposed in [7]. However, it has been realized that, in order for any ML algorithm to perform well, it is crucial to train the model with large amounts of data.

The data required to train the ML algorithms could be sensitive and be a threat to the data owners' privacy. The Internet of Things (IoT) devices and applications are usually deployed in our homes and workplaces, while the ML algorithms run remotely on cloud. This can result in unethical usage of the data shared with the cloud applications. Sharing of data even within an organization has issues because of privacy, competition, policies etc. These privacy concerns get aggravated further, when cloud services are adopted and inter-organizational data needs to be handled. The commercial value of that data plays an important role in these privacy breaches.

In order to tackle the serious privacy breaches while using cloud-based ML applications, privacy-sensitive data need to be stored and processed securely, privately, and within the ethical regulations. Electronic health/medical records, location information, browsing history, photographs are few examples of such private data. General Data Protection Regulation (GDPR) enforced by the European Union on May 25, 2018, aims to protect users' personal privacy, and provide data security [8]. GDPR suggests techniques like data minimization, anonymization, pseudonymization etc. for privacy protection.

978-1-6654 -4067-7/21/$31.00 ©2021 IEEE

Adhering to these regulations helps in building trust towards the data handlers.

In addition to the regulations, privacy enhanced ML techniques play an important role in preventing privacy and ethical breaches. For Eg., homomorphic encryption, differential privacy, multi-party computation, and federated learning are few such techniques. Such privacy enhanced ML techniques are being researched actively. In [9], a hybrid approach for breaking down large, complex Deep Neural Networks (DNNs) for cooperative, privacy-preserving analytics using a concept of Siamese fine-tuning is discussed. [10] describes how non-linear SVMs can be practically used for image classification. Classification is applied on data encrypted with a Somewhat Homomorphic Encryption (SHE) scheme. [11] compares the efficiency and privacy of two emerging solutions to privacy-preserving ML, namely local differential privacy and federated learning. Differential privacy is a distributed data collection strategy, where each client adds digital noise to data locally before submitting to the server. Federated learning, on the other hand, is for multi-parties to train privacy preserving ML models in the cloud services.

Federated Learning (FL) collaboration method of privacy enhancement was first coined by Google [12] & [13]. It is a privacy-preserving distributed machine learning framework, where the model reaches the data, instead of data reaching the model. The main idea in this framework is to build ML models based on datasets that are located at the data owners' device, thus preventing data leakage. The advances in the edge processing are synergizing such distributed data frameworks.

In this paper, the application of federated learning framework towards development of privacy enhanced energy prediction architecture for smart buildings is presented. A DNN model applied to the ASHRAE dataset is used to realize this framework. The framework is implemented in Python using PySyft and PyTorch libraries [14]. The accuracy and timing performances of this framework are compared with the centralized approach of ML. Section II describes the scenario & dataset along with the FL Framework. Section III discusses the data partitioning and feature engineering. Section IV shows the design, implementation, and evaluation of the framework. Finally, the conclusions are presented.

II. Scenario & Dataset

The architecture is of a horizontal federated-learning system, where all participants have the same data structure. The participants collaboratively train their machine-learning model with the help of a cloud server. A typical assumption is that the participants are honest, whereas the server though honest is curious. Therefore, no leakage of information from any participants to the server is allowed.

Fig.1 shows the scenario where the N different buildings defined as N data owners $\{B_1, . . . B_N\}$. Each of the data owners train a local machine-learning model using their respective datasets $\{D_1, . . .D_N\}$ [15].

Training process of such a system usually constitutes of the following steps. **Initialization:** The model owner at the cloud decides upon the architecture of the DNN model and identifies the participants by selecting random buildings. Buildings get the weather data from the Weather Forecaster. Model owner sends a copy of its model to buildings.

Step 1: At each building the data owner uses the local data to train its local model and compute gradients. The masked gradients are sent to the Trusted Third Party (TTP) server.

Step 2: The TTP server performs secure aggregation without learning information about any participant. The aggregated model is sent to the model owner for updating the global model.

Step 3: The model owner sends back the updated global model to the buildings' data owners.

Step 4: Data owners update their respective local models.

The random selection of data owners (buildings in this case) improves the model as discussed in [16]. Inclusion of all the large number of workers (data owners) in a training epoch, can create a situation wherein, changes done by one data owner will be cancelled out by the other. In other words, the model parameters from a data owner can become insignificant. Due to this situation, important changes recommended by one of the buildings will not be captured in the global model. This issue can be solved by using a small number of random data owners for each global epoch. However, if the number of workers is too small, then the model may take a very long time to converge. For aggregation performed in step 2, [16] suggests taking a weighted average of the received model. The weights are proportional to the amount of data contributed towards training by that data owner. Let n_k is the amount of data possessed by the k^{th} data owner and n be the total amount of data on which the model has been trained. Then, the weights at the model owner at $t+1$ th global epoch are taken as the weighted average of the weights from data owners as in (1).

$$w_{t+1} \leftarrow \sum_{k=1}^{N} \frac{n_k}{n} w_{t+1}^{k} \qquad (1)$$

Step 1 to 4 are repeated till convergence of the loss function. The objective of the local model is to minimize the loss function ϵ defined as in (2). The Root Mean Square Log Error (RMSLE) of federated learning is computed as an average of RMLSE of local models.

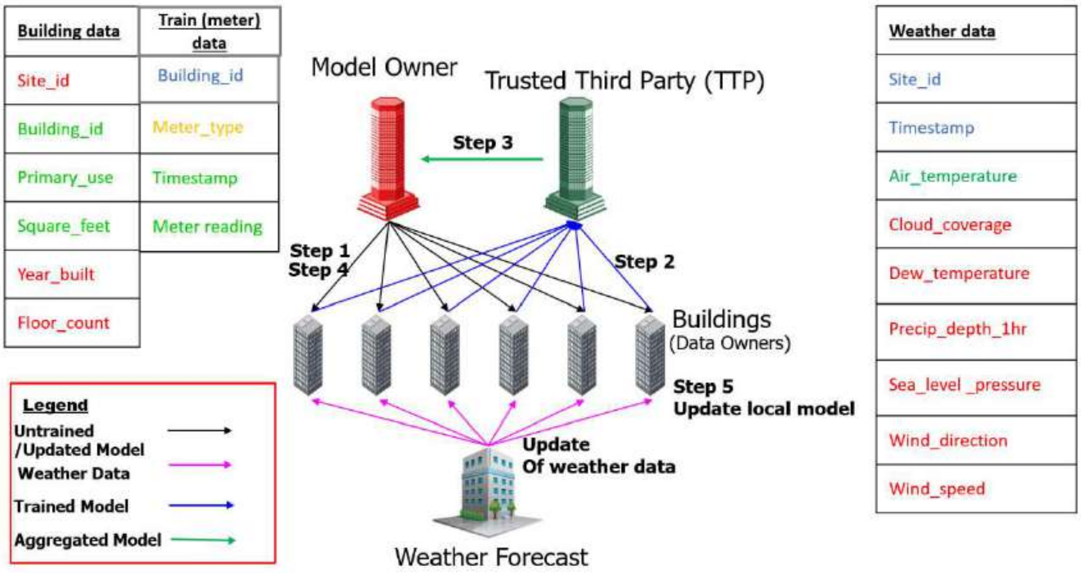
$$\epsilon_{FL} = \frac{1}{N} \sum_{k=1}^{N} \epsilon_k \qquad (2)$$

At each local model the RMSLE is given by (3).

$$\epsilon_k = \sqrt{\frac{1}{m} \sum_{i=1}^{m} \left(log(p_i + 1) - log(a_i + 1)\right)^2} \qquad (3)$$

Where, m = number of datapoint instances per batch. p_i = predicted meter reading for i^{th} row, a_i = actual meter reading for i^{th} row [17].

The dataset considered is from ASHRAE [17]. It contains the building data, meter data and the weather data provided as a part of the ASHRAE great energy predictor III competition. The competition is to build models, to accurately predict the energy consumption or meter reading. The meters are of four different types: namely, electricity, chilled water, hot water, and steam meters. The data features are listed in Fig. 1.



Building data

III. FEATURE ENGINEERING

A. Dataset description:

The ASHRAE dataset is vast, comprising data from more than 1000 buildings over a span of 3 years and of the following 3 types.

1) Train: Size of train data (20216100, 4).

Train data consists of a) Building_id - Refers to the identity (ID) of the building out of 1448 buildings, corresponding to the row, b) Meter - (0-Electricity, 1- Chilled Water, 2 - Steam, 3- Hot Water). c) Timestamp - It is the time corresponding to the meter reading. d) Meter Reading - The target variable after scaling it to with log function. The loss function is RMSLE on the meter reading.

2) Building: Size of building data (1449, 6)

Building Data contains a) Site_id - It is an ID pointing to the site at which the building is present, b) Building_id - A unique ID representing each building. c) Primary_use - it refers to the main purpose of the building, for what this building is being used for. For eg., education. d) Square_feet -It is the gross area of the building. e) Year_built -Year building was opened. f) Floor_count - Number of floors of the building.

3) Weather: Size of weather data (139773, 9)

Weather Data: a) Site_id: Unique Id representing the site of measurements. b) Timestamp: Time at which the reading was taken. c) Air_temperature: provided in degree Celsius. d) Cloud_coverage: Portion of the sky covered in clouds, in oktas e) Dew_temperature: provided in degree Celsius f) Precip_depth_1_hr: It refers to the amount of rainfall/precipitation occurred in one hour. It is measured in mm. g) Sea_level_pressure: refers to air pressure h) Wind_direction: The direction of wind flow in degrees (0-360). i) Wind_speed: It is measured in meters per second.

B. Preprocessing

Preprocessing involving cleaning, transforming, and reducing is based on the observations, which are discussed further in this sub-section.

Observation 1: Not every building has every type of meter. Majority of the buildings have electricity meters (meter 1). This non-uniform presence of meters can be seen in Fig. 2 which shows a plot of the meters present in each building.

Observation 2: A periodic trend in the meter reading across the day, week and yearly is noticed. These trends are expected as the energy consumption primarily depends on the weather patterns across the year as well as day.

Observation 3: Primary_use feature contains categorical data. Only five dominant categories, namely education, office, entertainment public services and lodging are seen and the number of samples in other categories are negligible.

Observation 4: The air temperature variation is highly correlated to the meter reading as expected.

To capture the trends which were observed in observation 2, timestamp column is split into 4 new columns: Hour, Day, Weekend and Month. 1 represents weekend, that is, when the day is Saturday or Sunday else it is 0. The tables are merged with features shown in red of Fig. 1, i.e., Site_id, Building_id and Timestamp. The following features are dropped after this join. 1. Floor_count: Most of the Buildings (80%) do not have floor count or have very low floor count. Year_built - Again most of the buildings do not have Year_built. No correlation between Year_built and power consumption has been observed. Next, Precip_depth_1_hr, Sea_level_pressure, Wind_direction, Wind_speed, Cloud_coverage, Dew_temperature and Site_id are the other features dropped as these do not show significant correlation with the meter reading.

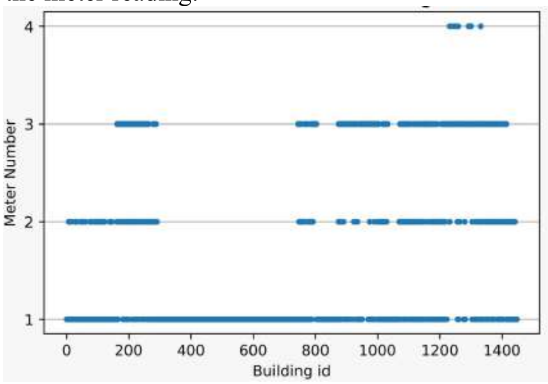

Fig. 2: Building_id versus meters available

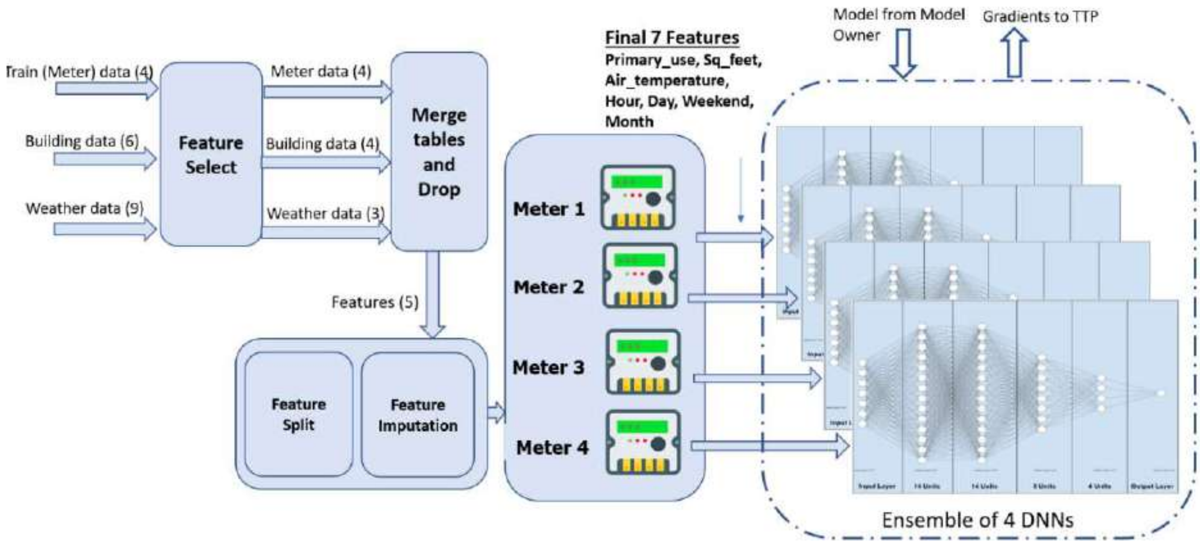

Fig. 3: Feature engineering and DNN model at each Data owner

The rows with meter reading 0 are dropped, as the hourly power consumption is not expected to be 0 generally, and 0-meter reading also does not contribute towards training. The missing values in a column are imputed with the median of the corresponding column. Since the buildings may not have all the four types of meters, an ensemble of 4 models has been created, each for predicting for meter. The data was thus split based on meter type. The shortlisted features are shown in green in Fig. 1. With the timestamp split into Hour, Day, Weekend, Month, along with Air_temperature, Square_ft, Primary_use are the 7 features fed to the DNN.

DNN comprises of a fully Connected Feed Forward Neural Network with Rectified Linear Unit (ReLU) as the activation function. The architecture of the model is arrived at progressively, with number of layers being added and a wider layer provided at the start to overcome underfitting.

The predicted meter reading with the Timestamp, Building_id and Site_id can be used in the visualization and further usage of the energy prediction data, which is beyond the scope of this paper. Fig. 3 details the processes discussed in this section.

IV. Implementation & Evaluation

The Jupyter notebook-based Python scripting using PySyft and PyTorch libraries is used to develop and evaluate the centralized and federated learning models. Both the models are trained in a CPU provided by Google Colab basic/free version.

A. *Centralized learning:*

In order to improve the training speed, the number of input variables (as mentioned in feature engineering) are reduced. The data normalization also helps the speed up the training process. The convergence of the model with different learning rates is observed experimentally. Results for the Learning rate = 0.001 and Batch size (m) = 512 are as seen in Fig. 4. The results presented here are for all the 1448 buildings' data considered meter wise. The training and validation tests were carried out epoch wise till convergence. The number of epochs required to converge, and the final accuracy depends on the distribution of data. Meters 2, 3 & 4 have data containing higher number of 0 values as compared to meter 1. Hence, higher number of epochs are required for convergence in case of meters 2, 3, 4. The reason for meter readings being 0 could be for instance, hot water not turned-on during summer months, resulting in 0 in meter 4 readings.

B. *Federated Learning:*

The FL framework uses the architecture as shown in Fig.1 and the ML model described in section III. 3 local epochs are considered for each global epoch fixed after experimentation. In order to delve deeper into the analysis, only meter 1 is considered and reduced sizes of building data set are considered.

1) *Accuracy:*

Fig.5 shows the RMSLE versus global epochs of federated learning for different sizes of datasets (10, 25, 50, 100) buildings for meter 1 computed using (2). It is observed that the performance does not vary drastically with increasing global epochs. In Fig. 6, the variation of RMSLE for increasing building numbers for both centralized and federated learning are seen. The centralized learning improves with increasing data size as expected. There is no such improvement in case of federated learning. This can be explained that, as the number of buildings increases and the changes due to one building gets canceled out by the other buildings. But this very fact is very useful because it prevents the global model from overfitting. The performance of the centralized model improves as expected.

The parameters that can be varied for experimentation at ML model level are the learning rate, batch size and depth of the model. In FL framework, the number of local epochs for one communication round, can be varied to study the performance. Better aggregation techniques are also recommended.

2) *Timing:*

Fig. 7 shows average time (in seconds) taken by the models to train for one epoch with different amounts of data. It can be observed that there is a massive difference between time taken by centralized model and federated learning model, approximately 70-100 times. To understand the timing requirements, a parallel algorithm has been implemented where in the PySyft calls of federated learning are avoided. Multiple ML models are run for each building data simultaneously. For realizing this model, the complete dataset is split according to data corresponding to each building and is stored in an array. Similarly, an array is made to store models corresponding to each building. The models are then trained with respective datasets using pure PyTorch. The training process is the same as centralized and operations are performed on simple tensors, unlike PySyft where pointers are used for operation on SyftTensors. Also, the weights for each model can be directly updated here. In comparison, each parameter in PySyft is a pointer to the value which needs to be updated [18].

The timing of this learning implementation is very close to that of centralized learning. Parallel learning has an overhead compared to centralized training as one needs to load and save multiple models and datasets. This overhead is trivial as compared to the delays due to inter process communications between the data owners and model owner in the FL framework, using PySyft. This inter process communication in PySyft is by means of sending or sharing tensors between workers (processes). It should be noted that all models are simulated in the same system. Overhead also increases as the number of buildings increases as expected.

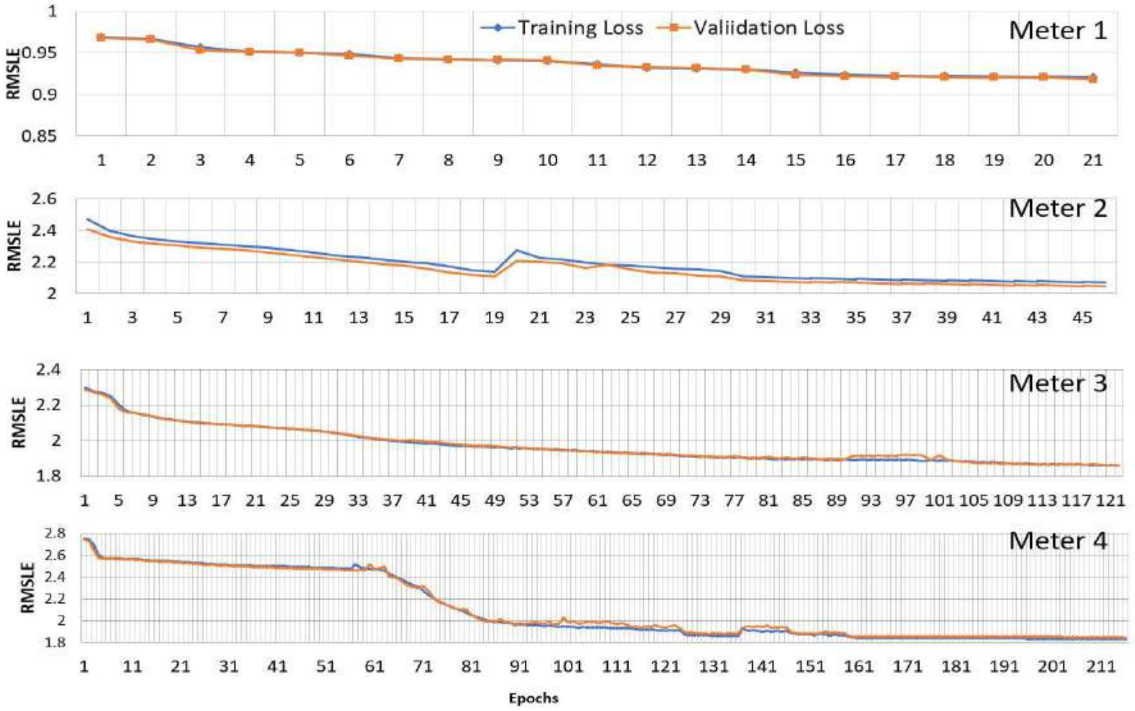

Fig. 4: RMSLE versus epochs of the DNN for different meters

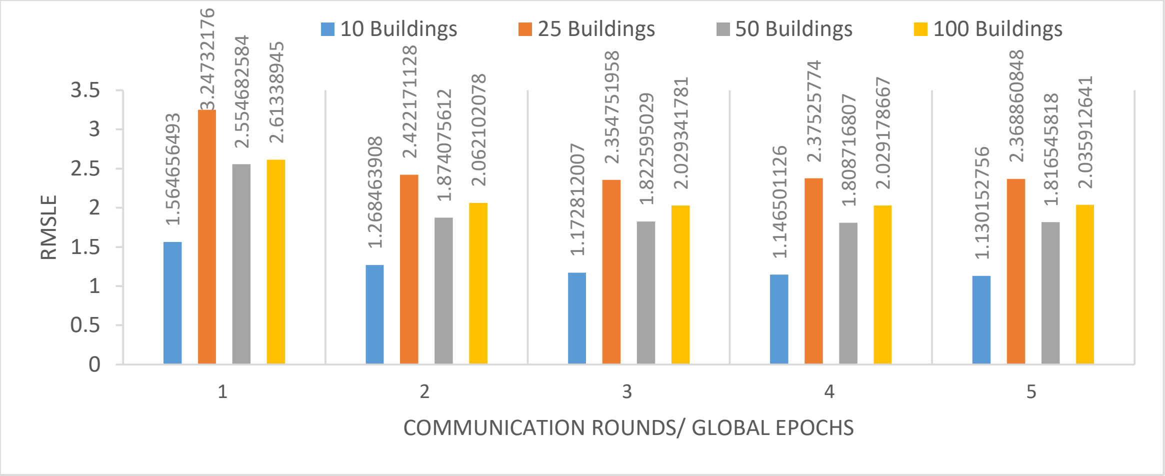

Fig. 5: RMSLE versus communication rounds of federated learning

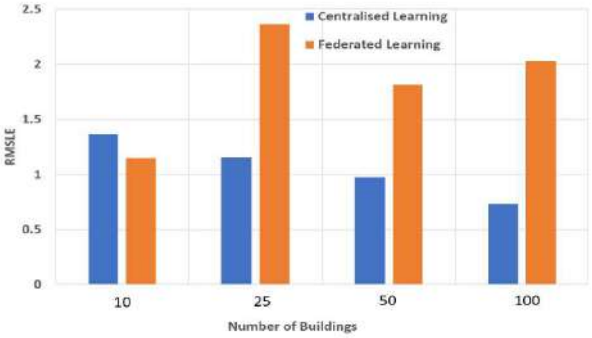

Fig. 6: RMSLE with increasing number of buildings centralized versus federated learning

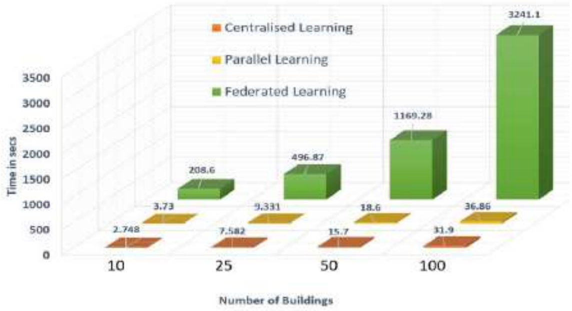

Fig. 7: Time taken with different number of building data for centralized, parallel, and federated learning.

V. Conclusions

The federated learning framework was applied successfully to the smart building energy prediction scenario. This enhances the privacy of the smart building energy prediction system as the data owners do not share the data with the model owners. Introduction of the TTP further helps in secure aggregation. The design details of how the federated learning framework is applied is presented along with the performance of this prediction model as compared to centralized method of machine learning. Further work can include more efficient implementation using better aggregation techniques than weighted average. Homomorphic encryption or differential privacy can be applied to enhance to prevent data and model leakages.

In centralized learning the local data is available at the cloud and can be de-anonymized. For example, by matching Site_id & timestamp of building data with the weather data, Building_id attribute can be narrowed down to very small number. The corresponding meter readings give an indication of occupancy/non-occupancy, aiding the burglary plans. In the case of federated learning data is not visible to anyone expect its owner, which will eliminate the risk of leaking sensitive information.

***Abstract*— Hardware Security plays a major role in most of the applications which include net banking, e-commerce, military, satellite, wireless communications, electronic gadgets, digital image processing, etc. Cryptography is associated with the process of converting ordinary plain text into unintelligible text and vice versa. There are three types of cryptographic techniques; Symmetric key cryptography, Hash functions and Public key cryptography. Symmetric key algorithms namely Advanced Encryption Standard (AES), and Data Encryption Standard use the same key for encryption and decryption. It is much faster, easy to implement and requires less processing power. The proposed 256-bit AES algorithm is highly optimized in Key schedule and Sub bytes blocks, for Area and Power. The optimization has been done by reusing the S-box block. We are optimizing the algorithm with a new approach where internal operations are 32-bit operations, as compared to 128-bit operations. The proposed implementation helps in re-using the same hardware in a pipelined fashion which results in an area reduction by 72% using slice registers, 62% using slice LUT's and 61% using LUT-FF Pairs. This in turn results in a power reduction by 78% in a FPGA implementation. The throughput (Mbps) of the proposed implementation using Virtex-7 (xc7vx485tffg1157) FPGA improved by 10%.**

Keywords*— *AES *(Advanced Encryption Standard),* ***FPGA*** *(field programmable gate array),* ***LUT*** *(Look up table),* ***Mbps*** *(megabit per second),* ***sub*** *(sub bytes),* ***shift*** *(shift rows),* ***mix*** *(mix column),* ***add*** *(add round key).*

I. Introduction

Cryptography is associated with the process of converting ordinary plain text into unintelligible text and vice versa. There are three types of cryptographic technique namely - Symmetric key cryptography, Hash functions and Public key cryptography.

Symmetric key algorithms namely Advanced Encryption Standard (AES), Data Encryption Standard use the same key for encryption and decryption. It is much faster, easy to implement and requires less processing power.

In this paper, we have discussed about implementation of area, power and performance-based architecture of 256-bit key AES algorithm. Also, we discussed about the PPA comparison of the conventional and proposed based implementation in FPGA.

II. Architecture of AES Algorithm

A. Architecture of AES algorithm

AES algorithm implementation is done using four operations namely Sub Bytes, Shift Rows, Mix Columns and Add Round Key. Fig. 1 shows the architecture of 256-bit AES algorithm. In total there are 14 rounds of operation for encryption and 14 rounds for decryption. The ciphertext after encryption will be transmitted across the channel. The receiver side will decrypt the message using same key which is used in encryption.

In 256-bit AES algorithm, the key size is 256 bits, but all the data size is 128 bits. Data include message to be encrypted, cipher text and the decrypted message.

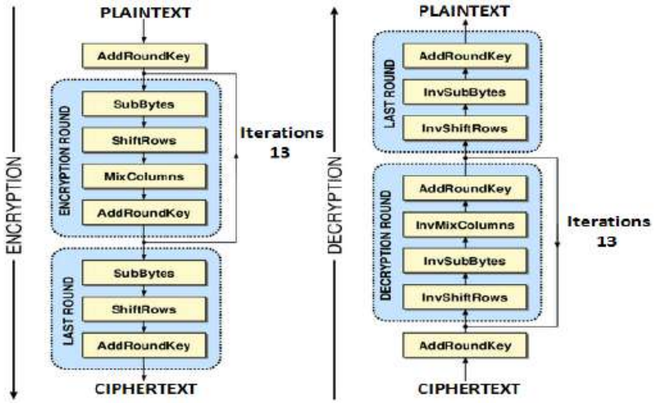

Fig. 1 Architecture of 256 AES Algorithm

Fig. 2 explains the internal data structure of 128-bit data. The 128-bit data is used as 4x4 matrix, where each elements of the matrix is of 8 bits. Since all the four operations are performed on columns basis, we convert the 128-bit data in 4x4 matrix with each element being 8 bits.

III. Implementation of AES Algorithm

This paper explains about the implementation of both conventional and proposed architecture of 256 AES algorithm. This paper also compares the Power, Performance and Area number in FPGA implementation.

A. Conventional Implementation of 256 bit AES Algorithm

256-bit AES encryption block is implemented in 14 rounds. Each round consists of Add Round Key, Sub Bytes, Shift Rows, Mix column. Round 0 consists of only Add round Key operation as shown in Fig. 3. Round 14 consists of Sub Bytes, Shift Rows and Add Round Key operations, which need 3 clock cycles as shown in Fig. 3. Rounds 1 to 13 consists of all the four operations as shown in Fig. 13. We do a distinct operation in each clock cycle. Hence once the hardware has been implemented for Add Round Key, Sub Bytes, Shift Rows, Mix column, the same hardware can be used for all the 14 rounds [7] [10]. None of the four operations shares the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

same clock cycle. Fig. 3 shows the sequence of round operation with specific sequence of 4 operations to complete the AES encryption. AES algorithm is serial process, i.e. output of first round is the input to the second round. Hence, we can use the same hardware for each round.

Round 0	01 cycle
Round 1 to 13	52 cycles
Round 14	03 cycles
Total	**56 cycles**

Table: 1 Cycles required in Each Round

		Cycle
Round 0	Add Round Key	1
	Sub bytes	2

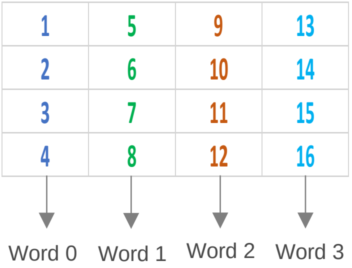
Round 14	Add Round Key	56

Fig. 3 Structure of conventional implementation

Fig. 3 shows the structure of conventional implementation of 256-bit key AES algorithm.

B. Data Structure

Fig. 4 shows the data structure of 128-bit matrix. Each column consists of 4 elements of 8 bits each, so in total we have 32 bits per word.



1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

Fig. 6 S box required for Proposed Method

Fig. 6 shows the proposed 32-bit AES implementation. We are doing operations per word (32-bits) in each cycle. Number of blocks required for conventional (128 bit) and proposed (32-bit) implementation are as follows

1) *S box - 16, 4 per clock cycle*
2) *Mix column block - 4, 1 per clock cycle*

In the proposed implementation, we are using the same S-box hardware for both encryption and decryption. Affine transform is the only difference between S-box (encryption) and inverse S-box (decryption). All the other logic (for encryption and decryption) is same for the S-box and inverse S-box. Hence, we are reusing every logic other than the Affine transform for encryption and decryption. Fig. 7 shows the mux selection between S-box and inverse S-box [1]. While doing AES encryption S-box path is chosen and while doing AES decryption inverse S-box path is chosen [1].

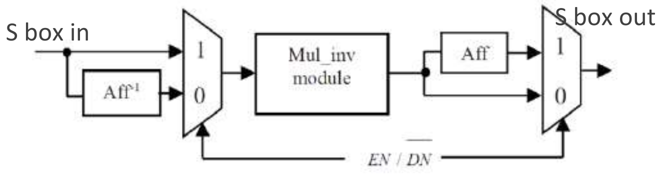

Fig. 7 Combined structure of S box and Inverse S box

C. Proposed 32 bit operations Implementation

In proposed 32-bit operation method, we are reusing S-box and Mix Column blocks. In proposed design "Mix Column" and "Add Round Key" together we called Mix block.

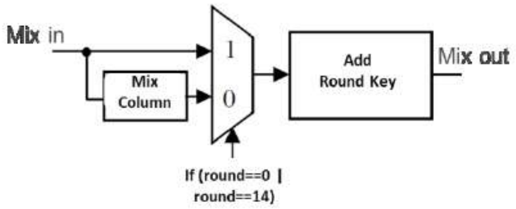

Fig. 8 Combined structure of Mix Column and Add Round Key - Mix

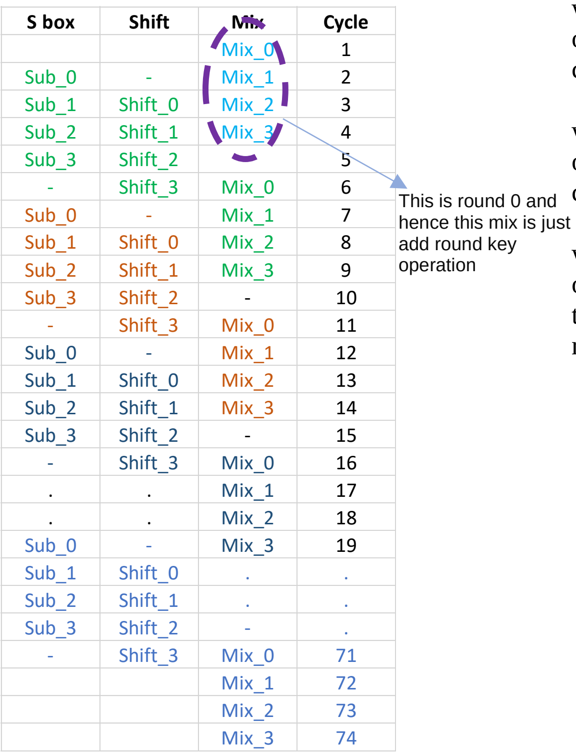
Fig. 9 shows the pipeline structure of the proposed design, where each color represents different round as follows,

Mix – round 0
Mix – round 1
Mix – round 2
Mix – round 3
Mix – round 14



S box	Shift	Mix	Cycle
		Mix_0	1
Sub_0	-	Mix_1	2
Sub_1	Shift_0	Mix_2	3
Sub_2	Shift_1	Mix_3	4
Sub_3	Shift_2		5
-	Shift_3	Mix_0	6
Sub_0	-	Mix_1	7
Sub_1	Shift_0	Mix_2	8
Sub_2	Shift_1	Mix_3	9
Sub_3	Shift_2	-	10
-	Shift_3	Mix_0	11
Sub_0	-	Mix_1	12
Sub_1	Shift_0	Mix_2	13
Sub_2	Shift_1	Mix_3	14
Sub_3	Shift_2	-	15
-	Shift_3	Mix_0	16
.	.	Mix_1	17
.	.	Mix_2	18
Sub_0	-	Mix_3	19
Sub_1	Shift_0	.	.
Sub_2	Shift_1	.	.
Sub_3	Shift_2	-	.
-	Shift_3	Mix_0	71
		Mix_1	72
		Mix_2	73
		Mix_3	74

This is round 0 and hence this mix is just add round key operation

Fig. 9 Pipelined structure of mix operation

From Fig. 9, each word having a size of 32 bits. In **cycle 1**, we are doing Mix operation of word 0 (mix_0). We can denote this as cycle1[round0(mix_0)].

Hence this 32-bit word is available to undergo 32-bit Sub operation. Hence in **cycle 2** we are doing sub operation of word 0 (sub_0) and Mix operation of word 1 (mix_1). We have valid input for "sub" block word 0 in clock cycle 2, and hence we don't need to wait for all the 4 words "mix" block operation to complete. We can denote this as cycle2[round1(sub_0), round0(mix_1)].

In clock **cycle 3**, we are doing sub operation for word 1 (sub_1), shift operation of word 0 (shift_0) and mix operation of word 2 (mix_2), and. We can denote this as cycle3[round1 (sub_1, shift_0), round0(mix_2)].

In clock **cycle 4**, we are doing sub operation for word 2 (sub_2) and shift operation for word 1 (shift_1) and mix operation for word 3 (mix_3). We can denote this as cycle4[round1(sub_2, shift_1), round0(mix_3)].

Since all 128-bit (4 words) round 0 mix operation completed, we don't have mix operation in cycle 5. In clock **cycle 5**, we are doing sub operation for word 3 (sub_3) and shift operation for word 2 (shift_2). We can denote this as cycle5[round1(sub_3, shift_2)].

Since all 128-bit (4 words) round 0 sub operation completed, we don't have sub operation in cycle 6. In clock **cycle 6**, we are doing round 1 shift operation of word 3 (shift_3) and mix operation of word 0 (mix_0) and. Since we already have the last byte value from sub_3, we are using that for mix_0. In this way we don't need to wait extra one cycle of shift operation to start the mix operation. We can denote this as cycle6[round1(shift_3, mix_0)].

In clock **cycle 7**, we are doing sub operation for word 0 (sub_0) and mix operation for word 1 (mix_1). We can denote this as cycle7[round2(sub_0), round1(mix_1)].

In clock **cycle 8**, we are doing sub operation for word 1 (sub_1) shift operation for word 0 (shift_0) and mix operation for word 2 (mix_2). We can denote this as cycle8[round2(sub_1, shift_0), round1(mix_2)].

In clock **cycle 9**, we are doing sub operation for word 2 (sub_2), shift operation for word 1 (shift_1) and mix operation for word 3 (mix_3). We can denote this as cycle9[round2 (sub_2, shift_1), round1 (mix_3)].

In clock **cycle 10**, we are doing sub operation for word 3 (sub_3) shift operation for word 2 (shift_2). The same order of execution repeats for all 14 rounds. We can denote this as cycle10[round2(sub_3, shift_2)]. The same sequence repeats for all 14 rounds.

Key Generation for Round 2

Fig. 10 Pipelined structure of Key gen block

As shown in Fig. 10, in cycle 6 we are using sub bytes S box for key generation block, because of this we don't need extra S box for key generation block. We are generating 128-bit key for every 5 cycles, so that it requires only 4 S box in one cycle. In conventional method, we need 8 S box for key generation block. 128-bit key generated in cycle 6 will be used in cycle 14 mix operation. Similarly, key generated in cycle 11 used in mix operation of cycle 19.

As shown in Fig. 10, in cycle 9 we have valid output for round 1 (cycle 5 to 9), so we need 5 cycles to perform round 1. Total we need 74 clock cycles to complete AES encryption.

IV. Conclusion

In this paper, we have compared the PPA numbers of conventional and proposed method in Virtex-7 (xc7vx485tffg1157) FPGA implementation of a 256-bit Key AES algorithm. The proposed implementation has an area reduction by 72% using slice registers, 62% using slice LUT's and 61% using LUT-FF Pairs. This results in a power reduction by 78%. The throughput (Mbps) of the proposed implementation improved by 10%. We proposed reusing the 32-bit Sub bytes and 32-bit Mix column blocks for 128-bit data, reusing the S-box for Sub Bytes and Key Schedule operations, reusing the same hardware for both encryption and decryption. The proposed method is generic and can be used for 128, 196 and 256-bit Key size. The proposed method is generic and can be used with word size operation of 16, 32, 64 bits.

***Abstract* -- This paper demonstrates the working of UWB MIMO antenna with individual and common feedline ports for excitation. Etched on a highly reliable dielectric, the functioning of designed antenna at different working states of radiating patch elements is evaluated and presented.**

Furthermore, the detailed study and analysis of the generated responses of antenna with common feeding system is elucidated. The variations of the antenna characteristics, geometrical modifications and design parameters are discussed.

Keywords -- Ultra-wideband (UWB), Wilkinson Power Divider (WPD), Multi-Input-Multi-Output (MIMO).

I. INTRODUCTION

With increasing technological advances, constant development in radio wave technologies is rightly acknowledged. In Wireless Communications, the designing of antenna which works under adverse conditions is necessary. Microstrip patch antenna is considered as simple and basic working antenna which paves path to design and fabricate antennas that have high frequency communication channels [6] .

Ultrawide band can be achieved through microstrip antenna with certain geometrical modifications. MIMO antenna uses more than one radiating element to offer high and multiple data transmissions [10]. Power dividers, Directional Couplers and Microwave filters can be used to enhance or isolate desired bandwidth [5] [7].

UWB with MIMO antenna is complex yet efficient combination to tune and obtain user demanded frequency applications in Academical, Industrial, Research and Realtime Implementations. This paper demonstrates the working of two proposed antennas along with brief discussion on their results, design parameters and challenges.

II. METHODOLOGY

A. DESIGN OF UWB MIMO ANTENNA

A MIMO antenna for UWB frequency range is proposed. Dimensions for circular patch antenna at 2.4GHz is calculated. Two circular radiating elements with better isolation is placed on Rogers RT/duroid 5870 ™ dielectric with relative permeability of 2.33 and loss tangent of 0.0012. This is further excited to resonate in ultra-wide band by using partial ground plane of height 20mm. The radius of the patch is calculated by the dimensions of rectangular patch antenna which gives 21.86mm at 2.4GHz.

With the substrate dimensions of 70mm x 140mm x 3.6mm and insertion of slots on the circular patches, the proposed design exhibits power transmission less than -10dB in UWB frequency range. The study and analysis of antenna parameters like radiation pattern, scattering, co and cross polarization, current distribution is presented. At maximum current and minimum voltage point on the surface, the antenna is modified such that the antenna parameters are changed.

Proposed UWB MIMO antenna consists of two radiating patch elements. Hence, two different feeding systems are used for antenna excitation. The working of antenna is now based on excitation magnitude of antenna ports 1 and 2.

Three port states can be derived from above condition. Excitation of antenna can be done with both the ports processing or any one of the ports being terminated. Evaluation of these possibilities are simulated in High Frequency Structure Simulator (HFSS).

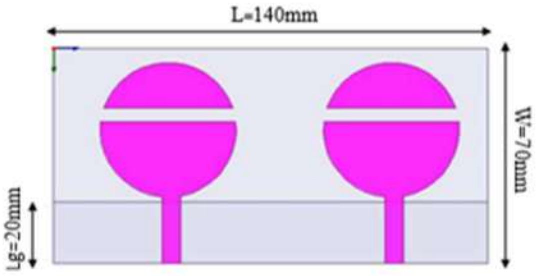

Fig. 1. Design 1 – UWB MIMO Antenna

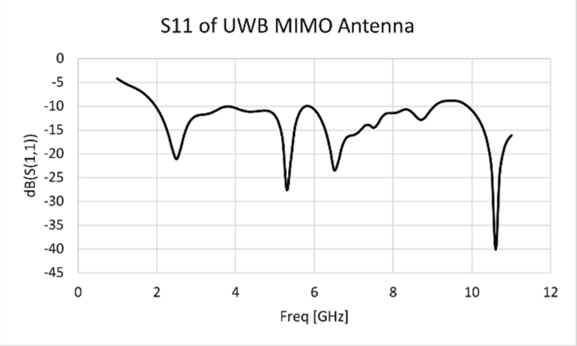

Fig.2. S-parameter (S11) of UWB MIMO Antenna

All the application frequencies like Bluetooth, WLAN, WiMAX, C-Band, X-Band achieved Return loss less than -10dB.

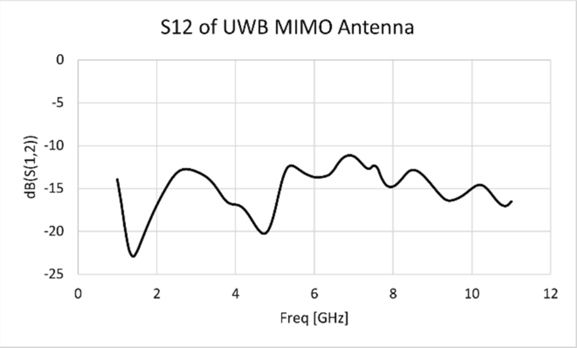

Fig. 3. S-parameter (S12) of UWB MIMO Antenna

S12 represents the power transmitted from port 1 to port 2. The Return loss obtained is less than -10dB.

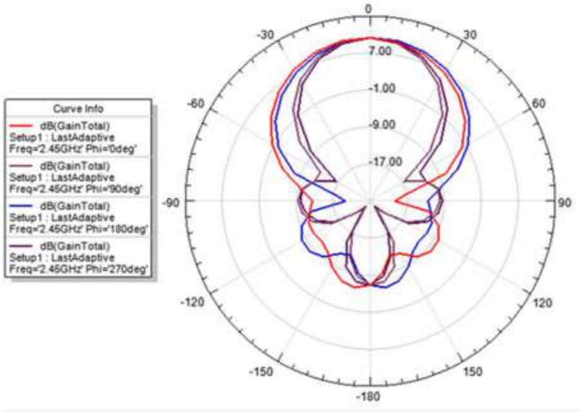

Fig.4. Radiation Pattern of UWB MIMO Antenna

Gain achieved for the proposed antenna is nearly 7dB.

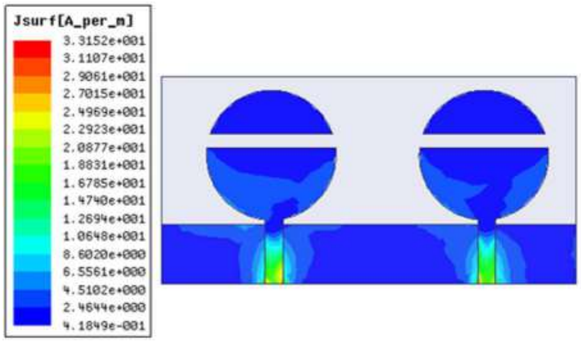

Fig. 5. Current Distribution of UWB MIMO Antenna

The surface current distribution of an antenna determines the electric current transmission all over the surface. This helps in identifying and modifying the antenna geometry to obtain desired outputs. Each color signifies the magnitude of current distribution at the specific area.

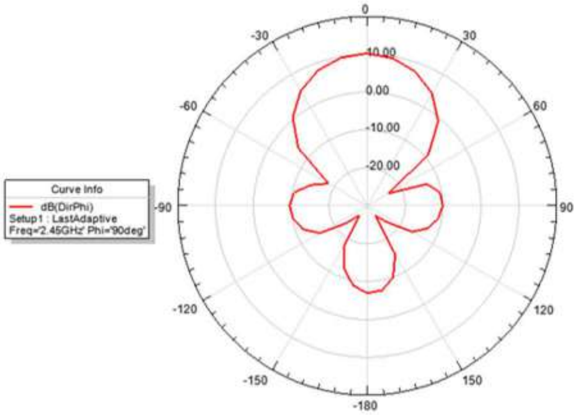

Fig.6. Co-Polarization of UWB MIMO Antenna

The Co-polarization of UWB MIMO antenna is presented above. The orthogonal radiation of obtained co-polarization is the cross-polarization of the proposed antenna. It is helpful to minimize the interference of radiating waves.

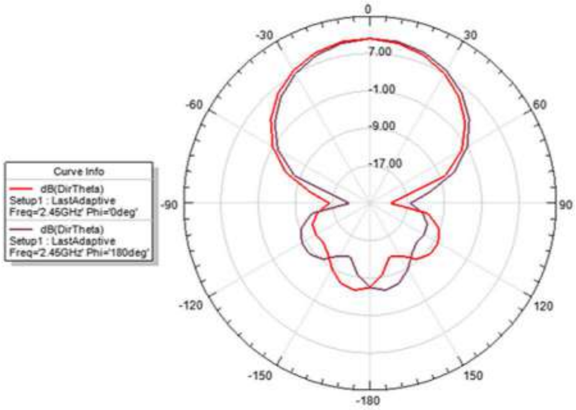

Fig.7. Cross-Polarization of UWB MIMO Antenna.

B. EXCITATION MAGNITUDES OF UWB MIMO ANTENNA

State 1: Excitation Magnitude (1,1).

Here, both the sources have equal magnitude. Both the ports are in ON state. Figure 2 is the Return loss obtained in this state. Figure 4 represents the radiation pattern with gain obtained.

State 2: Excitation Magnitude (0,1). Termination of Port 1.

In this state, the magnitude of port 1 is 0 (OFF state) and the magnitude of port 2 is 1 (ON state). The S-Parameters S11 and S12 when single source is excited is shown below.

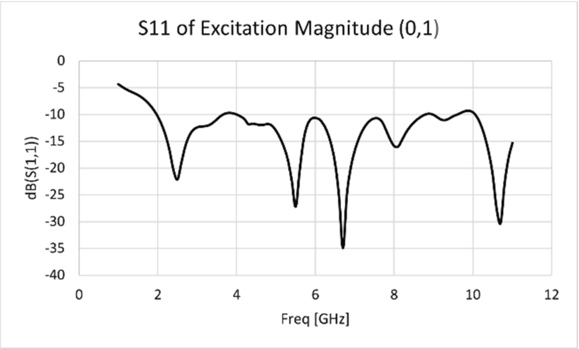

Fig.8. S11 of Excitation Magnitude (0,1)

Return loss when Port 1 is terminated.

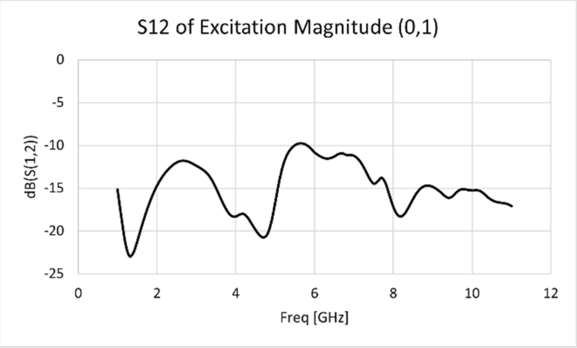

Fig.9. S12 of Excitation Magnitude (0,1)

Power transmission from port 1 to port 2 when port 2 is processed.

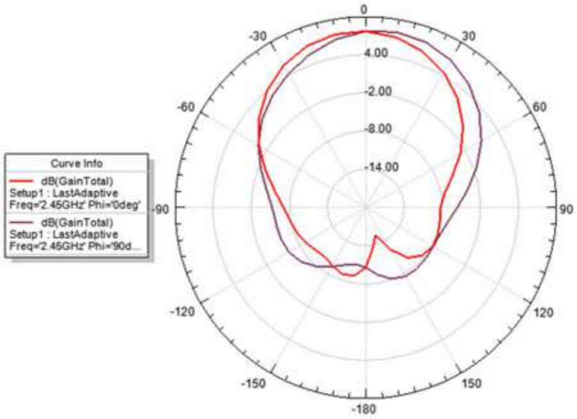

Fig.10. Radiation pattern for Excitation Magnitude (0,1)

State 3: Excitation Magnitude (1,0). Termination of port 2.

In this state, the magnitude of port 1 is 1 (ON state) and the magnitude of port 2 is 0 (OFF state). The S- Parameters S11 and S12 are shown below.

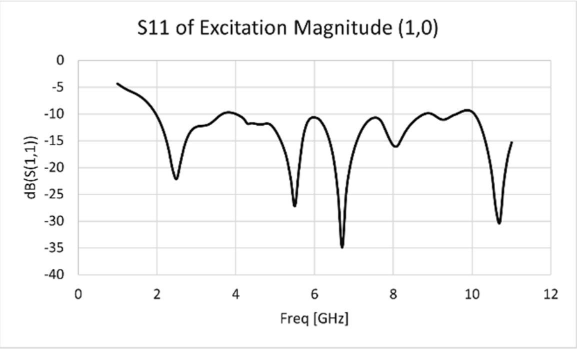

Fig.11. S11 of Excitation Magnitude (1,0)

Return loss when port 2 is terminated and port 1 is processed.

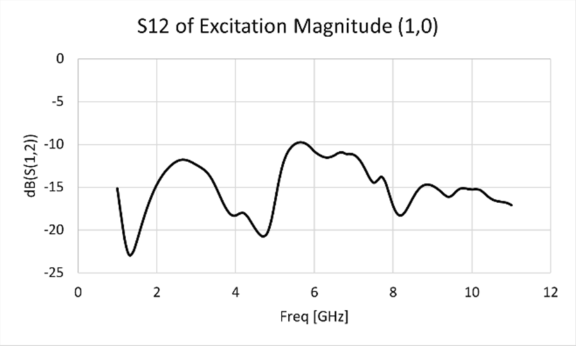

Fig.12. S12 of Excitation Magnitude (1,0)

Power transmission from port 1 to port 2 when port 2 is in OFF state.

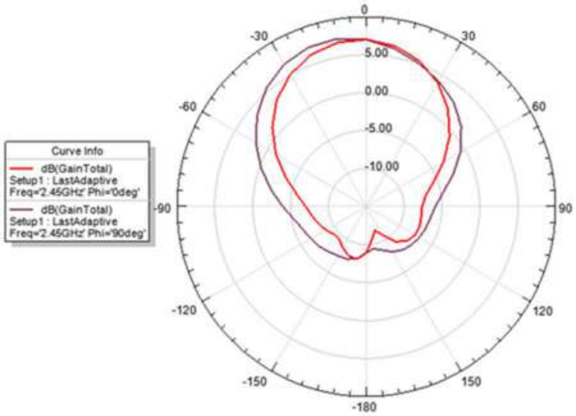

Fig.13. Radiation Pattern for Excitation Magnitude (1,0)

From the above S-Parameters for different excitation states, we can observe the change in Return loss when either of the port is terminated. The significant change in gain is illustrated by below table.

Table I. Maximum Gain at π= 0˚ and π=90˚ for excitation mechanisms

State	1	2	3
Excitation Magnitude **1-Active State** **0-Inactive State**	(1,1)	(0,1)	(1,0)
Port status	Port1 **ON** Port2 **ON**	Port1 **OFF** Port2 **ON**	Port1 **ON** Port2 **OFF**
Gain (dB)	**7dB** (Fig.4)	**4dB** (Fig.10)	**5dB** (Fig.13)
Return loss at 2.4GHz	**19.1433 dB**	**-20.3635 dB**	**-20.3635 dB**

C. DESIGN OF WPD BASED UWB MIMO ANTENNA

Design 1 is limited to classical representation of attaining UWB with MIMO antenna. Design 2 is proposed to avoid the challenges like individual feeding system and high Return loss. The proposed antenna with MIMO acts as type of array for common excitation. Two resistors are placed near the input ports to provide better isolation. The WPD is designed with proper positional and dimensional optimizations. This approach for required application is evaluated and commended with proper study of antenna result parameters.

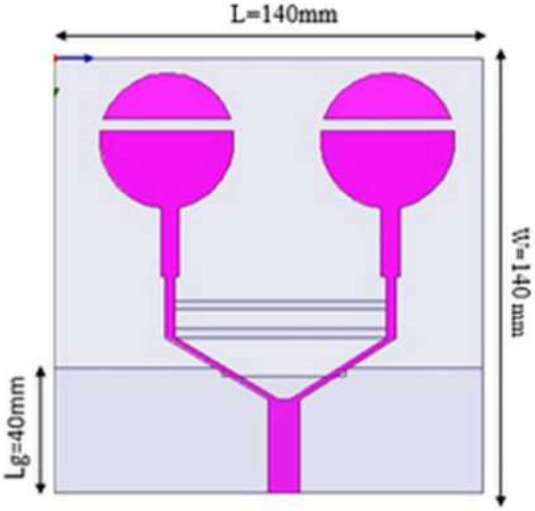

Fig.14. Design of Wilkinson Power Divider Based UWB MIMO Antenna

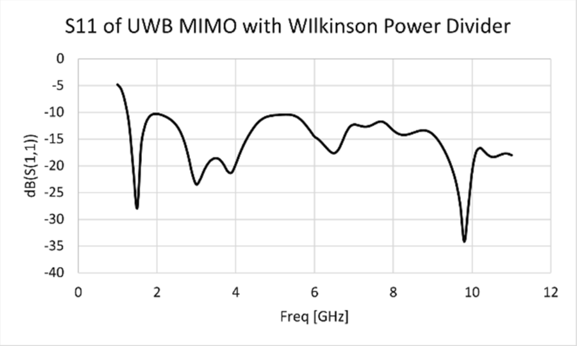

Fig.15. S11 of Wilkinson Power Divider Based UWB MIMO Antenna

Bandwidth of Ultrawide band is less than -10dB for proposed antenna.

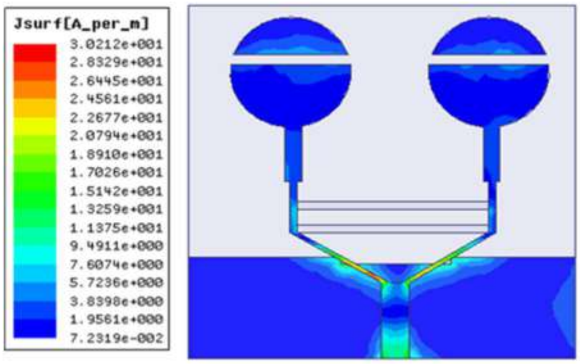

Fig.16. Current Distribution of Wilkinson Power Divider Based UWB MIMO Antenna

With slots etched on both patch and ground plane, the current distribution is presented. Here, the resistors placed are active elements which provide isolation for both input ports.

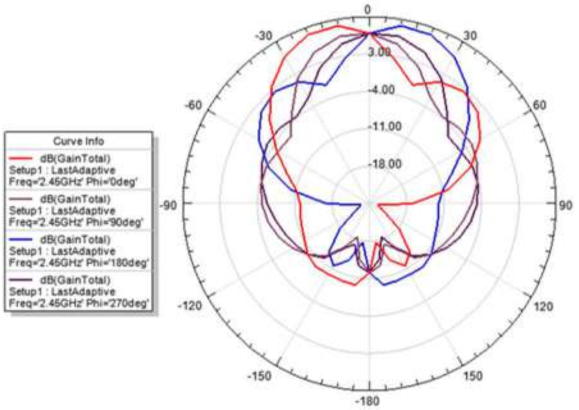

Fig.17. Radiation Pattern of Wilkinson Power Divider Based UWB MIMO Antenna

Evaluated at π= 0˚,90˚,180˚,270˚ and 360˚, the gain obtained for the proposed antenna is nearly 3dB.

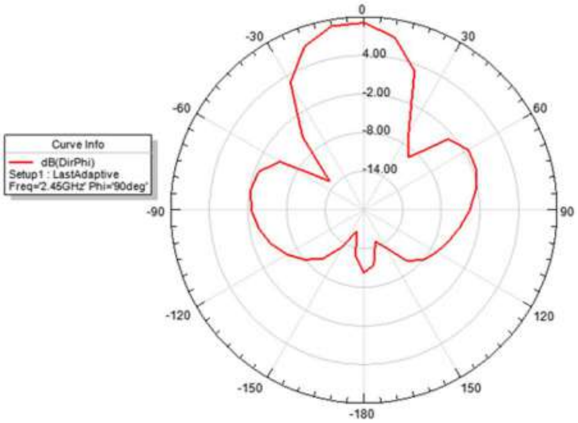

Fig.18. Co-Polarization of Wilkinson Power Divider Based UWB MIMO Antenna

Co-polarization and Cross-polarization of an antenna indicates the radiation of E-fields in its actual and orthogonal direction. Both the polarizations are indicated.

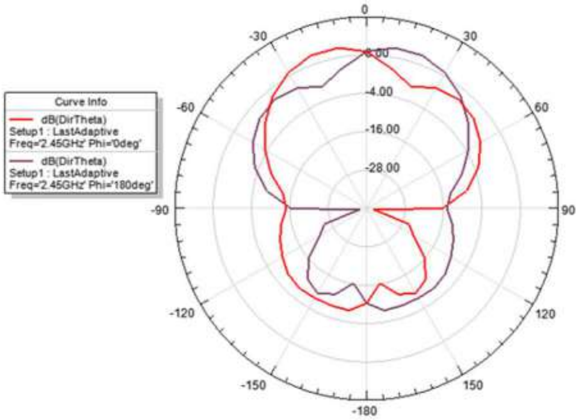

Fig.19. Cross-Polarization of Wilkinson Power Based UWB MIMO Antenna

III. RESULTS

Proposed antennas are designed and simulated in HFSS software. With solution frequency of 2.4GHz, the results are evaluated in terms of Return loss, Bandwidth, Gain and Current distribution. Below is the table which represents the antenna parameters and their responses for both design 1 and design 2.

Table II. Comparison of antenna parameters at 2.4GHz.

Parameters	**Design 1 (Fig.1)**	**Design 2 (Fig.14)**
S11	**-19.64dB** at **2.4GHz** (Bluetooth) **-10.9 dB** at **3.5GHz** (WiMAX) **-10.4dB** at **4GHz** (C-Band) **-21.5dB** at **5.5GHz** (WLAN) **-12.4dB** at **7.7GHz** (X-Band)	**-11.65dB** at **2.4GHz** (Bluetooth) **-18.5 dB** at **3.5GHz** (WiMAX) **-19.6dB** at **4GHz** (C-Band) **-10.6dB** at **5.5GHz** (WLAN) **-11.7dB** at **7.7GHz** (X-Band)
Bandwidth (dB)	**3.1-10.6GHz**. <-10dB **9-9.9GHz** <-8dB	**3.1-10.6GHz** <-10dB

Gain (deg)	**7dB** at **2.4GHz**
	Ɵ=0˚ to 180˚
	Π=90˚
		3dB at **2.4GHz**
		Ɵ=0˚ to 180˚
		Π=90˚

Current Distribution (in W)	1W for each port	2W

The proposed work is compared to previous related works [23] [24] [25], their important parameters are compared and analysed in Table III.

Table III. Comparison of proposed work with existing works.

Related works	**S11**	**Bandwidth (dB)**	**Gain (dB)**
[23]	<-15dB	**3.1-11.2GHz** Band rejection at **3.1-3.8GHz** (Wi-Fi) **5.2-5.8GHz** (WLAN)	Ranges from **2.5-5.5 dB** at given bandwidth
[24]	<-5dB	**2.5-10.6GHz** Band rejection at **5.2-5.8GHz** (WLAN) **7.92-8.395 GHz** (Uplink X-band) **7.252-7.75 GHz** (Downlink X-band)	**14dB** at **3.8GHz** **15dB** at **5.6GHz** **18dB** at **10GHz**
[25]	<-10dB	**3.4-11.7GHz**	**5dB** at **4.1GHz** **5dB** at **5GHz** **5dB** at **9.5GHz**
Proposed work	<-10dB	**2.4-10.6GHz**	**3dB** at **2.4GHz**

IV. CONCLUSION

In this paper, a UWB MIMO antenna is designed and simulated. Antenna excitation for multiple feed sources is analyzed. To avoid individual feeding systems, Wilkinson power divider is integrated with the MIMO system. This increases the Return loss of UWB frequency range throughout its bandwidth. The wireless application frequencies like Bluetooth, WLAN, WiMAX, C-Band, X-Band show decent Return loss in both the cases. Gain and current distributional changes for each antenna is briefed.

The results obtained for both individual fed and Wilkinson fed antenna is discussed. It is concluded that MIMO system with multiple source feeding involves the antenna radiation at different port stages. Using Wilkinson power divider, the gain and overall bandwidth Return loss has been amplified. Moreover, it provides better isolation which helps in achieving desired output.

***Abstract*—Predictive emission monitoring systems for gas turbines are important in the power generation industry. A key task in this context these systems is the prediction of flue gas emissions using process and environmental measurements that are easier to obtain. This paper presents methods for such predictions with an emphasis on explainability. A notable result is that despite the potential restrictions imposed by this emphasis, the numerical accuracy compares very favorably with prior work that uses models that are more difficult to explain.**

***Index Terms*—Predictive Emission Monitoring Systems; Exhaust Emissions Prediction; Gas Turbines; CO; NOx; Machine Learning.**

I. Introduction

Monitoring emissions from industrial systems, such as flue gas emissions from turbines, and in particular emissions of CO (carbon monoxide) and NOx (nitrogen oxides), are of growing environmental and regulatory concern and, consequently, there is a growing need to measure and estimate them accurately. While direct measurements are an obvious and effective method, such measurements often come with high associated costs in equipment, maintenance, and operations. There is therefore significant interest in estimating or predicting these emissions using other, more easily measured variables, such as temperatures and pressures in different parts of a turbine.

This paper studies such predictions of CO and NOx emissions experimentally, using a recently published dataset from prior work. A notable feature of this work is the emphasis on explainable predictions in addition to prediction accuracy.

The main contributions are:

- A detailed exposition of a valuable dataset from prior work, making it more accessible to further research.
- An experimental study of prediction accuracy of explainable methods.
- A detailed examination of some concrete predictors produced by such methods.
- A quantitative investigation of the merit of the attributes in this dataset for prediction.

The main results are:

- Contrary to what may reasonably be expected, limiting prediction models to those that are easily explainable does not result in a penalty in prediction accuracy.
- Simple and well understood explainable methods, such as M5P in particular, provide accuracies that are higher than those reported by more opaque models in prior work on the same dataset.
- Measures of attribute merit based on the *Relief* algorithms are better suited to this data than are measures based on correlation.

Outline: The domain and dataset motivating this work is described in Section II. Explainable prediction methods are outlined in Section III, followed by an experimental study of their prediction accuracy in Section IV. A few representative concrete predictors are examined in Section V. Attribute merit and selection is studied in Section VI. Related work is described by Section VII and Section VIII provides a summary.

II. Dataset

The work in this paper is based on a recently published dataset of turbine flue gas emissions due to prior work [1], [2]. The data span the years 2011 through 2015 and there are 36733 records in total. Each record includes the year in which it was collected along with the values of the attributes summarized by Table I. The first three columns of that table, which list the abbreviations, descriptions, and units of the attributes, are from the original dataset documentation while the remaining columns, which provide a brief description of the distributions of each attribute's values, are computed from the base dataset. The attributes in bold font, **CO** and **NOx**, are the dependent variables and the others are the independent variables.

Fig. 1 summarizes the attribute-value distributions using histograms. While the distributions of some attributes, such as ambient temperature (AT) and ambient humidity (AH) are unsurprising, some of the other attributes, such as compressor discharge pressure (CDP) and gas turbine exhaust pressure (GTEP), have interesting multimodal distributions. Others, such as turbine after temperature (TAT) and turbine inlet temperature (TIT) are characterized by highly skewed distributions and this observation may also be confirmed by noting the high magnitudes of the related statistics in Table I.

TABLE I
ATTRIBUTES IN THE TURBINE FLUE GAS EMISSIONS DATASET [1] ALONG WITH SOME COMPUTED STATISTICS.

Attr.	Description	Unit	Min	Mean	Variance	Skewness	Kurtosis	Max
AFDP	Air filter difference pressure	mbar	2.09	3.93	0.60	0.38	0.22	7.61
AH	Ambient humidity	%	24.08	77.87	209.13	-0.63	-0.27	100.20
AP	Ambient pressure	mbar	985.85	1013.07	41.77	0.19	0.44	1036.60

TIT	Turbine inlet temperature	C	1000.80	1081.43	307.52	-0.89	-0.05	1100.90

III. PREDICTING CO AND NOX

The primary task in the context of the dataset of Section II is predicting the values of the CO and NOx attributes given the values of some or all of the other attributes. Prior work has addressed this task using the connectionist approach and, in particular, using extreme learning machines (ELMs) [1]. In contrast, the focus of this work is on the use of simpler and more explainable machine learning methods. In addition to permitting human oversight and fine tuning, these models also exhibit very competitive accuracy, as summarized in Section IV. In particular, the mean absolute errors in prediction of several of the options listed below are lower than those reported in prior work on the same dataset.

A baseline is established by the 0-R (ZerR) method which predicts the overall mean value of the dependent attribute regardless of the values of the other attributes in an instance. The rule-based DTab method uses Decision Tables [3]. The LinR method uses linear regression with the Akaike information criterion [4]. The related SLin method uses simple linear regression, picking the attribute that gives the lowest squared error. The M5P method uses the *M5'* model tree algorithm [5], [6]. The REPT method builds a regression tree, using information gain, which is pruned using backfitting and reduced-error pruning. The RanT method builds a regression tree by randomly selecting k attributes at each node, using the implementation's default value of $k = 1 + \lfloor \log_2(m) \rfloor$, were m is the number of independent attributes. In this work, m is 9 (10 for one set of experiments) giving $k = 4$. Finally, RanF uses the popular Random Forest ensemble learning method [7].

IV. EXPERIMENTAL EVALUATION

The first set of results is summarized by Figs. 2 and 3, which depict the mean absolute error in the predictions of CO and NOx, respectively, for each calendar year of records in the dataset and for each of the methods noted earlier. In this set of experiments, the dataset was segmented by year and each method was evaluated on each segment using conventional 10-fold cross-validation. While there are a few easily discernible trends across dependent variables, years, and methods, one particularly notable one is the high accuracy of the M5P method. In this and other experiments (unless noted otherwise) the dependent attributes (CO and NOx) are predicted using only the independent attributes. That is, when studying the accuracy in predicting one dependent attribute, the other is excluded from the dataset completely during both training and testing phases.

The above experiments do not distinguish records within each segment by times of observations. Indeed, the dataset includes no timestamps beyond the year of observation, making such considerations difficult to address. To characterize the practical requirement that predictions are most useful when made forward in time, the next set of experiments makes predictions for each calendar year models trained on only the data from the previous calendar year. (The very first year, 2011, is included in training but excluded for predictions, and conversely for the very last year, 2015.) The results are summarized by Figs. 4 and 5. As may be expected, the greater restriction on the training data in comparison with that used by the earlier experiments maps to greater errors in prediction in general. However, as the figures illustrate, some of the methods are more resilient than others in this regard. In particular, the M5P method continues to exhibit the lowest or close to lowest errors in prediction for both CO and NOx.

The next set of experiments studies the effect of the availability of measured values of one of the dependent attributes when predicting the other. That is, unlike in all the other experiments reported here, this set of experiments retains the values of the CO attribute when training and testing a model for predicting NOx, and vice versa. Apart from gaining a better understanding of the data in general, this setup may also have practical ramifications in situations where one of the dependent variables is easier to measure (or to measure more frequently) than the other. The results are summarized by Figs. 6 and 7 using the same conventions as earlier figures. While there are small differences across methods and years, a general observation here is that the availability of the other dependent attribute's value does not significantly improve

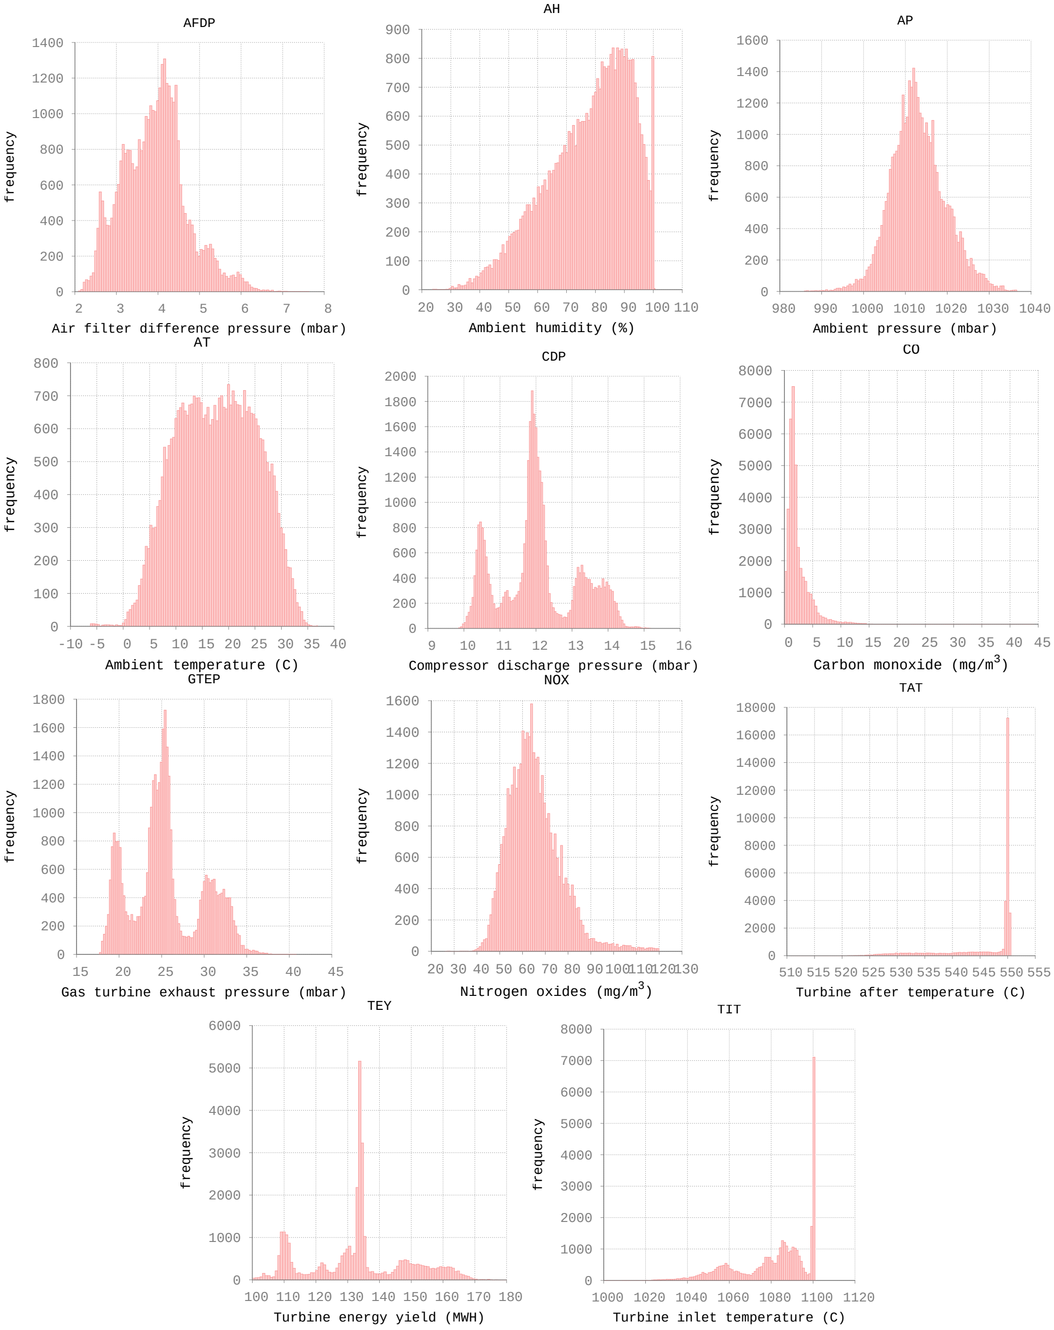

Fig. 1. Histograms for the attributes (Table I) in the experimental dataset [1].

prediction accuracy.

V. Examining Predictors

As noted earlier, this work emphasizes the use of explainable predictions and predictors in addition to the usual quality metrics studied in the previous section. It is interesting to note that one of the more consistently accurate predictors for this dataset is also one that produces prediction models that are scrutable to humans: The M5P ($M5'$) predictor. The implementation underlying the experiments reported in Section IV allows interactive examination of the tree produced by M5P as well as similar artifacts from other methods. A static version of a portion of such a tree appears in Fig. 11. In M5P, the leaves represent linear regression models while the interior nodes serve to guide the prediction to the best linear regression model by using the values of other attributes for branching. A representative sample of the linear regression models at the leaves appears in Fig. 10. Although this particular model is a rather large tree, it is nevertheless intuitively easy for a human to comprehend.

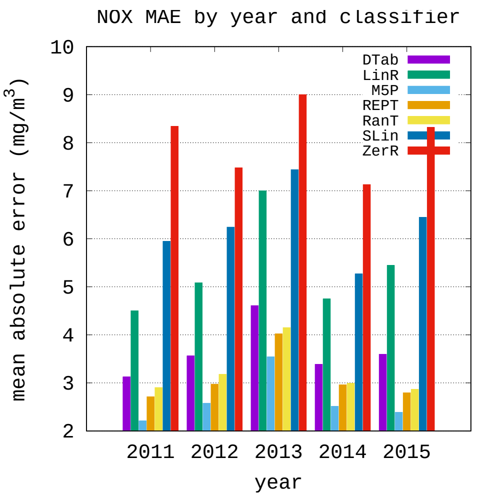

Fig. 3. Mean Absolute Error in NOx prediction by classifier and year.

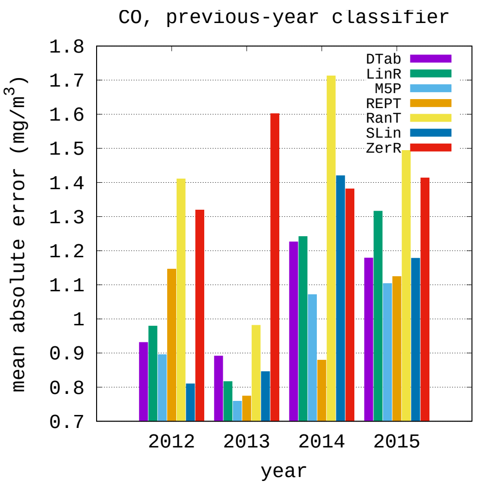

Fig. 4. Mean Absolute Error in CO prediction by previous-year classifier and year. (Year 2011 is used for training models for year 2012 but cannot be used for testing given this restriction.)

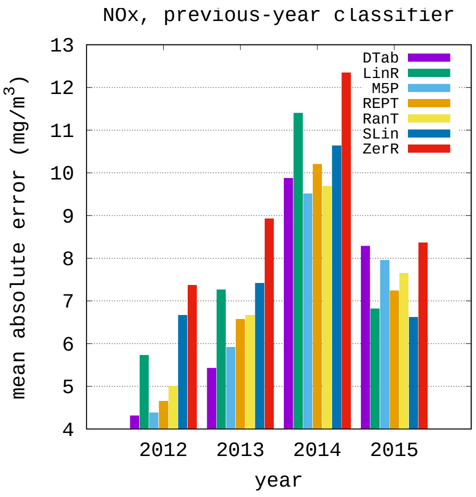

Fig. 5. Mean Absolute Error in NOx prediction by previous-year classifier and year. See also Fig. 4.

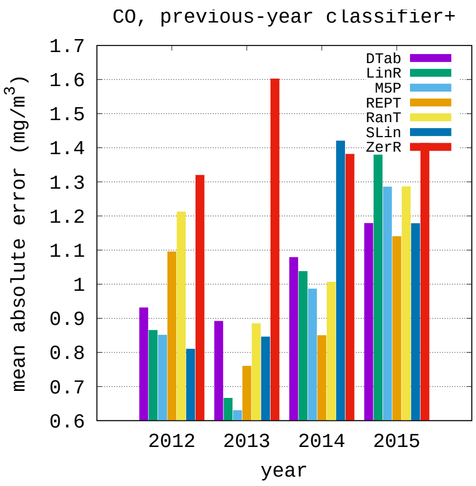

Fig. 6. Mean Absolute Error in CO prediction by previous-year classifier and year, using the other dependent attribute as well.

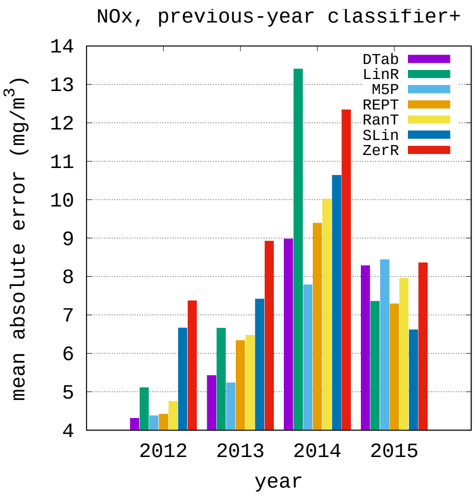

Fig. 7. Mean Absolute Error in NOx prediction by previous-year classifier and year, using the other dependent attribute as well.

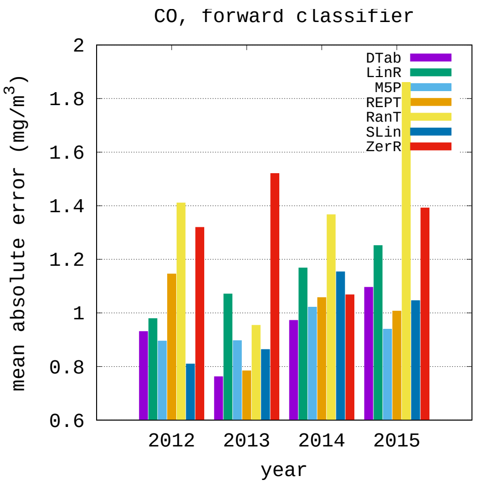

Fig. 8. Mean Absolute Error in CO prediction by forward classifier (using only historical data for each year) and year, using the other dependent attribute as well.

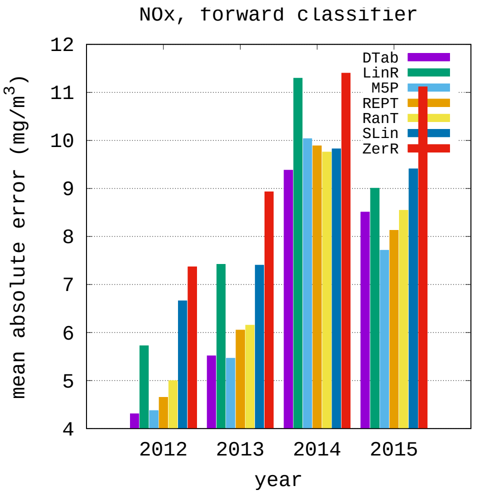

Fig. 9. Mean Absolute Error in NOx prediction by forward classifier (using only historical data for each year) and year, using the other dependent attribute as well.

Another one of the more accurate methods from the previous section, Decision Tables (DTab) also produces models that are suitable for human interpretation, although their tabular form is different from the hierarchical nature of the tree-based models such as M5P or RanT. An excerpt of the decision table produced for predicting NOx values using the 2015 data appears in Fig. 12.

VI. Attribute Merit

Measures of attribute merit (for regression) are frequently used to trim the set of attributes used for prediction. Although the set of attributes in the dataset and underlying domain in the present case is quite small, it is nonetheless useful to examine attribute merit to determine if some attributes may be omitted without significant negative impact on prediction accuracy.

Fig. 12. An excerpt of regression using a decision table.

Omitting an attribute may remove the need for hardware and other costs associated with its measurement.

Figs. 13 and 14 summarize the results of experiments quantifying attribute merit using the correlation metric. The results are a bit counter-intuitive as they allot low scores to several attributes that are intimately associated with the turbine operations (e.g., TIT, TAT, GTEP) and that may be reasonably assumed to have a significant impact on emissions.

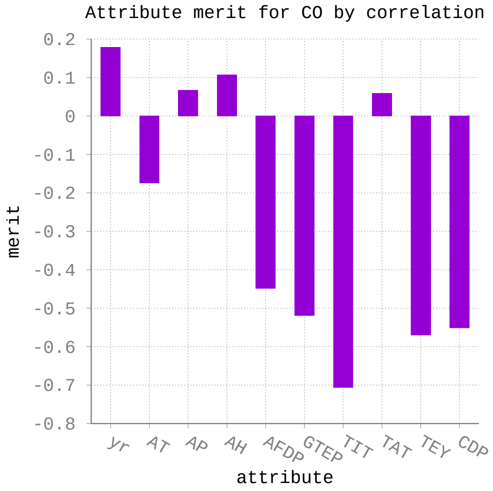

Fig. 13. Attribute merit using the correlation metric for CO prediction using combined data for all years 2011–2015.

Figs. 15 and 16 summarize similar results using the *RReliefF* metric of an attribute, which metric evaluates, for each instance (sampled), the value of that attribute for the nearest instances of the same and different classes [8]–[10]. A notable feature of this and related *Relief*-based attribute merit metrics is that they use contextual information to better estimate the merit of attributes in the presence of strong dependencies. With this metric, in contrast to the correlation metric above, some of the turbine sensor attributes have high scores, as does the air temperature (AT) attribute. These observations invite further study using a pruned set of attributes for predictions, and such work is ongoing.

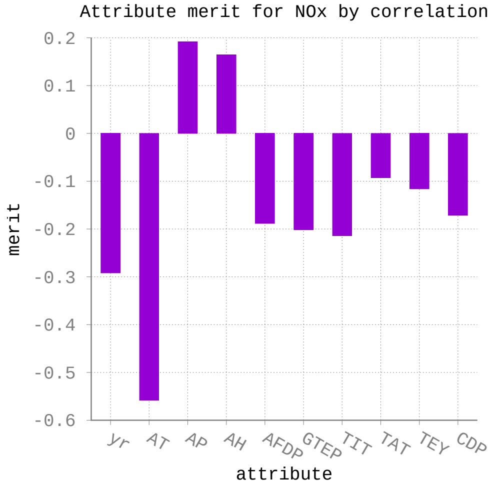

Fig. 14. Attribute merit using the correlation metric for NOx prediction using combined data for all years 2011–2015.

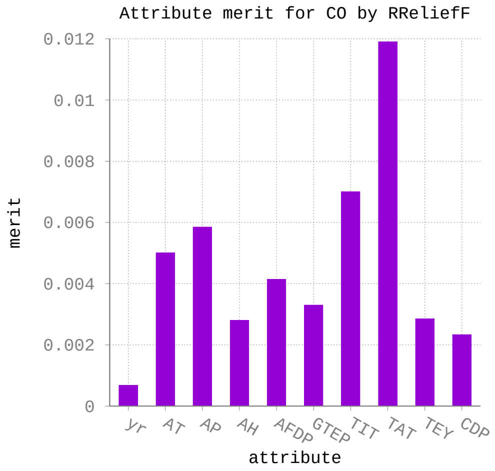

Fig. 15. Attribute merit using the *ReliefF* metric for CO prediction using combined data for all years 2011–2015.

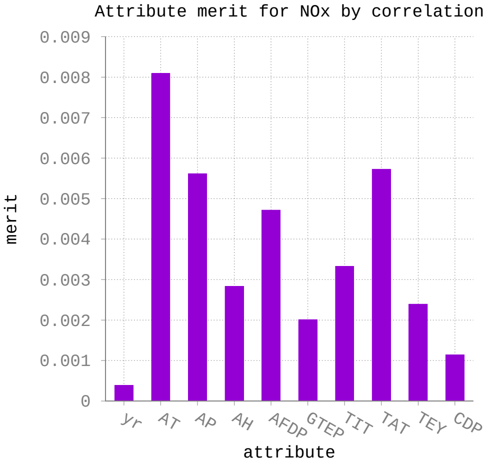

Fig. 16. Attribute merit using the *ReliefF* metric for NOx prediction using combined data for all years 2011–2015.

VII. Related Work

This work was motivated and enabled by prior work using the same dataset that used extreme learning machines (ELMs) for prediction and that provided the dataset as well [1]. This work focuses on explainable results and initially anticipated that emphasis to translate to a modest penalty in prediction accuracy. However, contrary to this expectation, the accuracy of the explainable models here is comparable and typically higher than the accuracies reported earlier, which is a very encouraging result. Although not included in this paper, some experiments on attribute selection with this data also use principal components analysis (PCA), and share some characteristics with work on dimensionality reduction [11].

The methods of this work are part of a larger class of data driven methods that have been successfully applied in diverse domains, such as financial indexes [12]. The evaluation of attribute merits and subsequent selection of a small subset of attributes may be viewed as an optimization problem with regression accuracy as merit and weighted costs of attributes (modeling physical-world costs of acquiring those data) as cost. It may then be studied in the context of the very large and diverse body of work on optimization methods and applications [13], [14].

VIII. Conclusion

Predicting CO and NOx levels in turbine flue emissions is a task of growing importance given the increasing need for such monitoring. While direct measurements provide the most reliable values, they are cumbersome and expensive. Augmenting such direct observations with predictions from more easily and inexpensively measured attributes, such as temperature and pressure values in the ambient environment and at key locations in the turbine, is a valuable way of reducing the cost and complexity of monitoring.

This paper has reported on an experimental study of the accuracy with which such predictions may be made, using a recently published dataset from prior work. In contrast to some earlier work, a notable feature of this work is the emphasis on explainable predictions. While one may reasonably expect this emphasis (restriction) to imply a penalty in prediction accuracy, the study reveals quite the opposite: These predictors provide higher accuracies than those reported in prior work on the same data. Ongoing work is studying the use of attribute merit metrics to trim the set of attributes used for prediction. Evaluations on other datasets are also planned.

Waterloo, Ontario, Canada
a24ibrah@uwaterloo.ca

***Abstract*—Data collected from social media such as tweets, posts, and blogs can assist in an early indication of market sentiment in the financial field. This has frequently been conducted on Twitter data in particular. Using data mining techniques, opinion mining, machine learning, natural language processing (NLP), and knowledge management, the underlying public mood states and sentiment can be uncovered. As cryptocurrencies play an increasingly significant role in global economies, there is an evident relationship between Twitter sentiment and future price fluctuations in Bitcoin. This paper assesses Tweets' collection, manipulation, and interpretation to predict early market movements of cryptocurrency. More specifically, sentiment analysis and text mining methods, including Logistic Regressions, Binary Classified Vector Prediction, Support Vector Mechanism, and Naïve Bayes, were considered. Each model was evaluated on their ability to predict public mood states as measured by 'tweets' from Twitter during the era of covid-19. An XGBoost-Composite ensemble model is constructed, which achieved higher performance than the state-of-the-art prediction models.**

Keywords*—Bitcoin, Sentiment Analysis, Market Movement, prediction Models, Ensemble Modeling, Validation Measures.

I. Introduction

Cryptocurrencies, such as Bitcoin, Ethereum, and Litecoin, are an alternative class of digital assets primarily used as a medium of exchange [1]-[5]. Public key cryptography and blockchain technology are utilized to facilitate decentralized peer-to-peer transactions. Bitcoin, created in 2009, is widely regarded as the world's first cryptocurrency. Following Bitcoin's success, numerous other cryptocurrencies, dubbed 'altcoins' have been developed. The rise of Bitcoin and altcoins has produced a deluge of data on social media platforms, blogs, forums, and countless other online mediums. There have been quite a few researchers trying to predict Bitcoin prices' behavior based on its emotions on social media platforms, such as Twitter, using various machine learning algorithms [6]-[8]. Researchers have been known to get some significant prediction results. However, very few focus on using ensemble modeling to achieve better prediction results.

XGBoost is an ensemble classifier that provides benefits such as no need for normalized data, scalability to larger data sets, and rule-based behavior that is easier for people to interpret. Thus, this paper aims to propose a Composite Ensemble Prediction Model (CEPM) using the notion of sentiment analysis. The CEPM framework is comprised of five stages, 1) text preprocessing, 2) Sentiment Scoring, 3) individual XGBoost classifications, 4) composite ensemble aggregation, and 5) model validation. In stage1, various preprocessing steps are performed, including word quantization, text stemming, and stop word removal. The second stage includes converting tweet text into a sentiment score as a representative of its emotion. Such a task is suited to VADER, a lexicon and rule-based sentiment analysis tool that can deal with the syntax usually used on social media. In the third stage, various instances of the XGBoost classifiers are used. The ensemble modeling is designed to maximize the model performance by utilizing a stacking of ensembles using a majority vote of XGBoost ensembles. Finally, the composite ensemble model is validated using accuracy, recall, precision, and F-scores quality measure. Experimental analysis on Twitter datasets collected during the era of COVID-19 shows that the CEPM model outperforms the individual models. It can be effectively used as an efficient (Bitcoin) BTC predictor to forecast the early market movement of Bitcoin even after the COVID-19 pandemic.

The rest of this paper is organized as follows: Section 2 provided a literature review. In section 3, the text preprocessing is discussed. Vader scoring is presented in section 3. Section 4 presents the adopted classifiers. In section 5, the proposed staking ensemble is introduced. Experimental results and analysis are discussed in section 6. Finally, section 7 concludes the paper and highlights future directions.

II. Literature Review

Several attempts have been made that uses sentiment analysis to predict the early market movement of cryptocurrencies using tweets sentiment [9]-[17]. In [9], authors compared the causality of tweet sentiments, tweet volume, and buyers' ratio to sellers on Twitter with the price returns and daily trading volumes of cryptocurrencies. It has been speculated that sentiments expressed on Twitter could help in predicting cryptocurrency price changes. Li et al. [10] have attempted to demonstrate this concept by training an Extreme Gradient Boosting Regression tree model (XGBoost) with Twitter sentiments to predict ZClassic price changes. The research in [10] provided the KryptoOracle to predict the Bitcoin price for the next minute

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

using current and historical data from Twitter sentiments and Bitcoin closing prices. XGBoost, a regression tree model, was used because of its performance, speed, and retraining simplicity. In [13], Jain et al. attempted to predict the prices of Bitcoin and Litecoin two hours in advance based on the sentiments expressed in current tweets. They wanted to investigate if social factors could predict the prices of cryptocurrencies. So they used a Multiple Linear Regression (MLR) model to predict a bihourly average price from the number of positive, neutral, and negative tweets accumulated every two hours. Authors in [14] compared the significance of different preprocessing techniques for tweets' sentiment analysis. They used four different machine learning algorithms to classify tweets, and they tested 16 different preprocessing methods. Based on their results, it was recommended to use lemmatization, replacing repeated punctuation, replacing contractions, or removing numbers. The research work in [17] attempted to characterize Twitter users who use controversial terms when mentioning COVID-19 on Twitter and trained various machine learning algorithms for classifying such users. The machine learning algorithms trained on these attributes included Logistic Regression, Random Forest, Support Vector Machine, Stochastic Gradient Descent, Multi-Layer Perceptron, and XGBoost. Random Forest had the highest AUC-ROC score out of all algorithms when trained on the baseline, demographic, and geolocation data.

III. TEXT DATA PREPROCESSING METHODS

To categorize a large data set as Twitter, the data be appropriately cleaned to save computational time and increase the data manipulation's overall accuracy. In heavily text-based datasets, stemming and stop word analysis are crucial in the proper analysis [19]-[22].

A. *Text Stemming*

Stemming is a pre-processing method utilized in text mining, natural language processing, and information retrieval applications. It is an effective approach to reduce grammatical and word conjunctions to essentially extract the root form or “stem” to improve searching by automatic sorting of word endings at the time of indexing and searching. Since certain words have similar semantic meanings but different word forms, stemming allows for a reduction in the number of distinct terms in a document and increases the number of retrieved documents. The decrease in overall variability of the text, thus shortening the final output processing time for an Information Retrieval System. In stemming, converting a word to its stem assumes each is semantically related, leaving separate words with different meanings. Two main errors occur with stemming: Over-stemming and under-stemming. In over-stemming, words with different stems are stemmed from the wrong root (false positive), and under-stemming is when words that should be stemmed to a specific root are not (false negative). Porter's stemming is an example of a truncating method that removes suffixes or prefixes of a word. It consists of five steps, where within each step, rules are applied until a condition is met. The suffix is removed if the condition is completed and the subsequent step is performed. The result at the end of the 5th step is the resulting stem. The rules follow the syntax: Porter Stemming usually provides a much better output compared to other stemmers, has less stemming error rates, and also the Porter Snowball stemmer framework is independent of the language being used. A drawback of using the porter stemming algorithm is that the stems produced are not always real words, and the five steps in the algorithm make it a time-consuming process.

B. *Stop Word Removal*

Stop words in documents occur frequently but are effectively insignificant as they are used to join words in sentences. These words do not contribute to the context, and due to their frequency, they hinder information comprehension. Therefore, they are removed because they increase the amount of text in data slowing down information retrieval effectiveness in text mining. Stop words include words like "and", "are", "because" etc.

IV. SENTIMENT ANALYSIS USING VADER SCORING

To categorize tweets, the words must be assigned a positive or negative relative to cryptocurrency markets. A predefined value was assigned to the tweet's specific words to predict cryptocurrencies' probability of increasing or decreasing based on tweet sentiment. These words were cross-referenced with programming libraries containing lexicons of words that were assigned positive and negative values. The text used in early market predictors for cryptocurrencies using tweets was weighted positively or negatively based on these predetermined values.

VADER is a lexicon and rule-based sentiment analysis tool that can handle words, abbreviations, slang, emoticons, and emojis commonly found in social media [23]. It is typically much faster than machine learning algorithms as it requires no training [23][24]. For each body of text, it produces a vector of sentiment scores with negative, neutral, positive, and compound polarities. The negative, neutral and positive polarities are normalized to be between 0 and 1. The compound polarity can be thought of as an aggregate measure of all the other sentiments, normalized to be between -1 (negative) and 1 (positive). VADER was introduced by C.J. Hutto and Eric Gilbert [24]. They found that it performed better than most other sentiment analysis tools and even surpassed some human judges.

V. FORECASTING MODELS

Several machine learning algorithms can be used to drill down the data to analyze how Twitter can be an early market indicator for cryptocurrency prices. Historical research indicates that the most commonly used Twitter Sentiment analysis tools include Vector Support Machines and Naïve Bayes to categorize the data into positive or negative reflections for cryptocurrencies in the market.

A. *Support Vector Machines (SVM)*

SVM is a supervised machine learning algorithm that can be used for classification. In this algorithm, each data item is plotted as a point in n-dimensional space (where n is the number of features), with the value of each feature is the value of a particular coordinate. For a binary categorization problem, the classification is performed by finding the hyperplane that differentiates the two classes, effectively separating the data

.

using an n-dimensional plane. In cryptocurrency Tweet predictors, the support vectors are positively or negatively valued words in tweets. SVM can be used to clearly and accurately predict an optimal threshold for positive or negative sentiment towards a cryptocurrency given a given tweet. In cases where there is no optimal solution utilizing a simple one-dimensional line, and data points have substantial outliers, the data needs to be graphed in a higher dimension. It is possible to create an n-dimensional hyperplane by transforming the data set that utilizes the same maximum distance characteristics as a two-dimensional hyperplane. By using kernel functions, mapping the data in higher dimensions is possible. For SVM, kernel functions can be represented in 3D space. These functions take low dimensional input space and transform them into a higher-dimensional space, therefore converting a non-separable problem to a separable problem. As the Logistic regressors do not optimize mislabeled data, we use SVM to minimize the classification error rather than solely rely on Naïve Bayes' likelihood. Therefore, the support vector machines model is chosen for the classification of mislabeled data. Using the hyperplane solution and mapping in the 3D plane, misplaced data can be encompassed in the proper classification. For applications in Twitter and cryptocurrencies, any Tweet related to cryptocurrencies is weighted with positive and negative values, then a hyperplane is placed to separate the data points. Once an initial hyperplane or line is determined and separates the data from each other, the ideal placement is determined. Maximizing the distances between the nearest data point and hyperplane determines the optimal solution. Once this best separating hyperplane is found, all data points added to the data set will be classified based on their position relative to the hyperplane.

B. *Naïve Bayes Classifier*

The Naïve Bayes classification is a simple model to apply to text mining. Naïve Bayes is practical as its assumptions include a feature vector and dependant variable Y. The optimal classification is determined through the maximum likelihood of the given function: While sentiment can have either a positive and negative meaning, for the sake of simplicity in this paper, a simple binary classification is used for Naïve Bayes classification. Thus or large amounts of data with a short 140-character document such as tweets, conditional-based probability can easily be used. There is little opportunity for varying thoughts in tweets about sentiments. This is based on the feature vector, words that are determined to be a positive or negative sentiment. Specifically, the frequency of these texts is collected for this specified model. In NB, targeted positive and negative words can be thought of as cues that direct each document being classified. Any words that appear multiple times with an insignificant or words that cannot be determined under any class can be removed from the documents to cleanse the data to ensure that probability calculations are more accurate. To account for negation, further manipulation of data with the addition of specific text to tag words with a negated meaning can then be counted as cues towards positive or negative sentiments accurately. The words are randomly grouped to determine the document's sentimental value, and each word's frequency is counted. Regardless of the word's position in a document, the words are placed to decrease frequency. This is based on the assumption that the word's position in the text does not affect how it is depicted in a document. The binary variable of each word is counted to determine the sentiment of the document. In this example, the tweet determines whether it is positive or negative or if the Bitcoin price increases or decreases. The maximum likelihood function is used using the prior class's probability with the likelihood that the document is given the class. Since we assume that the documents are independent of each other and do not affect the class, the maximum likelihood function becomes simpler to solve. Though the independence assumption is usually a constraint to using this model, tweets from individuals are unrelated to each other; thus, the independence assumption favorably works with the model.

VI. The Proposed Composite Ensemble Prediction model (CEPM)

We built a composite of the Extreme Gradient Boosting (XGBoost) using a majority vote over multiple cross-validations iterations. This composite is used to achieve a better overall prediction accuracy than baseline classifiers and individual boosting algorithms. XGBoost is a novel machine-learning algorithm that improves the gradient boosting decision tree (GBDT) and can be used for classification and regression problems [18]. XGBoost is a boosting-tree approach that integrates many weak classifiers to form a robust classifier. It uses the CART, classification, and regression tree model.

The CEPM framework is comprised of five stages, 1) text preprocessing, 2) Sentiment Scoring, 3) individual XGBoost classifications, 4) composite ensemble aggregation, and 5) model validation. In the initial stages, various preprocessing steps are performed, including text stemming and stop word removal. The second stage includes converting tweet text into a sentiment score using VADER. The VADER sentiment analysis algorithm was used to assign each tweet a compound sentiment score based on how positive, negative or neutral their words were. The final sentiment score is factored in the number of Twitter followers, likes, and retweets associated with each tweet. The closing price of Bitcoin, the final sentiment score, and the moving average of the last 100 data points were four input variables for our machine learning models. In the third stage, various instances of the XGBoost classifiers are used. The ensemble modeling is designed to maximize the model performance by utilizing a stacking of ensembles using a majority vote of XGBoost ensembles. In this paper, a 10-fold cross-validation method was employed. The dataset was divided into ten parts, 9 of which were taken in turn as the training set, one as the test set. The average value of the ten results was used as the evaluation value of the algorithm performance. Meanwhile, the experiment repeated the above process ten times, and ten evaluation values were obtained for each model, and their mean values and corresponding 95% confidence intervals were counted. The CEPM ensemble model is then validated using various quality measures.

VII. Experimental Analysis and Results

A. *Evaluation Metrics*

It was found that a confusion matrix is the most commonly used measure to determine the quality of the methods used in predicting the real-value cryptocurrency trading strategies. The confusion matrix provides a visual performance assessment of a classification algorithm as a matrix, which is then used to determine the quality of the results given the classification problem. For example, a confusion matrix can analyze models for understanding sentiments toward bitcoin in Tweets. Based on the words used in association with the term "bitcoin," each tweet is assigned to a negative or positive category. Positive tweets are indicators of upward movements in the bitcoin price. The most popular metrics used to evaluate the results presented in a confusion matrix include accuracy, precision, recall, and F-score. Each metric gives a value that can communicate whether the model is a good model or not [25]-[29] .

Accuracy is computed by determining the percentage of observations that were labeled correctly. This measure has been used as evidence to support the quality of some models used to predict bitcoin pricing. However, accuracy is not the most reliable metric since accuracy provides misleading results as the classes are not balanced, as is the bitcoin market. Accuracy is given as a percentage. The closer this value is to 100%, the better the model's predictive ability is. Precision measures the ratio of correct positive inputs. Recall, also known as the sensitivity, measures the ratio of the items present in the correctly identified input. These metrics focus on the true positives, making their results more reliable. If Precision is a higher ratio, it represents a robust predictive ability by the model. Lastly, the F-score; takes the weighted average of precision and recall, taking both false positives and false negatives. This metric is beneficial in evaluating cases with uneven class distributions [30]-[34].

B. *Experimental Datasets*

We used the Twitter dataset from [35][36]. The preprocessing steps over time with BTC's closing prices are computed per minute. As tweets are created much more frequently than once a minute, we aggregated all tweets' scores into a per-minute. The CEPM ensemble model is validated using accuracy, recall, precision, and F-scores quality measure. It can be shown from Table 1 that the XGBoost ensemble has the highest Precision, recall, and F-score as compared to Logistic regression, SVM, NB, and a single XGBoost. We have assessed the proposed CEPM model's performance using "accuracy" as another quality measure, as shown in Fig.1. It can be shown from Table 2 that the CEPM model has achieved an improvement of up to 21%, 16%, 18%, and 22%, in the Precision, Recall, F-score, and accuracy, respectively, as compared to the LR, SVM, NB, and XGBoost. In Fig.2, it can be illustrated that the proposed CEPM takes more iterations measured by the increase in the computational time as compared to other algorithms. Further adjustment to the number of iterations is considered future work to balance the trade-off between accuracy improvement and time overhead.

TABLE I. PRECISION, RECALL, F-SCORE (COVID-19 TWEETS)

	Precision	Recall	F-score
LR	0.6743	0.4532	0.54207141
SVM	0.64843	0.5543	0.59768152
NB	0.665732	0.65421	0.65992071
(XGBoost)	0.78953	0.809532	0.7994059
CEPM	0.8926	0.883474	0.88801355

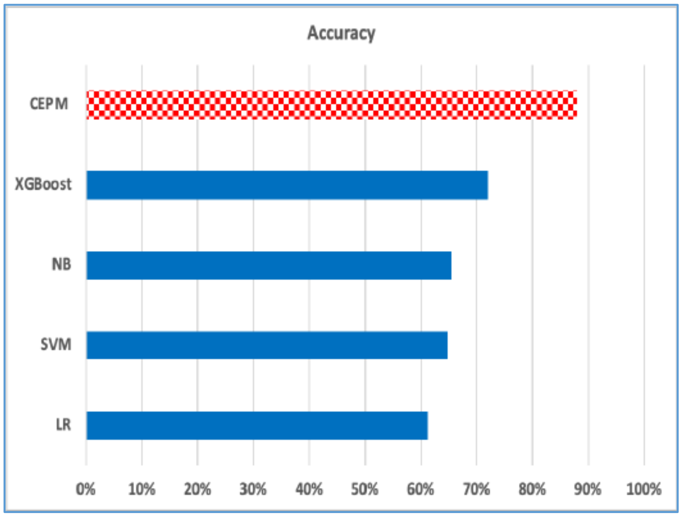

Fig. 1. Accuracy (COVID-19 Tweets)

TABLE II. % OF IMPROVEMENT IN PRECISION, RECALL, F-SCORE, ACCURACY (COVID-19 TWEETS)

Precision	Recall	F-score	Accuracy
21%	16%	18%	22%

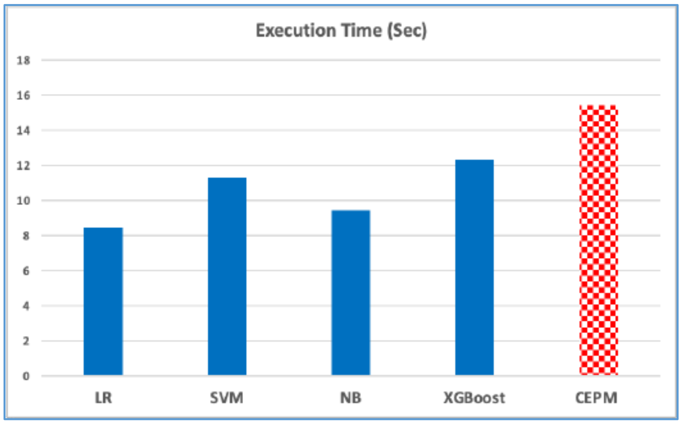

Fig. 2. Execution Time (COVID-19 Tweets)

VIII. CONCLUSION AND FUTURE DIRECTIONS

In this paper, we have developed a composite aggregate of the well-known XGBoost classifier to predict the BTC early market movement better. Experimental results show that the proposed CEPM outperforms other state-of-the-art techniques using Twitter datasets collected during the Era of COVID-19. The proposed model can be further adopted to forecast the BTC market even after the COV-19 pandemic to assess individuals and firms trading in future investments. Future research directions would include adjusting the number of incremental iterations of each XGBoost and incorporating various sentiment scoring schemes compared to VADER.

***Abstract*—In the era of digital transformation, when scholarly literature is rapidly growing, there are hundreds of papers published online daily in different fields, especially in the academic field. The huge volume of research papers published makes it difficult to find an expert/scholar to collaborate within a specific research area. This considers one of the most challenging factors in academia. Many researchers have proposed several methods to rank the authors based on their expertise in a specific area, focusing on co-citation, using keywords and their principal areas of research. The significant relationship or collaborations between scholars are credible. This paper explores the existing methods and tools in related studies to obtain author expertise among the scholarly network in determining the expertise in a specific area. Also, the semantic relations in the heterogeneous networks are presented with an overview of building a visual scholarly network that is beneficial in many pieces of research in data mining and related areas.**

Keywords— Expert Finding, Co-colleaperation, Semantic Similarity, Expert Scholar.

I. Introduction

Presently, the global collaboration between researchers expands that researchers and universities encourage knowledge and resource exchange. Researchers now disseminate their knowledge and publications throughout the world. Besides, digital technology has the power to bridge the distance and promote cross-disciplinary and cross-border collaborations inspiring scholarly networks enhancing the social activity experience at conferences creating a better professional network [1].

From 1945 till 1970 had been the age of rapid growth amongst scholars. Print publishing was customary in the years between 1971 and 1995. Subsequently, researchers experienced the digital age between the years 1996 to 2004. Since 2005, the era of open access and publications took 10 degrees shift. Thus, it is evident that the Internet had been the major contributor to the rise of scholarly community networks [2].

Besides, scholarly communities have revolutionized the method of information publication and research sharing. Many academic communities that provide guidance have emerged influencing the structure of the research community. The website ResearchGate was designed to facilitate access to scholarly research in increasing the collaboration between researchers. People from around the world get registered on this to retain an instant online presence. It allows researchers to maintain their online presence and provides them with a convenient platform to exhibit the research, before publication. Researchers frequently use such platforms to review the research with the scholarly community, in creating professional partnerships. Google Scholar that supports new, inexperienced scientists to obtain assistance and advice from experienced professionals in the field is the best example. Despite this easy access, there are shortcomings in accessibility, usability, support from a range of contributions, open infrastructure, and most importantly, community building in scholarly communication and publishing [3].

According to [4], 265 young researchers use the Internet for informal communication and social networking to create and publish their work. Hence, comprehending the academic and scholarly networks is essential in handling different aspects of ongoing research. The scholarly articles create a professional community where researchers build social networking and connections through old collaborations while creating new links with relevant work. A scholarly network allows improved personal visibility through online profiles of the publications, areas of expertise, and through related content sharing. In the scholarly sphere, a community is a cluster of researchers having similar perspectives on the areas of science. The literature is filled with identifying the communities within a network through structured texts. This assists in various aspects, not being limited to, finding the trend analysis, searching for bibliographic recommendations, and looking for experts in a specific area [5].

However, the academic knowledge contains a massive sum of research work and academic expert information. Every domain needs experts who research the relevant field to explore new dimensions in the specific field. An expert is a master of a particular domain and possesses in-depth knowledge of the related area. Experts have extraordinary subject knowledge in the area of expertise due to the number of years of experience and research work done over a while. In the past decade, obtaining assistance from an academic research expert has gained some attention in simplifying complex tasks. Researchers have developed expert finding systems based on Machine Learning and Natural Language Processing. They had worked with scholarly networks and had collected datasets from large organizational and academic databases to discover the expertise of an individual [6].

Searching for a resource-person is to know the expertise of someone, who excels in a particular area. In some instances, authors are from similar areas of expertise but differ in the specialized field. There are many papers written on computer science. Identifying an author specialized in computer science is crucial because, the author can be a specialist in Artificial Intelligence, Networks, Web Development, or Data Science. Similarly, it is applied to all other domains of science, technology, other humanities groups, and where research work is applied [7].

Despite the advancements in the research domain, this field is still progressing. The researchers are trying to make it more efficient, less time-consuming, and uncomplicated. Most of the studies that focus on automating this process by using the similarity of the keywords [8], the heterogeneous semantic similarity of texts [9], and collecting information about experts through citation networks [10]; containing a group of authors

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

with similar interests can be from different perspectives as presented in Fig.1.

This study presents an overview of studies to scout the author's expertise in the academic network. Also, exploring the heterogeneous information networks is presented through this. Searching for a potential collaborator or an expert within the network is one of the most challenging factors in academia. Additionally, an overview of the process of building a scholarly network is presented.

The rest of the paper is organized as follows. In Section II, we review some related works on the Expert Finding in Scholarly Data categorize them into four sections. While in Section III, we present a discussion on the limitations of the existing methods. The final Section IV concludes the paper with a summary.

II. EXPERT FINDING IN SCHOLARLY DATA

Recurrent Scholarly datasets make the complexity of the researchers improves gradually. This causes a growing interest in obtaining author expertise through an automated process since various researchers with different areas of expertise gather in conducting research projects.

In fact, in many instances, the researcher's expertise recognition is of vital importance. This can be conducted through qualitative attributes or evaluation since there is no known or established ground to assess the data and its needs.

A. Scholarly Data Analysis

There are several approaches under multi-type correlations amongst diverse academic entities within scholarly, big data environments. These industries and academic societies have attracted attention towards scholarly big data. There had been numerous studies conducted to explore international academic collaborations. The collaborator can identify through two aspects as behavioral and attitudinal perspectives [11].

Xia et al. [3], have presented a comprehensive survey of Big Scholarly Data (BSD). They have introduced the complete background of the BSD and have presented an overview of the relevant technologies used in data management. They start with scholarly data collection that has an acquisition framework and information extraction. Besides, they have performed various analyses on popular datasets like statistical analysis, scholarly network analysis, scholarly text mining, etc. They have also divided the scholarly network into five categories. That includes Co-author Networks, Citation Networks, Co-citation Networks, Bibliographic Coupling Networks, and Co-Word Networks. The Scholarly Text Mining is based on Textual Pattern Analysis and Topical Analysis.

Kwiek [12], has investigated the behavioural aspect, for the International Research Collaboration (IRC), and for the attitudinal aspect, the International Research Orientation (IRO) was studied. The dataset used for this study has collected through 17,211 survey forms filled by university scholars from 11 European countries. Additionally, the research has addressed an important question "What makes some European academics more prone to collaborating with international colleagues in research than others?" The results of the experiment found that for the academic-discipline, individuals in hard academic fields consider their research less internationally concerned (low IRO), while they are intensely collaborating with international communities (high IRC). The opposite situation was observed among individuals in soft academic fields. Whiles the results for the academic-generation factor in all 11 European countries for international collaboration, was the lowest among the younger generation of scientists (joined academia since 2001).

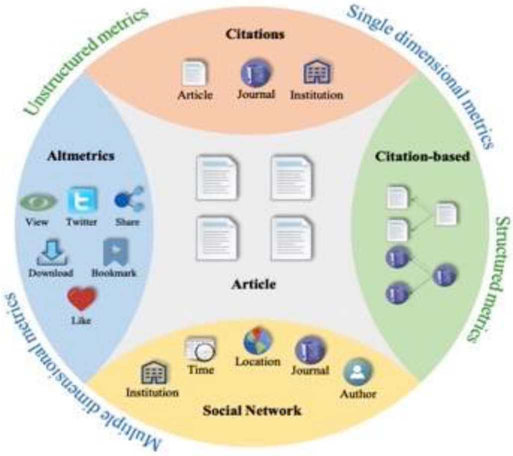

Fig. 1. Types of citation networks [10].

Kyvik et al. [13], examined the degree of scientific collaboration in research for four Norwegian research universities in order to find the effectiveness of research collaboration on the quantity and the quality of research outcomes. Accordingly, it mainly investigates whether the respondent conducts most of their research alone, in a formal group under the university administration, or within an international network. Further, they employed three independent logistic regression models (OLS-regression) to find effective and relevant factors on the research performance of individuals. As a result, the strongest influencer on the number of publications of a researcher is their membership in an international research network.

Liu et al. [14], presented a novel technique to detect scholarly communities that will identify it using unstructured data. For this purpose, they have used three different types of datasets from the real-world. The nodes and edges present between the nodes are basically used to show researchers and the collaborations between those researchers respectively. The proposed technique has three main steps with multiple sub-steps in them. The technique is based upon Reference Entity Recognition, Researcher Relatedness Quantification, and Community Clustering.

Zhou et al. [15], proposed the multi-dimensional network analysis method (AIMN), aims to address the activeness of researches and the popularity of the articles within a social context. It is a computational method that describes multi-type correlations amongst basic academic entities including three relations, Researcher-Researcher, Researcher-Article, and Article-Article. Moreover, they used an improved algorithm known as the Random Walk with Restart model (RWR) in order to calculate the similarity relevance of two nodes. Their results found that an overall performance average consists of between 101-140 nodes, and the performance of AIMN outperformed three other methods compared; MVCWalker, CCRec and basic RWR without AIMN.

Batagelj et al. [16], explored the bibliographic networks and introduces the concept of time in it by using temporal quantities. Also, they have used the authorship network in order to get the author with the largest number of works, and the citation network to know the most cited paper. Thus, by implementing the multiplication of networks, where the derived network can reveal more properties such as temporal co-occurrence, temporal co-authorship, and temporal citations between the journals. Moreover, presented a calculation of fractional productivity of an author in order to calculate the group productivity of authors. Whereas, the properties calculated from the citation network for peer review show that an author can have a smaller number of citations over a large number of years and vice versa.

Batagelj et al. [17], focused to present peer review as an emerging research field by determining the relationships between authors, journals, and their fields. They have taken the time frame of 1950-2016 to determine the relationships, includes citations, recommendations, and collaborations over the specified time period. In this way, by determining authors, their publications, journals, and collaborations at different stages, they made a path to trace evolution over time. Authors have found out three stages of this emerging field. These include the first one that is before 1982 which was the most influential one, then from 1983 to 2002 which is based on biomedical journals, and then the last one from 2003-2016 that contained more specialized journals.

B. Expert Recommendation Systems

Online research search engines and forums are used by many researchers locating scientific articles, in exploring experts to work with, and discovering the venue of publishing, However, they do not receive the optimal outcomes in the initial phases due to the keyword-based searches and lack of interest towards the data. Several recommendation approaches have been proposed in ranking the authors on their expertise in a specific area, some focusing on co-citation, and others on the keywords.

Xiancheng Li et al. [18], proposed a network approach in expertise retrieval. They studied credit allocation for co-authors based on credit allocation algorithms on author-papers using MeSH connections. They employ the HeteAlloc credit allocation algorithm based on path similarities. Here the main task is to allocate credit for each MeSH term in a paper, to correspond to the entire publication history of authors to find out their expertise. However, the unweighted version of the HeteAlloc algorithm is employed since the MEDLINE dataset mostly carries publications with numerous MeSh terms. Compared with the DHA and BL models, this method proved more effective in classifying scholarly expertise when served in different areas.

West et al. [19], extended the capabilities of the Eigenfactor Recommendation algorithm (EFrec) score, proposing two methods as author-based [19], and citation-based [20]. The author-based Eigenfactor was applied in the social science research network (SSRN), which can successfully analyze the author's contribution. Hence, the listing of the authors is quantitative and is based on the number of citations (Fig.2). The results for the author ranking reflect that the first 20% of the authors are responsible for the overall 7.8% Eigenfactor score in author rating. The Institution ranking results show that the US is responsible for 70% Eigenfactor score in the social science research network.

On the other hand, the citation-based method based on finding the most relevant papers for a given article (seed paper). The algorithm creates possible orders for the relevant papers for different users by utilizing the hierarchical arrangement of scientific knowledge. The overall results of an online comparison between EFrec and other recommendation methods co-citation and co-download by using the A-B testing environment indicate that in click-through rates (CTR) the co-citation has 0.26% while EFrec 0.24%, but EFrec comprises a wide range of recommendation coverage than co-citation.

Sriramoju [21], has proposed a framework based on the principle of heat diffusion algorithm that takes three different matrices and conducts web mining. Thus, by bringing the requested web pages and web users into various relationships and compute ranked outcomes. A prototype application was constructed where the findings are primarily related to the consistency of ranked results. The analytical results show that the proposed framework for heat diffusion is successful in seeking the best expert search results.

Javadi et al. [22], proposed the Expert Finding System (EFS), which takes as input the user name and keywords that indicate expertise in that field. Hence, based on that a certain number of ranked experts are the output of the model (Fig.3). Consequently, it provides a list of expert's names in order to collaborate with an expert in a specific field, with an accuracy of 71.50%. However, the high cost and complexity of the calculation of the resemblance of the keywords was a serious problem in the execution. Thus, for saving efficiency, two measurements were estimated and saved for the existing 38,531,031 keyword pairs for the similarity measure period of two years (2012 and 2013).

Zevio et al. [23], proposed a model for finding the experts in the scholarly articles which take the input of data, graph mining, and semantic annotation in order to access the semantic concepts in any scholarly article. Also, they used bi-pattern mining with a new substitute is presented in which the enumerations are reduced by the restriction of component patterns. As a result of precision 0.28 and recall 0.46 by selecting 12 patterns that contained IE field.

Zhou et al. [24], developed a methodology for the extraction of knowledge and expert findings from a numerous article. Compared to the other industry-oriented models, the novelty of the work lies in the use of a hybrid approach that employs not only graph mining (graph abstraction) but also text mining (machine learning algorithms) presenting more comprehensive output. Where the authors, title, and keywords were parsed from the raw data file using CERMINE parser.

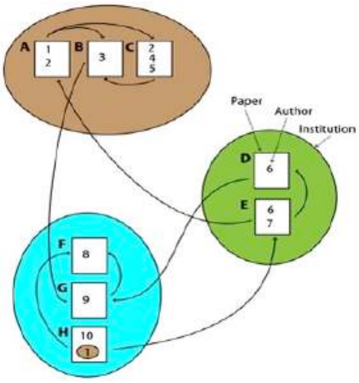

Fig. 2. Journals, authors, institutions citation network [19].

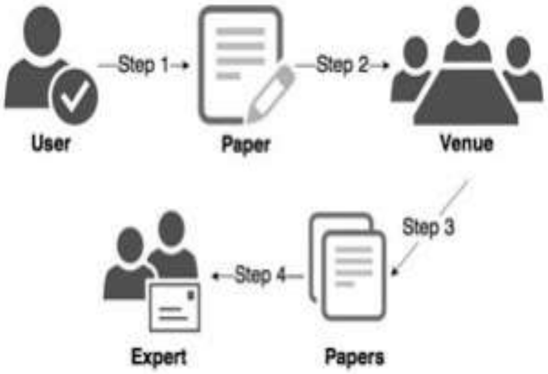

Fig. 3. Expert Finding System model [22].

Liang et al. [25], presented five different models in order to determine a group of experts rather than individual experts, thus by giving a query about a specific topic. Three types of variables were introduced which play a vital role in evaluation: Queries (Q), Documents (D), and Group (G), where the five models are, GDQ, GQD, QDG, QGD, and DGQ. For the evaluation process, the retrieval matrices MAP, p@k, and NDCG@k were used. The results indicate that the QDG model was estimated to be the least performing model among all.

Vergoulis et al. [26], proposed a novel approach known as VeTo, for expanding the set of experts based on the scholarly knowledge graphs. VeTo utilized the latent patterns between the topics and their published venues for the extraction of field specialists. According to the aggregate similarities based on Author-Paper-Topic (APT) and Author-Paper-Venue (APV) meta paths. As result, VeTo-APT and VeTo-APV in both VLDB and SIGMOD conferences achieved better performance, thus by combining both meta paths VeTo will be capable to identify some unique good results.

C. Similarity in HINs

The advancement in Information Communication Technologies makes the nature of the networks heterogeneous, increasing the complexity of the network. Thus, every node carries a different relationship with the other node. Nevertheless, it has a great capability for knowledge discovery due to its enriched semantic.

Kong et al. [27], presented a simple way to classify heterogeneous networks by taking an account of each relationship between the nodes with the use of meta paths and graphs, thus aims to give class labels to these nodes collectively using graphs. The bibliographic graph network (Fig.4) is the used experiment example which has five different types of nodes including author, paper, conference, term, subject, venue. And thus, the heterogeneous networks were classified using graphs, just by using a dependence tree by applying the Breadth-First Search algorithm and send the longer paths into the path set and iterate the process.

Hoang et al. [28], highlighted the importance of establishing a hybrid recommender system that enables scientists to collaborate and find relevant materials. Also, they used acquaintances-based collaboration such as friendship and co-authorship. Research cooperation factored in scientific conferences, co-authors, and collaboration period. In addition, in evaluating the research cooperation metric, the time is included to value co-authors with recent publications more than the ones with outdated publications. The research similarity, on the other hand, describes the success rate for a pair of researchers who have never co-published a paper. This criterion is the more critical one, since unlike the research cooperation that is a quantitative review of the history already known to authors, the research similarity reveals information previously unknown.

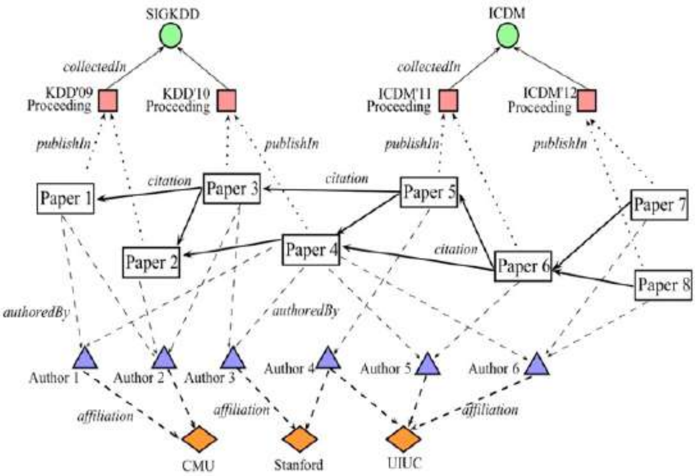

Fig. 4. The bibliographic graph network [27].

D. Semantic Relations

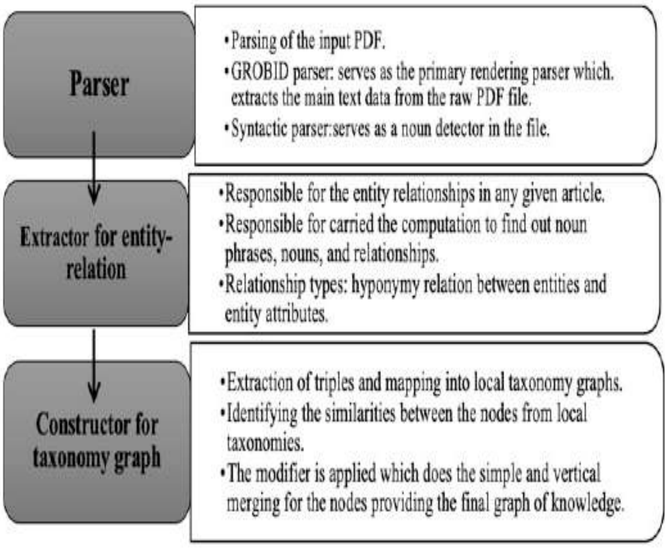
In this era of digitalization, extracting useful or required data from any soft PDF article is a challenging task. A lot of recent studies have been focused on this topic as this can provide useful insights and important data for computation.

Al-Zaidy et al. [29], proposed an approach to extracting data from any given number of documents, which they have incorporated iterative learner and a pattern learning external syntactic in order to extract the semantic relations between the entities. the knowledge base gained by the process in Fig.5, is then fed to a pairing sheet which is usually hypernym-hyponym. As a result, compared to the existing web IE tools, the proposed system established an improvement of the accuracy over 23% to scholarly documents.

Chen et al. [30], proposes a novel technique Weighted Heterogeneous Information Network Containing Semantic Linking (WHIN-CSL) for citation recommendations in three phases. Thus, by the abstract-abstract similarity among any of the two papers, then computing the citing linking hence select the topmost similar papers as semantic linking. Then, build undirected weighted HIN with semantic linking. As result, WHIN-CSL outperforms five baselines including PV-DBOW, PW, PWFC, MMRQ, and BM25, with a 6.9-8.4% better performance percentage for the ANN dataset and 14.3-20.4% better performance percentage for the DBLP dataset.

E. Scholarly Data Visualization

It requires a sort of time to organize and to analyze the scholarly article being published online qualitatively and quantitively. Therefore, in order to organize scholarly networks, the visualization technique is employed to organize the data by the use of statistics and other mapping methods.



Parser
•Parsing of the input PDF.
•GROBID parser: serves as the primary rendering parser which. extracts the main text data from the raw PDF file.
•Syntactic parser:serves as a noun detector in the file.
Extractor for entity-relation
•Responsible for the entity relationships in any given article.
•Responsible for carried the computation to find out noun phrases, nouns, and relationships.
•Relationship types: hyponymy relation between entities and entity attributes.
Constructor for taxonomy graph
•Extraction of triples and mapping into local taxonomy graphs.
•Identifying the similarities between the nodes from local taxonomies.
•The modifier is applied which does the simple and vertical merging for the nodes providing the final graph of knowledge.

Fig. 5. The proposed model workflow [29].

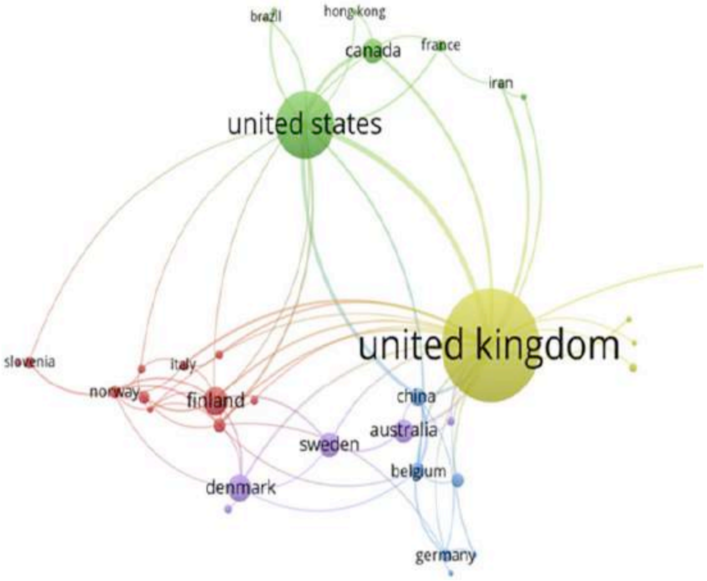


Fig. 6. Visualization of Country co-authorship network [31].

Mokhtari et al. [31], presented a bibliometric visualization and overview of the Journal of Documentation (JDoc) from its initiation from 1945-2018. Also, VOSviewer software utilized for the visualization process and implementation of various techniques such as co-occurrence, co-authorship, and co-citations (Fig.6). Also, the result was represented as ranked tables and graphs, mainly focus on the communicative and influence networks of several scientific actors, and productivity in JDoc.

While Tang et al. [32], tested the International Journal of Fuzzy Systems (IJFS) for the bibliometric data to provide optimization for the evolution and overall development. While incorporates the trends of citation, publication, citation sources, and the details of the paper which are highly cited from the IJFS journal.

Isenberg et al. [33], concentrate on the analysis and visualization of the keywords in three conferences VAST, IEEE InfoVis, and Vis/SciVis. with a total number of 2629 keywords in 1097 papers from 2004–2013. Further, the top 10 keywords are considered for analysis the similarity that occurs between the conferences. The result illustrates that the communities have the similarity in research orientation and the concerns which are of common interest. Additionally, for the 15 most frequent keywords Tableau was used in order to calculate the linear trend lines.

Liu et al. [34], proposed a new system using mining techniques named Web of Scholars. Also, the model uses methods such as searching, mining, and other complex network visualization corresponding to scholars from the field of computer science hence, provides accurate recommendations by the use of querying semantically. Where it relies mainly on the knowledge graph, the model can effectively be used as an interoperable tool which can provide the in-depth analysis.

III. DISCUSSION

This study reviews some existing methods in finding an expert scholar. Initially, it provides an overview by analyzing scholarly data and exploring the importance of international academic collaboration. Next, it provides an overview of how to discover individuals by processing the content of published research papers of a specific field. Next, a scholarly recommendation is obtained using an algorithm based on a network of heterogeneous information. Finally, the visualization techniques in academic networks are discussed. Table I presents a review of the literature study with some of its limitations. The tools and methods of links to the scholars in academia are low. The objective is to develop an interactive visualization network that assists postgraduate students and expert scholars in finding professionals and experts in specific research areas based on expertise.

IV. CONCLUSION

Due to the expanding availability of scholarly datasets, the increase in research problems, and the complexity in research, there has been a growing interest in obtaining the author expertise through an automated process since many researchers from different areas of expertise are required to work on that research projects. While a very common problem that faces the expert finding methods is the qualitative analysis or evaluation as there is no known or established ground to assess that data and it needs several additional measures. This study reviews some existing methods in finding an expert scholar. This also presents an overview of the importance of analyzing scholarly data, finding the semantic similarity in heterogeneous networks, and the visualization techniques in academic networks, that reveal important Implicit information. Additionally, this discusses the approaches, the factors to work on, and some of their limitations. There have been studies conducted by many authors to identify the best author amongst the scholarly community. Nevertheless, the problem of finding the best scholar has not been properly addressed yet. Thus, it is evident that a more systematic and theoretical analysis is required in that matter.

TABLE I. REVIEW OF THE LITERATURE STUDY

Approach / Technique	Objective	Limitation	Works-on	Author (s)
Inferential statistics and a multivariate model approach	•International academic collaboration • Focus on academic research internationalization using cluster of academic discipline	• No clear overview of the intensity of IRC and IRO • Quantification of international co-authorship was done in a self-report base, rather than examine true hard calculations using available academic databases	Co-Author	[3,12]
Analysis using OLS-regression	Find the effectiveness of research collaboration on the quantity and the quality of research outcome	The used of regression models with weak outcome	Co-Author	[13]
Node Embedding	• Discoviring from community clustering: authors mentioned in nearby lines in academic articles belong to a similar research area • Researcher Name Disambiguation (RND)	Their assumption for the authors mentioned in nearby lines belong to a similar research area may fall in some area	Co-Citation, Research Content	[14]
The Random Walk with Restart Model	Building AIMN multidimensional academic network with an improved RWR-based algorithm for recommendations	• Lacks of a justified semantic perspective into the scholarly datasets for extracting insight into the academic collaboration • An adequately detailed discussion on the adjustment plan of the coefficient in the employed equations is missing	Co-Citation, Co-Author, Research Content, Academic Activity	[15]
Network Multiplication	Exploring the bibliographic networks by introducing temporal quantity	No account of the properties of nodes and links thus may affect calculations and computational speed	Co-Citation, Co-Author,Co-Words networks	[16,17]
Credit Allocation	Analyses the degree of each co-author's contribution to collaborative work and assigns expertise level according to it	Lack of ground truth is a big drawback in the validation of this model	Co-Author	[18]
Eigenfactor Recommendation algorithm (EFrec)	EFrec algorithm: citation-based method which based on finding the most relevant papers for a given article (seed paper)	Relaying only on the citation without any semantic information is time-consuming to construct	Co-Citation, Co-Author	[19,20]
Heat diffusion-based ranking	Web mining method to rank the experts from the web search engine query	Lack of ground truth is a big drawback in the validation of this model	Co-occurrence, Co-Words	[21]
Similarity between keywords	Expert Finding System (EFS) using the bibliographic details of author papers, venue, and published articles	High cost and complex-ity of calculation the keywords from more than one perspective in just a period of two years	Co-occurrence, Shared neighbors	[22]
Probabilistic language modeling techniques (Bayes' Theorem)	Five different models in order to determine and ranking a group of experts	Needs more advanced ways to extract individual expert for more efficient identification of an expert given a query topic	binary, graded, and number	[24,25]
Graph-based	Using Graph Mining and semantic annotation for expert finding	The techniques use only the recent patterns which may greatly reduce the accuracy of the collaboration results	Co-Citation, Co-Author	[23]
	VeTo, for expanding the set of experts based on the scholarly knowledge graphs	Their method outperforms all other tested methods, yet its superiority over the baseline method is neglectable especially regarding the obtained results for the SIGMOD	Co-venues, Co-publications topics	[26]
	Classify heterogeneous networks for each relationship between the nodes with the use of meta-paths and graphs	No training or any experiment results	Co-venues, Co-Author	[27]
	Build a collaborators recommender system (CRS) depending on knowledge and acquaintance-based collaborations	Only observes the researchers who either have collaborated in publication in the past or are connected through one or more colleges who have co-authored	Research Content, Academic Activity, Co-Author	[28]
	Build the Web of Scholars system using mining techniques	With regard to scholars' composition, there are no clear approaches to describe the rela tionship in the knowledge graph	Co-Citation, Co-Citation	[34]
VOSviewer	Bibliometric visualization and overview of the Journal of Documentation (JDoc)	• No similarity comparison with the global co-keywords • This study excludes the papers which are not part of the selective database thus under- estimate the impact of studied journals	Influential countries, institutes, authors, author keywords, global keywords	[31]
	Visualization of International Journal of Fuzzy Systems (IJFS) for the bibliometric data	Keyword "fuzzy" is the core of the Journal and the topics being published in IJFS. Thus, it should be excluded where more than 50% of the authors keywords have it	Global keyword, author keyword analysis	[32]

Ward's method and a Squared Euclidean distance metric	Analysis and visualization of the keywords in three conferences VAST, IEEE InfoVis, and Vis/SciVis	Having one shared vocabulary among the three conferences instead of separate three, would enable the authors to broaden their re- search scope and to generalize their findings to a more comprehensive domain of literature	Co-word	[33]

***Abstract*—Cryptography is the foundation and core of network security. Privacy protection, sensitive information is particularly important, so whether it is system development or app development, as long as there is network communication. As data plays very critical steps for IOT devices it's very crucial that cryptography applied to the databases as well. A lot of information needs to be encrypted to prevent interception and tampering. Many people use cryptography on a daily basis, not everyone is aware of it. This paper investigates the applications of cryptography in the context of databases and offers suggestions to enhance security and privacy.**

Keywords— security, privacy, public key, encryption

I. Introduction

With the popularity of blockchain and cryptocurrencies, more and more people are adopting the foundation slot of blockchain-cryptography. Because cryptography is one of the keys to the safe operation of the blockchain. There exist three categories of cryptographic algorithms known as symmetric cryptography, asymmetric cryptography (public key), and cryptographic hashing. These types are part of most encryption systems, and we'll discuss each of the next and to find where the strengths and weaknesses are. In addition to this, we need to look at what kinds of risks and attacks on cryptography. Then we can talk about the application of cryptography and database encryption techniques.

Cryptography has been a science for many years, and it has been recorded that first cryptography inscriptions were carved around 1900 BC in the tomb of an ancient Egyptian nobleman, Khnumhotep II. The inscription used some strange sacred carving symbols instead of more common symbols. It is not intended to hide information, perhaps to manifest prestige by changing forms.

In 100 B.C., at the height of the Roman Empire, Caesar used encryption to send secret messages to front-line troops. The "Caesar Code" is probably the most mentioned historical password in the literature. In a replacement password, each character in clear text is replaced by a different character to form a redaction. The variant used by Caesar is password conversion in three locations. Each letter is forwarded with three locations so that the letter A is replaced by the letter D, the letter B is E, and so on. The letter X is replaced by A.

In the early 1970s, IBM customers requested for encryption, and IBM set up an "encryption group" led by Horst-Feistel. A password called Lucifer" was created by the encryption group. In 1973, the National Standards Administration, now renamed to National Institute of Standards and Technology (NIST) proposed group passwords, which became national standards. IBM realized that lots of commercial products are purchased with no encryption support at all. Lucifer also known as DES (Data Encryption Standard) was adopted to provide that support.

DES was hacked in 1997 in a desperate search attack. The DES encryption key size was very small. As computing power grows, all the different combinations of the brute force are calculated to obtain possible clear text information. In the 1980s, there was only one option which was DES. But times have changed. Today, we have more choices, stronger algorithms, faster, and better design. Now, the question is how to choose.

In 1997, NIST again proposed a new group password scheme and 50 proposals came. In 2000, Rijndael was adopted and renamed to AES (Advanced Encryption Standard) [1-2]. In order to provide security in the database, this paper investigates the applications of cryptography in the context of databases and then offers suggestions that can provide security and privacy. The organization of the paper is as follows: section II presents cryptography definition and types, section III presents some of the existing cryptographic algorithm that provide security to the database, section IV is the analysis of cryptography, section V shows the method of analysis, section VI offers some suggestion to enhance security and privacy in the database and section VII is the conclusion.

II. The Definition of Cryptography

Encryption is converting data to make it unrecognizable and useless to unapproved persons; the most secure technique is to use mathematical algorithms and variable values called "keys". The keys you choose, in general, are random strings that are entered through encryption and are integrated into the data transformation. To decrypt the data, you must enter the exact same key.

Cryptography begins with plaintext which is not encrypted. The plaintext is converted into ciphertext with encryption as shown in fig. 1. This ciphertext can be converted back to usable plaintext using decryption. The encryption and decryption is based upon the type of cryptography scheme being employed and some form of key. This process is sometimes written as follows:

$$C = E_k(P) \qquad (1)$$

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

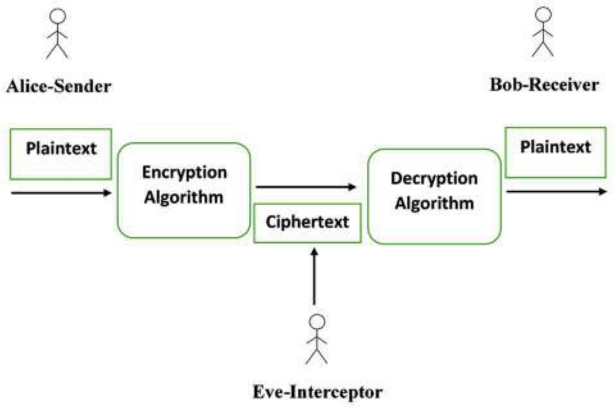

Fig. 1. Cryptography process

$$P = D_k(C) \quad (2)$$

P = plaintext, raw data, data to be encrypted
C=ciphertext, some camouflage or transformed output of clear text
E=encryption process, the process of turning clear text into a red tape in some way.
D=decryption process, the process of restoring redaction into clear text
k=the key, specialized tools used in encryption or decryption

Cryptography resembles similar mathematical algorithms for encrypting and decrypting messages, while the scientific analysis of cryptography and the destruction of encryption schemes. Cryptography is a secret term that refers to a wide range of research writing, including encryption and cryptographic analysis [3].

Three types of cryptography algorithms are discussed here:

A. Symmetric Cryptography

When making clear or secret edict transformations of information, the password system using the same key is solved and decrypted. Figure 2 shows the symmetric cryptography where both Alice and Bob share the same key.

Security in this scheme depends on the secret key and the encryption algorithm security.

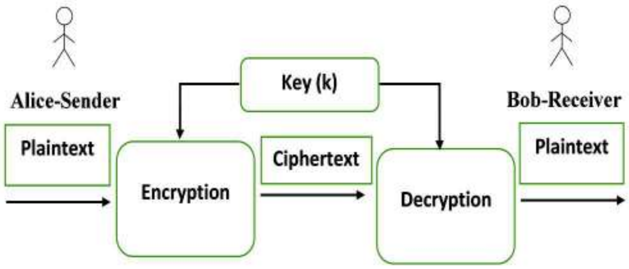

Fig. 2. Symmetric Cryptography

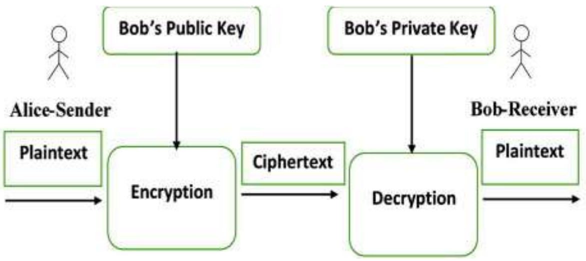

Fig. 3. Asymmetric encryption

Advantages: Algorithm open, fast, high level of secrecy, small footprint.

Disadvantages: Key distribution and management is complex.

Purpose: Encryption with large amount of information.

Representing algorithms: DES algorithm, 3DES algorithm, IDEA algorithm, AES algorithm.

Problem: If the receiver forges a message and falsely is sending it, the sender cannot excuse that it cannot resolve the confirmation of the message and cannot achieve digital signature.

B. Public-Key Cryptography

Encryption and decryption keys are not the same password system when transforming information with clear or secret text. In the asymmetric password system, every user uses one key for encryption and another key for decryption. The key used for encryption is called a public key and the key used for decryption is called private keys which is a secret key for each user. Figure 3 shows the asymmetric encryption where Alice encrypts the plaintext using Bob public key and Bob decrypt the ciphertext using his own private key [4].

Advantages: The sender and the receiver do not require to set up a secure channel to exchange their key, the key space is generally small which reduces the challenges in the key management procedure.

Disadvantages: Slow implementation, not suitable for heavy communication load situation

Purpose: Encrypting critical, core confidential data.

Representing algorithms: RSA algorithm, ElGamal algorithm, elliptic curve encryption algorithm.

Problem: Because the public key is open to the public, if a person uses his own public key encrypted data to send to us, we cannot determine who sent it. If we use the private key to encrypt the data, anyone who knows our public key can decrypt our data.

C. Cryptographic Hashing

The cryptographic hashing is a hash function that is suitable for encryption. Hashing is mainly used to provide integrity property which ensures that the information is correct and no unauthorized person or malicious software has altered the data. This is a mathematical algorithm of any size, a string of map data fixed size and one-way functions, that is, a function is actually not feasible conversion. Hashing algorithms are useful to protect data from unauthorized modification.

III. The Encryption Algorithms

Day by day people's awareness of the importance of information security is growing with the development of information technology and digital society. In 1997, the National Bureau of Standards announced the implementation of the "American Data Encryption Standard (DES)". Civil forces began to fully intervene in the research and application of cryptography, and the use of encryption algorithms such as DES, RSA, SHA, etc. increased. With the increasing demand for encryption strength, AES, ECC, and so on have recently emerged [4-7].

The following section shows the comparison of the two main types of encryption algorithm used in symmetric systems - DES and AES and two encryption algorithms used in asymmetric encryption algorithms- RSA and DSA.

A. *Data Encryption Standard (DES)*

DES encryption algorithm is a grouping password, with 64 bits for grouping data encryption and key length is 56 bits. Both encryption-decryption uses a similar algorithm. The DES encryption algorithm is the secret of the key, while the public algorithm, including the encryption and decryption algorithm. In this way, only those who have the same key as the sender can interpret the redaction data encrypted by the DES encryption algorithm. Therefore, the DES deciphering encryption algorithm is the encoding of the search key. For a 56-bit-long key, if searched by the method of exhaustion, the number of operations is 2 of 56 squares [8-9].

B. *Advanced Encryption Standard (AES)*

In the late 20th century, it is the rapid development of computers, component manufacturing process progress makes the computer processing power much more strong, DES will not provide enough security. On January 2, 1997, the National Institute of Standards and Technology: NIST announced its desire to recruit advanced encryption standards: AES), to replace DES. The U.S. federal government adopted this block encryption algorithm as a standard as well as has been analyzed by multiple parties and widely used worldwide.

AES encryption is an advanced encryption standard algorithm in cryptography, the encryption algorithm adopts the symmetric packet password system, the key length is supported by at least 128, 192, 256, the group length is 128 bits, and the algorithm should be easy to implement a variety of hardware and software.

The cryptographic algorithm requirements are reversible so that the decryption algorithm can correctly recover the cleartext. Take AES, in the case of key fixing, clear text and redaction are one-to-one correspondence throughout the input space.

Therefore, the various parts of the algorithm are also reversible, and then the sequence of operation of each part is designed to be reversible, the redaction can be correctly decrypted. DES and AES algorithm comparison summary highlighted in Table 1.

TABLE I. Comparison of DES and AES Algorithms

Type	*Key Length (bits)*	*Security*	*Computing Speed*	*Resource Consumption*
DES	56	Low	Medium	Medium
AES	128 192 256	High	High	Low

C. *Rivest Shamir Adleman (RSA)*

RSA encryption algorithm is the most influential public key cryptography algorithm and is generally regarded as one of the best public key schemes. It was proposed by Ron Rivest, Adi Shamir and Leonard Adleman in 1977. All three were working at the Massachusetts Institute of Technology at the time. RSA is made up of the initial letters of their three surnames. RSA has been recommended by ISO as the first algorithm that can be used simultaneously for both encryption and number signature and is resistant to all known password attacks so far and RSA encryption algorithm used as a public key data encryption standard. RSA uses a very simple numerical fact which is to multiply two large prime numbers, but very difficult to decompose its product type where the product can be exposed as an encryption key.

D. *Digital Signature Algorithm (DSA)*

DSA is based on integer finite domain discrete pairs, an important feature of DSA is that two prime numbers are exposed, so that when using someone else's p and q, even if you do not know the private key, you can confirm whether they are random, or do it. This is not possible with the RSA algorithm. Compared to RSA, DSA is used only for signatures, while RSA can be used for signature and encryption. Table II shows the comparison between RSA and DSA.

TABLE II. Comparison of RSA and DSA Algorithms

Type	*Maturity*	*Security*	*Computing Speed*	*Resource Consumption*
RSA	High	High	Low	High
DSA	High	High	High	Only for Digital Signature

IV. The Analysis of Cryptography

According to the attacker's knowledge of the clear text, redacted and other information, password analysis are four types: ciphertext-only attack, known-plaintext attack, chosen-plaintext attack, and chosen-ciphertext attack.

A. *Ciphertext-only Attack*

The attacker had no supporting information in his hands other than the intercepted message. Secret attacks are one of the most common types of password analysis and the most difficult.

This way can be used to attack both the symmetric password system and the asymmetric password system.

B. Known-Plaintext Attack

The attacker uses some ciphertext and also knows the relationship between the part of plaintext and ciphertext. For example, if you are in a conversation that follows a communication protocol, because the protocol uses a fixed keyword, such as "login" and "password", analysis can determine the redaction corresponding to that keyword. If the transmission is a legal document, unit notice, and other types of documents, because most of the documents have a fixed format and some agreed text, in the interception of more documents, you can infer some text, phrases corresponding to the secret.

C. Chosen-Plaintext Attack

The attacker knows the encryption algorithm and can select the clear text and get the redaction corresponding to the corresponding clear text. This is a more common type of Mima analysis. For example, an attacker who intercepts valuable redaction and acquires an encrypted use device and enters any clear text into the device to obtain the corresponding reduction is based on the attacker's attempt to crack the valuable redaction. Select clear text attacks are often used to crack information content encrypted with a public key password system.

D. Chosen-Ciphertext Attack

The attacker knows the encryption algorithm and can select a redaction and get the corresponding clear text. Using this method of selecting a redaction attack, the attacker's target is usually the key used by the encryption process. Digital signatures based on a public key password system are vulnerable to this type of attack.

V. The Method of Analysis

From the analysis of the password, three methods can be used in the process of password analysis, namely, the method of poor attack, the statistical analysis method, and the mathematical analysis method.

A. Poor Attack Method

The idea of cracking the poor attack method is to try all the possibilities to find out the clear text or key. The poor-lifting attack method can be divided into two categories, the poor-lifting key, and the poor-lifting explicit text. The poor key refers to the attacker, in turn, using various possible decryption keys to intercept the secret text, to try to translate, if a decryption key can produce meaningful clear text, then the corresponding key is the correct decryption key. The poor text means that an attacker encrypts all possible clear text while keeping the encryption key unchanged, and if the result of a piece of clear text encryption is consistent with the intercepted message, the corresponding clear text is the message sent by the sender [10-11].

In order to combat the attack, the modern cryptographic system is often designed by expanding the key space or improving the complexity of encryption and decryption algorithms. When the key space is expanded,

- The method of raising the key in the process of cracking need to try more decryption key,
- Improve the complexity of the encryption, decryption algorithm,
- Will enable the attacker whether the use of a poor key or poor method of the password system to crack,
- Each crack attempt requires a higher computational overhead for a perfect modern cryptographic system, and
- The cost of using poor attack methods to crack is likely to exceed the value of a secret edit.

B. Statistical Analysis Method

Statistical analysis is a method to crack by analyzing the statistical laws of clear and text. Some classical cryptographic system encrypted information, secret letters and letter combination of statistical laws and clear text is exactly the same, such a cryptographic system is easy to be cracked by statistical analysis. The statistical analysis method first needs to obtain the statistical law of the dense text, on the basis of which, the statistical law of the dense text is compared with the known clear statistical law, and the correspondence of the clear and dense text is extracted, and then the secret text is cracked.

In order to combat statistical analysis attacks, the password system should be designed to avoid the consistency of the clear text in the statistical law, so that the attacker cannot analyze the statistical law of the paper to infer the clear text content.

C. Mathematical Analysis Method

Most modern cryptographic systems take mathematical problems as the theoretical basis. Mathematical analysis refers to the method by which an attacker solves an unknown amount such as deciphering a key by mathematically using some known quantities, such as the correspondence of some clear and texts, against the mathematical basis and cryptography characteristics of the cryptography. Mathematical analysis is an important way to crack a password system based on mathematical difficulties.

VI. Database And Cryptography

In this part, this paper researches on the database about cryptography. Some knowledge related to cryptography is studied and the combination of this knowledge and database is used [5, 12-13].

The database is a storehouse of data that is prepared, deposited, and managed according to the data structure, and data is the most central property in information systems. A database, like the human brain, is at the heart of all information systems. Once the brain is damaged, it is bound to affect the body function of the whole person. Similarly, if data is lost, destroyed, or leaked in the database, it is bound to cause incalculable damage to the enterprise. Therefore, the encryption protection of data in the database has become an important part of database security. There are three main dangers to the database:

Loss of availability - Loss of availability means that legitimate users cannot use database objects.

Loss of integrity - Integrity loss occurs when a database accidentally or maliciously performs unacceptable operations.

This can happen when you create, insert, update, or delete data. The outcome is corrupted data which results in incorrect decisions.

Loss of confidentiality – It is due to illegal or unintended exposure to confidential information. Loss of confidentiality can lead to unlawful practices, security coercions, and harm to public confidentiality.

Access control – It is a security mechanism of the database management system (DBMS) to prevent unapproved access. After the login process is cleared only through a valid password-protected user account, the user can access the database.

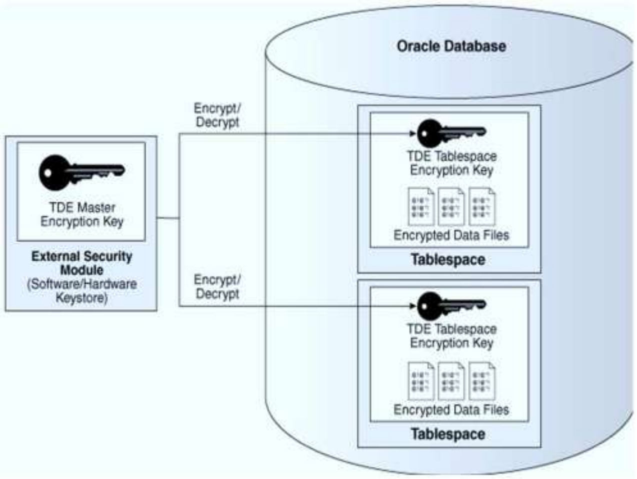
So we will need to take steps to control the risks. The first step is traffic control. It is a distributed system containing a large amount of traffic from one site to another, as well as within a site. The second step is traffic control prevents data from being transmitted as unapproved agents.

The flow policy outlines the channels where information can flow and describes the security classes for data and transactions.

The last step is data encryption refers to encoded sensitive data transmitted on a public channel. Since data is in an incomprehensible format an unauthorized agent can't understand even if he gets access to the data.

How is the database is encrypted? In most cases, the database will use transparent data encryption. For example, the Oracle database used a lot for the encryption as shown in Fig. 4. Database transparent encryption refers to the encryption and decryption of data in the library, the access to the database program is completely unaware. In particular, the application system, which does not need to make any modifications and compilation, can be directly applied to the encryption library.

Two types of data types are unstructured data and structured data. Examples of unstructured are documents and pictures, and the example of structured data is data in a database. Data in both types are important and require encryption protection. Structured data is usually hosted centrally and contains valuable business-sensitive information, so it is especially important to protect it with encryption.



Oracle Database
Encrypt/ Decrypt

Tablespace
TDE Master Encryption Key
External Security Module (Software/Hardware Keystore)
Encrypt/ Decrypt
TDE Tablespace Encryption Key
Encrypted Data Files
Tablespace

Fig. 4. Cryptography in Oracle Database [14]

Even though the process of decrypting will damage the efficiency of the use of the database the encryption of the database is still necessary to protect the necessary measures to avoid the harsh reality of frequent leakage of sensitive data. Encryption of the Database will increase security significantly. Encryption prevents data from data leakage and malicious destruction and stores data in a confidential manner and presents direct access to the data.

The majority of the encryption solutions application code requires calls to cry forward functions. This is costly because it often requires a deeper knowledge of the application and expertise to program and maintain software. In general, most enterprises spend minimal time on this or don’t have relevant expertise to modify existing applications and invoke encryption routines. Oracle transparent data encryption uses nested encryption capabilities deep into the Oracle database to solve the encryption problem.

Application logic executed through SQL does not need to be changed and still works. It can be further explained that the application doesn’t need to worry about encryption and decryption. The programmer will write the usual code to insert/update or delete the date in the application table. Oracle database will encrypt data as it writes to the disk and similarly decrypts reading data from disk to maintain the functionality of the application. This is important because current applications typically expect unencrypted application data. Displaying encrypted data can at least confuse application users and even break existing applications [15-16].

VII. Conclusion

Nowadays 5G is taking over its predecessor, the cloud era is coming, research suggests that the future of IT architecture, more is cloud-based design. If more data is stored on the cloud, then if cloud vendors steal and analyze user data, it will seriously violate our privacy. Malicious DBAs and developers, as also mentioned in the threat model, tend to have higher database permissions, even if they don't have permissions, and if they have a way to read the cache, the data will also leak. So how do we protect our data?

Therefore, the current performance of homomorphic encryption cannot meet the normal needs, if commercial to database level, this survey suggests that the need for further study by cryptographers. Encryption is only a small part of database security, more content needs to be the joint efforts of everyone, but also hope to see more people engaged in the field of database security in the future.

Abstract — **There are various causes related to the appearance of wounds in people that are cause several health problems. Earlier detection and easy monitoring is essential for the correct treatment of this problem. The pandemic time that we live in is causing the people not to go to the hospital to treat the various wounds. This paper performs the revision of the methods for measuring the wound size, but the wounds' color can detect other parameters. This study also proposed a technique for further implementing the detection of wounds with the camera available in off-the-shelf mobile devices. As future work, the method will be implemented to correct wound size in an Android application.**

Keywords **– Wound area; Mobile application; segmentation; image processing techniques.**

I. INTRODUCTION

The measurement of wound area is essential to reduce the appearance of other health problems in the future [1], [2], such as infected wounds and chronic wounds. The constant monitoring of wound areas is specialty important in chronic wounds [3], [4]. It is an injury to the body related to violence, accident, or surgery, typically involving laceration or breaking of a membrane, usually damaging to underlying tissues [5].

Mobile devices are equipments that embeds several sensors, including imaging sensors that are commonly called digital cameras [6], [7]. Currently, the mobile devices' cameras have high quality, allowing the reliable capture of images for further processing to identify the wound size [8], [9]. Other sensors are available in the mobile device to enable a more accurate method development for this type of measurement, determining the distance between the device and the surface to calculate the wound's correct size [10], [11].

This paper intends to propose an architecture of a method for the local measurement of the wound area with a mobile device with an Android operating system. However, this paper starts with reviewing the literature's implemented methods to find the best way to be implemented.

As results of this paper, it is verified that the most implemented techniques are the capture of the image, the conversion of image to grayscale, the performance of threshold to enhance the contrast of the image with Otsu's thresholding algorithm, the implementation of segmentation with threshold, the finding of contours of the wound, and the measurement of the wound area as the number of pixels.

This paragraph finalizes the introduction of the paper. Next, Section II presents the related work found in the literature. The methodology used to identify the best methods was introduced in Section III. Section IV presents the proposed method and the results of the analysis. We are finalizing this paper with the discussion and conclusions in Section V.

II. RELATED WORK

Various studies use mobile devices to measure the wound area with a camera embedded on mobile devices. The authors of [12] performing multiple stages for the measurement of the wound area, including the selection of saturation plan, the inversion and filtering of saturation values, the performance of segmentation with threshold.

In [13], the authors performed the detection of a wound. Initially, the authors inserted calibration marks to identify the localization of the region of the injury. After that, the authors used a method to convert the image to grayscale, and it is transformed from RGB to YCbCr color space. Next, the Principal Component Analysis (PCA) was performed on the Cb and Cr color channels. Thus, it is possible to find the fly's subspace with the maximal contrast between the wheel and the surrounding erythema. The authors performed the dimensionality reduction by finding an orthogonal projection of the high-dimensional data into a lower-dimensional subspace. The implementation finished with the median filtering, the threshold to enhance the contrast of the image with Otsu's thresholding algorithm, the erosion operation on the binarized image, and the suppression of the structures connected to the image border dilation operation.

The authors of [14] converted the image to HSV color space (hue, saturation, value), and they performed the segmentation. Next, they extracted the saturation space from

978-1-6654-4067-7/21/$31.00©2021

color space and implemented the threshold to enhance the image's contrast with Otsu's thresholding algorithm and the dilation operation. After that, the implemented method finds the contours from the binary image using the Suzuki85 algorithm. The number of black pixels inside the segmented image was calculated to design a plot healing curve.

In [15], the authors started with the color correction and color calibration on original 2D images to measure the wound area. Next, 3D reconstruction and segmentation were performed to compute the wound perimeter. Finally, the authors design the contour in a 2D plane, calculated the area as the number of pixels between the outlines, and translated the measured pixels to real-world measurement units.

The authors of [16] calculated the approximate size of a wound, inserting and adjusting a rectangle box in the image.

In [17], the images of wounds are segmented in the ulcer region with image decomposition using the parametric equations that define the toroidal geometry. After that, the resulted image is decomposed in different contrast levels. Next, the threshold technique was performed to enhance the contrast of the image with Otsu’s thresholding algorithm, and the contours of the wound were detected. In continuation, the resulted image was transformed from RGB to grayscale, creating an appearance model using linear combinations of discrete Gaussians (LCDG) and minimizing the noise with a Generalized Gauss-Markov Random Field (GGMRF) image model for the calculation of the area of the wounds.

The authors of [18] applied different techniques, including white balance, anti-glare, Enhance Local Contrast (CLAHE) algorithm, the level set algorithm to find the boundary of the wound, and the snakes model algorithm to define an energy function of the image to detect the size of an injury.

In [19], the authors performed several actions, including the detection of small bright rectangular regions in each image using thresholding and convolution, the combination into one patch of the overlapped areas, the detection of candidate patch sequences based on intensity change, and the segmentation to analyze the wound images.

The authors of [20] started with the extraction of RGB channels from images, extracting the blue channel. Next, the histogram equalization was performed. Before the application of segmentation techniques, the picture was converted from RGB to grayscale. Next, the average low pass filter is applied, and the threshold is calculated. In continuation, the degree intensity image is converted to a binary image, and Otsu’s thresholding algorithm is used to highlight the contrast of the picture. After that, the Asymmetry, Border irregularity, Color, and Diameter were extracted, and the image was denoised for the extraction of Region of Interest (ROI) of the wound. Finally, the Support Vector Machine (SVM) was implemented for the classification of the wounds.

In [21], the authors extracted an image from videos, and they computed the absolute scale of the wound with optics equations. Finally, the methods traced the contour with wound boundary detection for the calculation of the wound area.

The authors of [22] started applying the Mask-Recurrent Convolutional Neural Network (RCNN) model to segment the wound. In continuation, the 3D mesh is rasterized, generating a top view image and the matrix of face indices. The Expectation-Maximization (EM) approach was implemented, and a projective transform matrix of the image was calculated. Next, the image is segmented, and the RANSAC algorithm was used to calculate the best fitting hyperplane. Finally, the authors calculated the faces and the wound's boundary, computing its depth, area, volume, and axes.

In [23], the implemented method starts with applying a mask to select the relevant part. Next, matching common points on the input images was found, estimating each image's camera positions. In continuation, the camera calibration parameters were refined, building the point cloud model, a polygonal mesh, and the texture. Finally, the 3D reconstruction is performed for the measurement of the wound area.

The authors of [24] cropped the center of the wound and removed the unnecessary artifacts. Next, the image was resized and re-sampled to extract the saturation plane of the HSV color model. In continuation, the authors calculated the contour with the contrast between infected and normal skin, and the authors smoothed the image with a Gaussian filter. After that, the authors applied the snakes model algorithm to define an image's energy function, and they transformed it into a grayscale image. The grayscale image was segmented, building the contour of the wound for further measurement of wound size.

In [25], the authors performed segmentation, feature extraction and segmentation, sequentially.

The authors of [26] started with the scaling of the image and photogrammetric 3D reconstruction. Next, the position and orientation of each image in the 3D space were estimated. With these features, the authors performed the feature matching process. In continuation, the authors evaluated the surface of the object by a dense point cloud. After applying histogram equalization, the Otsu’s thresholding algorithm was used to enhance the image's contrast. The induration was cropped for the identification of the margin of the rough. Finally, the elliptical approximation of induration margins was calculated, and the wound area was measured.

In [27], the authors started with the segmentation of RGB images into foreground and background. After that, the Minimum Bounding Rectangle (MBR) of the region of interest is cropped. Next, the image is binarized and converted to grayscale. After that, the ISODATA algorithm was used to find a threshold for the image, and the Line Segment Detector (LSD) approach was implemented to find the ticks of the measurement tool. After grouping the ticks by angle, only the segments with more than 5 degrees of difference to the group with more elements. Finally, the distance between ticks in pixels serves to measure the wound area converted to centimeters.

The authors of [28] started with the normalization of the images. After that, they applied the SEED algorithm for superpixel segmentation to identify the superpixels that are skin. The skin area was reconstructed with superpixels, and the wound area was detected.

In [29], the OpenCV library was used to apply a coin detection algorithm. After that, the image is segmented, and a rectangle was created around the wound. Next, the grabCut algorithm was used to measure the wound area. Still, the intensity values of colors with OpenCV histogram were calculated. Finally, the coin detection algorithm was implemented to improve the wound area measurement.

The authors of [30] performed the 3D reconstruction of the body's wound part, and they mapped the 3D model to the 2D plane. After applying the image segmentation techniques, the scale conversion algorithm was implemented to measure the wound area.

III. METHODS

Various methodologies can be implemented for the identification of the wound. This paper proposes a method to be implemented in an Android application to identify the wound area.

The Android devices have different types of cameras with other qualities, and they can be used for the accurate recognition of the wound area.

This paper intends to identify the best method for the identification of the wound area. It is essential to identify the stages that are the most implemented in the various studies.

Based on the studies available about this subject in IEEE Xplore, ScienceDirect, Google Scholar, and PubMed Central by the following keywords "wound", "measurement", "size", "image processing", and "mobile device", we selected the studies with the best fit of the purpose for the identification of the wound area. After that, the stages of the various methods were presented in section II.

As only 19 studies were selected for the research and the statistical validity, we chose the methods implemented in more than 10% of the studies selected from the literature.

The various stages implemented in the different studies were statistically analyzed to identify the wound area measurement's best techniques.

IV. EXPECTED RESULTS

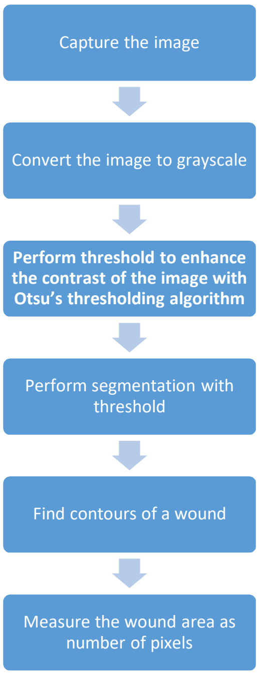
Table I presents the results related to the available literature methods in more than two studies (10%), showing that only eight techniques are included.

TABLE I. RANKING OF THE METHODS IMPLEMENTED FOR THE WOUND AREA MEASUREMENT

Method Implemented	Number of Occurrences
Perform segmentation with threshold	14
Measure the wound area as the number of pixels	12
Convert image to grayscale	5
Perform threshold to enhance the contrast of the image with Otsu's thresholding algorithm	5
Find contours of the wound	4
Perform 3D reconstruction	4
Perform the histogram equalization	3
Crop the center of the wound	3

In general, the majority of the studies implemented the segmentation of the images with threshold. It is always related to the identification of the wound area as the number of pixels. However, the implementation of these methods was revealed more efficiently with images in grayscale. Also, Otsu's thresholding algorithm is the most implemented method for the threshold. Only four studies identified the contours, but the ways that identified the shapes represent the methods with a smaller number of strategies implemented.

In general, we can say that identifying the wound area can be performed with the sequence of methods presented in Figure 1. The accuracy of the proposed technique will be analyzed and reported in the future.



Capture the image
Convert the image to grayscale
Perform threshold to enhance the contrast of the image with Otsu's thresholding algorithm
Perform segmentation with threshold
Find contours of a wound
Measure the wound area as number of pixels

Fig. 1. Proposed sequence of methods for wound area measurement.

V. DISCUSSION AND CONCLUSIONS

This paper analyzed the sequence of methods implemented for the wound to measure images captured from mobile devices. A smaller number of studies for the wound area measurement with mobile devices can be improved with the various experiments that will be performed.

In general, it is expected that the best results will be achieved with the implementation of the following sequence of methods: capture the image, convert image to grayscale, perform threshold to enhance the contrast of the image with Otsu's thresholding algorithm, perform segmentation with threshold, find contours of the wound, and measure the wound area as the number of pixels.

As final work, it will be necessary to implement a method for converting pixels and centimeters considering the distance between the camera and the surface captured. It can be performed with the proximity sensors available in the mobile device or other methods that will be studied.

***Abstract*—Cyber Physical Systems (CPS) are widely deployed and employed in many recent real applications such as automobiles with sensing technology for crashes to protect passengers, automated homes with various smart appliances and control units, and medical instruments with sensing capability of glucose levels in blood to keep track of normal body function. In spite of their significance, CPS infrastructures are vulnerable to cyberattacks due to the limitations in the computing, processing, memory, power, and transmission capabilities for their endpoint/edge appliances. In this paper, we consider a short systematic investigation for the models and techniques of cyberattacks and threats rate against Cyber Physical Systems with multiple subsystems and redundant elements such as, network of computing devices or storage modules. The cyberattacks are assumed to be externally launched against the Cyber Physical System during a prescribed operational time unit following stochastic distribution models such as Poisson probability distribution, negative-binomial probability distribution and other that have been extensively employed in the literature and proved their efficiency in modeling system attacks and threats.**

***Index Terms*—Cyber Physical Systems, System Security, Stochastic Process, Cyberattacks, Poisson distribution, Negative Binomial(NB) distribution.**

I. Introduction

Cyberattacks are meant to deliberate an exploitation of system resources and/or components in order to compromise necessary data and lead to utilize the system in illegal usage (i.e., cyber-crimes). Examples of illegal uses of the systems includes information and identity theft, buffering overflow, damaging system's utilities and others. Usually, the cyberattack follows a vulnerability to realize a threat which is an event that results in a security violation. Practically, cyberattacks are launched through a series of actions to compromise the security services (such as availability, integrity, and confidentiality) of the cyber physical systems such as military system, banking systems, telecommunication systems, transportation systems and smart power grids. Therefore, the cyberattacks have become potential threat that affect the cyber physical systems (CPSs) of our society with wide range of consequences [1]. To support this argument, Figure 1 shows the total cost of cyber-crimes in seven countries for three consecutive years 2013-2015 according to the cost of cyber-crime study published by Ponemon institute [2], where the cost expressed in millions of dollars (US$) and comprised around 252 different companies.

Due to the rapid advances of cyberattacks and threats techniques such as, advanced persistent threats, file-less malwares, zero-days exploits [3], cyberattack data analytic has emerged as an important area of cybersecurity research field. Thus, utilizing the cyberattack data needs to characterize the statistical attributes exhibited by the data through an analytical modeling mechanisms that enable us to investigate the cybersecurity implications. Indeed, several techniques were investigated to model the incoming cyberattacks rate against cyber-systems where most of them have been developed using probabilistic (i.e., stochastic) approaches such as Model based Markov chains [4], [5], Model based Hawkes Process [6], Model based Poisson [7] and Model based negative binomial distributions models [8] as well as other probabilistic processes.

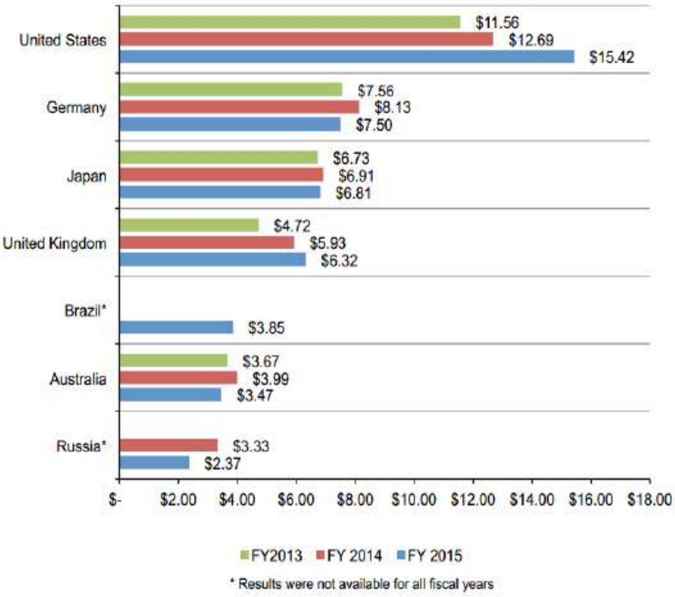

Fig. 1. Total cost of cyber-crimes in seven countries

Indeed, cyber-crimes and cyber-attacks have become a fast-growing area of crime, since criminals can destructively exploit the speed and anonymity of the Internet world to commit a wide range of criminal activities that cause serious harm and real threats to victims worldwide. Recently, the prediction study developed in [9] showed that cyber-crimes are going to increase in a linear trend and thus more security efforts should be emphasized in face of such crimes and

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

cyber threats.
In this paper, we propose a short review of models and techniques for *cyber-attacks and threats rate* against any cyber-physical systems such as, network of computing or storage modules. The cyberattacks are assumed to be externally launched against the Cyber Physical System during a prescribed operational time unit following stochastic distribution models such as Poisson probability distribution, negative-binomial probability distribution and other that have been extensively employed in the literature and proved their efficiency in modeling system attacks and threats [8].

The rest of this paper is organized as follows. Section II provides a brief mathematical background for probabilistic system models. Section III describes the state-of-art stochastic techniques to model the cyber-attacks in the used in the area of attacks-modeling. Finally, Section VI concludes the paper.

II. Related Research

CPS communication networks are usually used to communicate essential information of stringent surroundings and services in real time system connectivity of either synchronous or asynchronous modes [10]. Nevertheless, CPS infrastructures are vulnerable to cyberattacks and instructions occasioned by the restrictions of their computation, processing and communication abilities [11]. Typically, Cyber physical system's intrusion detection system (CPS-IDS) are established to distinguish various external cyberattacks and intrusions formulas lunched against the system components or applications with random rates of attacks.
In the field of cyber physical system design [12], the redundancy mechanisms to develop solutions for fault tolerant structures have been studied extensively. For instance, Triple-Modular-Redundancy (TMR) [13] technique was proposed earlier to generate true outputs on condition that no less than two out of three segments (modules) generate true outputs. This in turn is taking place by employing three replicas of a every system module and using a voter to process the results of the system outputs. For more about the fault-tolerant system techniques and structures, the reader is directed to navigate through [14] which provides a respectable chronological review for such systems.
While considering the design of secure cyber physical systems or cyberattack-tolerant CPSs, only few researches have been deliberated on applying redundancy mechanisms to prolong the system survivability against the different cyberattacks. Recalling the Transparent Runtime Randomization (TRR) proposed in [15], where multiple randomized redundant memory places are allocated for executing program's and software packages' trying to prevent attackers of being able to locate and exploit the decisive address locations of a susceptible software and programs. Another noticeable work on system security have been investigated in [16] to evaluating the survivability specifications of a cyber-system using a model-driven techniques. Moreover, several probabilistic methodologies to model the cybersecurity requirements and factors for several CPSs has been deemed and investigated such as the work presented in [17] employing the Markov Chain-based scheme [18].

Recently, machine learning-based techniques have been widely employed to develop cybersecurity solutions to defend and protect the communication networks of IoT and CPS against several cyber-attacks and intrusions. Examples of cyberattacks detection based machine learning techniques employed to address CPS security concern: Shallow Neural Network (SNN) [19], Convolutional Neural Network (CNN) [20], K-Nearest Neighbors (KNN) [21], Decision Tree Method (DTM) [22], Support Vector Machine (SVM) [23], and others. For instance, Q. Abu Al-Haija et. al. [24] presented a novel deep-learning-based detection and classification system for cyber-attacks in IoT communication networks employing convolutional neural networks. They evaluated their model, using NSL-KDD dataset scoring accuracy results of almost 99.3% and 98.2% for the binary-class classifier (two categories) and the multiclass classifier (five categories), respectively. Besides, they validated their system using a 5-fold cross-validation, confusion matrix parameters, precision, recall, F1-score, and false alarm rate. As a result, they showed that their system outperformed many recent machine-learning-based IDCS systems in the same area of study.
In this paper, we propose a short review of models and techniques for *cyber-attacks and threats rate* against any cyber-system of interest (such as, network of computing or storage modules) that are launched during the time unit of interest (such as, hours, days, moths) using *probabilistic distribution* modeling such as *Poisson probability distribution and negative-binomial probability distribution* that proved their efficiency in modeling system attacks and threats [8].

III. System Security Analysis

Cyber-Physical Systems (CPSs) are composed of integrated set of interacting subsystems, such as computation, processing, networking, physical processes, and other, to achieve a collective specified task and accomplish a common goal/application. The interconnection of system elements is often architected in series configuration, parallel configuration, or $k-out-of-n$ configurations. The security of the system can be described as a measurement of probability that the system will perform its objective(s) (i.e. survive) at a certain satisfactory level within a given period of time. The system security is considered one of the major factors to characterize the cyber physical system abilities in achieving the design objectives and deliver the agreed-on services.

A. Security of Series Systems

Series systems are formed by cascading system elements in a sequential interconnection fashion as illustrated in Figure 2. The major characteristic of series systems is that they can function properly only when all their connected elements function properly, i.e., fully inter-dependent systems. This is similar to layered hierarchical systems that communicate

Notation	Description
E_i	The Element i of the system model
P_i	The Probability that element i is attacked
n_i	The number of components used for sub-system i.
k_i	The number of operating elements used for sub-system i.
X	The random variable for the number of attacked elements.
$f(k; n; p)$	The binomial distribution function of three parameters.
S	The number of sub-systems.
$n_i - k_i$	The number of redundant elements in subsystem i.
$p(x)$	Probability of subsystem attack following Poisson process.
λ_{ij}	The attack rate of the j^{th} element of sub-system i.
E_{ij}	The j^{th} element of sub-system i.

information from one level to the next. As a result, the security of a series system is entirely depending on the security of its interconnected elements.

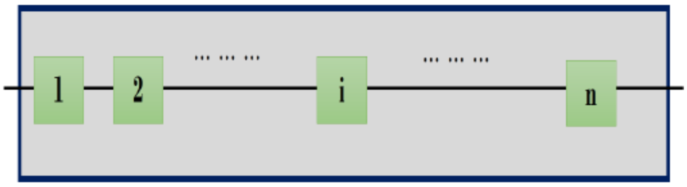

Fig. 2. System Model Using Series Interconnection of several subsystems

To measure the system security of series models, lets consider that we have a system with n elements connected in series (E$_1$, E$_2$, E$_3$, ... E$_n$) with P$_i$ is the probability that element E$_i$ is attacked, then:

The probability that element E$_1$ survive = (1-P$_1$)
The probability that element E$_2$ survive = (1-P$_2$)
The probability that element E$_i$ survive = (1-P$_i$)

Since the elements of the system are attacked independently, then the system security can be computed as:

$$(1 - P_1)(1 - P_2)...(1 - P_{n-1})(1 - P_n)$$

$$SystemSecurity = \prod_{i=1}^{n}(1 - P_i) \tag{1}$$

B. Security of Parallel Systems

Parallel systems are formed by connecting system elements in parallel interconnection fashion as illustrated in Figure 3. The major characteristic of parallel systems is that the system is attacked only if all of its components are compromised, that is, it can still function properly if some of the connected elements function properly. This similar to networked system that communicate information from node to node. Thus, the security of a parallel system depends on the comprising (due to attack) of all system elements.

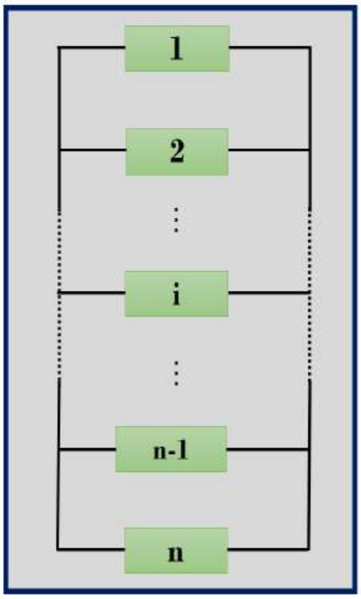

Fig. 3. System Model Using Parallel Interconnection of several subsystems

To measure the system security of parallel models, lets consider that we have a system with n elements connected in parallel (E$_1$, E$_2$, E$_3$, ... E$_n$) with P$_i$ is the probability that element E$_i$ is attacked, then:

The probability that element E$_1$ is attacked = (P$_1$)
The probability that element E$_2$ is attacked = (P$_2$)
The probability that element E$_i$ is attacked = (P$_i$)

Since the elements of the system are attacked independently , then the system security can be computed as the probability of at least one element is surviving, as follows:

$$1 - [(P_1)(P_2)...(P_{n-1})(P_n)]$$

$$SystemSecurity = 1 - \prod_{i=1}^{n}(P_i) \tag{2}$$

C. Security of k-out-of-n Systems

Even though series and parallel models can be used to represent the connectivity structure for many elements of the cyber systems, however, real systems may include a combination of both representations configured in $k - out - of - n$ systems where k is the minimum number of operating elements in the cyber system, i.e. active/operational elements. Thus, such system is compromised if k or more out of n components are compromised due to cyberattacks. In other words, the system is attacked when $(n - k + 1)$ of its elements are attacked/compromised. Indeed this is a generalized model representation that can be used to generate the different schemes/scenarios by setting the values of k and

n as follows:

Generalization - *For any cyber physical system* with k active/operating elements and includes n as total number of elements for both operating and sandy-redundant elements, the system can be developed in one of teh following interconnection architectures:

$$\begin{cases} Series - system & \text{if} \quad k = n \\ Parallel - system & \text{if} \quad k = n \\ k - out - of - n - system & \text{if} \quad k < n \end{cases}$$

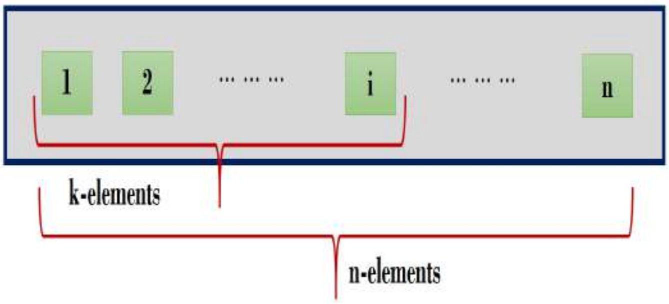

Fig. 4. System Model Using $k - out - of - n$ Interconnection of several subsystems

To measure the system security of $k - out - of - n$ models, lets consider a cyber system with n elements (E$_1$, E$_2$, E$_3$, ... E$_n$) where the elements are attacked independently with probability P$_i$, i.e., the probability that element E$_i$ is attacked/compromised. For simplicity, lets assume that all elements have the same probability of attack, that is: P$_1$ = P$_2$ = ... P$_i$ = p. In this way, the the probability of attack follows the $probabilisticbinomialdistribution$ with parameters k, n and p.
Let X be the random variable representing the number of attacked elements following the binomial distribution with parameters $n \in N$ and $p \in [0, 1]$, then, we write $X \sim B(n, p)$. The probability of getting exactly k successes in n trials is given by the probability mass function:

$$f(k, n, p) = P(X = k) = \binom{n}{k} p^k (1-p)^{n-k} \qquad (3)$$

for $k = 0, 1, 2, \ldots, n$, where $\binom{n}{k}$ is the binomial coefficient is defined by the next expression:

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}$$

Now, for the system to survive, i.e. to be secure, the number of attacked elements should not exceed $k - 1$ of the system elements, and thus the system security can be calculated as follows:

$$SystemSecurity = P[X < k] = \sum_{i=0}^{k-1} f(i, n, p) \qquad (4)$$

D. *Security of Parallel-Series Systems*

Generally, large system are composed of several subsystems that are interconnected to accomplish their outcome based missions with maximum probability of success. The use of series systems in connecting the elements of subsystem is highly undesired since series system is risky and highly vulnerable for cyberattacks sine the compromising of only one element of the system will cause the system to shut down. To increase system security, the system can be designed with several sub-systems connected in series, but have an internal parallel structure for the interconnected elements (i.e. $k = n$), as illustrated by the scheme given in Figure 4.
To measure system security, consider a system composed of (S) sub-systems each with n$_i$ elements connected in parallel where P$_{ij}$ is the probability of attack of the j^{th} element of sub-system (i). Since the elements of system are attacked independently, the security of the system can be calculated as follows:

System Security = Security (subsystem$_1$) x Security (subsystem$_2$) x ... x Security (subsystem$_S$)

System Security = $(1 - \prod_{j=1}^{n_1} P_{1j})$ x $(1 - \prod_{j=1}^{n_2} P_{2j})$ x ... x $(1 - \prod_{j=1}^{n_i} P_{ij})$ x ... x $(1 - \prod_{j=1}^{n_s} P_{Sj})$

$$SystemSecurity = \prod_{i=1}^{S}(1 - \prod_{j=1}^{n_i} P_{ij}) \qquad (5)$$

E. *Security of Complex Systems*

Practically, many real system are configured by connecting several subsystems in series, but having an internal $k - out - of - n$ structure(i.e. $k < n$).
In this case, for the system to be secure, the number of attacked elements in each subsystem (i) should not exceed k$_i$-1 of the subsystem elements, therefore, the cyberattacks rate over the system elements should be modeled a probabilistic distribution model. Indeed, there two common approaches to model the cyberattacks rate over the system element; namely, Binomial probability distribution and Poisson probability distribution.

In the case of Binomial probability distribution: All elements in every subsystem are attacked with equally likely probability (p), then:

System Security = Security (subsystem$_1$) x Security (subsystem$_2$) x ... x Security (subsystem$_S$)

System Security = $(\sum_{j=0}^{k_1-1} f(j, n_1, p_{1j}))$ x $(\sum_{j=1}^{k_2-1} f(j, n_2, p_{2j}))$ x ... x$(\sum_{j=1}^{k_{sj}-1} f(j, n_s, p_s))$

$$SystemSecurity = \prod_{i=1}^{S}\sum_{j=1}^{k_i-1} f(j, n_i, p_{ij}) \qquad (6)$$

In the case of Poisson probability distribution: The elements in every subsystem are attacked with probability (p) according to Poisson process distribution as follows:

$$p(x) = \begin{cases} \dfrac{e^{-\alpha}\alpha^{x}}{x!} & \text{if} \quad x = 0, 1, 2, ..., L \\ 0 & \text{if} \quad otherwise \end{cases} \tag{7}$$

System Security = Security (subsystem$_1$) x Security (subsystem$_2$) x ... x Security (subsystem$_S$)

System Security = $(1 - \sum_{j=1}^{k_1-1} p_{1j})$ x $(1 - \sum_{j=1}^{k_1-1} p_{1j})$ x ... x$(1 - \sum_{j=1}^{k_1-1} p_{sj})$

System Security = $\prod_{i=1}^{S}(1 - \sum_{j=1}^{k_i-1} p_{ij})$

$$SystemSecurity = \prod_{i=1}^{S}(1 - \sum_{j=1}^{k_i-1} \frac{e^{-\alpha}\alpha^{j}}{j!}) \tag{8}$$

IV. Stochastic Models of Cyber-attacks

In the area of *attacks modeling* for designing security solutions for cyber-system, *stochastic techniques* [25], [26] have been well studied. An example of using *stochastic* technique to model cybre attacks, where Poisson variables [27] where used to characterize the attack processes in cloud computing networks. Such a system take into consideration the inter-dependencies amongst vulnerabilities/attacks in a given attack path. Similarly, Poisson Process have been widely and employed in [7], [28], [29] to model several types of system attacks and vulnerabilities, for instance, the process of the virus-infection [7] that infect a network of computers for a period of time due to individual infection.

In the same context, work in [8] modeled the cyber-attacks using negative binomial (NB) probability distribution, where, the proposed a generalized linear models (GLMs) using to predict the number of successful cyber-intrusions into computer network. Moreover, several other stochastic approaches were used to model the several attacks on the system such as the log-normal distribution [30] and Pareto distribution [30], Circular Statistics [31], Hawkes distribution [6] and Beta distribution for cyber-security risk analysis [28].

In more specific situations such as the modeling extreme cyber-attack, both works in [32], [33] proposed a model based extreme value theory (EVT) to model and investigate the extreme cyber-attack rates phenomenon where [32] utilized the value-at-risk as a natural measure of intense cyber-attacks. Such a model can describe and predict the extreme cyber-attack rates at a very satisfactory accuracy, whereas [33] showed that EVT can offer long-term predictions compared with some other models such as graybox time series theory (TST) models with higher rates of accuracy. Moreover, [34] proposed vine copula approach to model model the cyber-security risks with high-dimensional dependency. Furthermore, contributors of [35] proposed a new concept of stochastic cyber-attack process using Long-Range Dependence (LRD).

As a case study, they applied the model on the low interaction honeypot data-set and thus they confirmed that LDR model is feasible to predict cyber-attacks in order to provide an early-warning for defenders to adjust their system security. Finally, Table I summarizes the techniques used to model cyber-attacks for different applications using probabilistic approaches.

TABLE II
Stochastic Models for Cyber-Attacks and Threats Rates

Research	Modeling Technique	Attack Type	Application
[5] [7] [26] [28]	Poisson-Process Model	Cyber-threats, Viruses, Attacks, Vulnerabilities	Virtual network, Computer network, Cloud computing, Network Porosity
[8]	Negative-Binomial Model	Virus Infection	Organization's Computer Networks
[4] [27]	Markov-Chains Model	Cyber-Threats (Bot, Low rate attacks-DoS)	Multiport Scan (KISA) & Computer network
[29]	Log-Normal Distribution Model	Invasive Software (viruses, worms, Trojan horses)	large-scale computer network
[29]	Pareto-Distribution Model	Cyber-Intrusions	large-scale computer network
[30]	Circular-Statistics Model	Malware infections	Live Network Monitoring by Spamhaus
[5]	Beta-Distribution Model	Cyber-Risk	Cybersecurity Risk analysis
[6]	Hawkes-Process Model	Cyber Attacks	Information systems
[31] [32]	Extreme-Value Theory (EVT) Model	Extreme-Cyber Attacks	Network telescope & honeypot data-sets
[33]	Vine-Copula-GARCH Model	Mmultivariate Cybersecurity Risks	Network of virtual nodes
[34]	Long-Range Dependence (LDR)	Cyber-attacks	Honeypot data-set

Recently, more appreciated solutions appeared with the emergence of deep-learning techniques, such as the recent intelligent self-reliant cyberattacks detection and classification system for IoT communication using deep convolutional neural network [36]. The authors of this up-to-date work, has no longer assuming any stochastic approach to predict the incoming cyberattacks, instead, they developed a new intelligent system that can detect the slightly mutated cyberattacks using deep convolutional neural network (CNN) leveraging the power of CUDA based Nvidia-Quad GPUs for parallel computation and processing. Indeed, they obtained a very attractive and superior results by recording a very-high accuracy results for the classification of cyberattacks.

V. Conclusions

This paper presented an investigation study for CPS security against external cyberattacks for different redundant architecture scenarios including series, parallel, series-parallel, and k-out-of-n systems. Besides,the paper presented a methodical study for the stochastic approaches employed in the modeling of cyberattacks rates over the cyber physical Systems with multiple subsystems and redundant elements. Hence, this paper provides an important insight for researchers who works on developing security system solutions for cyber physical systems.

***Abstract*—The impact of many factors on stock price has made the prediction of the stock market a problematic and highly complicated task to achieve. IoT analytics has enabled predictive analysis concerning the stock market, with internet search trends, reactions to current events, Twitter data, and historical stock returns as input data. Although inconsistencies remain as to which data sources are deemed most adequate, data preprocessing techniques have successfully overcome data integrity issues and unstructured data formats in specific applications. Additionally, advancements in computational power and machine learning technologies have led to the ability to handle tremendous amounts of information, accompanied by the growth of interest in this specific domain. In this paper, a Multivariate Multistep Output Long-Short-Term-Memory (MMLSTM) model is proposed to provide a one-week prediction on the stock close value for the technology company, "Apple Inc." with the stock name "AAPL". A large variety of data sources enabled by IoT platforms have been employed to model the impact of public sentiment and engagement on the closing price of this particular stock by looking at Google Search Trends, e-News headlines, and Tweets involving AAPL and its products. The proposed MMLSTM has improved the Mean Square Error (MSE) of up to 65% compared to ARIMA and Random Forest models. In addition, the proposed MMLSTM has outperformed most of the LSTM models introduced in the literature.**

I. Introduction

In-depth market analysis is continually refined to forecast stock behaviour. Multiple factors are involved in predicting the stock market trends, such as physical factors, physiological, rational, and irrational behaviour. Combining these factors ensures the volatile nature of stock prices; however, it becomes very difficult to predict it accurately. The knowledge of how a stock will perform provides insight to investors looking to invest. It can also aid the marketing teams of the stock's respective company. Public reaction to stock information and the sentiment of the information on the stock itself are two ways to decipher stock trajectories, which have yet to be thoroughly studied in combination with predictive models. Various financial institutions and traders have created their prediction models for competitive advantages. However, it has been hard to achieve higher-than-average results on the Returns on Investment (ROI). Nevertheless, the appeal of predicting the stock market as an accurate forecasting process can potentially lead to profits of millions of dollars. The forecasting problems are typically classified into one of three categories:

- Short term forecasting (seconds, minutes, days, weeks, or months)
- Medium-term forecasting (1-2 years)
- Long term forecasting (<2 years)

Numerous research papers have attempted to solve the stock forecasting problem over the years [1] - [5]. The researchers in [1] use various machine learning algorithms and social media news to perform stock forecasting. The work outlined in [2] compares multiple machine learning algorithms' effectiveness in the stock market forecasting of the SP 500 Index. Additionally, current market research tends to leverage knowledge obtained from local sources, and so a more diversified approach is needed to account for a global network of influencers and investors [3]. The inclusivity of public opinion that is not limited to English web text mining was a key feature that this research paper aimed to implement by looking at Google searches done worldwide and including Twitter sentiment analysis of Tweets from all languages [4][6].

In this paper, we propose a stock price prediction model, explicitly focusing on the technology-based company, Apple Inc. The actual stock values are forecasted instead of just the positive and negative fluctuations of the stock close. Various versions of LSTM models were initially explored before a specific model was selected. A Multistep Output Long-Short-Term-Memory (MMLSTM) is proposed in this paper to provide efficient stock forecasting. The stock market volatility [4] is strongly influenced by social and news media, which are extensively reviewed in this paper. The proposed model is applied to Google Trends, news headlines, and Twitter datasets. For the latter two datasets, VADER is used to detect the headlines and Tweets' sentiment, respectively. A daily average of the news sentiments and the Tweet sentiments are used as two separate features to the model. The VADER's ability to detect sentiment on colloquial terms is essential to the work discussed in this paper, as inclusivity is prioritized. Through this method, a more accurate sentiment of Tweets written using everyday

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

terminology will be incorporated as opposed to only professional terminology.

Experimental results show that the inclusion of both features pertaining to sentiment data and certain Google Trends aided in optimizing the model with the lowest error. The one-week forecast using MMLSTM achieved an average MAPE of 0.05932. The key aspects of this model are the diversity of the data sources and demographics. The structure of the paper is presented as follows: Section II and III provide a background and literature review of related work in stock forecasting using a variety of different textual and numeric datasets. Section IV provides a framework of the proposed model. Section V provides the experimental analysis. A discussion on the results is presented in section VI. Finally, the conclusion and future directions are presented in section VII.

II. LITERATURE REVIEW

In this section, a literature review on the usage of sentiment analysis for stock forecasting is discussed, along with an analysis of the potential of Google Trends' predictive capabilities.

A. Sentiment Analysis for Stock Forecasting

Over the years, various methods have been explored for predicting the price of a stock, but researchers have recently started using sentiment analysis for stock forecasting. In specific, these researchers have performed sentiment analysis on data obtained from two sources: news and social media. For example, in [7], sentiment classification of Tweets, which were labeled as either negative, positive, or neutral, has been conducted to train and tune a classifier. The classifier is based on SVM employing a wrapper approach, which constructs two linear-kernels trained to distinguish between positive and negative-or-neutral and vice versa. The Tweet is labeled as neutral when the two classifiers disagree, which occurs rarely. To process the data, they followed a typical bag-of-words computation procedure by applying tokenization, lemmatization using LemmaGen, and n-gram construction, which included unigrams and bigrams, the feature set, and the TF-IDF weighting scheme. The computed sentiment values were then used to model the relation between Twitter sentiment and DJIA.

The authors in [8] also used bag-of-words to perform sentiment analysis on Twitter data for stock forecasting. Still, they pre-processed the data to remove Tweets that had been retweeted to reduce redundancy. Tweets that were not in the English language were also discarded. Although bag-of-words is widely used to perform sentiment analysis, it fails to capture the sentiment by ignoring the sentences' structure. Thus, the authors in [1] have proposed an approach that uses the Sentiment Treebank to obtain sentiment from Tweets and news headlines. Their approach incorporates the sentence structure using deep learning to create a model for every sentence in the textual dataset. Compared to the bag-of-words approach, the suggested approach can use sentiment label phrases with ≈ 10% accuracy [1].

Similarly, the researchers in [9] used bag-of-words, noun phrases, and named entities to create a representation of financial news headlines to predict stock prices. After performing comparative analysis, they concluded that using noun phrases performed better than bag-of-words to predict the stock price.

A significant drawback of using these approaches is that they fail to capture the sentiment conveyed through informal text such as slang and acronyms. However, an increase in the use of sentimental analysis for various applications using text from social media has led to a number of open-source software that can be integrated into any learning-based model with ease. For example, in [10], the researchers have proposed a simple yet effective tool that combines lexical features with a rule-based model to generate a numerical sentiment value that categorizes text with varying sentiment intensities instead of labeling it as 1 if positive, 0 if neutral, and -1 if negative. The lexical features used in VADER are a combination of acronyms and slang words used in micro-blogging, such as Tweets to convey a sentiment with commonly used lexicons such as LIWC [10].

B. Google Trend Analytics

Another aspect that is being considered in the forecasting of the stock market is data from Google Trends, an application released by Google in May 2006, which shows how frequently a given search term is entered into Google's search engine. Google Trends was the precursor to Google Insights for Search, which was released in 2008, which provides insights into search terms used in the Google search engine. However, in 2012, the applications were merged in Google Trends. Google Trends does this by analyzing the popularity of various search queries across many regions and languages. It then graphs this data to compare it against the search volume of different queries over a period of time. This allows the user to see and compare the relative search volume of searches of one or more terms. The research work in [6] proposes a method to evaluate internet search data's predictive capabilities via Google Trends. They offered to treat Google Trends as a useful proxy for investors' attention regarding a particular company's stock belonging to the SP 500 Index. They found that the overall directional movement of the SP 500 Index correlated directly with the search volume series; however, they did note that often it "depends on which specific term is being searched for, and by extension the sentiment of the term itself" [6]. Overall, they hypothesized that while Google Trends can be considered a valid indicator of investor interest, it is conditional on the specific search term's inherent sentiment. A trading strategy was proposed through the generated Google Trends forecasts, which resulted in a 40% outperformance of a traditional buy-and-hold strategy. This adds validity to the reasoning behind including Google Search Trends as a feature for the proposed model discussed in this paper.

III. STOCK FORECASTING MODELS

Various algorithms have been successfully applied for stock forecasting; each of them is suited for forecasting for multiple reasons and different periods. In this section, some of these techniques are explored.

Autoregressive Integrated Moving Average (ARIMA): The univariate ARIMA model in [11] was used to predict stock price fluctuations. This type of model is heavily based on the moving average of the dataset. It provides an overall idea of the trends in a data set through the average of a subset of numbers. This technique is extremely useful for forecasting long-term trends for any period, e.g., calculating a 3-year, 5-year, and 20-year moving average. Stock market analysis often provides a 50 or 200-days' moving average to help forecasting where the stock market could be heading. For stock forecasting, a predicted closing price is decided for each day based on the average of a set of previous days observed values. Each prediction uses the latest set of values, hence the term "moving average". While this method has its advantages for showing the current market trend, it fails to account for future changes that may impact the stock price, making it overly unsuitable for long-term forecasting [11].

Linear Regression: A linear regression model application in stock forecasting is discussed in [12]. Linear regression is one of the basic machine learning algorithms. This model determines the relationship between the independent variables and the dependent variable. Linear regression is a simple technique; however, one of the most significant issues with utilizing linear regression algorithms is that it is prone to outliers, making it easily influenced by one-time jumps in the stock data. An assumption that the data is linearly related also must be validated for linear regression to be effective.

Artificial Neural Network (ANN): Stock market forecasting requires analyzing huge amounts of nonlinear data. Hence, an outbreak of advanced intelligent techniques is being implemented in this field to identify the hidden and complex patterns within the stock market. An ANN model achieves this through a self-learning process by adjusting approximators to find the input-output relationship of large, complex datasets, which enables accurate stock price predictions [13], [14], [15].

Random Forest (RF): RF utilizes an ensemble technique for stock forecasting and, as a result, is capable of performing both regression and classification tasks. It operates by constructing multiple decision trees during the training time, which provides an output in the form of a mean regression of each decision tree. An RF model is implemented in [16], and this model is capable of making steady predictions when many trees are used.

SVM: SVMs have also been used in more recent studies to forecast stock prices [2], [16], [17], as SVM is one of the best-known binary classifier models. The SVM model is an alternative to the ANN model. The difference between the two types of models is that while ANNs aim to minimize classification errors within the training data, SVMs can reduce classification errors within training data to achieve less error across test data. SVMs typically display higher accuracy in high-volatility stock markets.

IV. The Proposed MMLSTM model

An LSTM model is a special kind of Recurrent Neural Network (RNN), consisting of three gates, with the main difference being that the hidden layers in the LSTM model are fitted with LSTM cells to control the input flow. The three gates within the LSTM architecture are:

- Input Gate: Adds information to the cell state
- Forget Gate: Removes information that is deemed irrelevant to the model
- Output Gate: Selects the information to be shown as output

The LSTM models can provide a more efficient analysis of time-dependent variables. Additionally, this type of model can hold on to past information. Finally, this model can identify long-term dependencies for future prediction, making the model quite suitable for stock market analysis. The gates of an LSTM control how much input and memory are taken. An LSTM is chosen over other RNNs as it can tackle the vanishing gradient problem and the exploding gradient problem seen with other RNNs caused by an abundance of backpropagation. Research work in [13], [14], [18] show promising results of implementing an LSTM model for stock price prediction. There exist various LSTM models, such as univariate, multivariate, multi-step time series forecasting, etc. In this paper, a Multiple Input Multi-Step Output LSTM (MMLSTM) model is proposed. This particular model is used in multivariate time series forecasting problems. The output series is separate but depends on the input time series and requires multiple time steps to reach the output series. An LSTM model allows for multi-step prediction, which is useful for predicting multiple days in advance. This is beneficial, especially in a field such as stock forecasting, in which knowing the current and future state of the stock market is the key to profitability.

Fig.1 Dataset Excerpt

A. Data and Model Structure

Nine features were used to predict one target variable, the stock close value for Apple Inc. An example of the dataset is shown in Fig. 1. The first five features pertained to the level of interest in certain topics were obtained from Google Trends. The next feature depicts the weighted, aggregated sentiment from Tweets about Apple stock. The aggregated daily number of comments on SeekingAlpha news headlines and their respective sentiment values were the next two features. And finally, the lagged actual stock closing values were considered as a feature and the target variable. Each of the features was normalized between zero and one so that they were all on one common scale. The nine features mentioned above are listed as F0 through F8, respectively. The proposed MMLSTM model takes in 90 rows of feature data, representing 90 past days of data, to forecast one week of the stock close price. Therefore, at time t, features from t-89 to t are used to forecast the future stock value for time t to t+7.

B. Finalized Hyperparameters

Numerous combinations of MMLSTM units and epochs were tested to minimize the loss function measured by the MSE value, as discussed in section IV of this paper. Fig. 2 shows the loss plot for the final chosen configuration, which was 1 LSTM layer, with 64 LSTM units, followed by a dropout layer with a fraction of 0.4, and one dense layer, trained with 50 epochs and the “Adam” optimizer. It was found that adding LSTM stacks caused the model to be under-fit. Fig. 3 shows the loss plot of a model fit with a stacked LSTM, whereas Fig. 4 and 5 show significantly fewer under-fitting signs when a single LSTM layer is used. In these two figures, the training loss is lower than the validation loss, and the validation loss converges better. A flowchart of the proposed model is illustrated in Fig. 6. The final model parameters after using Bayesian Optimization were 43 LSTM units and 56 epochs of training.

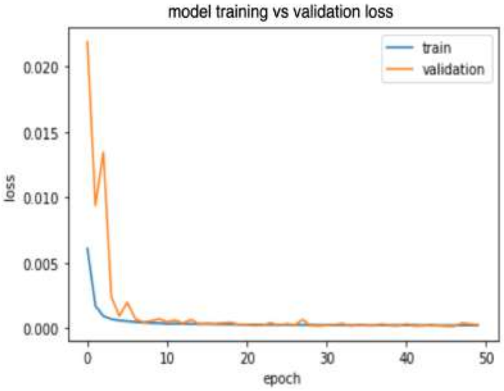

Fig. 2. Single Layer LSTM 64 units (Selected features).

Data Collection
Scraped Tweets
Extracted news headlines and number of comments
Extracted Google Trends
Downloaded Apple stock close dataset
Feature Engineering
Translated all Tweets to English
Sentiment Analysis on Tweets and News Headlines with Sentiment VADER
Weighted Tweets from Influencers
Prepared daily averaged Twitter sentiment, headline sentiment, number of comments, Google Trends
Feature Selection
Conducted linear regression to predict the entire test set with all features and found their respective coefficients
Features with positive coefficients were kept in the dataset
MMLSTM Modeling
Separated features and target variable into 90 day windows to train and 8 day windows to predict
Split the data: First 65% train, next 20% validation, last 15% test
LSTM: LSTM layer (43 units), Dropout layer (0.4), Dense layer, Adam optimizer, 56 epochs
Error Metrics
Calculated mean and median MAPE

Fig. 6. Flowchart of the proposed model

V. Experimental Analysis and Design

Under-fitting is described as when a model does not comprehensively learn patterns from the training data. When the loss is plotted, this can be identified visually as the point before convergence between the training loss and validation loss. This portion is generally where the training and validation data are similar, alluding to a high bias, albeit a low variance. Overfitting occurs when a network is over-trained, which can be identified as the curve behaviour past the convergence point. The train and test error move in opposite directions, with the test error continually increasing. Telltale signs of over-fitting are the properties of low bias and high variance. The high variance source is noise in the training data, which might not be part of the test data [19]. After following linear regression coefficient ranking, as previously mentioned, the train versus validation loss plot illustrates a lower loss, faster convergence, and lack of over and under-fitting. There is a slight spike at the beginning of the validation plot, reflecting an unrepresentative validation dataset, which questions the model's ability to generalize [20].

A. Data Processing

Twitter data: The workflow of processing Tweets from Twitter can be seen in Fig. 7. The Tweets have been scraped from Twitter using the "SNSCRAPE" library for a date range between 2009-01-01 and 2020-11-11. A total of four different keywords have been used to generate .csv files containing the date, text from the tweet, and the respective Twitter user id. In the first stage of data processing, the duplicated Tweets were removed using the "drop duplicates ()" function from the pandas library. This was necessary in some cases where Tweets contained more than one of the keywords used to scrape, and as a result, the Tweets were scraped more than once. Tweets containing less than six characters had to be discarded from the dataset to detect the Tweets' language. The number of discarded Tweets were verified during every run of this workflow, and in all cases, only a small percentage of Tweets (approximately 5 %) were discarded.

To further justify the discarding, a Tweet that contained less than six characters was also assumed to be more likely to be a neutral Tweet. The Twitter user id of each Tweet was compared with a list of stock influencer user ids that were manually curated using online forums [21], [22], [23]. Tweets were assigned a weight, which was multiplied by the compound sentiment of that respective Tweet. A weight of 2 was applied to the Tweets obtained from stock influencers, and a weight of 1 was applied to all other Tweets. This was done to mimic the increased impact that influencer Tweets were assumed to have on public opinion. The average daily sentiment was then calculated from the weighted compound sentiments.

News Headline data: The news headlines in the proposed framework have been processed, as shown in Fig 8. The text for each headline, along with the data and the number of comments, have been curated in a .csv file, with all data from SeekingAlpha. The headlines have been processed to remove duplicate headlines, and a sentiment value was added using VADER. Similar to the Tweet sentiment aggregation, the sentiment for the news headlines was aggregated daily.

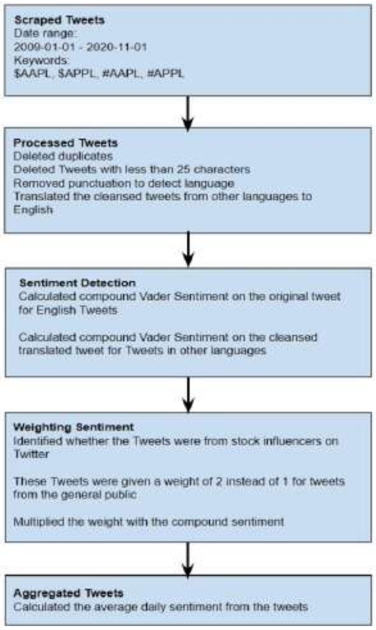
Google Trends data: The Google trends for the queries listed in the workflow in Fig. 9 were obtained monthly. The same overall level of interest for the month was a valuable indicator for all days of that month.

B. Feature Selection Methods

Two different feature selection methods were implemented to decide on the inclusion of the obtained features.

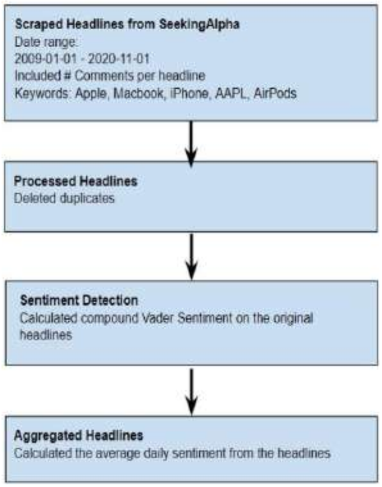
Correlation analysis: To conduct feature selection through correlation analysis, the following heat map seen in Fig. 10 was obtained. This method deemed that Twitter Sentiment and News Sentiment were not valuable features due to their low correlation. When the finalized model was run, omitting these two features, the error obtained was approximately 10.4%.

Linear regression coefficient ranking: The second feature selection method attempted is Linear Regression (LR) coefficient ranking. In this method, all features were used in a linear regression algorithm to predict the target variable. The resulting coefficients for the model and its corresponding features were stored. A threshold for the coefficient value is then used to determine which features should be omitted from the dataset.



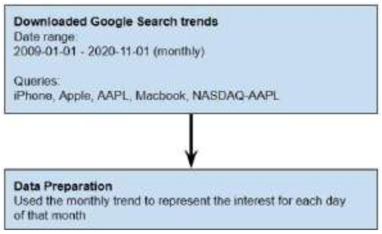
Scraped Tweets
Date range:
2009-01-01 - 2020-11-01
Keywords:
$AAPL, $APPL, #AAPL, #APPL
Processed Tweets
Deleted duplicates
Deleted Tweets with less than 25 characters
Removed punctuation to detect language
Translated the cleansed tweets from other languages to English
Sentiment Detection
Calculated compound Vader Sentiment on the original tweet for English Tweets
Calculated compound Vader Sentiment on the cleansed translated tweet for Tweets in other languages
Weighting Sentiment
Identified whether the Tweets were from stock influencers on Twitter
These Tweets were given a weight of 2 instead of 1 for tweets from the general public
Multiplied the weight with the compound sentiment
Aggregated Tweets
Calculated the average daily sentiment from the tweets

Fig. 7. Twitter Extraction, Pre-processing, Daily Sentiment Aggregation.



Scraped Headlines from SeekingAlpha
Date range:
2009-01-01 - 2020-11-01
Included # Comments per headline
Keywords: Apple, Macbook, iPhone, AAPL, AirPods
Processed Headlines
Deleted duplicates
Sentiment Detection
Calculated compound Vader Sentiment on the original headlines
Aggregated Headlines
Calculated the average daily sentiment from the headlines

Fig. 8. News Headline Extraction, Pre-processing, Daily Sentiment Aggregation.



Downloaded Google Search trends
Date range:
2009-01-01 - 2020-11-01 (monthly)
Queries:
iPhone, Apple, AAPL, Macbook, NASDAQ-AAPL
Data Preparation
Used the monthly trend to represent the interest for each day of that month

Fig. 9. Google Search Trends Extraction and Data Preparation.

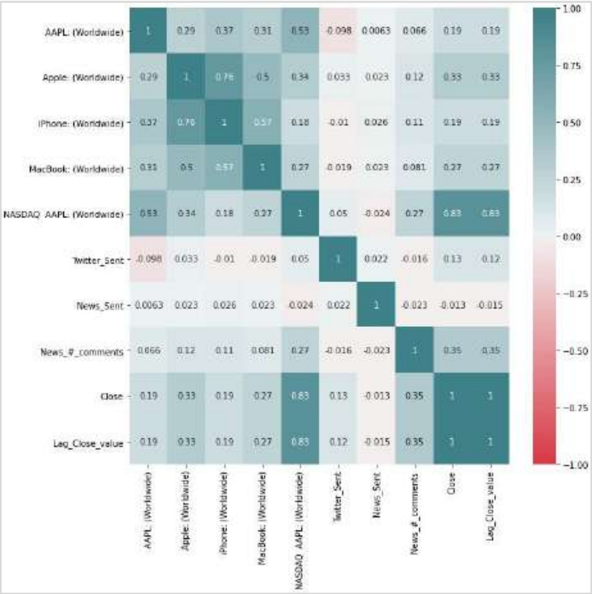


Fig. 10. Heatmap of Correlation between Features and Target Variable.

Using this method and keeping all features with positive coefficients, only five features remained in the dataset. These features include the Google Search Trends for iPhone and NASDAQ-AAPL, Twitter and News Sentiment, as well as the previous day stock close price. When the final model was run using only these features, the error amount was approximately 5.9%. When comparing the two feature selection methods with the error obtained when using all features, it was found that using LR coefficient ranking had the best result. For this reason, the subset of features corresponding to the LR coefficient ranking method was chosen for the final model.

C. Data Sources and Types

Four different datasets have been used in the proposed model. The first dataset consists of the stock price, while the second dataset consists of Google Search Trends data. The third and fourth datasets consist of sentiment values derived from news/financial headlines and Tweets from Twitter, respectively.

Stock price dataset: The $AAPL stock price has been obtained from Yahoo! Finance for the time period between 2009-01-01 to 2020-11-11. In particular, the daily closing price has been extracted as it is commonly used for stock price prediction by researchers, for example, in [1] and [8]. Stock prices are not updated on the weekends, and so the preceding weekday values are kept the same throughout the weekends.

Google Trends dataset: The number of people searching for terms related to the AAPL stock was retrieved from Google Trends from January 2009 to November 2020. The dataset consists of numerical values representing the number of times a term has been searched on Google monthly. The terms used to obtain the search trend include AAPL, Apple, iPhone, MacBook, and NASDAQ-AAPL.

News headlines dataset: The news headlines were searched using the stock symbol for Apple and collected from SeekingAlpha over a time period of 11 years. SeekingAlpha was used because of the strong correlation established between the price of a stock and articles published on this platform by the researchers in [24] and [25]. This final dataset consists of the title of the news article, the date, and the number of comments on each article. A sentiment value was also added to the dataset for each headline.

Twitter dataset: Tweets from Twitter have also been obtained for the same time period of 11 years. The Tweets were searched using three different keywords, which were aggregated into one dataset. Specifically, the hashtag and the ticker symbol (e.g., $AAPL) were used as one of the keywords since it has been found effective to obtain Tweets relevant to predicting stock price [1]. Other keywords used to search for Tweets include #AAPL, $APPL, and #APPL. This final dataset consisted of the user's id, text in each Tweet, date, and sentimental value.

D. Data Analysis and Discussion

The ARIMA one-day prediction and Random Forest with 1000 trees models were created to conduct a comparative analysis. The ARIMA model (results included in Table 1) was altered such that the true values were appended to the model history to match the MMLSTM prediction period. The ARIMA model achieved a MAPE of 35.452%. The Random Forest model had a notably higher error than the MMLSTM as it predicts the entire test set at once, as opposed to steps-like as the MMLSTM. The proposed MMLSTM achieved an improvement of more than 65% as compared to the Random Forest model.

The mean absolute percentage error is regarded as one of the most widely used metrics for prediction/forecast accuracy. This is because it is both scale-independent and is easy to interpret. However, the MAPE has some significant disadvantages, such as the fact that it produces infinite or undefined values for zero and/or close-to-zero values, which leads to percentages and ratios that are not intuitive. Prediction models rely on minimizing errors through numerical optimization, and the MAPE throws off these optimizers. Thus, there is a need to explore a new metric to be used for stock price prediction. Another drawback is that the MAPE "puts a heavier penalty on forecasts that exceed the actual than those that are less than the actual", as mentioned in [26]. Considering an example where the observation is 150 and the forecast is 50 results in a relative error of 50/150=0.33, and the result would be 50/100=0.50 in the opposite situation. Researchers in [27] propose a new measure for stock price prediction, which they called the mean arctangent absolute percentage error (MAAPE). This MAAPE measure was derived from looking at the MAPE but from a different angle. The critical difference between MAAPE and MAPE is that the MAAPE inherently preserves the MAPE properties while overcoming the problem with MAPE caused by the division by zero. The MAAPE accomplishes this by using bounded influences for outliers by considering the ratios as an angle rather than a slope. Listed below are the formulas of the MAPE and MAAPE for comparison:

$$MAPE_t = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{A_t - F_t}{A_t}\right| \quad (1)$$

Aₜ denotes, the actual value at data point *t*, and *Ft* represents the predicted/forecasted value at data point *t*, with *N* indicating the number of data points.

$$MAAPE_t = \frac{1}{n}\sum_{t=1}^{n}(AAPE_t) \quad (2)$$

$$AAPE_t = arctan\left|\frac{A_t - F_t}{A_t}\right| \quad (3)$$

TABLE I: COMPARATIVE ANALYSIS

	MMLSTM	ARIMA	Random Forest
Mean MAPE %	6.328	34.117	18.343
Mean MAAPE %	6.311	32.115	17.483

TABLE II: A COMPARISON OF THE MODELS WITH DIFFERENT FEATURES

	Mean MAPE %	Mean MAAPE %
All Features	13.547	13.363
Without F5 and F7	10.414	10.359
Without F0, F1, F3, F6	6.328	6.311

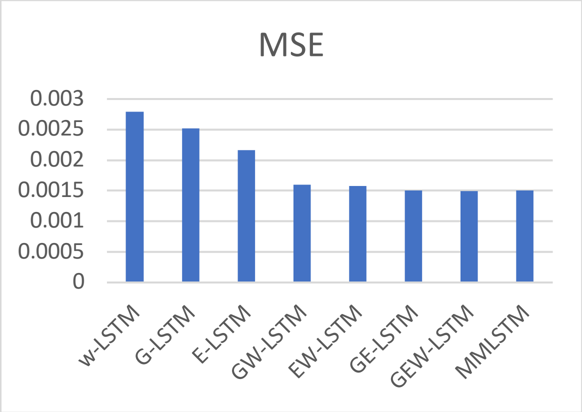

Fig. 10. A Comparative Analysis with the LSTM Models in [28]

As shown in Eq.3, if *Aₜ* is set to zero or even close to zero, the MAPE would result in an infinite or undefined value, which leads to an overall increase in outliers. Table II compares the two different error metrics for the proposed model and the different feature selection techniques. The inclusion of features F5 and F7: Twitter Sentiment, and News Headline Sentiment, respectively, resulted in the lowest percentage error values for both metrics. This confirms that public sentiment has an impact on the price of Apple stock. In [28], various LSTM models were created and trained with windows of 22 days of data to predict for the next 1-day volatility of the KOSPI 200 index, using explanatory variables as input data. Their LSTM architecture consisted of three LSTM layers with 0.3, 0.8, and 0.8 drop-out values, respectively, and two fully connected layers. The LSTM layers consisted of 10, 4, and 2 units, and the model was trained with 150 epochs. Their validation data consisted of 20% of the training data. It is trained on the previous 90 days to forecast the next seven days instead of just a one-day forecast. Given the additional days of forecast, the proposed MMLSTM has achieved similar performance to the GEW-LSTM and GE-LSTM models introduced by Kim and Won [28], and it outperforms all other models, including the W-LSTM, G-LSTM, E-LSTM, GW-LSTM, and the EW-LSTM. One of the main advantages of the proposed MMLSTM is that it has a much simpler architecture than what is described in [28] with comparable prediction performance.

VI. Discussions

In this paper, forecasting Apple Stock using an MMLSTM has effectively predicted the stock pieces for the next 7 days. It was found that the Google translate library used in our experiments limits the number of characters analyzed per day. An alternative to this would be to find libraries with sentiment detection capabilities in multiple languages such that translation error is minimized. This would also aid in combating translation errors, as the sentiment in phrases of one language may not always be the same as when it is translated. This would happen if the headlines or Tweets contained idioms that are generally language-specific and do not make sense when taken out of linguistic context. The model's generalizability can also be improved by implementing a time series cross-validation or merely increasing the dataset's size and diversity. This research work could be further expanded by incorporating the prediction of multiple stocks. Additionally, using the volatility of other companies' stock could potentially complement the forecast of Apple stock. An example shown in Fig. 12 is when the news headline's sentiment [30] is labeled negative; however, the headline favors Apple.

VII. CONCLUSION AND FUTURE DIRECTIONS

Deep learning forecasting algorithms are gaining importance in deciphering relevant features in obtaining the closest forecast to reduce the uncertainty from the complex and dynamic market information [29]. In this paper, forecasting Apple Stock using a proposed MMLSTM model has been shown to predict the stock pieces for the next week effectively. The key aspects of this model are the diversity of the data sources and demographics. A variety of data sources enabled by IoT platforms such as social media networks have been employed, particularly Google

Search Trends, e-News headlines, and Tweets involving AAPL and its products. The sentiment detection methods used could also be expanded to aggregate multiple methods, such as a Google API or another sentiment detection library, such as TextBlob.

Additionally, other machine learning models, such as SVMs, renowned for stock prediction, could be tested using the same features as in the proposed LSTM model. Sensitivity analysis using different weights for the sentiment of Apple experts' Tweets could also be performed to achieve higher forecast accuracy. The proposed MMLSTM model, along with the selected features, could be extended to forecast cryptocurrency [31][32] in future work. The trend of Bitcoin price, one particular type of cryptocurrency, is similar to that of Apple stock, this paper's subject. Both Apple stock and Bitcoin price saw exponential growth, albeit this growth in Bitcoin occurred later, around 2018. The size of specific cryptocurrency price datasets may not be as vast as the Apple stock dataset used in this paper, which dated back to 2009 due to the more recent development of cryptocurrency. The scope of the MMLSTM models can be extended to numerous use cases, including forecasting other stocks and cryptocurrencies [29][33].

***Abstract*—Cryptography algorithms are standards for any security-based industry. Internationally widely accepted and used cryptography algorithms like AES, DES rely heavily on finite field arithmetic which needs to be performed efficiently, to meet execution speed and design constraints. This paper aims to provide a concise perspective on designing efficient architectures in finite field arithmetic. In this paper, we propose Galois field arithmetic using irreducible polynomial to generate the S-box for AES using 128, 192, and 256-bit Keys. Cryptographic algorithms are more prone to side-channel attacks, so we implemented this algorithm instead of using a lookup table-based approach. The proposed Galois Field implementation of arithmetic operations are unique which can be extended to any primitive polynomial of any word size GF(2^n). A novel scheme is proposed for AES S-box, Inverse S-box, and validated using a Xilinx Virtex-7 FPGA.**

Keywords*—*Advanced Encryption Standard (**AES**), Data Encryption Standard (**DES**), Extended Euclidean Algorithm (**EEA**), Affine-transformation, Greatest Common Divisor (**GCD**), Galois field (**GF**), Substitution Box (**S-box**), Inverse Substitution, Field Programmable Gate Array (**FPGA**)

I. Introduction

Cryptography allows the organization to protect data and keep confidence in the electronic world. The increase in technology especially in the field of communication, information transmitted electronically resulted in an increased reliance on Cryptography and authentication. Cryptography means the transformation of information into a format that is unreadable for an unauthorized user. There are several algorithms designed to protect data like DES, Triple DES, RSA, Blow fish, Two fish, and AES. These are unbreakable encryption algorithms of the future. Some algorithms can be hacked using various crypto analyses like Side Channel attacks, Differential Power Analysis, etc.

Any field consisting finite number of elements is defined as finite field. F={elements} on which if we perform any binary operations like addition, subtraction, multiplication, division on elements result is said to be field. For any prime number 'p' there exists a finite field of p elements. GF(P) is represented as a field of p elements. GF(P^m) represents a field of P^m elements. Finite fields are also called Galois fields. The number of elements in a field is defined as an order of the field. Arithmetic operations are explained in GF(2^8) order. Inverse does not exist for infinite field, so it is mapped to zero. We represent the field in the form of the equation.

AES algorithm is a symmetric encryption algorithm that uses a single key for encryption and decryption. Encryption and decryption steps are described in figure Fig. 1. AES uses the keys of various lengths like 128,192,256 bits. 128-bit data plain text input is converted in a 4x4 byte matrix, followed by substitution and arithmetic operations in Galois field GF(2^8) like addition, multiplication. All these are done in a systematic way called Round. The round includes a series of logical and arithmetic operations in GF(2^8).

II. Advanced Encryption Standard

A. Implementation of AES

Encryption algorithms use the concept of encryption and decryption [6] i.e.

Plain text + Cipher key →Cipher text

Cipher text + Cipher key→Plaintext

Complete algorithm lies in creating these cipher text by adding cipher key to plain text. The main important operations of AES are S-box, inverse S-box, mix-columns, and inverse mix-column [5].

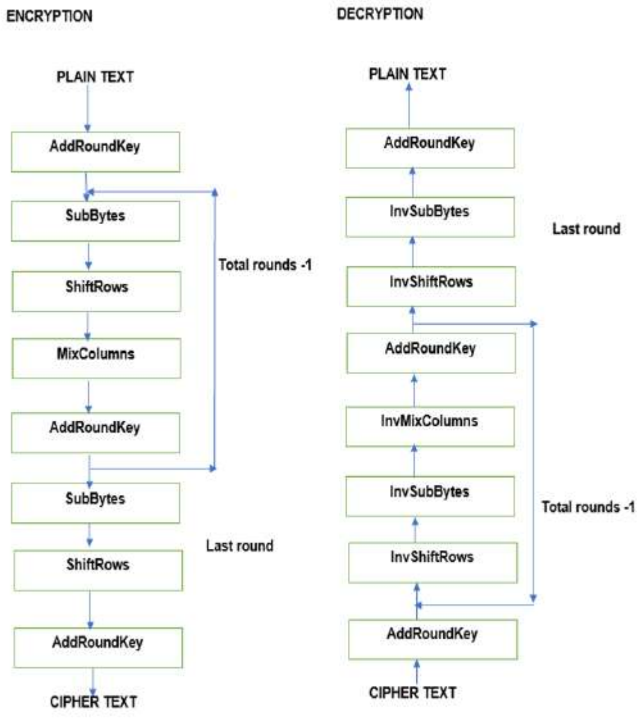

Fig. 1. AES algorithm flow chart

B. S-Box operations

AES algorithm is implemented in rounds, consists of the following computations for encryption.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Substitute from S-box: Shifting of bytes in a matrix. **Shift rows of the matrix:** Replacement of bytes from the boxes. **Mix columns:** Multiplying with constant. **Add round key:** Bitwise exclusive or operation.

Similarly, for decryption we need to perform steps in reverse order.

Substitute from inverse S-box: Shifting of bytes in a matrix. **Inverse Shift rows of the matrix:** Replacement of bytes from the boxes. **Inverse mix columns:** Multiplying with inverse constant. **Add round key:** Bitwise exclusive or operation.

The number of rounds depends on the key listed below.

128 bits key – 10 rounds

192 bits key – 12 rounds

256 bits key – 14 rounds

Depends on the key data undergoes several rounds like sub bytes, shift rows, mix columns and add round key for encryption and decryption. A separate algorithm is used for key expansion in each round not mentioned here.

C. *Substitution from S-box*

S-box is implemented from series of steps where the inverse is calculated using the Extended Euclidean Algorithm. EEA needs bits multiplication, addition, and division in the Galois field which is discussed in section III.

The S-box is generated by using multiplicative inverse of a given number in GF(2^8) = GF(2) [k]/ P(k), where P(k) is a primitive polynomial ($k^8 + k^4 + k^3 + k + 1$).

III. Implementation of S-box and Inverse S-box

We get 8 bits of data as an input for sub byte transformation operation, we need to follow the sequence of steps for encrypting data.

A. *Steps in the creation of S-box*

- Convert the given binary number into field GF(2^8).
- Check field equation is not zero for finding inverse.
- Perform inverse GF(2) [k] / ($k^8 + k^4 + k^3 + k + 1$) for finding inverse of an equation.
- Perform affine transformation and convert field equation to number again.

B. *Steps in the creation of Inverse S-box*

- Convert the given binary number into field GF(2^8).
- Perform inverse affine transformation.
- Check field equation is not zero for finding inverse.
- Perform inverse GF(2) [k] / ($k^8 + k^4 + k^3 + k + 1$) for finding inverse of an equation and convert to number again.

C. *Inverse using Extended Euclidean Algorithm*

Extended Euclidean Algorithm is an extension to Euclidean Algorithm. This algorithm is used in calculating coefficients of Bezouts Identity.

If a, b are coprime in the equation ax+by=gcd(a,b) then x = inverse of a modulo(b), y=inverse of b modulo(a). This equation can be extended to polynomial in any Galois field. In this paper we used the concept of EEA for finding inverse in S-box and Inverse S-box steps.

D. *Algorithm for Galois field GF(2^8) multiplication*

Multiplication is defined as a multiplication of two polynomials modulo and irreducible reducing polynomial in the finite field [3].

Let A(k), B(k) and C(k) belongs to Galois field GF(2^n) and P(k) be the irreducible polynomial generating GF(2^n) multiplication in GF(2^n) is defined as polynomial multiplication modulo the irreducible polynomial P(k), namely.

C(k) = A(k) multiply B(k) mod P(k). In this S-box implementation mod P(k) is ignored because A(k) multiply B(k) is always less than P(k).

The algorithm for Verilog implementation is implemented in the below figure Fig. 2 and variables are mentioned below.

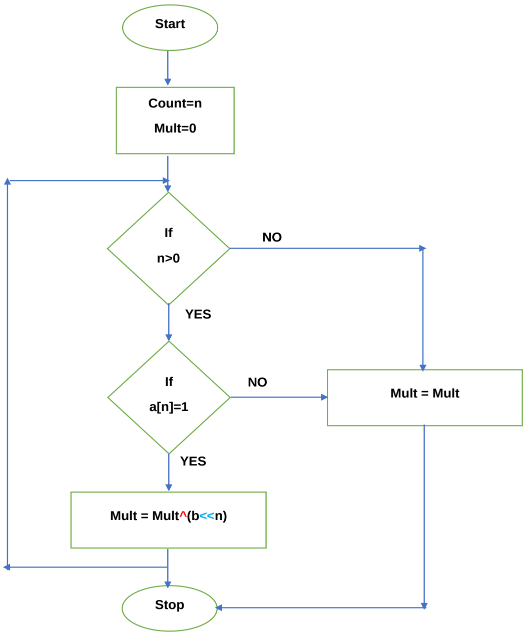

Fig. 2. Galois Field Multiplication

- a is a multiplier, b is the multiplicand
- Count = “n” which is the bit length of multiplicands
- “^” is xor operation and “<<” is bitwise left shift
- Final product will be stored in Mult

An illustration is mentioned with help of an example

A=10101, B=10101, n= 5

Example: 10101 X 10101

10101
00000x
10101xx
00000xxx
10101xxxx

Mult 100010001

E. Algorithm for Galois field GF(2^8) division

The division algorithm in the Galois field is similar to binary division. The algorithm for Verilog implementation is implemented in the below figure Fig. 3, Fig. 4, and some variables are used mentioned below.

Example:

Divisor = 001010011

Dividend = 100011011

Normal division algorithm deals with these steps, these cannot be implemented directly we need to undergo some steps for finding a quotient.

K^6+K^4+K+1) $K^8+K^4+K^3+K+1$ (K^2+1

$\underline{K^8+K^6+K^3+K^2}$

$K^6+K^4+K^2+K+1$

$\underline{K^6+K^4+K+1}$

K^2

For finding quotient we need to find the count value for shifting of the divisor and adding an extra bit at MSB.

Initial →

Count =1, symbol '||' denotes binary or operation.

Divisor → 0001010011 checking the logic (dividend || divisor) > (divisor<<1'b1)

The dividend →0100011011 If yes, we need to shift the divisor and increase the count value.

Final →

Count =3

Divisor after shifting → 0101001100

Dividend → 0100011011

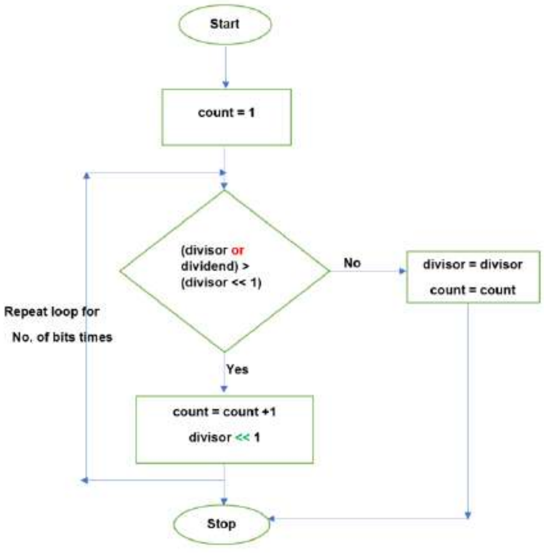

Fig. 3. Count value

Now we need to do actual division

Quotient → 000000000 count =3

Divisor → 101001100

Dividend → 100011011

until the count value >0 we need to do steps

Step1: quot→0000000000

Checking the logic ((dividend ^ divisor) < dividend)

yes, quot → 0000000000 || 0000000001

quot → 0000000001

dividend →dividend ^ divisor

divisor → divisor >> 1'b1

count = count -1 →2

Step2:

quot → 0000000001

Checking the logic ((dividend ^ divisor) < dividend)

No, quot →0000000010

divisor → divisor >> 1'b1

count = count -1 →1

Step3: quot→0000000100

Checking the logic ((dividend ^ divisor) < dividend)

yes, quot → 0000000100 || 0000000001

quot → 0000000101

dividend →dividend ^ divisor

divisor → divisor >> 1'b1

count = count -1 →0

End of steps Final quotient →0000000101 →K^2+1 (shown in the above example)

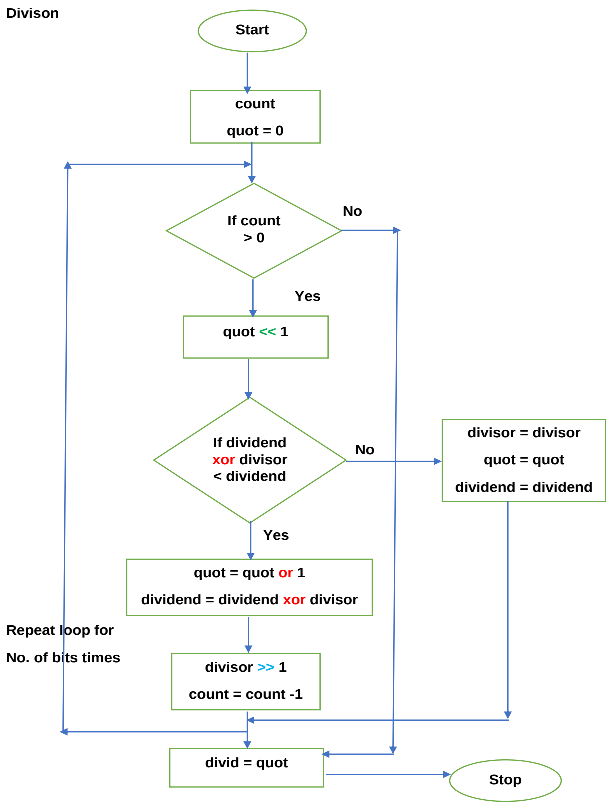

Fig. 4. Galois Field Divison

F. Algorithm for creating inverse GF(2^8)

Finding a multiplicative inverse needs operations addition, multiplication, and division. Implementation is defined in both binary and decimal.

The inverse of 197 mod 3000 using Extended Euclidean algorithm

Step1: Find GCD of 3000 and 197

3000 = 15(197) + 45
197 = 4(45) + 17
45 = 2(17) + 11
17 = 1(11) + 6
11 = 1(6) + 5
6 = 1(5) + 1 (Inverse exits for 197)

Step2: Writing in reverse order

1 = 6 - 1(5)
= 6 - 11(-6) =2(6)-1(11)
= 2(17) - 3(11)
= 8(17) - 3(45)
= 8(197) - 35(45)
= 533(197) - 35(3000)

Applying mod → 1= 533(197) mod 3000 - 35(3000) mod 3000 →1= 533(197) mod 3000
533 is the inverse of given 197 mod 3000

Similarly, we can use the same algorithm for the Galois field to find the inverse

Find the inverse of 01010011 mod 100011011

$K^6+K^4+K+1)$ $K^8+K^4+K^3+K+1$ (K^2+1
$\underline{K^8+K^6+K^3+K^2}$
$K^6+K^4+K^2+K+1$
$K^6\underline{+K^4+K+1}$
K^2)K^6+K^4+K+1 (K^3+K^2
$\underline{K^6+K^4}$
$K+1)$ K^2 (K
$\underline{K^2+1}$
1

(Inverse exists of a given number)
By following similar steps, we find inverse value.

A=$k^8+k^4+k^3+k+1$ B= k^6+k^4+k+1

k^2=A - B(k^2+1); k^2+1=0 -1(k^2+1)

k+1 = B – k^2(k^4+k^2); k^6+k^2+1= 1- (k^4+k^2)(k^2+1)

1 = k^2–(k+1) (k+1); k^7+k^6+k^3+k= (k^2+1)–(k+1) (k^6+k^2+1)

The inverse of 01010011 mod 100011011 is 11001010

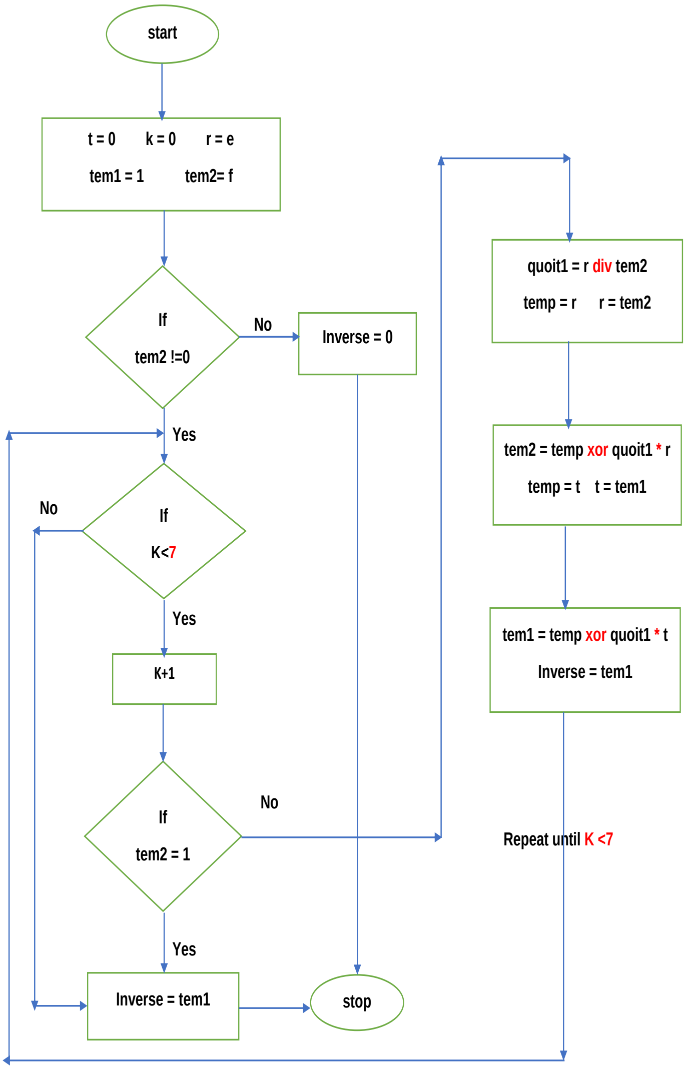

Fig. 5. Galois field Multiplicative Inverse

The above-mentioned algorithm is implemented in a sequence of steps using primitive polynomial e i.e. k^8+ k^4+ k^3+ k+ 1.

- F is a polynomial for which inverse must be found.
- If f = 0 inverse is 0.
- Some variables are used k, t, tem1, r, tem2.
- Division "div" and multiplication "*" algorithms are used.
- Until the value of K reaches less than 7 we keep on performing the steps for reaching the remainder 1.
- The final inverse of the polynomial will be tem1 in the following series of steps, temp and quoit1 variables are used for calculation purposes.

G. *Affine transform and S-box*

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \text{Multiply} \begin{bmatrix} k_7 \\ k_6 \\ k_5 \\ k_4 \\ k_3 \\ k_2 \\ k_1 \\ k_0 \end{bmatrix} + \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}$$

V. Conclusion

Every GF(2^n) has many valid irreducible polynomials. The proposed Galois field arithmetic method is unique and can be used with any valid irreducible polynomial in GF(2^n) to generate the S-box and inverse S-box for AES for 128, 192, and 256-bits Key. We implemented this algorithm instead of using a lookup table-based approach to overcome side-channel attacks. These algorithms can be synthesized in all FPGAs and implemented as ASIC. The proposed algorithms have been used and validated to generate S-box and inverse S-box on a Xilinx Vertix-7 FPGA. This design can be verified in all FPGA's. Future work concerns deeper analysis in improving power, performance, and area [PPA] of these Galois field arithmetic operations in various cryptographic applications.

Multiuser Data Dissemination in OFDMA System Based on Deep Q-Network

Yuan Xing, Haowen Pan, Bin Xu, Tianchi Zhao, Cristiano Tapparello, Yuchen Qian

***Abstract*—In this paper, a multiuser data dissemination problem is analyzed in an orthogonal frequency division multiple access(OFDMA) downlink system. By dynamically allocating subchannels and power to the mobile users, the system aims to minimize the time consumption in order to successfully deliver data to multiple mobile users under the restriction of total energy consumption. Both the objective and the constraint of the optimization are related to the real-time resource allocation strategies. Moreover, neither the statistics nor the full channel state information is known to the base station. In order to solve the global optimization problem with partial channel information, a Deep Q-Network algorithm is adopted. The numerical results show that compared with the other algorithms, Deep Q-Network can learn the optimal resource allocation strategies and achieve very good system performance.**

***Index Terms*—OFDMA, Energy efficiency, Data dissemination, Global optimization, Deep Q-Network.**

I. Introduction

As a promising multi access technique, orthogonal frequency division multiple access(OFDMA) is applied to many broadband wireless communication systems. Adapting OFDMA on multiple users wireless transmission can sufficiently exploit multiple users diversity in order to enhance the overall system performance. In [1], the optimization is formulated as maximizing a weighted sum information rates while satisfying both power and additional receiver-specific rate requirements in multiple parallel Gaussian broadcast channels.

In order to reduce the energy consumption in communication system, energy-efficient communications attracts much attentions. It is an effective metric to evaluate efficiency of the energy consumption [2]. The energy efficiency problem in OFDMA wireless communication systems has recently been discussed [3]–[5]. In [3], the authors study the energy-efficient resource allocation in OFDMA cellular networks. The energy efficiency is maximized under certain quality-of-service (QoS) requirements. In [5], the authors maximize the energy efficiency of the worst-case link under the information rate, total transmit power and available subcarrier constraints. In most of these works, the OFDMA resource allocation optimization problems are solved with statistical or complete knowledge about the environment. Very few papers formulate the optimization as global optimization problems. In [6], the optimization aims at maximizing the total energy efficiency of T time instants. Adapting to the dynamics of the user arrivals and channel state information, a real-time transmission policy can be found out.

In this paper, we consider a base station disseminate data to multiple mobile users. The power allocation and subchannel assignment are designed to meet the system requirements. The optimization problem is formulated as minimizing the time consumption in order to successfully deliver the required data to each user under the total energy consumption constraint. For the optimization, both the objective and the constraint are affected by the resource allocation strategy in each specific time slot. If the statistics of the channel is known to the base station, the problem is formed as a NP-hard problem, like traveling salesman problem [7]. However, the full channel information is unknown to the base station, which makes this problem even harder to be solved. We propose to apply the Deep Q-Network algorithm to solve the problem. Deep Q-Network has been widely adopted to solve complicated communication problems [6], [8]–[11]. In our model, Deep Q-Network is adopted in the optimization framework to make the dynamic resource allocation decision. The simulation results demonstrate that Deep Q-Network outperforms the other existing algorithms in solving the optimization problem.

II. System Model

In a downlink broadcast system: the base station serves K mobile users. There are N subchannels. $\mathcal{N} = \{1, 2, ..., N\}$. By properly adjusting the power allocation p_k and the subchannel assignment $\mathcal{I}_k$ to each user, the base station aims to disseminate the information payload B_k to each user in the shortest time. The system model is shown in Fig. 1.

The broadband spectrum is divided into several subchannels. Each subchannel has identical bandwidth W. Any subchannel can be allocated to any user k. The subchannels assigned to user k form the set $\mathcal{I}_k$. $\mathcal{I}_k$ is the subset of $\mathcal{N}$.

$$\mathcal{I}_1 \cup \mathcal{I}_2 \cup ... \cup \mathcal{I}_K \in \mathcal{N} \tag{1}$$

OFDM is utilized to convert the frequency selective wireless channels into multiple parallel flat channels over different subcarriers. We assume time is slotted and channel fading is approximately the same within one subchannel and independent across different subchannels in each time slot [11]. We

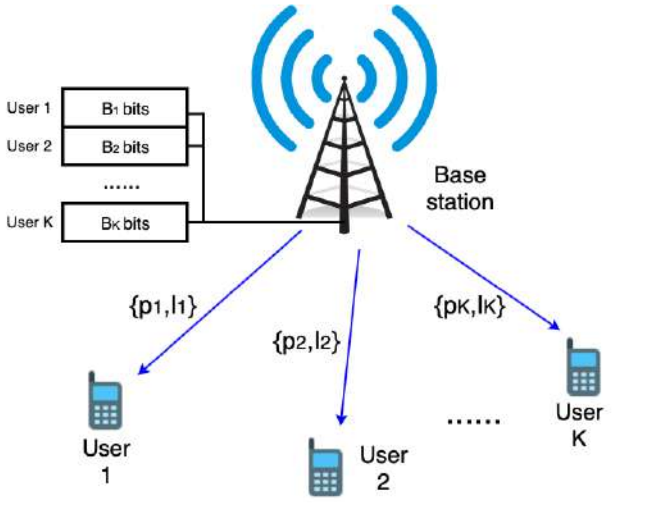

Fig. 1. Transmission from base station to multiple mobile users over parallel frequency channels.

define the channel gain between the transmitter and the kth user on the nth sub-channel at time t as:

$$h_{kn}(t) = \alpha_k g_{kn}(t) \tag{2}$$

where $g_{kn}(t)$ denotes the frequency dependent small-scale fading power component and assumed to be exponentially distributed, due to the Rayleigh fading channel feature.

$$\alpha_k = l_k(t)^{-\beta} \tag{3}$$

which denotes the path loss between the base station and user k. β is the path-loss exponent.

We define a subchannel selection threshold $\hat{p}_{sub}$ for each subchannel. For each individual user k, all N subchannels are classified into two categorical sets at time t: good subchannel set $\mathcal{N}_k^G(t)$ and bad subchannel set $\mathcal{N}_k^B(t)$:

$$\mathcal{N}_k^G(t) = \{\arg_{n\in\mathcal{N}} |h_{kn}(t)|^2 > \hat{p}_{sub}\} \tag{4}$$

$$\mathcal{N}_k^B(t) = \{\arg_{n\in\mathcal{N}} |h_{kn}(t)|^2 \leq \hat{p}_{sub}\} \tag{5}$$

In the real-time broadband communication system, acquiring the entire channel state information(CSI) is at extremely high cost. Hence, in this paper, we suppose only $\mathcal{N}_k^G(t)$ is available at the base station, the full CSI is unknown. The unique good subchannel set is denoted as

$$\mathcal{N}_k^u(t) = \{n | n \in \mathcal{N}_k^G(t), n \notin \mathcal{N}_j^G(t), j \in \mathcal{K}/k\} \tag{6}$$

where all the subchannels are only good for user k. We define the shared good subchannels as those good subchannels are qualified for multiple users. We evenly distribute shared good channels to all users. After distribution, the remaining extra subchannels are randomly assigned. From the shared good channels, the subchannels assigned to user k is included in set $\mathcal{N}_k^s(t)$. The ultimate assigned subchannel set for user k is defined as

$$\mathcal{N}_k^{tot}(t) = \mathcal{N}_k^u(t) \cup \mathcal{N}_k^s(t) \tag{7}$$

The power can only be allocated to the subchannels in $\mathcal{N}_k^{tot}(t)$ for user k. The total power allocated for user k at time t is denoted as $p_k(t)$, which is equally allocated to each subchannel in $\mathcal{N}_k^{tot}(t)$, the power allocated to each particular subchannel is $\frac{p_k(t)}{\mathcal{N}_k^{tot}(t)}$. In each time slot, b bits loaded information is transmitted on each subchannel. At time t, the Bit Error Rate(BER) of transmission from base station to user k on subchannel n in the case of M-ary QAM is given by:

$$BER_{k,n}(t) = 0.2e^{-1.6\frac{p_k(t)}{\mathcal{N}_k^{tot}(t)(2^b-1)}\frac{h_{kn}(t)}{\sigma_n^2(t)}} \tag{8}$$

where

$$\sigma^2(t) = N_o(t)W \tag{9}$$

denotes the variance of additive white Gaussian noise at time t. $N_0(t)$ is the noise power spectrum density.

We define the data successfully delivered to user k at time t as $R_k(t)$.

$$R_k(t) = \sum_{n\in\mathcal{N}_k^{tot}(t)} r_k^n(t) \tag{10}$$

$r_k^n(t) = b$ when all b bits data are received with no error on subchannel n. Otherwise, $r_k^n(t) = 0$ and a retransmission has to be issued.

III. Optimization Problem Formulation

The base station holds B_k bits information for each user. By appropriately allocating power $p_k(t)$ in real-time, the optimization problem is to minimize the time consumption T to successfully deliver B_k bits data to each user under the total energy consumption constraint $\hat{E}$. the optimization is formulated as:

$$\mathcal{P}_1: \begin{array}{ll} \underset{\{p_k(t)\}}{\text{minimize}} & T \\ \text{subject to} & \sum_{t=1}^{T} R_k(t) \geq B_k, \quad \forall k \in \mathcal{K} \\ & \sum_{t=1}^{T}\sum_{k=1}^{K} p_k(t)d_c \leq \hat{E} \end{array} \tag{11}$$

where d_c denotes the channel coherence time.

$\mathcal{P}_1$ is a complicated long term optimization problem. Data delivery can be seen as the shortest path problem. The energy consumption constraint affect the transmit decision at each time slot. It's unable to be solved by Dynamic Programming since very limited channel information is known to the base station. All these obstacles makes the Deep Q-Network(DQN) a fitting tool to solve $\mathcal{P}_1$.

In DRL, the system state s is consist of: the number of subchannels assigned to users $|\mathcal{N}_k^{tot}(t)|$, the accumulated throughput

$$R_k^{acc}(t) = \sum_{u=1}^{t} R_k(u) \tag{12}$$

the accumulated energy consumption

$$E^{acc}(t) = \sum_{u=1}^{t}\sum_{k=1}^{K} p_k(u)d_c \tag{13}$$

the accumulated sum throughput

$$R^{acc}(t) = \sum_{k=1}^{K} R_k^{acc}(t) \tag{14}$$

The system state s is denoted as:

$$\begin{aligned} s_t = [&|\mathcal{N}_1^{tot}(t)|, ..., |\mathcal{N}_K^{tot}(t)|, R_1^{acc}(t), ..., R_K^{acc}(t), \\ &E^{acc}(t), R^{acc}(t)] \end{aligned} \tag{15}$$

where $\mathbf{s}_t \in \mathbf{R}^{1\times(2K+2)}$. The set of all states is denoted by $\mathcal{S}$.

We define the power allocated $p_k(t)$ to each user k in a particular time slot t as the action $\mathbf{a}_t$:

$$\mathbf{a}_t = [p_1(t), p_2(t), ..., p_k(t)] \in \mathbf{R}^{1\times K} \tag{16}$$

where $p_k(t) \in [0, P]$, $\sum_{k=1}^{K} p_k(t) \leq P$. The whole action set is denoted as $\mathcal{A}$.

The evolution of our system can be described by a Markov process. The first system state starts at $t = 0$:

$$\mathbf{s}_0 = [|\mathcal{N}_1^{tot}(0)|, ..., |\mathcal{N}_K^{tot}(0)|, 0, ..., 0] \tag{17}$$

and the final state $\mathbf{s}_T$ in which $t = T$, i.e.,

$$\begin{aligned} s_T = [&|\mathcal{N}_1^{tot}(T)|, ..., |\mathcal{N}_K^{tot}(T)|, B_1, ..., B_k, \\ &E^{acc}(T), KB] \end{aligned} \tag{18}$$

At time slot t the system is in a generic state $\mathbf{s}$, the transmitter selects an action $\mathbf{a}_t \in \mathcal{A}$, and the system moves to a new state $\mathbf{s}'$. $w(\mathbf{s}, \mathbf{a}_t, \mathbf{s}^{'})$ denotes the reward when the current state is $\mathbf{s} \in \mathcal{S}$, action $\mathbf{a}_t \in \mathcal{A}$ is selected and the system moves to state $\mathbf{s}^{'} \in \mathcal{S}$.

Since we aim at minimizing data delivery time consumption under total energy constraint, both the optimization target and the constraints have to be related to the reward [11]. In order to design a proper reward function, optimization $\mathcal{P}_1$ is reformed as:

$$\mathcal{P}_2: \quad \begin{aligned} &\underset{\{p_k(t)\}}{\text{minimize}} && T \\ &\text{subject to} && \textstyle\sum_{t=1}^{T} R_k(t) \geq B_k, \quad \forall k \in \mathcal{K} \\ & && \frac{KB}{\sum_{t=1}^{T}\sum_{k=1}^{K} p_k(t)d_c} \geq \hat{\Gamma} \end{aligned} \tag{19}$$

where

$$\hat{\Gamma} = \frac{\sum_{k=1}^{K} B_k}{\hat{E}} \tag{20}$$

which denotes the energy efficiency threshold. The energy efficiency at time t is denoted as:

$$\Gamma(t) = \frac{\sum_{k=1}^{K} R_k^{acc}(t)}{\sum_{u=1}^{t}\sum_{k=1}^{K} p_k(u)d_c} \tag{21}$$

In each time slot, $\Gamma(t)$ is compared with $\hat{\Gamma}$, which effectively tracks the energy consumption condition. We define $\sigma(t)$ as the energy constraint satisfactory indicator.

The reward function is defined as:

$$w(\mathbf{s}, \mathbf{a}_t, \mathbf{s}^{'}) = \min(R_1^{acc}(t), ..., R_K^{acc}(t))\sigma(t) \tag{22}$$

$$\sigma(t) = \begin{cases} 1 & \Gamma(t) \geq \hat{\Gamma} \\ 0 & \Gamma(t) < \hat{\Gamma} \end{cases} \tag{23}$$

The optimization problem $\mathcal{P}_2 = (\mathcal{S}, \mathcal{A}, p, w)$ can then be seen as a Markov Decision Process from state $\mathbf{s}_0$ to state $\mathbf{s}_T$ on the Markov chain with states $\mathcal{S}$ and probabilities $\{p_{\mathbf{s},\mathbf{s}'}(\mathbf{a})\}$, actions $\mathbf{a} \in \mathcal{A}$, and rewards $w(\mathbf{s}, \mathbf{a}, \mathbf{s}^{'})$. Without knowledge about $\{p_{\mathbf{s},\mathbf{s}'}(\mathbf{a})\}$, our objective is to find, for each possible state $\mathbf{s} \in \mathcal{S}$, an optimal action $\mathbf{a}^*(\mathbf{s})$ so that the optimization goal is achieved. A generic policy can be written as

$$\pi = \{\mathbf{a}(\mathbf{s}) : \mathbf{s} \in \mathcal{S}\} \tag{24}$$

IV. Solving Optimization with Deep Q Network

Procedure 1 : Deep Q Network algorithm training process

```
1. Randomly generate the weight parameter $\theta$ for the $eval\_net$. The $target\_net$ clones the weight parameters $\theta' = \theta$. $u = 1$. $t = 1$. $D = d = 1$.
2. The base station acquires $\mathcal{N}_k^G$ from all the users in order to calculate $\mathcal{N}_k^{tot}$. $\mathbf{s} = \mathbf{s}_0$.
3. Randomly generates a probability $p \in [0, 1]$.
   IF $D > D_{ini}$ and $p \geq \epsilon_{ch}$:
      Play the action $\mathbf{a}$ as: $\mathbf{a} = \max_{\mathbf{a}\in\mathcal{A}} Q(\mathbf{s}, \mathbf{a})$
   ELSE:
      Randomly play the action from action set $\mathcal{A}$.
4. $R_k^{acc}(t)$ and $E^{acc}(t)$ are renewed and feedbacked to the base station. At the end of each time slot, the channel updated, base station acquires $\mathcal{N}_k^G$ from all the users and calculate $\mathcal{N}_k^{tot}$. The system state is updated to $s'$.
5. $ep(d) = \{s, \mathbf{a}, w(s, \mathbf{a}, s'), s'\}$. $d = d + 1$. If $D$ reaches the maximum of experience pool, $D$ remain constant, $d = 1$, otherwise, $D = d$. $s = s'$. $t = t + 1$..
6. After experience pool accumulates enough data, from $D$ experiences, randomly select $D_s$ experiences to train the neural network $eval\_net$. Back-propagation method is applied to minimize the loss function Loss($\theta$). Clone the weight parameters from $eval\_net$ to $target\_net$ after several time intervals.
7. IF $s' = s_T$:
      $s = s_0$. $t = 1$. $u = u+1$. If $u = U$, algorithm terminates, otherwise, go back to step 2.
   ELSE:
      go to step 3.
```

In this section, Deep Q-Network is applied to solve the proposed optimization. The main idea of DQN is to train a neural network to find the cost function(Q function) of a particular system state and action combination. When the system is in state $\mathbf{s}$, and action $\mathbf{a}$ is selected, the Q function is denoted as $Q(\mathbf{s}, \mathbf{a}, \theta)$. θ denotes the parameters of the Q network. The purpose of training the neural network is to make:

$$Q(\mathbf{s}, \mathbf{a}, \theta) \approx Q^*(\mathbf{s}, \mathbf{a}) \tag{25}$$

According to the DQN algorithm [12], two neural networks are used to solve the problem: the evaluation network and the target network, which are denoted as $eval\_net$ and $target\_net$, respectively. Both the $eval\_net$ and the $target\_net$ are set up with several hidden layers. The input of the $eval\_net$ and the $target\_net$ are denoted as s and s', which describe the current system state s and the next system state $\mathbf{s}'$, respectively. The output of $eval\_net$ and $target\_net$ are denoted as $Q_e(\mathbf{s}, \mathbf{a}, \theta)$ and $Q_t(\mathbf{s}, \mathbf{a}, \theta')$, respectively. The evaluation network is continuously trained to update the value of θ, however, the target network only copy the weight

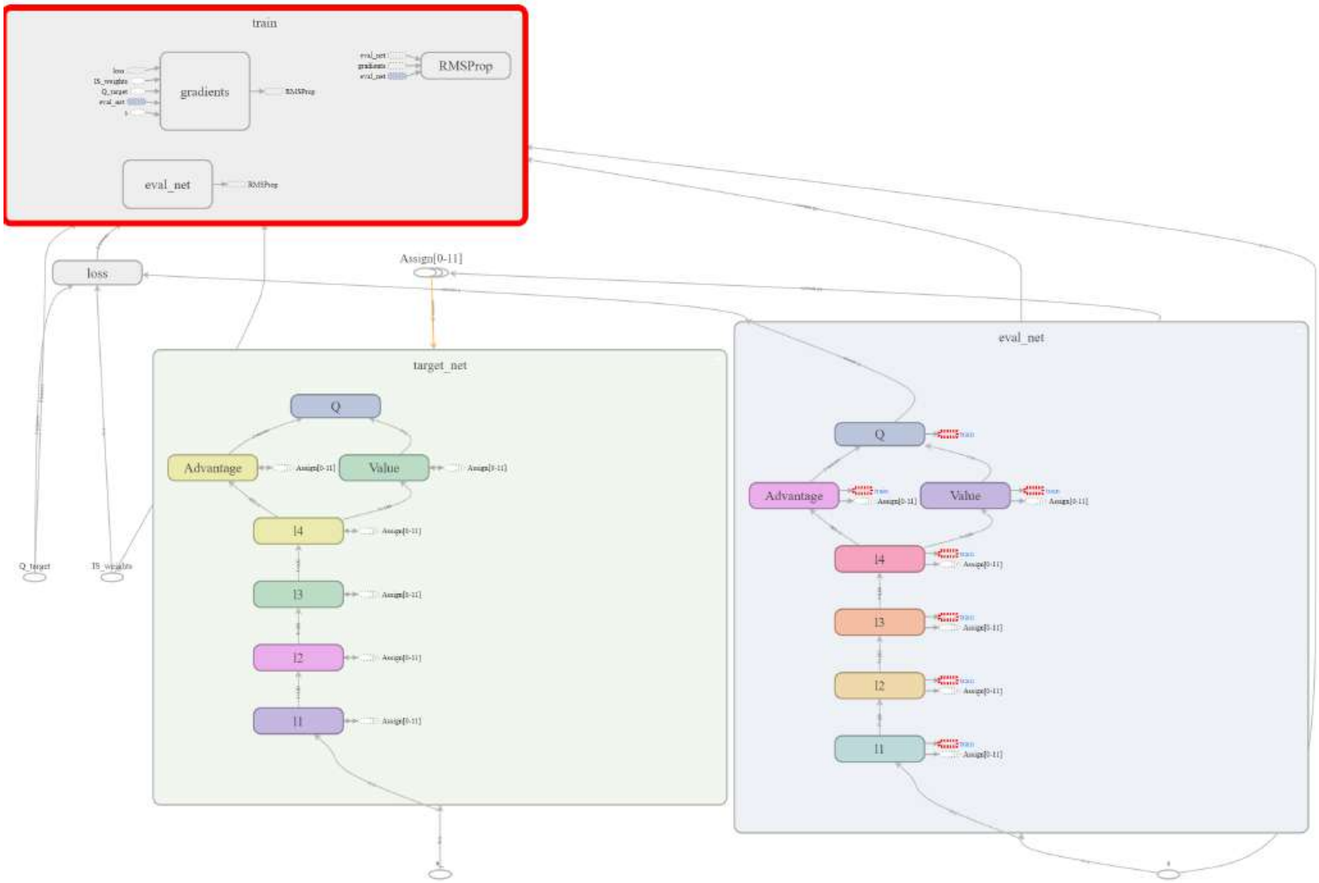

Fig. 2. The framework of Deep Q-Network.

parameters from the evaluation network intermittently (i.e., $\theta' = \theta$). In each neural network learning epoch, the loss function is defined as:

$$\text{Loss}(\theta) = E\left[(y - Q_e(\mathbf{s}, \mathbf{a}, \theta))^2\right]. \tag{26}$$

y represents the real Q value, and is is calculated as:

$$y = w(\mathbf{s}, \mathbf{a}, \mathbf{s}') + \gamma \max_{\mathbf{a}' \in \mathcal{A}} Q_t(\mathbf{s}', \mathbf{a}', \theta') \tag{27}$$

where γ is the reward discount. As the loss function updates, the values are back-propagated to the neural network to update the weight of the $eval\_net$.

In order to better train the neural network, we apply the experience reply method to remove the correlation between different training data. Each experience consists of the current system state s, the action $\mathbf{a}$, the next system state $\mathbf{s}'$, and the corresponding reward $w(\mathbf{s}, \mathbf{a}, \mathbf{s}')$. The experience is denoted by the set

$$ep = \{\mathbf{s}, \mathbf{a}, w(\mathbf{s}, \mathbf{a}, \mathbf{s}'), \mathbf{s}'\} \tag{28}$$

The algorithm records D experiences and randomly select $D_\mathbf{s}$ (with $D_\mathbf{s} < D$) experiences from D for training. $D_{ini} = 10000$. After the training is finished, $target\_net$ clones all the weight parameters from the $eval\_net$ (i.e., $\theta^{'} = \theta$).

The algorithm used for the DQN training process is presented in Algorithm 1. In the algorithm, we define in each training iteration, we generate D usable experiences ep, and select D_s of all for training the $eval\_net$. In total, we suppose there are U training iterations. We consider that for both the $eval\_net$ and the $target\_net$, there are N_l layers in the neural network. The structure of DQN is shown in Fig. 2.

V. Simulation Results

We conduct the experiment with the National Instruments/Ettus Research Universal Software Radio Peripheral(USRP) N210 with the CBX daughterboard in order to measured the indoor channel. The number of the mobile user is $K = 3$. The total number of available subchannels is $N = 16$. Each subchannel has same bandwidth $W = 10^3$Hz. The users are randomly distributed around the base station and remain stationary throughout the whole T data transmission time slot. The channel gains from the base station to all users are approximately in range $[-80, -60]$dB. The path loss exponential is $\beta = 2$. The noise power spectrum density is $N_0 = 170$ dBm/Hz. $b = 9$ bits are transmitted by each symbol on each subchannel. The channel coherence time is $d_c = 1$ms. The subchannel selection threshold is $\hat{p}_s = 10^{-7}$. The required delivered data for all users are same: $B_1 = ... = B_K = B = 450$ bits. $p_k(t)$ is selected from $[0.3, 0.2, 0.15, 0.1, 0.075, 0.05, 0.0375, 0.025, 0.0125, 0.00625]$

TABLE I
DQN SIMULATION PARAMETERS

Deep Q Network	Value
Number of hidden layers (N_L)	4
Number of nodes of each hidden layer	100
Learning rate (ϵ)	0.00005
Mini-batch size	10
Training starting step	10000
Experience pool	60000
Initial exploration rate(ϵ_c)	1
Final exploration rate(ϵ_c)	0.1
Exploration interval	0.001
$target\_net$ weight replacement interval	500
Training episodes	60000

mW. $\sum_{n=1}^{K} p_k(t) \leq P$. $P = 0.3$mW. The energy consumption constraint $\hat{E}$ are regulated as 3.9×10^{-4} J and 4.5×10^{-4} J.

The simulation parameters used for DQN are presented in Table I. The exploration rate ϵ_c decreases from 1 to 0.1 with 0.001 interval. The software environment for simulation is TensorFlow 0.12.1 with Python 3.6 in Jupyter Notebook 5.6.0.

In Fig. 3, the time consumption T and moving average of energy constraint satisfactory $\bar{\eta}$ are observed throughout the learning process. An training episode lasts T time slots, an episode is over if B bits data are successfully received at each user. If at the end of the eth episode, $\sigma(T) = 1$, we define $\eta(e) = 1$, otherwise, $\eta(e) = 0$.

$\bar{\eta}$ is the moving average of $\eta(e)$ in $e = 100$ episodes.

$$\bar{\eta} = \frac{\eta(e-99) + ... + \eta(e)}{100} \tag{29}$$

Higher $\bar{\eta}$ denotes the higher probability of satisfactory of energy consumption constraint. We observe that as the training goes on, both T and $\bar{\eta}$ converges. With lower energy consumption constraint $\hat{E}$, more time is consumed to finish data transmission.

We apply $N_t = 1000$ test data to test the performance of DQN trained with differnt reward discount γ. Of N_t test data, N_s data satisfy the energy consumption constraint $\hat{E}$. ζ_E is defined as:

$$\zeta_E = \frac{N_s}{N_t} \tag{30}$$

$\bar{T}$ is the average time consumption of N_t test data. If $\gamma = 0$, the myopic solution is learnt. The strategy only maximize the immediate reward at each particular system state without considering system dynamics. If $\gamma = 1$, each system state are equally considered. Both $\gamma = 0$ and $\gamma = 1$ don't achieve good learning effect. Fig. 4 shows that when $\gamma = 0.75$, the base station consumes least time to successfully deliver required data to all users, while has the highest probability of energy constraint satisfactory. Hence, the optimal reward discount is $\gamma = 0.75$.

In fig. 5 and fig. 6, the performance of Deep Q-Network is compared with the state of the art. For Maximum power transmission method, we equally allocate 0.1 mW power to each user and continuously transmit with that strategy until the required data are delivered to all the users. For Minimum power transmission method, each user is allocated with 0.0125 mW power. Random transmission need to randomly select an

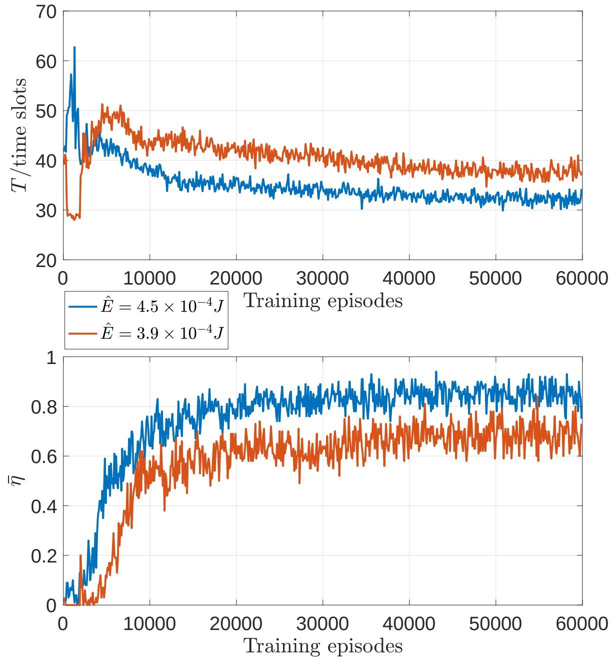

Fig. 3. The convergence on time consumption T and $\bar{\eta}$(moving average of η) in Deep Q-Network training process. $\gamma = 0.75$.

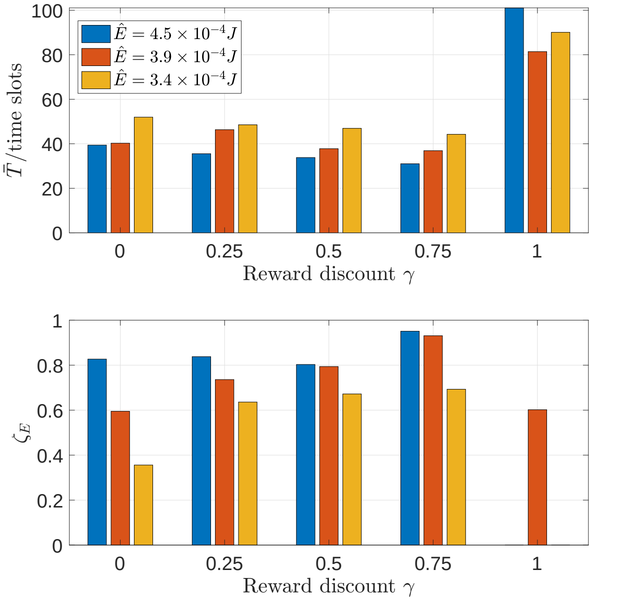

Fig. 4. The performance comparison of average time consumption $\bar{T}$ and energy consumption constraint satisfactory probability ζ_E on reward discount γ.

action in each time slot. We allow the energy consumption constraints to vary. We can observe that Deep Q-Network outperforms all the other four algorithms. Maximum and Minimum power transmission can only guarantee a good performance on either time consumption and constraint satisfactory. The myopic solution doesn't consider the long term reward, hence achieves bad performance on both time consumption and energy consumption. Compared with DQN, the random transmission can achieve similar energy consumption performance, however consumes more time to finish data dissemination. Deep Q-Network is proved to learn the optimal solution.

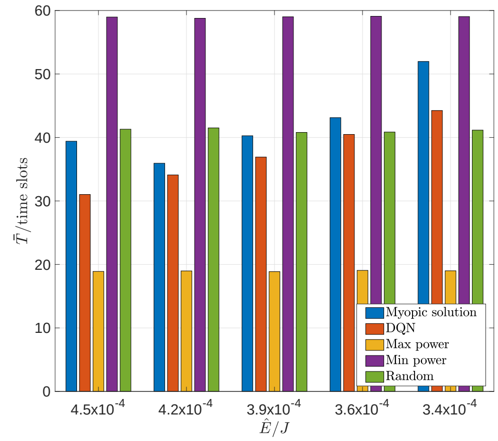

Fig. 5. The comparison of time consumption between Deep Q-Network and other algorithms on energy consumption constraint $\hat{E}$.

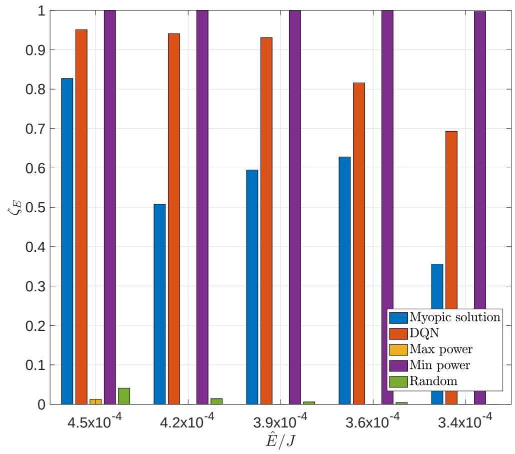

Fig. 6. The comparison of energy consumption between Deep Q-Network and other algorithms on energy consumption constraint $\hat{E}$.

VI. Conclusion

The multiple users data dissemination problem is explored in a OFDMA downlink system. The system aims to minimize the data transmission time under the total energy consumption constraint. In order to solve this global optimization in real-time, a Deep Q-Network method is proposed to determine the optimal transmission strategy in a real-time. Without the prior knowledge about the channel information, the Deep Q-Network can learn the variation of the wireless channel and dynamically provide the resource allocation strategy for the base station. Compared with the state of the art, the proposed Deep Q-Network achieves the best system performance on both time and energy consumption.

***Abstract*—In this paper, we consider the server allocation problem in edge computing. We consider a system model where there are a number of areas or locations, each of which has an associated Base Station (BS), where we can deploy an edge cloud with multiple servers. Each edge cloud will process application requests received at the corresponding BS from users in the corresponding area. The system manager/operator has a budget to deploy a given number of servers to the BSs. Our goal is to come up with a server allocation plan, i.e., how many servers to deploy at each of the BSs, such that the overall average turnaround time of application requests generated by all the users is minimized. In order to achieve the optimal solution for the problem, we resort to queueing theory and model each edge cloud as an M/M/c queue. Analysis on the problem motivates a Largest Weighted Reduction Time First (LWRTF) algorithm to assign servers to edge clouds. Numerical comparisons among various algorithms verify that *Algorithm LWRTF* has near-optimal performances in terms of minimizing the average turnaround time. Simulation results using the CloudSim Plus simulation tool also verify that *Algorithm LWRTF* achieves better performances compared to other reasonably designed heuristic algorithms.**

***Index Terms*—Edge computing, edge cloud, queueing theory, numerical method, simulation approach.**

I. Introduction

Facilitated by emerging communication, networking, and information technologies, such as 5G [1], Internet of Things (IoT) [2], [3], Artificial Intelligence (AI) [4], etc, our current era is witnessing a proliferation of services and applications that are provided at the edge of the Internet. These services and applications include augmented reality [5], virtual reality [6], cognitive assistance [7], gesture recognition [8], mobile gaming [9], and online social networks [10], [11]. All these applications can be computation-intensive and/or communication-intensive, increasing the requirements for various resources from mobile devices. However, mobile devices (i.e., mobile phones, tablets, IoT devices, etc.) are still limited in terms of storage size, computation capacity, communication bandwidth, and battery life. Cloud computing has been applied to execute the applications offloaded from the mobile devices. However, various issues arise due to long latency and limited bandwidth from mobile devices to remote clouds.

Recently, the *edge computing* paradigm [12], [13], which extends cloud computing to the edge of the Internet, has been proposed to support applications originating from the edge of the Internet. By running applications on relatively small computing systems deployed at the Internet edge, edge computing allows users to exploit computing power outside of the mobile devices without incurring long access delays to remote clouds. Several other terms have been used, such as fog computing, cloudlets, edge-centric computing, mobile edge computing, etc [5], [14]–[17]. In our discussion, we will consistently refer to them as *edge computing*. The small computing systems deployed at the Internet edge will be called *edge clouds*. In our discussion, the mobile devices are only treated as clients and will not help other mobile devices process tasks.

In edge computing, a fundamental problem is the server allocation problem, which has been considered by various existing works [18]–[21]. In most existing works, the system model for an edge cloud is largely simplified. In [21], the numbers of servers in all the edge clouds are fixed and equal to each other. In [19] and [18], the numbers of servers in the edge clouds are not the same; however, they are still fixed; the problem is to derive the edge cloud placement given some capacity constraints to minimize the edge cloud access delay, while the queueing time and execution time of application requests are not considered. In this paper, we assume that the number of servers at an edge cloud is flexible, and we want to arrive at the optimal server allocation plan so that the average turnaround time for all application requests is minimized.

Our main contributions in this paper are as follows. We consider the server allocation problem using queueing theory; each edge cloud is modeled as an M/M/c queueing system. We design a Largest Weighted Reduction Time First (LWRTF) algorithm to allocate servers to edge clouds. Numerical comparisons among various heuristic algorithms verify that *Algorithm LWRTF* has near-optimal performances in terms of minimizing the average turnaround time. We demonstrate the accuracy and validity of a simulation based approach (using the CloudSim Plus simulation tool [22]) by comparing the numerical results from queueing theory and the simulation results. Simulation results using the CloudSim Plus simulation tool also verify that *Algorithm LWRTF* achieves the best performance compared to other reasonably designed heuristics.

The rest of the paper is organized as follows. Section II presents the system model. In Section III, we present some preliminary analyses on the server allocation problem. In Section IV, we propse the Largest Weighted Reduction Time

TABLE I
IMPORTANT NOTATIONS USED IN THE PAPER

Notations	Meaning
N	total number of servers
B	total number of BSs
b_i	the ith BS
t_e	application request's average execution time on a server
μ	request departure rate on a server; $\mu = 1/t_e$
T	time period under discussion
m_i	the number of requests generated in b_i during time period T
λ_i	request arrival rate at b_i; $\lambda_i = m_i/T$
$\boldsymbol{\lambda}$	the request arrival rate vector for the B BSs
n_i^{min}	the minimum number of servers that must be deployed at b_i
n_i	the number of servers deployed at the ith edge cloud
$\boldsymbol{n}$	the server allocation vector
$t_{s,i}$	the average turnaround time for application requests at b_i
t	the average turnaroudn time for all application requests

First (LWRTF) algorithm in detail. In Section V, we introduce several reasonably designed heurisitics for the same problem. Comparisions among the LWRTF algorithm and other heuristic algorithms using both numerical methods and high-fidelity simulations are presented in Section VI. We conclude our paper and give future work directions in Section VII.

II. SYSTEM MODEL

We denote the set of all BSs in the target region as $\mathcal{B} = \{b_1, b_2, \cdots, b_B\}$, where B is the cardinality of the set, i.e., the total number of BSs. We can deploy an edge cloud at each BS to serve the area/location covered by that BS. For notational convenience, we will also use b_i to refer to the edge cloud deployed at the BS, the location of the BS, and the user area covered by the BS. The system model with multi-server edge clouds is shown in Fig. 1.

We assume that all the servers in the system have the same execution speed, and that all the application requests/tasks have an average execution time of t_e following the exponential distribution. Equivalently, when the requests are executed on an edge server, the depature rate of the requests can be calcualted as $\mu = 1/t_e$.

During a time period of T, m_i application requests are generated in user area b_i and will be offloaded to the edge cloud for processing. Assume that the application request arrivals follow a Poisson distribution. We can calculate the application request arrival rate at b_i as $\lambda_i = m_i/T$. The *turnaround time* for a given application request consists of the queueing time and the execution time of the request at the corresponding edge cloud.

The service provider has a budget to deploy N servers across all the edge clouds. Let n_i be the number of servers to be deployed at b_i, $\forall i = 1, 2, \cdots, B$. Since deploying more servers will definitely help to reduce the average turnaround time, we will deploy all the N servers, i.e., $\sum_{i=1}^{B} n_i = N$. The service provider wants to derive a server allocation plan in order to minimize the average turnaround time for all application requests generated within the target region. Table I lists the important notations used in the paper; some of them will be introduced later.

III. PRELIMINARIES

Given a valid N, we aim to derive an optimal server allocation plan to minimize the average turnaround time of all application requests. A naive approach is allocate the servers such that the numbers of servers of the edge clouds are proportional to their request arrival rates. However, we find that this approach can result in very poor performances in terms of minimizing the average turnaround time for all the application requests. Besides, we find that other reasonably designed heuristics may be unstable and result in poor performances in many situations. This movitates us to delve deeper into the problem. We resort to queuing theory in order to derive the optimal solution for the problem.

The edge cloud at a BS is modeled as an M/M/c queue, i.e., the Erlang C model [23]. Let $\rho_i = \frac{\lambda_i}{n_i \mu}$. The probability that an arriving application request is forced to join a queue at b_i (i.e., all n_i servers are currently occupied) is given by:

$$\begin{aligned} C(n_i, \lambda_i/\mu) &= \frac{\frac{(n_i\rho_i)^{n_i}}{n_i!}\frac{1}{1-\rho_i}}{\sum_{k=0}^{n_i-1}\frac{(n_i\rho_i)^k}{k!} + \frac{(n_i\rho_i)^{n_i}}{n_i!}\frac{1}{1-\rho_i}} \\ &= \frac{1}{1+(1-\rho_i)\frac{n_i!}{(n_i\rho_i)^{n_i}}\sum_{k=0}^{n_i-1}\frac{(n_i\rho_i)^k}{k!}}, \end{aligned} \tag{1}$$

which is the Erlang C formula. The average turnaround time (consisting of the queueing time and the execution time) of requests that are processed at b_i is

$$t_{s,i} = \frac{C(n_i, \lambda_i/\mu)}{n_i\mu - \lambda_i} + \frac{1}{\mu}. \tag{2}$$

Thus, the average turnaround time of all application requests generated within the entire region is:

$$t = \frac{\sum_{i=1}^{B}(\lambda_i t_{s,i})}{\sum_{i=1}^{B}\lambda_i}. \tag{3}$$

Besides, for the queueing system to be stable at b_i, we must have $n_i\mu - \lambda_i > 0$. Let

$$n_i^{min} = \lfloor \lambda_i/\mu \rfloor + 1, \forall i = 1, 2, \cdots, B. \tag{4}$$

Here, n_i^{min} is the minimal number of servers that must be allocated to edge cloud b_i.

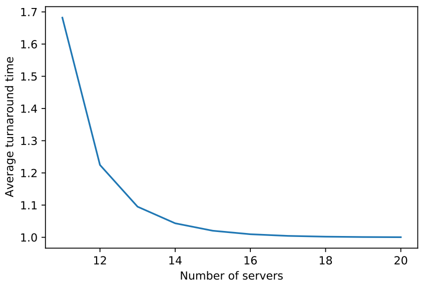

Fig. 2. Average turnaround time with respect to the number of servers.

The optimization problem can be formulated as follows:

$$\begin{aligned} \underset{n_i, \forall i=1,\cdots,B}{\text{minimize}} \quad & t \\ \text{subject to} \quad & n_i \geq n_i^{min}, \forall i = 1, \ldots, B. \\ & \sum_{i=1}^{B} n_i = N. \\ & \text{Equations (1), (2), and (3).} \end{aligned}$$

The complexity of the above optimization problem lies in the following aspects. First, it is an Integer Programming problem with an exponentially large solution search space; these kinds of problems are generally NP-Hard. Second, the closed-form expression of the objective function is quite complex, resulting from the complexity of the Erlang C formula; the fact that $C(n_i, \lambda_i/\mu)$ involves factorial and exponentiation operations on the solution variables (n_i's) makes various relaxation-based convex optimization techniques inapplicable here.

It is intuitive and easy to verify that when the application request arrival rates at the BSs are equal to each other, the server allocations at the BSs should be balanced. In other words, the number of servers at one location will not differ from that at another location by more than 1. The balanced server allocation for the case with equal request arrival rates has been verified in our previous works [24]–[26].

Next, we consider the general case where the request arrival rates at the BSs are not necessarily equal to each other. For each queue at each edge cloud to be stable, the number of servers deployed at b_i should satisfy the following constraint,

$$n_i \geq n_i^{min} = \lfloor \lambda_i/\mu \rfloor + 1, \forall i = 1, 2, \cdots, B. \qquad (5)$$

We must have $N \geq \sum_{i=1}^{B} n_i^{min}$. Any valid server allocation plan should allocate at least n_i^{min} servers at b_i. Thus, the server allocation problem becomes how to allocate the remaining $N - \sum_{i=1}^{B} n_i^{min}$ servers to the B edge clouds.

IV. Algorithm LWRTF

We design a Largest Weighted Reduction Time First (LWRTF) strategy to assign the remaining servers to the edge clouds one by one. Our design is motivated by how the average turnaround time changes with respect to the number of servers in a multi-server queueing system, as shown in Fig. 2. In Fig. 2, we set $\mu = 1$ and $\lambda = 10$. When we have 10 servers, the system is unstable, i.e., the average turnaround time is infinite. For the queueing system to be stable, we should have at least 11 servers. When the number of servers is small, adding one server will result in a large reduction in the average turnaround time. When the number of servers is large, the average turnaround time will be already close to 1, and adding more servers will provide minimal reduction in the average turnaround time. This indicates that when we consider allocating servers to the edge clouds, we should take into consideration the amount of reduction in the average turnaround time. Intuitively, we should allocate our next server to the edge cloud that can achieve a large reduction in the average turnaround time. For the M/M/c queueing system at b_i, adding one server to the system will reduce the average turnaround time. The reduction time can be calculated as follows:

$$\Delta t_{s,i} = \frac{C(n_i, \lambda_i/\mu)}{n_i\mu - \lambda_i} - \frac{C(n_i + 1, \lambda_i/\mu)}{(n_i + 1)\mu - \lambda_i}. \qquad (6)$$

Algorithm LWRTF

Require: N: the total number of servers; B: the number of BSs; t_e: application request's average execution time; m_i: the number of applicaiton requests at b_i, $\forall \lambda_i, i = 1, \cdots, B$, during time period T.

Ensure: **n** = $(n_1, \cdots, n_B)$: the server allocation vector.

```
 1: $\mu = 1/t_e$;
 2: $\lambda_i = m_i/T$;
 3: for $i = 1, \cdots, B$ do
 4:     $n_i^{min} = \lfloor \lambda_i/\mu \rfloor + 1$;
 5:     $n_i = n_i^{min}$;
 6:     Calculate $\Delta t_{s,i}$ according to Equation (6);
 7: if $N < \sum_{i=1}^{B} n_i^{min}$ then
 8:     return null;
 9: for $j = 1, \cdots, N - \sum_{i=1}^{B} n_i^{min}$ do
10:     $idx = \underset{i}{\text{argmax}}\{\lambda_i \Delta t_{s,i} | i = 1, \cdots, B\}$;
11:     $n_{idx} = n_{idx} + 1$;
12:     Update $\Delta t_{s,idx}$ according to Equation (6) with updated
        $n_{idx}$;
13: return n;
```

Besides, different edge clouds have different request arrival rates, λ_i's. A larger λ_i will have a more significant influence on the overall average turnaround time given the same amount of reduction in the average turnaround time. Thus, our strategy is to assign the server to the edge cloud with the largest $\lambda_i \Delta t_{s,i}$ value among all the edge clouds.

The detailed procedures are described in **Algorithm** LWRTF. The algorithm will first assign n_i^{min} servers to edge cloud b_i, and calculate $\Delta t_{s,i}$ in a for loop (lines 3 to 6). The algorithm returns null if it finds the input invalid (line 7). Line 10 gets the index of the edge cloud with the largest weighted reduction time. Line 11 assigns the next server to the corresponding edge cloud. Line 12 updates the reduction time after the server has been assigned to the edge cloud.

```
Algorithm Proportional
Require: $N$: the total number of servers; $B$: the number of BSs; $t_e$: application request's average execution time; $m_i$: the number of applicaiton requests at $b_i$, $\forall \lambda_i, i = 1, \cdots, B$, during time period $T$.
Ensure: n = $(n_1, \cdots, n_B)$: the server allocation vector.
1: $\mu = 1/t_e$;
2: $\lambda_i = m_i/T$;
3: for $i = 1, \cdots, B$ do
4:     $n_i^{min} = \lfloor \lambda_i/\mu \rfloor + 1$;
5:     $n_i = n_i^{min}$;
6: if $N < \sum_{i=1}^{B} n_i^{min}$ then
7:     return null;
8: for $j = 1, \cdots, N - \sum_{i=1}^{B} n_i^{min}$ do
9:     $idx = \underset{i}{\text{argmax}}\{\lambda_i N/(\sum_{i=1}^{B} \lambda_i) - n_i | i = 1, \cdots, B\}$;
10:    $n_{idx} = n_{idx} + 1$;
11: return n;
```

After all the remaining servers have been assigned, the server allocation vector, $\boldsymbol{n}$ will be returned.

It is worth noting that when the application request arrival rates, λ_i's are equal to each other, *Algorithm LWRTF* will also generate a balanced server allocation, which is the optimal solution for this special case. This demonstrates that *Algorithm LWRTF* is applicable to both special cases and general cases.

V. Comparing Heuristics

In this section, we explore other reasonable heuristic algorithms that also try to minimize the average turnaround time for all applicaiton requests. All the heuristics will first allocate n_i^{min} servers to the ith edge cloud. After that, they use different methods to assign the remaining $N - \sum_i^B n_i^{min}$ servers to the selected edge clouds one by one.

Algorithm Proportional: This algorithm tries to achieve a server allocation where the number of servers of edge clouds are proportional to their request arrival rates. That is, n_i should be close to $\lambda_i N/(\sum_{i=1}^{B} \lambda_i)$. The algorithm will assign the next server to the edge cloud with the largest $\lambda_i N/(\sum_{i=1}^{B} \lambda_i) - n_i$ value among all edge clouds. The details of the algorithms are presented in **Algorithm** Proportional.

Algorithm Largest Server Shortage Severeness First (LSSSF): The server shortage severeness of an edge cloud is defined as $1/(n_i\mu - \lambda_i)$. This algorithm assigns the next server to the edge cloud with the largest $1/(n_i\mu - \lambda_i)$ value among all edge clouds. The intuition is to assign the next server to the edge cloud that has the severest shortage of servers. Algorithm LSSSF only needs to replace line 9 in **Algorithm** Proportional with "$idx = \underset{i}{\text{argmax}}\{1/(n_i\mu - \lambda_i) | i = 1, \cdots, B\}$;".

Algorithm Largest Weighted Server Shortage Severeness First (LWSSSF): This method adds the weight λ_i to the server shortage severeness. It assigns the next server to the edge cloud with the largest $\lambda_i/(n_i\mu - \lambda_i)$ value among all edge clouds. Algorithm LWSSSF only needs to replace line 9 in **Algorithm** Proportional with "$idx = \underset{i}{\text{argmax}}\{\lambda_i/(n_i\mu - \lambda_i) | i = 1, \cdots, B\}$;".

Algorithm Largest Reduction Time First (LRTF): This method is the simpler case of *Algorithm LWRTF*. It assigns the next server to the edge cloud with the largest $\Delta t_{s,i}$ value among all edge clouds. Algorithm LRTF only needs to repace line 10 in **Algorithm** LWRTF with "$idx = \underset{i}{\text{argmax}}\{\Delta t_{s,i} | i = 1, \cdots, B\}$;".

VI. Evaluations

A. Numerical Comparisons Among Different Server Allocation Algorithms

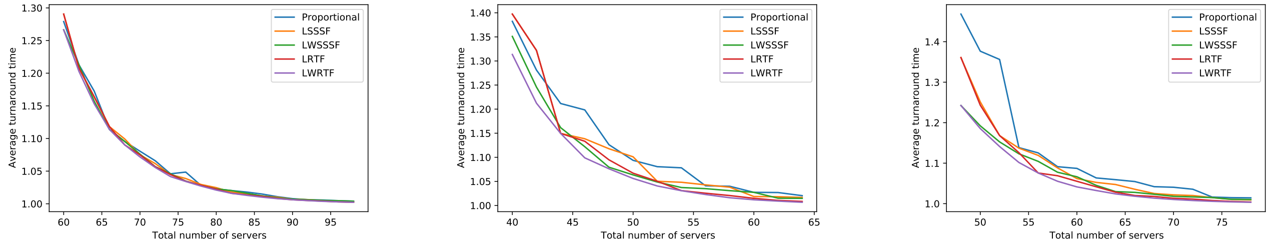
In this subsection, we use numerical results from queueing theory to verify that *Algorithm LWRTF* acheives the best performances in terms of minimizing the average turnaround time compared to other reasonably designed heuristics.

In the first numerical comparison setting, we let $\mu = 1$ and $B = 8$. We randomly generate floating point λ_i values within the range of $[1, 10)$. In our second comparison setting, we let $\mu = 0.1$ and $B = 8$. We randomly generate floating point λ_i values within the range of $[0.1, 1)$. In both settings, we generate the total numbers of servers in the following way. For a given request arrival rate vector $\boldsymbol{\lambda} = (\lambda_1, \cdots, \lambda_B)$, we vary the number of servers, N, within the range of $[\lceil 1.2 \sum_{i=1}^{B} n_i^{min} \rceil, 2 \sum_{i=1}^{B} n_i^{min}]$, with a step size of 2. We start with $\lceil 1.2 \sum_{i=1}^{B} n_i^{min} \rceil$, instead of $\sum_{i=1}^{B} n_i^{min}$, because doing so can avoid the cases where all the algorithms generate the same server allocation with very large average turnaround time, making their comparisons in other configurations hard to be observed.

Fig. 3 shows the results for the first comparison setting. Fig. 3(a), Fig. 3(b), and Fig. 3(c) show the comparisons with request arrival rate vectors of $\boldsymbol{\lambda}_a^1$, $\boldsymbol{\lambda}_b^1$, and $\boldsymbol{\lambda}_c^1$, respectively, where $\boldsymbol{\lambda}_a^1 = (7.82, 7.21, 8.05, 3.96, 3.46, 4.70, 4.98, 6.54)$, $\boldsymbol{\lambda}_b^1 = (3.90, 2.32, 2.06, 7.82, 1.35, 1.51, 3.13, 6.84)$, and $\boldsymbol{\lambda}_c^1 = (4.15, 2.05, 1.25, 9.54, 2.78, 8.91, 1.81, 5.44)$. The variances of $\boldsymbol{\lambda}_a^1$, $\boldsymbol{\lambda}_b^1$, and $\boldsymbol{\lambda}_c^1$ are 2.80, 5.27, and 9.08, respectively. $\boldsymbol{\lambda}_a^1$, $\boldsymbol{\lambda}_b^1$, and $\boldsymbol{\lambda}_c^1$ represent the cases with a relatively low variance, medium variance, and large variance, respectively.

Fig. 4 shows the results for the second comparison setting. Fig. 4(a), Fig. 4(b), and Fig. 4(c) show the comparisons with request arrival rate vectors of $\boldsymbol{\lambda}_a^2$, $\boldsymbol{\lambda}_b^2$, and $\boldsymbol{\lambda}_c^2$, respectively, where $\boldsymbol{\lambda}_a^2 = (0.53, 0.83, 0.61, 0.96, 0.79, 0.32, 0.55, 0.89)$, $\boldsymbol{\lambda}_b^2 = (0.28, 0.90, 0.70, 0.14, 0.17, 0.46, 0.39, 0.68)$, and $\boldsymbol{\lambda}_c^2 = (0.22, 0.28, 0.17, 0.65, 0.96, 0.12, 0.98, 0.79)$. The variances of $\boldsymbol{\lambda}_a^2$, $\boldsymbol{\lambda}_b^2$, and $\boldsymbol{\lambda}_c^2$ are 0.0413, 0.0654, and 0.1156, respectively. $\boldsymbol{\lambda}_a^2$, $\boldsymbol{\lambda}_b^2$, and $\boldsymbol{\lambda}_c^2$ represent the cases with a relatively low variance, medium variance, and large variance, respectively.

All the numbers reported here have been trimmed without affecting meaningful comparisons. According to the results, generally, when the relative variance of $\boldsymbol{\lambda}$ is small, all the algorithms have close performances. The performance differences among the algorithms become clearer when the variance of $\boldsymbol{\lambda}$ increases. In all evaluated configurations, not all of which have been included in the paper, *Algorithm LWRTF* results in the



(a) $\boldsymbol{\lambda}_a^1$ (b) $\boldsymbol{\lambda}_b^1$ (c) $\boldsymbol{\lambda}_c^1$

Fig. 3. Average turnaround time comparisons among the five heuristic algorithms (first comparison setting).

Fig. 4. Average turnaround time comparisons among the five heuristic algorithms (second comparison setting).

most stable performances and always achieves the minimum average turnaround time.

B. Validation for the Simulation Based Approach

In this subsection, we validate the accuracy of the CloudSim Plus [22] simulation platform. CloudSim Plus, an independent fork of CloudSim [27], is a discrete-event simulation tool designed for modeling and simulating cloud computing infrastructures and services. It defines many classes/interfaces for entities in the cloud computing environments, including *Datacenter*, *Host*, *Vm*, and *Cloudlet* (the interface/class that corresponds to an application request). It also defines the interfaces/classes for common concepts/techniques used in cloud computing, such as *CloudInformationServices* (serving as a registry of all resources in a cloud), DatacenterBroker (acting as a cloud customer that accepts application requests and submits them to the cloud), *VmAllocationPolicy* (used by the data center to allocate hosts for VMs), *VmSchedulingPolicy* (defining how a host schedules the VMs assigned to it), *CloudletScheduler* (defining how a VM schedules the cloudlets, i.e., application requests, assigned to the VM), etc. For most Java interfaces, the simulation tool provides some basic implemtations, and makes implementations of customized classes quite convenient. The simulation tool can also be easily tweaked and modified to provide high-fidelity simulations for edge computing.

To validate the accuracy of the CloudSim Plus simulation tool, we first generate random sets of application requests. The application requests are expected to have an average execution time of 10 seconds. Equivalently, the average departure rate of the requests when executed on a server is expected to be $\mu = 0.1$ (tasks/second). In other words, every second, it is expected that a server can finish 0.1 application requests. Notice that the actual average execution time and average departure rate of the reqeusts may slightly differ from the expected values, since the requests are randomly generated. We consider a time period of $T = 1000$ seconds. We conduct four groups of compharsions between the results from numerical methods and the simulations. We vary the numbers of requests as 350, 450, 550, and 650 in these four groups, respectively. Correspondingly, the request arrival rates for the four groups are $\lambda_1 = 0.35$, $\lambda_2 = 0.45$, $\lambda_3 = 0.55$, and $\lambda_4 = 0.65$, respectively. In each comparison group, we vary the number of servers that execute the requests. We consider 5 numbers of servers starting from $\lceil \lambda_i / \mu \rceil + 1$. Having smaller numbers of servers, for example, $\lceil \lambda_i / \mu \rceil$, will tend to make the queueing system unstable and result in very high turnaround time, which is not practal in the real world. For a specific scenario with a given set of random requests and the given number of servers, we first calculate the average turnaround time using the numerical method, i.e., using Equation (2), and then derive the average turnaround time through CloudSim Plus simulations.

The comparisons between numerical and simulation results are presented in Table II. We can tell from the table that, in most comparison scenarios (except for a few rare scenarios when the number of servers is too small), the numerical results and the simulation results are very close. We briefly touch upon some potential reasons for the differences between the numerical and simulation results. First, queueing theory

characterizes a system with an infinite time length, assuming that there will be an infinite number of requests coming and leaving all the time, which is different from the CloudSim Plus simulation, where we only consider one time period with duration $T = 1000$ seconds. We can imagine that when we simulate multiple time periods consecutively, the interferences between different time periods will come into play and bring the simulation results closer to the numerical results. Second, queueing theory assumes that $t_e = 1/\mu$ strictly follows the exponential distribution and λ_i's strictly follow the Poison distribution, while a specific set of requests, though randomly generated, will not follow these distributions perfectly. Despite these obvious reasons that may result in differences between the numerical results and simulations results, they are actually very close, as we can tell from the table. In most of the scenarios, the difference between the numerical and simulation results differ by less then 1%. This validates the reliability and accuracy of the simulation platform, and justifies using CloudSim Plus simulations to evaluate various server allocation algorithms.

C. Simulation Comparisons Among Different Server Allocation Algorithms

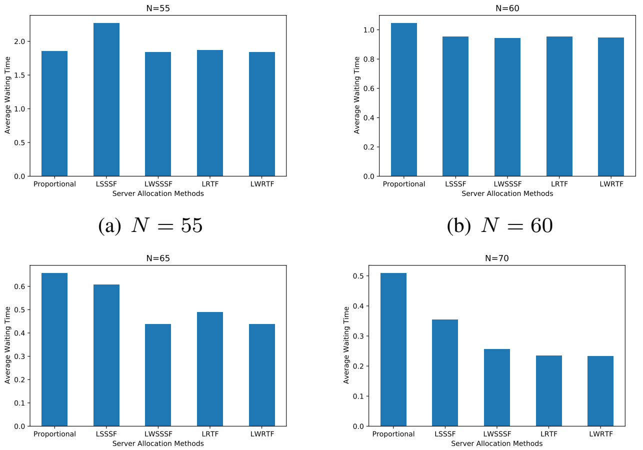
In this subsection, we use CloudSim Plus simulations to compare different server allocation algorithms. We design the simulation settings as follows. The number of BSs is $B = 8$. The average execution time of all requests is $t_e = 10$ seconds. Equivalently, $\mu = 0.1$. For CloudSim Plus simulations, we consider a time period of $T = 1000$ seconds. During this time period, the vector of the numbers of requests generated within the 8 user areas is: $(150, 250, 400, 500, 550, 600, 900, 1000)$. We have sorted the numbers of requests in the ascending order, since it will not affect the simulation results in any way. We can then calculate the request arrival rate vector as $\boldsymbol{\lambda} = (0.15, 0.25, 0.4, 0.5, 0.55, 0.6, 0.9, 1.0)$. We have $\sum_{i=1}^{8} \lambda_i/\mu = 43.5$. Thus, the absolute minimum number of servers needed is 44. In the real world, if the number of available servers is small, i.e., too close to 44, the edge cloud will tend to become overloaded and unstable, according to the results from queueing theory. We consider four scenarios where the numbers of servers are $N = 55$, 60, 65, and 70, respectively.

With the values for μ, $\boldsymbol{\lambda}$, and N, we can derive the server allocation plans using the 5 heuristic algorithms. Then, we use each of the server allocation plans to run the CloudSim Plus simulation and derive the simulated average turnaround time. For the given request set, the average execution time is the same for different heurisitics. To clearly see the differences among the different algorithms, we compare the average waiting time (which is equal to the average turnaround time minus the average execution time) of different algorithms.

The comparison results for the 4 scenarios are presented in Fig. 5. When the number of servers is comparatively small (Fig. 5(a) and Fig. 5(b)), the server allocations are not that flexible because we need to allocate an enough number of servers to each cloud to make the edge clouds stable. In these cases, most of the heuristics can arrive at the best server allocation and they achieve similar average turnaround time; still, some algorithms (for example, *Algorithm LSSSF* in Fig. 5(a) and *Algorithm Proportional* in Fig. 5(b)) may not be able to achieve the minimum average turnaround time. When the number of servers is large, all algorithms have more room to explore for a better server allocation. However, all the other heuristic algorithms are not stable, and may arrive at very large average waiting times when a much smaller average waiting time is possible. Nevertheless, *Algorithm LWRTF* always achieves the optimal average waiting time, and thus, the optimal average turnaround time. The results are consistent with that of Section VI-A. We can conclude that *Algorithm LWRTF* is superior to other reasonably designed heuristic algorithms and achieves near-optimal performances in minimizing average turnaround time for all the application requests.

VII. CONCLUSION AND FUTURE WORK

In this paper, we consider the server allocation problem in edge computing. We design the Largest Weighted Reduction Time First (LWRTF) algorithm to generate the server allocation plan. Extensive evaluations by both the numerical method and the simulation approach verify that it achieves



(a) $N = 55$

(b) $N = 60$

(c) $N = 65$

(d) $N = 70$

Fig. 5. Average waiting comparison among the five heuristic algorithms using CloudSim Plus simulations.

the minimum average turnaround time compared to other reasonably designed heuristics.

We plan to conduct future work in the following directions. First, the applicaiton request model can be extended. For example, each application request may require multiple processing units and each server can have multiple processing units. Second, the communication delays between the mobile users and the edge clouds can be taken into consideration. Third, more practical system models for the edge clouds should be explored; these include queueing network, as compared to separate queueing systems used in our current study, and time-shared queueing model, where the processing power of the servers can be time-shared for all arriving requests.

— In real world datasets missing al es are so common. ost achine Learning algorithms won't wor with missing al es, and so they sho ld be handled before training the model. It is a common practice to imp te the missing al es with central tendencies ean, edian, ode , b t choosing a partic lar one among them is not an easy choice to ma e. This paper analy es the impact of sing each central tendency for different distrib tions of data. S ewness and the presence of o tliers are considered for selecting the data for analysis. Certain pres mptions ha e been made before the examination, and performance metrics s ch as acc racy, UC OC, precision, recall, and score are analy ed to pro e dispro e the ass mptions.

—

. Introd ction

Real-world data may have more missing values compared to the processed data available in machine learning repositories. In Machine Learning, handling missing values is vital, and it has an excellent chance of impacting the model's performance. Hence, analyzing the performance for different values becomes extremely necessary.

In this paper, we have analyzed the performance of classification models on imputing with different central tendencies. The analysis is made on two categories: skewness of the data and presence of outliers. Considering skewness, data that is highly skewed with zero and right-skewed are analyzed. Considering outliers, data with outliers on both sides of the boxplot's whiskers and few outliers are analyzed. Certain assumptions have been made for these categories, and they are checked for truthness.

. andling missing al es

There are several reasons like a failure in recording the data and data corruption, due to which the data gets lost. Missing data handling is crucial to keep up the representativeness of the sample. If left untreated, the missing values can have a severe impact on the analysis. Moreover, the datasets should be preprocessed to fit the machine learning algorithms.

There are three main approaches to dealing with missing values: Imputation, Omission, and Analysis.

2.1 Imputation is filling the missing value with some value that makes sense, mostly a central tendency. Features with continuous numeric data can be imputed with the mean, mode, or median and categorical data can be imputed with the mode or median of the data available.

Pros:

- Imputation comes in handy when the dataset is small and implementation is straightforward.
- Data is not lost when compared to the other handling methods.

Cons:

- Imputation can cause a leakage of data
- It can add bias and variance due to the approximations.

2.2 Omission is the process of removing the observations with the missing value from the dataset. It is one of the most used methods to treat null values. Two techniques of omission are – Listwise deletion and Pairwise deletion. If there is at least one value missing in the listwise deletion technique, that record is dropped, and the model is run on record with a complete set of values. Whereas in pairwise deletion, the record is not deleted completely, and instead, the omission is based on the values included in the analysis.

Pros:

- Omission of missing data builds an accurate and robust model.

Cons:

- Data and Information loss
- Cannot use this method when the missing value percentage is high.

2.3 Analysis is the process of using predictive modelling techniques to predict the missing value for the records. Analysis can help in building a more accurate model.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Pros:

- Creating a predictive model is not required for each attribute with a missing value.

Cons:

- The analysis method is time-consuming.

Imputation is a crucial method to analyze further because it’s not time-consuming and easy to implement. In this paper, we will examine the impact of imputing the missing values with each central tendency.

. ss mptions

Considering the fact that the range of the data and outliers will have an impact on the mean and median, certain assumptions have been made. They are:

ero s ewed data – Missing values in data that is highly skewed with the presence of zero must be imputed with zero (median and mode). For example, a dataset containing school students’ information will have zero as the income column’s value in most records. But a group of competent students working on sponsored projects may get a stipend, and it changes the mean of the record. If any record is missing, we can assume that the student is not earning and impute with zero.

ight s ewed data – Missing values in skewed data should not be imputed with mean. If the data’s tail has a large difference with the peak, the data’s mean will be significantly impacted. Hence, it would not be a better choice to impute the missing values.

ith o tliers – Same as skewed data, data’s mean is not immune to outliers’ presence. To reduce the impact of an outlier, we can remove it before calculating the mean. But in data with a sizable number of records outside the whiskers of a box plot, we must account for the outliers to make a decision. In that case, imputing the missing values with mean is not a better choice.

itho t few o tliers – Data with most of the values between the boxplot’s whiskers will have an almost similar value for the central tendencies. Hence, every central tendency will be giving similar results.

. Experiment set p

Python project with minimal human intervention is used to make the analysis. It reduces manual errors, which may impact the results of the study. The project was designed to take dataset and input file as input, and perform analysis and return the results in a compressed file. The processes performed were also automatically documented for analyzing the results later.

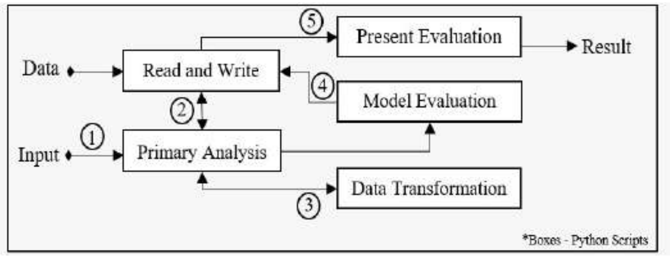

Fig. 1. Experiment setup

The primary analysis script will be reading the user(our) inputs to perform the analysis. The input file will contain particulars such as dataset file name and information about the dataset required to train the machine learning model. Then the primary analysis script will call read/write script to read the dataset. The pandas dataframe created from the data will then be sent to the data transformation script to perform analysis and imputation. This script will perform on-hot encoding, label encoding, scaling, and imputation based on the input file. Three dataframes, each with mean, median, and mode imputed, will be created at this stage to study the performance.

Three dataframes will be passed to the model evaluation script, where various machine learning models will be trained, and their metrics are captured. All three dataframes are trained with RandomForest, LogisticRegression, K nearest neighbors, and State Vector Machine algorithms. Training and evaluating the data with these different algorithms, each using distinct methods for prediction, will help us understand which central tendency has better performance on which algorithm. Evaluation metrics such as Accuracy, AUC-ROC score, precision, recall, and F1 score are captured for every trained model. Analyzing all of these parameters will give us a clear idea about the impact of each central tendency.

Dataframes are split into train and test set using the Stratified shuffle split, and the same is used to perform the cross-fold validation of 10. Stratified shuffle split will ensure that both train and test set contains the same amount of distribution of the imputed feature, and it ensures that the same amount of imputed records are found in both train and test set. The same is used to generate ten different train and test sets to recreate the cross-validation function[3]. Using ten-fold cross-validation will ensure that captured results are not particular to one set of records. It will help us get more data on the performance for the analysis.

Evaluation metrics will then be passed to the presenting evaluation script through the read/write script. This script will document the analysis results and then plot the results using the matplotlib library for comparison. The plotted graphs, steps performed, and input files are then packaged and compressed for later analysis.

This experimental setup is designed to impute given the feature and perform analysis on the classification models. With a little tweaking, this setup can be used to perform analysis on regression models too. Besides, it can also be modified to train data on various algorithms and return the best algorithm and the trained model, like GridsearchCV and RandomsearchCV.

. ataset sed

A dataset containing features will all the features mentioned above is hard to find. So, we decided to use two different datasets to analyze all required distributions. They are Census income data and Heart disease data.

Census income data contains all required distributions but the data without outliers. This data had some missing values on features that we are not analyzing. It being a large dataset, dropping those records didn’t lead to much data loss. If we could follow the same for every missing value in reality, this analysis would not have been needed. Unfortunately, we could come across a dataset where we can't afford to lose even a single record. So it becomes necessary to proceed with this research. To analyze the data without outlier, we have used heart disease data, which has a feature with only one value away from the whisker of the boxplot.

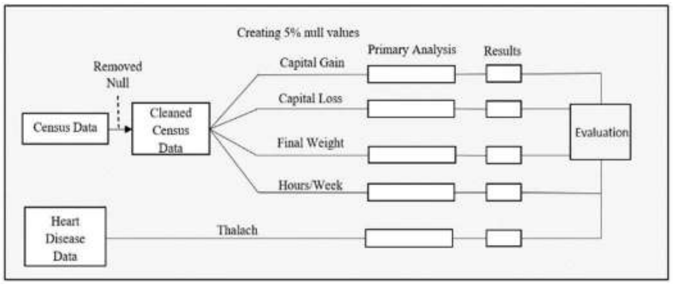

Fig. 2. Analysis performed

Since these datasets don't contain missing values on the required features, we have randomly removed the available values to create missing values. 5% of the data is removed to make a good impact when imputation is analyzed. When analyzing each feature, we ensured that other features are not touched to ensure results are independent of other factors.

• nalysis

Data identified has undergone an initial analysis to identify nominal and ordinal categorical features and numerical features. This information was included in the input text file for the primary analysis script to understand and analyze. The packaged results are then evaluated to get the below results.

ero s ewed data

In the census income dataset, capital gain and capital loss features have more than 75% of the values as zero. It can be seen at histogram and violin plot that most of the values of these fields are skewed near zero. For this kind of dataset, mode and median will be the same(zero), and we can see that the mean is far away from zero. In this kind of dataset, we can't use IQR to detect the outliers because both the 25th and 75th quartile values will be zero, so the IQR will also be zero. So we can't consider the results of this data for outliers, and we can consider it only for skewness.

	count	mean	std	min	25%	50%	75%	max
capital_gain	30162.0	1092.007858	7406.346497	0.0	0.0	0.0	0.0	99999.0
capital_loss	30162.0	88.372489	404.298370	0.0	0.0	0.0	0.0	4356.0

Fig. 3. Zero skewed distribution

According to the mean and standard deviation of the cross-validation (Table 1), the analysis results show only a minor difference in different central tendencies' performance. Imputing mean gives slightly less accuracy compared to others. But other metrics such as AUC-ROC, precision, recall, and F1 are better for imputing with mean. This dataset being unbalanced, we have to rely upon the latter metrics to select a better performing model. Contradictory to our assumption, the mean gives comparatively better results for zero skewed distribution. The results of KNN are deviating from the results of other models, which should be further analyzed to get a clear picture.

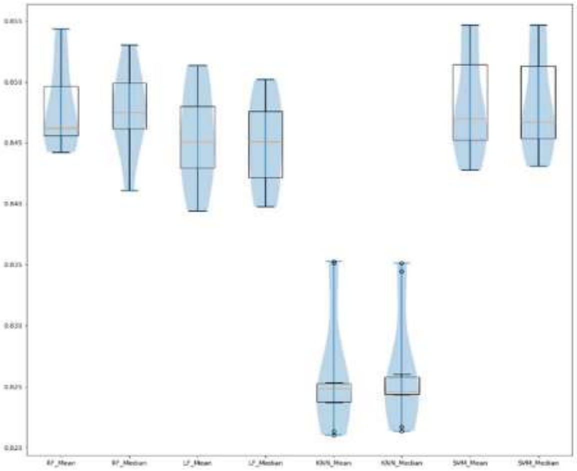

Fig. 4 a). Zero-skewed accuracy(capital_gain)

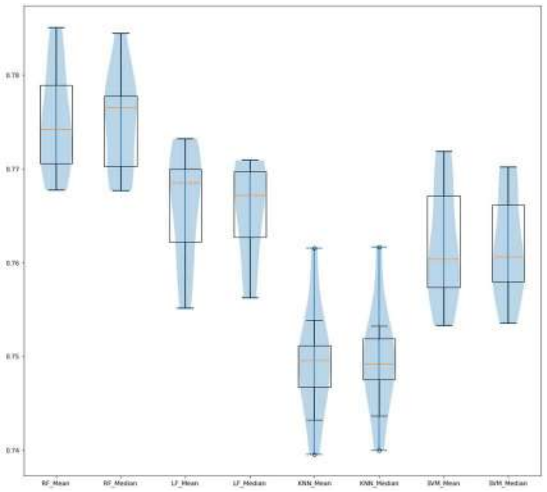

Fig. 4 b). Zero-skewed AUC(capital_gain)

But analyzing all the results of cross-validation gives a different picture. Some better-performing datasets show better results on imputing with mean than the median. In most cases, imputing with mean gives better results, i.e., looking at the boxplot's percentile lines shows that the mean's median is higher.

ight s ewed data

In the census income dataset, the fnlwgt feature is right-skewed, with most of its value peaking on the left side. It can be seen at histogram and violin plot that there are many values outside the whiskers. So we can consider the results of this data for both outliers and skewness.

	count	mean	std	min	25%	50%	75%	max
fnlwgt	30162.0	189793.83393	105652.971529	13769.0	117627.25	178425.0	237628.5	1484705.0

Fig. 5. Right skewed distribution

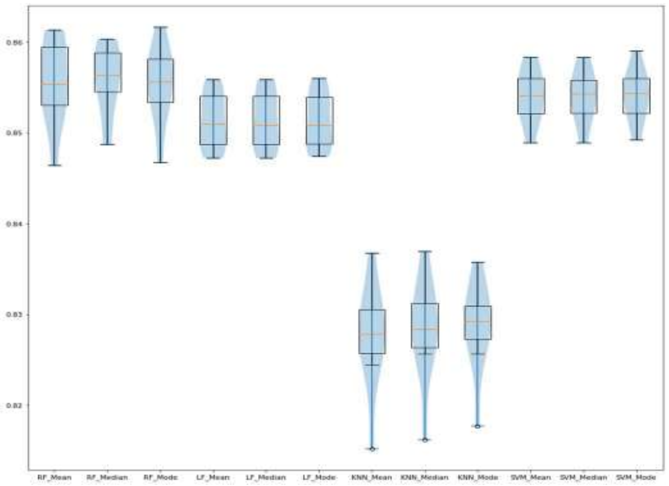

Fig. 6 a). Right skewed accuracy

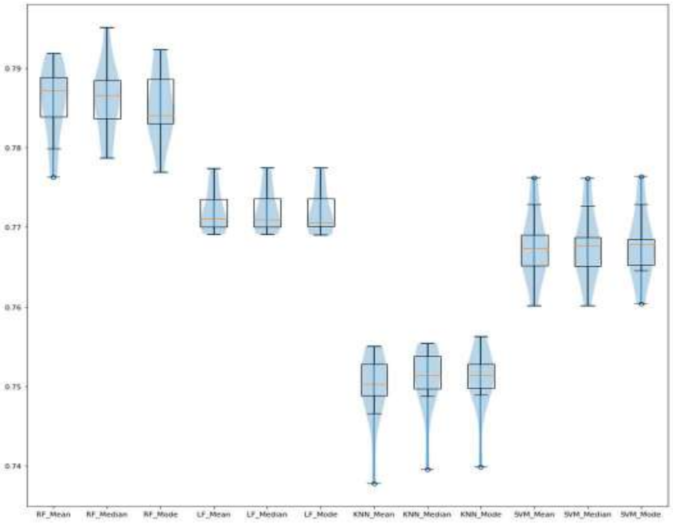

Fig. 6 b). Right skewed AUC

Considering both the mean of the results (Table 2) and the distribution of the results for each cross-validation (Fig. 6), there is no clear evidence that any central tendencies have precedence over the other. The impact of skewness should be analyzed further to get a clear understanding.

ith O tliers

In the census income dataset, hours per week have many outliers. From the boxplot, we can see that outliers are present at both sides of the whiskers, with a peak around the median. For this feature, the mode and median will be the same.

Except for the Random Forest, all other algorithms provide more or less the same results for mean and median. It's due to the fact that there is no significant difference between both's values. Having the same mode and median, with skewness of both sides, made mean to be close to mode. Comparing both, mode gives a better performance in this feature, which proves our assumption.

	count	mean	std	min	25%	50%	75%	max
hours_per_week	30162.0	40.931238	11.979984	1.0	40.0	40.0	45.0	99.0

Fig. 7. With outlier - distribution

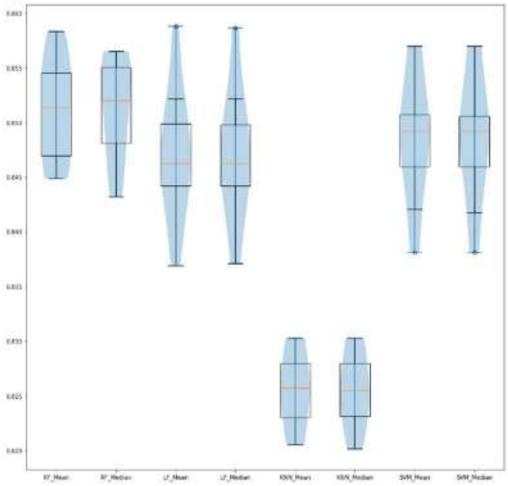

Fig. 8 a). With outlier accuracy

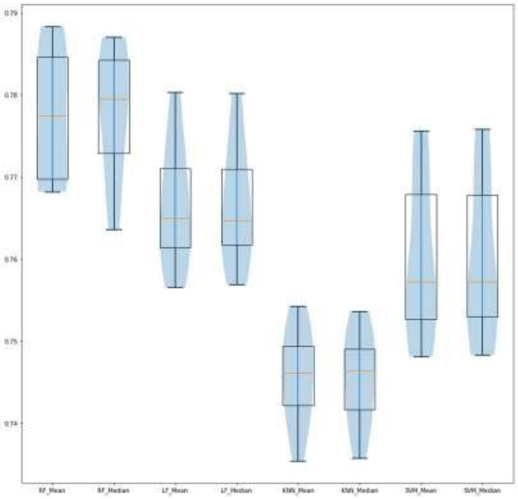

Fig. 8 b). With outlier AUC

itho t few o tliers

In the heart disease dataset, thalach has only one outlier. Since it’s not so distant from the whisker, it can be included in the analysis. From the histogram and boxplot, we can see that most of the values are peaked around the median.

	count	mean	std	min	25%	50%	75%	max
thalach	303.0	149.607261	22.875003	71.0	133.5	153.0	166.0	202.0

Fig. 9. Without outlier - distribution

In most cases, mode gives a better performance in this feature. If we closely look at Table 4, the mode offers better accuracy and AUC performance, and the same was reflected in the boxplot. In most algorithms, mode gave good results on the validation dataset that produced underperforming models. The percentile lines of the boxplots also support our claim that mode provides better performance. Contradictory to our assumption, not all central tendencies have near values, so they impacted the performance.

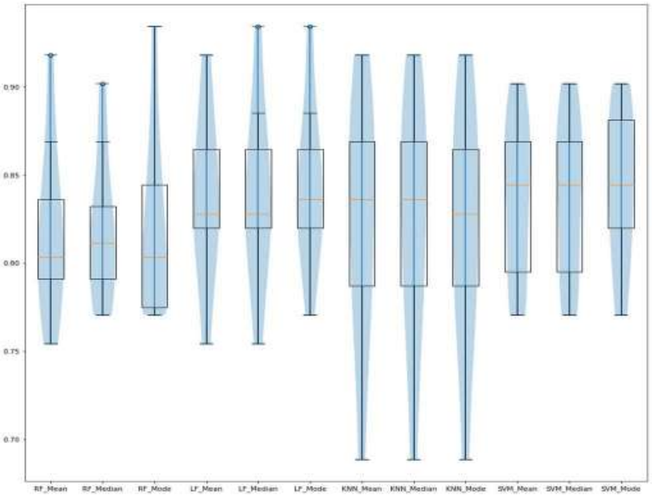

Fig. 10 a). Without outlier accuracy

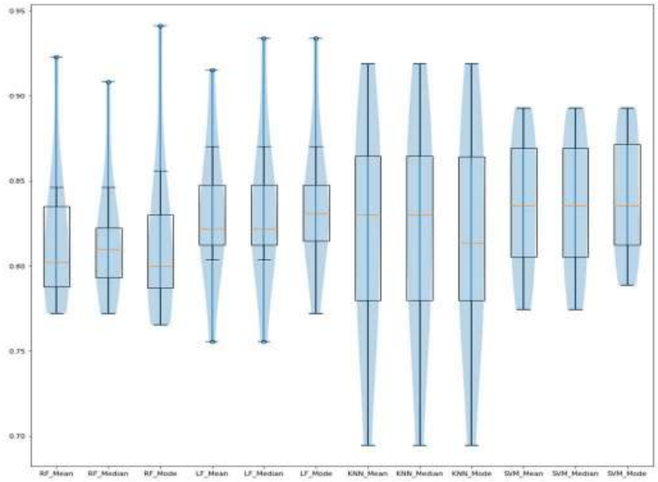

Fig. 10 b). Without outlier AUC

. t re wor s

We may have to consider the importance of a feature in the prediction to get an exact picture of the impact of imputation. Hence, we will perform the same analysis on the features with high importance for modelling.

Results are varying for different algorithms, and so we should analyze the impact of imputation on algorithms. The importance of features must be taken into account to get precise results.

***Abstract*—Wearing a mask is a requirement in the Covid-19 pandemic for the general public. While it is one of the several must-do actions to prevent forward spread in the Covid-19 infections, at the same time, the effect of wearing a mask in naïve face recognition systems have shown lower system performance in several cases and conditions. Simultaneously, only a handful of research studies have focused on a non-medical face mask with realistic images data set. This research proposed a new data set of realistic fabric face mask data set to be evaluated using surface curvature and gray level co-occurrence matrix (GLCM). The classification applied support vector machine (SVM). One hundred seventy-six images in the data set were analyzed with various properties, resulting in several experiments. The experiments' parameters were color properties, approaches in surface curvature, i.e., Gaussian, mean and principal curvature, angle and distance in GLCM, GLCM properties, i.e., contrast, homogeneity, correlation and energy, also kernel functions in SVM. The best accuracy result, 87.5%, was derived from the combinations of these parameters. This research also improved the running time of the recognition process while maintaining the system's performance.**

***Keywords*—Covid-19, face mask recognition, gray level co-occurrence matrix, support vector machine, surface curvature**

I. Introduction and Motivation

Covid-19 is a contagious disease caused by a new strain of the coronavirus. The indications can include fever, cough, shortness of breath. In difficult situations, it can induce pneumonia and breathing complications. Close contact with respiratory droplets of an infected individual spreads the virus. Touching surfaces contaminated with the virus and touching their eyes, nose and mouth can also infect a person [1]. The Covid-19 outbreak was declared as Public Health Emergency of International Concern (PHIC) by WHO on Jan 30, 2020. This statement is WHO's most crucial alarm to unite all countries to take notice and take effort immediately [2]. To stop the spreading of the Covid-19, wearing a mask is one of several requirements to protect a healthy society and prevent forward spreads. Even in cases where visitors who do not live together come to a family's house, they should wear masks if the physical distance cannot be maintained or when the home's ventilation is in poor condition [3]. Furthermore, wearing a mask is needed for the general public, regardless of whether they have gotten two doses of Covid-19 vaccines [4].

As the public needs to wear a mask in their daily lives, naïve face recognition systems have shown lower system performance in several cases and conditions [5,6]. This reduction of performance might occur due to the nose and mouth on the face area being covered. Although the upper half of the face, i.e., eyes and eyebrows, has a more considerable influence on the recognition performances, the lower part of the face, i.e., nose and mouth, if covered, still weaken the recognition performance [6,7]. Wearing a mask is one of the examples of occlusion problems in the research of face recognition. Other occlusion problems are wearing glasses, attributes such as hats and hair accessories, having a mustache, situations where objects covering the face's area, pose variations and exceptional cases like low-resolution problems and blurred faces [8]. In this research, wearing a mask was treated as the focused problem for occlusions, and the data set of face mask images was created for masked face and barefaced images. For the part of the data set of masked face images, the recognition system's input included whole masked face images as they were not divided into occluded or un-occluded areas on the face. This principle also applied for part of the data set of barefaced images.

During Covid-19 pandemic global event, the number of research focusing on face mask challenges has been increased. These researches have focused on detecting whether individuals wear a mask in public to help authorities monitor and maintain safety during the Covid-19 pandemic [9-12]. Moreover, the number of research on identifying individuals while wearing a face mask has also improved significantly [5,13-15]. The purpose of identifying individuals while wearing a mask is to help the public use face recognition systems correctly but safely without taking off the mask. In [5], the performance evaluation was compared using two academic face recognition systems, i.e., ArcFace and SPhereFace and one commercial system, MegaMatcher 11.2 SDK Neurotechnology. Multi-Task Cascaded Convolutional Neural Network (MTCNN) and support vector machine (SVM) was studied in [13]. Improvement using cosine distance combined with transfer learning was analyzed in [14]. In [15], the authors studied de-occlusion distillation for knowledge transfer evaluated with three synthetic and realistic face mask data sets.

Contradictory with the rocketing numbers of research focusing on face detection and recognition during Covid-19, there are still very few data sets specifically designed using a real face mask that implements real-life situations. Sometimes, the data set was created with an image editing approach [16], and sometimes they are parts of the larger variations of the occlusion data set [17]. This research proposed creating a face mask data set containing respondents

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

wearing a real face mask with two variations of pattern and color of fabric or non-medical mask. The first reason behind choosing fabric or non-medical mask for the data set is the lack of fabric or non-medical face mask data set. The second is because the fabric face mask is recommended by WHO to be worn by the general public under the age of 60 and people who do not have underlying health conditions [3]. WHO recommends the medical mask to be worn by medical workers, people who have symptoms of Covid-19 and those who take care of them. WHO also recommends that medical masks be worn by older people (age 60 years and over) and people with underlying health conditions when the physical distancing of at least one meter cannot be achieved [18]. Furthermore, in the early days of the Covid-19 pandemic, the medical mask's availability was prioritized for the health workers. As a result, the government recommends using fabric masks for the general public [19].

In addition to constructing a realistic fabric face mask data set, this research also studied a combination of surface curvature and gray level co-occurrence matrix (GLCM). Both work as an extractor of features. The motivation behind this proposed combination of methods was due to the pattern and color of fabric masks that suitable for using methods for texture analysis, such as GLCM, that operated as a statistical approach. Moreover, the surface curvature further enhances the difference of arrangements in color and intensity of spatial relations in images. The effect of approaches using surface curvature, i.e., Gaussian curvature, mean curvature and principal curvature, were studied along with the angle, distance and properties of GLCM. The property of images, such as color, also affects the recognition performance. This research further evaluated the color properties by separating the color components. The classification method was completed by support vector machine (SVM). The SVM kernel function's effect was also assessed to achieve better recognition performance.

This paper's writing is settled as follows: Section I displays the research background and the authors' motivations. Section II explains the theory behind surface curvature and GLCM. Section III describes the creation of the data set and the design of the recognition system. Section IV discusses the results, and Section V concludes.

II. Surface Curvatures and Gray Level Co-occurrence matrix (GLCM)

A. Surface Curvatures

A surface in $\mathbb{R}^3$ is a set of points $S \subset \mathbb{R}^3$ that is two dimensional where each point $\boldsymbol{p} \in S$ has a neighborhood which can be parametrized by two coordinates [20],

$$\boldsymbol{x}: \mathbb{R}^2 \supseteq U \to \mathbb{R}^3: (u, v) \mapsto \boldsymbol{x}(u, v) \tag{1}$$

The curvature of a surface $S \subset \mathbb{R}^3$ at $\boldsymbol{p} \in S$ measures the rate at which S leaves the tangent plane to S at $\boldsymbol{p}$. Several approaches calculating the surface curvature are Gaussian curvature, mean curvature and principal curvature. In a way, Gaussian and mean curvature can be obtained from principal curvature and vice versa using different approaches [21]. In this research, Gaussian and mean curvature were obtained first using the first and second fundamental form. The principal curvature was calculated from Gaussian and mean curvature.

If $\boldsymbol{x}: U \to \mathbb{R}^3$ then the Gaussian curvature (*Gc*) and mean curvature (*Mc*) are calculated in (2) and (3), respectively [21].

$$Gc = \frac{LN - M^2}{EG - F^2} \tag{2}$$

$$Mc = \frac{EN + GL - 2FM}{2(EG - F^2)} \tag{3}$$

E, *F* and *G* are the first fundamental form's coefficients and *L*, *M* and *N* are the second fundamental form's coefficients.

The principal curvature (*P*) are the roots (*Pmax* and *Pmin*) of the quadratic equation of (4)

$$x^2 - 2Mcx + Gc = 0 \tag{4}$$

Hence, by calculating the quadratic equation's roots, *Pmax* (5) and *Pmin* (6) are obtained [21].

$$Pmax = Mc + \sqrt{Mc^2 - Gc} \tag{5}$$

$$Pmin = Mc - \sqrt{Mc^2 - Gc} \tag{6}$$

B. Gray Level Co-occurrence Matrix (GLCM)

Gray level co-occurrence matrix (GLCM) is a method to characterize the distance and angle relationship between the pixel of interest and its neighbors. The distance and angle relationship are essential between two pixels because this repeated distribution forms texture in the spatial position [22].

Assuming *I(k,k)* is the neighborhood of the pixel of interest (p_c, q_c), the co-occurrence value is the distribution of co-occurrence values at a certain distance (*d*) and angle (θ) from (p_c, q_c). The co-occurrence matrix for *I(k,k)* called C_M is defined in (7) and (8) [23].

$$C_M = \sum_{n=1}^{k} \sum_{m=1}^{k} \begin{cases} 1 & if\ I(n,m) = k\ and\ I(n + d_x, m + d_y) = k \\ 0 & else \end{cases} \tag{7}$$

$$d_x = d.cos(\theta), d_y = d.sin(\theta) \tag{8}$$

Fig. 1 shows the spatial relationships of distance and angle of the pixel of interest (p_c, q_c) and its neighborhood. The *d* represents the distance between the pixel of interest and its neighbor while the angle is formatted in the square bracket. In this research, variations of distance and angle can be seen in Fig. 1. [0,*d*] expresses *d* distance and 0^0 angles, [-*d*,*d*] expresses *d* distance and 45^0 angles, [-*d*,0] expresses *d* distance and 90^0 angles, [-*d*, -*d*] expresses *d* distance and 135^0 angles and [*d*,0] expresses *d* distance and 270^0 angles. The distances experimented in this research was *d*=1 for 0^0,45^0,90^0 and 135^0 ([0 1; -1 1;-1 0;-1 -1]) and *d*=2 for 0^0 and 270^0 ([2 0;0 2]).

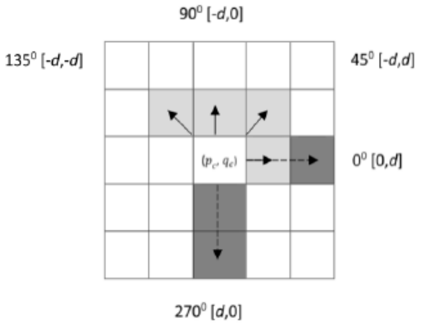

Fig. 1. Spatial relationships of distance and angle of the pixel of interest and its neighborhood; dashed arrow line is for [2 0;0 2] while the solid arrow line is for [0 1; -1 1;-1 0;-1 -1].

Properties in GLCM, i.e., contrast, homogeneity, correlation and energy used in this research for each C_M and angle (θ) as it can be seen in (9)-(12), respectively [24].

$$f_{contrast}^{\theta} = \sum_{i=1}^{L}\sum_{j=1}^{L}(i-j)^2 C_M \qquad (9)$$

$$f_{homogeinity}^{\theta} = \sum_{i=1}^{L}\sum_{j=1}^{L}\frac{C_M}{1+|i-j|} \qquad (10)$$

$$f_{correlation}^{\theta} = \sum_{i=1}^{L}\sum_{j=1}^{L} C_M\left[\frac{(i-\mu_i)(j-\mu_j)}{\sqrt{(\sigma_i)^2(\sigma_j)^2}}\right] \qquad (11)$$

$$f_{energy}^{\theta} = \sum_{i=1}^{L}\sum_{j=1}^{L}(C_M)^2 \qquad (12)$$

where

$$\mu_x = \sum_{i=1}^{L}\sum_{j=1}^{L} xC_M\, , (\sigma_x)^2 = \sum_{i=1}^{L}\sum_{j=1}^{L} C_M(x-(\mu_x)^2) \quad (13)$$

III. Data Set and Design of Recognition System

Fig.2. shows the design of the recognition system. The training set consisted of RGB images of masked face and barefaced, while the testing set only consisted of RGB images of masked face. The images tested in this research were gathered from 8 respondents of adult male and female. Each respondent was taken 22 pictures when using a fabric face mask and when he/she was in a barefaced, with variations in positions and angle in tilting left, right, up and down. This research's total number of images was 176 images. 90% of total images were collected for the training set and the remaining 10% for the testing set. For masked face images, respondents were asked to wear two different colored and patterned fabric masks. While for barefaced images, respondents were asked to wear no attributes at all. The images were then resized for the final resolution of 200x150 pixels in RGB color space. The data set personally conducted in this research was then called Realistic Fabric Face Mask Data Set version 1.0 (RFFMDS v1.0). It is still a growing data set because more images for the fabric face mask and more respondents are still gathered. Fig. 3 is an example of images in the training and testing set from RFFMDS v1.0.

The next step of the design was to convert RGB images of both training and testing sets to one set of grayscale images and three sets of each RGB channel's separations. There were four sets to be evaluated by the system, gray set, red channel set, green channel set and blue channel set. The images then were altered into 2D arrays containing the surface value. This surface value was proportional to the value of the intensity of the appropriate image data. Fig. 4 is the example of alteration into 2D arrays with the surface value as the height. The *x* and *y* are the column and row of the image, while the *Z* is the height proportional to the image's intensity value where the maximum height is one and the minimum is zero, corresponding to the brightest and darkest pixel, respectively.

The images then were extracted to calculate four different surface curvature types, Gaussian curvature, mean curvature, max principal curvature and min principal curvature. As stated earlier in Section I, the surface curvature's motivation was to amplify the difference of arrangements in color and intensity of spatial relations in images. These extracted curvatures were arranged to improve the next step of the system's process, the GLCM. GLCM works best to analyze the texture of images hence chosen as the method in this research. The color and pattern of fabric face mask created a unique texture that can be examined with the GLCM. GLCM's properties in this research were contrast, homogeneity, correlation and energy. The distance and angle variations of GLCM were also assessed in this research.

The classification utilized support vector machine (SVM), and three different kernel functions of linear, radial basis function (rbf) and polynomial kernel (order 3) were engaged in the training phase. The system results were performance's calculation of accuracy and process's time. This research aimed to find the combinations of variations in color and gray input images with the extraction of curvature types with different properties, angles, and distances of GLCM and classified with different kernel functions of SVM that gave the best accuracy with the fastest time. All simulations in this research were conducted using Matlab with 16GM RAM and Intel(R) Core (TM) i7-7500U CPU @ 2.70GHz, 2.90 GHz.

IV. Results and Discussion

A. Experiment 1

In the first experiment, comparing different combinations of methods for extracting features and classification was set side by side. The experiment was conducted on the same testing and training set of images from RFFMDS v1.0. In experiment 1, the experiment's highlight was to analyze the curvature extraction with the classification method and or the combination of curvature extraction with other feature extraction methods. There were two classification methods, i.e., distance calculation with Euclidean (*ED*) and support vector machine (*SVM*). Principal component analysis (*PCA*) to reduce dimension was also investigated in this experiment. Our proposed idea was to combine the extracted curvature features with gray level co-occurrence matrix (*GLCM*) to complement each other and improved recognition performance.

Table I shows the results of experiment 1. Curvature types, i.e., Gaussian curvature (*G*), mean curvature (*M*), max principal curvature (*Pmax*) and min principal curvature (*Pmin*), were evaluated for each combination of methods. The results were presented in a percentage format. From Table I, it can be observed that the simplest classification method of Euclidean distance did not give satisfactory results for each extracted curvature type. To further study the curvature effect in the recognition system, verified with another classification method such as *SVM* and the data analysis such as *PCA* were investigated. *PCA* mainly used as dimensional reduction method to eliminate the sorted eigenvalues that were less than a specific threshold. The idea behind was that the fabric face mask contained various patterns and colors, so maybe not all the information was useful to be put inside the recognition system hence the reductional dimension. To maximize the difference between the two categories, *SVM* was selected. This research operated in a one-vs-all type of manner in *SVM* classification.

Combined *PCA* with *ED*, recognition performance improved slightly, but some were not. Using *SVM* as the classification method also did not improve recognition performance. Until this attempt, no combination seems to improve recognition performance. The proposed idea in this research was to incorporate extracted curvature features with texture analysis method, *GLCM*, and then classified by *SVM*. The motivation behind the combination of surface curvature and *GLCM* was to amplify the variances in color and intensity of spatial relations in images using surface curvature before *GLCM*. The result improved significantly for *Pmax* (max principal curvature) feature, which resulted in 81.25% accuracy. This value was almost more than 2.5 times the previous best result (31.25%). While the max principal curvature feature increased, the mean curvature (*M*) was also improved but did not reach the satisfying rate. Contradictory, the Gaussian curvature (*G*) and min principal curvature (*Pmin*) produced a lower rate.

B. Experiment 2

Continuing from experiment 1, concentrating on the proposed idea that resulted in the best combination from experiment 1, i.e., extracted curvature with *GLCM* and classified by *SVM*, experiment 2 was conducted with the variation of *SVM* kernel functions. The kernel functions of *SVM* tested in this research were linear, rbf and polynomial order 3.

Table II shows the results from experiment 2. The previous experiment's result in Table I used rbf as the proposed idea's kernel function (81.25%). Table II shows that compared to the rbf kernel, using linear kernel function mostly lowered the rate and using polynomial function slightly lowered the recognition rate for the max principal curvature feature (75%) while other extracted curvatures gave varied results. It can be concluded from experiment 2 that rbf kernel offered the best result while the polynomial offered the second-best for max principal curvature feature. It appeared not surprisingly, the data in this research is not separable linear.

C. Experiment 3

Experiment 3 was conducted to study the color's effect on the research. The data evaluated in this research was the fabric face mask which had a unique pattern and color compared to the medical face mask. The color separation from RGB color space might affect recognition performance.

The training and testing set images were converted into gray images in the previous experiments (experiment 1 and 2). In this third experiment, the images were separated into red channel (*R*), green channel (*Gr*) and blue channel (*B*). Experiment 3 was conducted only for max principal curvature feature because it showed promising results from experiments 1 and 2.

Table III displays the results for these color variations. It shows that while in experiment 2, the *SVM* linear kernel function only offered the best result of 37.50%, in experiment 3, it achieved 68.75%. This effect also happened for the polynomial kernel function, it achieved 81.25%, while in experiment 2, it only achieved 75%. The rbf kernel in experiment 3 achieved the same performance as experiment 2. The red channel (*R*) and green channel (*Gr*) were preferred as they showed better results than gray image data.

D. Experiment 4

Experiment 4 was directed to witness the outcome of angle and distance variations for *GLCM*. In previous experiments (1-3), the angle and distance were set to be two pixels between pixel-of-interest and its neighbors while the angles' variation were 0^0 and 270^0 ([2 0;0 2]). In experiment 4, the distance was set to be one pixel between pixel-of-interest and its neighbors. The angles' variation were 0^0, 45^0, 90^0 and 135^0 ([0

1; -1 1;-1 0;-1 -1]). The effect of angle and distance was studied for each color separation and *SVM* kernel functions for the best feature, max principal curvature (*Pmax*).

Table IV displays the results for these variations. Varying the angle and distance in *GLCM* produced improved recognition performance for linear and rbf kernel while it lowered the polynomial recognition rate. It gave the highest accuracy result in the entire experiments (1-4) of 87.5% using red channel for rbf kernel. The recognition performance was improved by considering the relationship between the pixel of interest and its neighborhood choice.

E. Experiment 5

Experiment 5 was managed to calculate the time consumption for the recognition system process. The idea was to search for a combination of methods to reduce time consumption while keeping the same recognition performance (*Acc*) of 87.5%.

From Table V, it can be observed that variations were *Combo 1*, *Combo 2*, *T1* and *T2*. *Combo 1* consisted of max principal curvature (*Pmax*) feature with four properties of GLCM (contrast, homogeneity, correlation and energy) classified with rbf kernel of *SVM*. The distance was set to be 1 pixel between pixel-of-interest and its neighbors. The angles' variation were 0^0, 45^0, 90^0 and 135^0. Fundamentally, the best result from experiment 4. For *Combo 2*, the same principles were applied while only varied for GLCM's properties. *Combo 2* used only two properties, i.e., contrast and correlation. *T1* was the time spent testing only one image, while *T2* was time spent on training and testing all the training and testing set images.

Using only two properties of *GLCM* to reduce the time while keeping the same recognition performance (87.5%) was achieved in experiment 5. 0.0023 seconds was successfully shortened for *T1* and 0.116 seconds for *T2*.

V. CONCLUSION

A face recognition system with realistic fabric face mask data set was built in this research. Combining surface curvature and GLCM as feature extractors and SVM for classification were applied to improve recognition performance. Several experiments were conducted, including the parameter for color properties, GLCM properties, GLCM angle and distance properties and SVM kernel functions properties. The best accuracy of 87.5% resulted from these various parameters in the feature extraction and classification methods. It can be concluded that combining surface curvature with GLCM improved recognition performance. Moreover, choosing only two properties of GLCM, i.e., contrast and correlation, shortened the running time for the recognition process while maintaining the system's performance.

Upcoming future research can try a deep learning algorithm if the total number of images in the data set increases significantly. The partial face recognition using essential areas in the face may also be evaluated.

***Abstract*—Single event upset (SEU) is a significant problem in analog, digital, and mixed signal circuits. The extent of the attacks increases in radiation susceptible environments such as military and aerospace. Phase locked loop (PLL) is ubiquitous and usually employed as data recovery or clock signal in some electronic devices used in these environments. Single event transient causes ionizing particles to interact with the transistor and generate more leakage current that can result in malfunctioning of the transistor. A radiation hardened PLL is proposed whereby each block is designed to be SEU tolerant. Dual and triple redundancies are employed in the design of phase-frequency detector and frequency divider, respectively. The results show that the phase-locked loop operates from 3.5 to 4 GHz with the center frequency of 3.9 GHz. The phase noise of the voltage-controlled oscillator is estimated to be -109.5 dBc/Hz at 10 MHz offset frequency and the jitter is 128 ps at 3.9 GHz.**

I. INTRODUCTION

Short channel transistors, owing to their low noise margin and immunity, are more susceptible to single event upset (SEU) such as radiation and ionization effects. This causes energized particles to deposit charges in the transistor, which results in slight changes in its composition. The charge participates in the process of diffusion and generates electron-hole pair. The induced current increases and might alter the usual operation of the device. Studies have shown that SEU introduces errors into both combinational, sequential, and analog circuits. So, virtually every circuit in the field of VLSI design is prone to this effect. Ionization of particles or cosmic rays create oxide-traps and free carriers in silicon. The adverse effect is that there are formations of dangling bonds in $\mathrm{Si0_2}$ – bulk interface that affect the functionality of the transistor. Single-event transient is also referred to as unwanted asynchronous signals, which can have adverse effects on the performance of a circuit. It propagates through signal paths and causes undesirable responses in the circuit. SEU can change the state of digital circuits from 0 to 1 and vice versa, thereby, causing errors or indeterminate state. Radiation effects introduce particles such as proton, heavy ion, neutron etc. that can result in primary and secondary interactions. The charged particle (proton, electron, ion) participate in primary interactions and induces ionization while the neutron, because of its chargeless nature, bombards with heavy nuclei and generates secondary particles such as alpha, gamma, and beta. This can further produce additional current in transistor device by exciting the electrons in the bulk silicon. Initially SEE was not considered in older technologies, but the scaling down of transistor channel has pushed for its consideration. Short channel effect, such as drain induced barrier lowering (DIBL), is one of the major problems of CMOS technology scaling. The $\mathrm{I_{OFF}}$ current increases as a result of high leakage current, which eventually reduces the $\mathrm{I_{ON}}$ /$\mathrm{I_{OFF}}$ current ratio. In this case, it might be a little bit difficult to switch off the transistor and the device is no more suitable for digital applications. The effects of single event can produce additional leakage current that deteriorate the performance of the transistor. There are various studies that employed circuit-level simulation to discuss SEU and characterize its effects in a circuit. A comprehensive review of single event upsets is presented in [1] followed by improvements in single even transient (SET) modeling for future technologies. This approach incorporates energy disposition, peripheral charge sharing phenomenon, and its collection mechanism. Monte Carlo-based radiative energy disposition is used to simulate radiation effects with a purpose to predict its associated physical phenomena and examine the behavior of electronic circuits and devices under irradiation. It includes the upsets of muons and energetic electrons, which were not observed in experimental approach [2]. Song et al proposed an experimental approach to validate the simulation-based techniques. It is shown that the results are in good agreements, but the heavy ion experiments can resist different simulation conditions and is more accurate for SEU evaluation [3]. Phase locked (PLL) loop consists of both analog and digital building blocks that are easily prone to single event upset. This can unlock the PLL from its locking condition and alters its

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

features such as loop stability and dynamic response. In this work, we propose SEU-resistant phase locked loop structure, estimate the phase noise and jitter, and compare the results with related work in the literature.

The paper is organized as follows: Section II presents the proposed PLL architecture and examines the design of each component. Section III discusses the jitter and phase noise measurements and Section IV draws the conclusion.

II. PROPOSED SEU-HARDENED PHASE LOCKED LOOP

The proposed architecture, as shown in Fig. 1, is made of the usual blocks; voltage controlled oscillator, frequency divider, charge pump/loop filter, and phase frequency detector. However, each component is designed to resist single event transient by employing radiation-hardened logic gates, flip-flops, and triple modular redundancy (TMR).
Unlike conventional tri-state PFD, the phase frequency detector (PFD) we employed in this work is designed with two D flip flops, but without NAND gate. The reset path is also modified in order to reduce delay. Each D flip flop comprises of radiation hardened inverter and NAND gate, which are proposed in [4, 5].

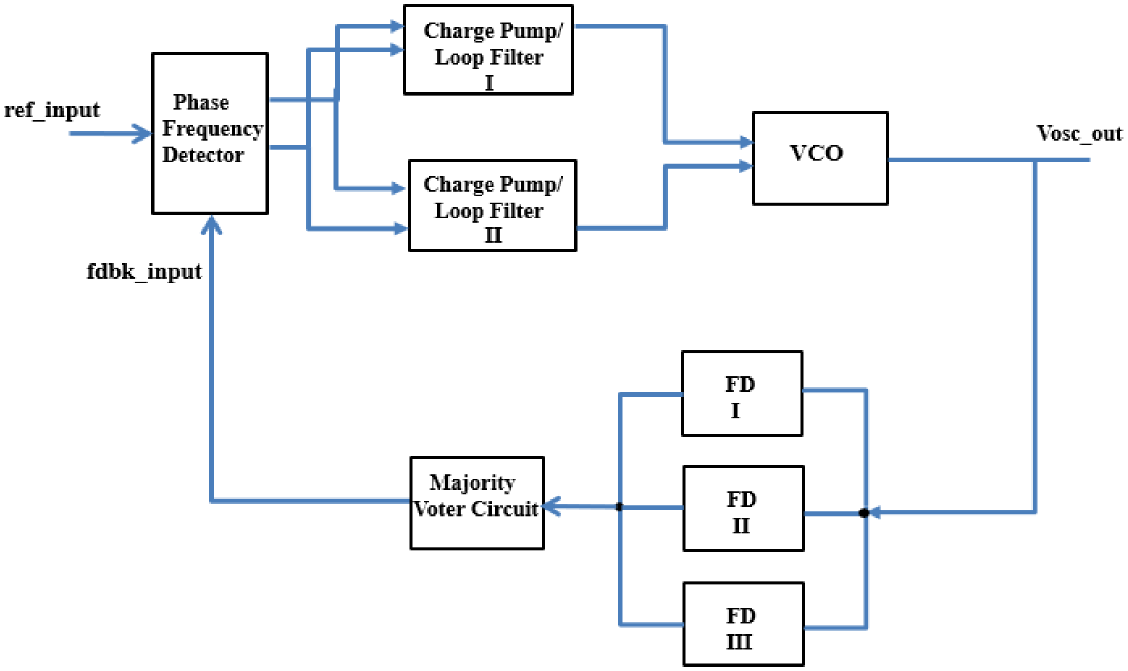

Fig. 1. Proposed single event tolerant PLL.

It is demonstrated experimentally that the inverter alleviates total ionizing dose (TID), has least variation in switching point, high energy efficiency, and occupies small silicon area. Similarly, the two input NAND gate is a standard cell radiation tolerant device, which consists of 4 inputs and 2 output.

The detailed information about its operation and why it is radiation resistant is already presented in [4]. The purpose of PFD circuit in phase locked loop is to sense the frequency and phase differences in the reference and feedback inputs. It generates outputs (UP and DOWN) that are applied to the input of charge pump. Since the CP/LF is an analog circuit, we duplicate the block so as to create alternative paths for the output from loop filter. By employing redundancy in the circuit design, one of the outputs is preserved even when the other is affected by radiation. The basic configuration of charge pump consists of biasing circuit, which supplies (draws) constant current to (from) the output when the UP (DOWN) signal is high. In this case, the two outputs of phase frequency detector are translated to charge pump current. The capacitors in the loop filter are discharged and charged through the current in order to generate the control voltage that serves as the input to voltage controlled oscillator [6]. For good noise rejection and optimum loop stability, the loop parameters are carefully chosen. The control voltage pulls up or pulls down the frequency of VCO depending on which of the two PFD's inputs is leading. The output continues to fluctuate until the PLL is locked. At this point both the reference input and feedback are in phase and the phase frequency detector generates no error signal. Therefore, the stable output frequency of VCO at lock condition is considered as its operating or center frequency. The voltage controlled oscillator is designed to be SEU tolerant by employing two different sets of three stage current starved VCO. Each oscillator has a modified version of the delay stage shown in Fig. 2(a). The inverter is also radiation hardened with a total of four inputs and two outputs. In addition, it has two other inputs (V_{ctrlA} and V_{ctrlB}) which controls the NMOS transistors in the inverter configuration. The ring oscillator has a similar cascaded structure like the conventional CSVCO, but only two inputs of the delay stage are controlled and driven by an inverter within the same ring, while the other inputs are controlled by an inverter from another ring [7]. For instance, if one of the inputs of ring oscillator is affected by single event transient, its output is minimally delayed because the alternate inverter of the ring inverter can still drive the output. As shown in Fig. 2(b), the outputs from both ring oscillators are driven by other delay stages until the drive strength is sufficient for a single inverter to generate the final output. The transistors are properly sized for the desired center frequency of 3.9 GHz and tuning range of 3.5 GHz to 4 GHz. This is discussed extensively in Session 3.

Frequency divider (FD) and VCO are highly vulnerable to single event upset because they operate at high frequency. If the divider is affected by SET, the feedback signal and charge pump are also affected, which leads to distortion in the phase of voltage controlled oscillator and increases the bit error rate (BER). Therefore, it is desirable to design a radiation hardened FD for phase locked loop, most especially for high radiation environment, such as spacecraft and military applications. The radiation tolerant flip flop is cascaded in three folds to obtain divide-by-eight frequency divider. Subsequently, the outputs of three different FD are applied to each of the inputs of voter circuit. By considering that one of the dividers is struck by radiation, the two remaining frequency dividers still produce the desired outputs which aids the voter circuit to elect the majority and output the correct value. Although the voter circuit is not modified for radiation effect, it can be made less radiation sensitive by adding dummy transistors or guard rings to its layout [8].

III. PHASE NOISE AND JITTER MEASUREMENTS

A typical PLL is characterized by its phase noise, jitter, tuning range, and power consumption. The voltage controlled oscillator, being the heart of phase locked loop, contributes largely to the total phase noise in PLL [9]. The purity of spectral is also determined by VCO. The sources of noise from oscillator can be categorized into 3 major parts: thermal noise, flicker noise, and power supply noise. In this work, we have only considered device noise (flicker and thermal noise) because they contribute majorly to phase noise performance [10]. Both are random and act as baselines or minimum phase noise obtainable in VCO. We present phase noise in terms of deviation of the output of VCO from the reference input. It is expressed as:

$$L\{\Delta f\} \approx \frac{8kTV_{DD}}{3\eta P\, V_{char}} \frac{{f_0}^2}{\Delta f^2} \qquad (1)$$

where η , V_{char} , Δf are constant, device voltage characteristics, and offset frequency, respectively. f_0 is the centre frequency, P is power consumption and is given as:

$$P = N \times V_{DD} \times I_{DD} \qquad (2)$$

Jitter is also a critical issue in analog design because a clock with timing errors or an oscillator with high jitter in its waveform can drastically limit the speed of digital interface, alters the dynamic range of ADC, and increases BER. It is a measure of deviation, in time domain, of oscillator’s output from its ideal clock. Since the creation of redundancy in radiation-hardened VCO design employs more transistor, each transistor device contributes to circuit delay and increases the jitter. Depending on the operating frequency of oscillator and its delay, the rise and fall time of VCO fluctuates, which have adverse effects on the accumulated jitter. The equation for jitter is presented in (3);

$$\sigma_{\Delta T} = \kappa\sqrt{\Delta T} \qquad (3)$$

and the proportionality constant, κ, is

$$\sqrt{\frac{8}{3\eta}}.\sqrt{\frac{kT\times V_{DD}}{P\times V_{Char}}} \qquad (4)$$

From Fig. 3, the phase noise -109.5 dBc/Hz measured at 10 MHz offset frequency and -125 dBc/Hz measured at 100 MHz offset, which is the corner frequency. It can be inferred that at low frequency, the phase noise is dominated with $^1/_f$ noise and the thermal noise is predominant at high frequency. Similarly, for the jitter, the minimum value is 90 ps at operating frequency of 3.5 GHz. The jitter increases linearly until it reaches maximum value at 3.7 GHz. The centre frequency of the radiation hardened VCO is 3.9 GHz and it produces a jitter of 128 ps. By using (5), we obtained the tuning range of the proposed PLL as 12.8%, which is lower when compared with non-radiation hardened structure [11, 12]. Fig. 4 is the layout of the delay stage of radiation-hardened voltage-controlled oscillator.

$$F_{TR} = \frac{f_{max} - f_{min}}{f_{center}} \tag{5}$$

IV. CONCLUSION

This work examines radiation effects on phase locked loop and propose a structure which is resistant to single event upsets. The phase frequency detector is designed with radiation hardened, D flip flop, NAND gate, and inverter. Two different CP/LPF are used in order to create alternative path for the control voltage to the voltage controlled oscillator. The proposed PLL structure operates from 3.5 to 4 GHz and the open loop phase noise is -109.5 dBc/Hz at 10 MHz offset. In addition, the results show that the maximum jitter is obtained at 3.7 GHz and reduces to 128 ps at centre frequency of 3.9 GHz.

***Abstract*—This paper introduces two transmit/receive switch designs for 7 Tesla magnetic resonance spectroscopic imaging. Both designs based on microstripline-based couplers. The first is a dual-tuned 1H/13C switch with two concentric microstriplines on each side of the switch. A branch line technique from transmission line theory is applied to compact the switch to half of its initial dimension. The second proposed design is a dual tuned 1H/13C microstripline-based switch with one microstripline in each side of the switch. The second design benefits from the harmonics of an initial resonance signal to shift the first and second harmonics to the same Larmor frequencies of the 1H and 13C nuclear spins when exposed to 7 Tesla static magnetic field. The first design serves 1H and 13C RF Coils, working independently. Whereas the second design works with a dual resonance 1H/13C RF coil. The first and second designs achieved good matching less than -15 dB and -10 dB, respectively. They achieved low insertion loss less than -0.6 dB and -1.2 dB, respectively. The isolation between couplers in the first design is higher than 60dB. Furthermore, the isolation between the amplifier port and the receiver for both switches designs are higher than 60dB as well. The proposed switches are promising in reducing the number of T/R switches and the area of the place they need in the transmit front-end when multichannel RF coils are used.**

***Index Terms*—couplers, dual tuned switch, microstripline (MSL), magnetic resonance spectroscopic imaging, radiofrequency (RF) coil, pi-shaped technique.**

I. Introduction

13C MRI is a noninvasive molecular imaging method that investigates the metabolic differences in organic molecules. These changes in biochemical processes are a measure to the existence of different diseases [1]. Since 13C available in many organic molecules, its abnormal quantification (because of the metabolic changes) might indicates to many diseases. A hyperpolarized process can be used to enrich 13C concentration and improved its MR signal to detect diseases. These include: Prostate cancer [2], brain tumors [3], diabetes [4], variety of inflammatory conditions [5, 6, 7], cardiovascular disease [8], and cardiac metabolism [9].

RF coils in MRI are used to interrogate 1H and/or X-nuclei. To interrogate spins of any type of atomic nuclei, the coil should resonate at a frequency equals the speed of precession of the nuclear spins of the element under interest when exposed to a certain strength of the static magnetic field. A single or multichannel 1H RF coils that resonant at a single operating frequency are extensively introduced in [10, 11]. Similarly, commercial single or multichannel 13C RF coils are available [12]. Multichannel RF coils have been used to achieve better coils performance and hence enhance the quality of the scanned image. The performance of the coils improves by increasing the rotating magnetic field (B1) and the signal-to-noise-ration (SNR), and by decreasing the Electric field and hence the specific energy absorption rate (SAR) [13, 14, 15]. For 7 Tesla MRI, the 1H and 13C coils resonate at 298MHz and 75MHz, respectively. RF coils for 1H and 13C are designed independently and in dual resonance [16]. However, the available of commercially dual-tuned 1H/13C multichannel coils are essential to the SNR imaging of all body areas [1]. The challenge also is in the front end transmit RF circuit. From transmit/receive (T/R) switches perspective, the number of the required switches, and their size are also a challenge. The ability to design a dual tuned switch to handle the signal to/from a dual resonance coil at the same time is essential, accordingly.

Once RF coils are used to transmitting/receiving RF signals to/from the body, T/R switches must be used in the RF-transmitter front-end to handle the signal to/from the RF coils. For a 1H single resonance RF coil, a T/R switch is required to deliver the amplified signal power to the RF coil or to handle the received MR signal from the coil to the receiver. T/R switches of different topologies are introduced in the literature, some of which use PIN diodes [17], transistors [18, 19], and MEMS [20, 21]. A PIN diodes-based switch is designed to reduce the switching time to 1μs [17]. Transistors-based switches [18, 19] are proposed to minimize the operating current, power, and fields distortion but they obeyed less SNR values. A dual tuned MEMS-based 1H/19F T/R switch compared to PIN diodes-based topology is introduced in [20]. Results showed the advantage of MEMS topology in achieving higher isolation, and the advantage of PIN diode topology in achieving higher image SNR [21].

A dual tuned 1H/31P switch for 3 Tesla MRI is designed with an insertion loss of 0.7 dB and 1.2 dB for 1H and 31P, respectively [22]. A T/R switch for preclinical 14.9 Tesla is presented in [23] with an insertion loss of 1 dB. A compact dual tuned 1H/23Na switch was introduced with a compact size to handle the signals into two RF coils of frequencies corresponding to the speed of rotation of 1H and 23Na atomic nuclei [24]. The advantage of the MSL-based coupler switch over the conventional couplers in heat dissipation and its capability in handling more power signal is explained in [25]. The first disclosed switch design in [25] is successfully used with 32 channels RF coils in [26].

In this paper, two different designs of T/R switches are proposed. In the first design, we introduce a dual tuned 1H/13C T/R switch to handle two signals at the same time to/from two different single resonance 1H and 13C RF coils. The proposed dual tuned switch based on microstripline coupler technology with two concentric MSLs on each side of the switch, each connected with a coil. A branch line technique from circuit theory is applied to compact the size of the proposed switch. In the second design, we introduce a novel dual tuned 1H/13C T/R switch with single MSL on each side of the switch that can deliver a dual resonance signal (corresponding to the 1H and 13C frequencies) to/from a dual resonance 1H/13C RF coil.

II. Dual-tuned Double-Coupler MSL-based 1H/13C T/R Switch

A. The Working Principle and Research Method

Although modern MRI scanners employ separate transmit and receive RF coils, some imaging of body parts such as head and knee imaging still used transmit/receive RF coil. This type of coil requires T/R switch to separate the transmitted and received signals. Once a dual-tuned 1H/X-nuclei T/R RF coil is used, a dual-tuned 1H/X-nuclei T/R switch is required for integration with this coil. To understand the working principle of dual tuned T/R switches, the block diagram of the first proposed design is drawn in Figure 1. This switch consists of pair of two concentric microstripline-based hybrid couplers. Each coupler in the left side has been joined with the corresponding coupler in the right side using metallic rods. The inner and outer MSLs couplers on each side of the switch are corresponding to 1H and 13C signals, respectively. During transmit, two couplers of MSLs on the left side are used. The 1H and 13C RF signals are directed from ports 1&5 (power amplifiers' ports) to ports 2&6 (RF coils' ports). This is accomplished by forward biasing all PIN diodes in the switch. During receive, all PIN diodes are reverse biased and the detected 1H and 13C signals are directed from ports 2&6 to the receiver ports 4&8. This switch has been designed using CST Microwave Studio as shown in Figure 2. This design relies on folded microstripline-based hybrid couplers to create a T/R switch with dimensions 240mm × 220mm. RO3010 Rogers substrate with height 1.27mm, ε_r=10.2 and tanδ=0.0022 has been used.

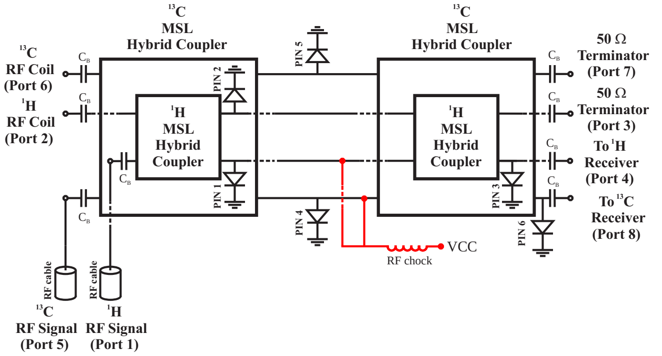

Fig. 1. Block diagram of a dual-tuned T/R switch

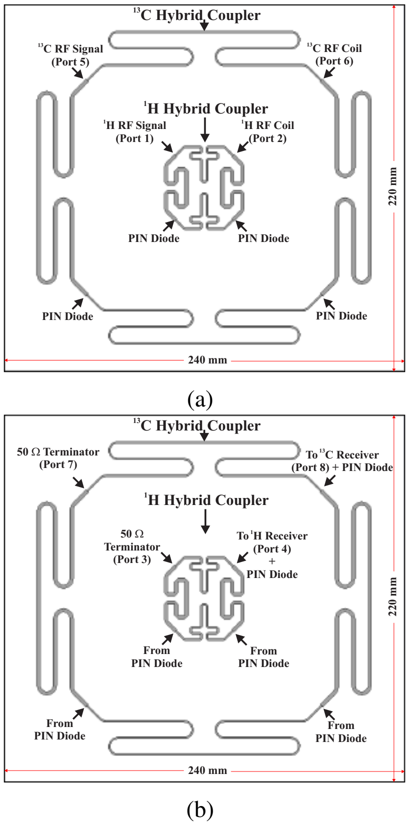

Fig. 2. The 1H/13C T/R switch using two concentric MSL couplers at (a) the top and, (b) the bottom face.

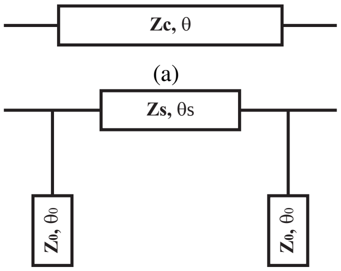
B. Compacting the Switch using the pi-Shaped Technique

Quadrature hybrid couplers are considered valuable passive devices in several modern communication systems. However, designing such couplers for applications operate at low frequencies increases the occupied area in the system. Therefore, several techniques have been proposed to miniaturize the overall size of the designed couplers [27, 28, 29, 30]. In this context, a pi-shaped technique [29] has been applied to reduce the size of the dual-tuned T/R switch in Figure 2. This technique makes use of the transmission line theory and



(a)

(b)

Fig. 3. (a) Conventional transmission line, (b) pi-shape equivalent transmission line.

TABLE I. 75 MHz coupler with θ_s=45

	Z_c=50 Ω, θ=90°		Z_c=35.355 Ω, θ=90°	
Z_s	70.71 Ω	w=0.45 mm	50 Ω	w=1.07 mm
θ_s	45°	l=189 mm	45°	l=184 mm
Z_0	70.71 Ω	w=0.45 mm	50 Ω	w=1.07 mm
θ_0	45°	l=189mm	45°	l=184 mm

replaces each branch in the coupler by a pi-shaped equivalent circuit as shown in Figure 3. A pi-shaped equivalent circuit comprises one series transmission line associated with two open stubs at its terminals.

The pi-shaped equivalent transmission line parameters are calculated based on the following:

$$Z_s = \frac{Z_c\, sin\theta}{sin\theta_s} \tag{1}$$

$$\frac{tan\,\theta_o}{Z_o} = \frac{cos\theta_s\ - cos\theta}{Z_c\, sin\theta} \tag{2}$$

where Z_c is the characteristic impedance and θ is the electrical length of the conventional transmission line. In Equation 1, Z_s is the characteristic impedance of the series transmission line in the pi-shaped equivalent circuit with θ_s electrical length. The two open stubs have characteristic impedance Z_o and electrical length θ_o. The calculations of the pi-shaped equivalent transmission line parameters have been summarized in Table I. These calculations are based on predefined values of θ_s and θ_o which have been chosen to be 45°. Our analysis showed that using greater angles can more compact the structure . However more compacting leads to unrealistic microstriplines widths which might not be able to handle high power signals for this application. In addition, this table summarizes the corresponding width "w" and length "l" for each microstripline branch in the coupler. It is worth to mention that, these calculations have been done for the 13C coupler (the outer coupler). Figure 4 shows the compact dual-tuned T/R switch where C_p is a shunt capacitor replacing each adjacent open stubs in the pi-shaped equivalent transmission lines. This capacitor has a value of 72.5 pF. The dimensions of the T/R switch in Figure 4 show that the pi-shaped technique reduces the classical T/R switch design to the half.

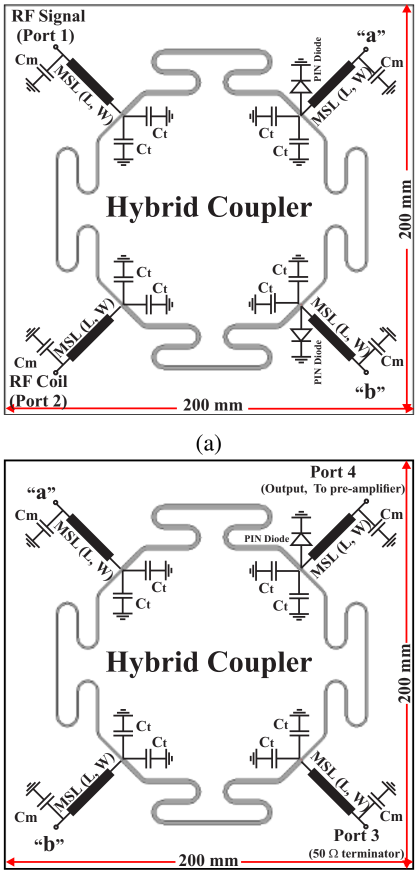
III. Dual-tuned Single-Coupler MSL-based 1H/13C T/R Switch

This switch is being designed to deliver a dual tuned signal, of 1H and 13C frequencies, to/from a dual resonance 1H/13C RF coils, simultaneously. It comprises a single microstripline-based hybrid coupler on each side of the switch rather than 2 couplers on each side compared to the previous switch, see the block diagram of the switch in Figure 5. During transmit, a signal of two resonance frequencies (corresponding to 1H and 13C at 7 Tesla) will bypass from the power amplifier(s) at port 1 to the dual resonance 1H/13C RF coil at port 2. During this mode, the PIN diodes are forward biased. During receive mode, the MR received signal from the 1H and 13C RF coils will be delivered from port 2 to the the receiver at port 4. During this mode, the PIN diodes are reverse biased. This switch relies on the first and second harmonics of the microstripline-based hybrid coupler. After an iterative simulations of the coupler, the obtained first and second harmonics can be shifted to two frequencies corresponding to 1H and 13C. The shifting process has been accomplished by shunt capacitors (C_t=61pF). The matching network has been accomplished by matching capacitor (C_m=13pF) and a MSL of specific length (l=30mm) and width (w=1.2mm). Figure 5 shows the dual-tuned single-coupler microstripline-based 1H/13C T/R Switch where the hybrid couplers have been



(a)

(b)

Fig. 6. First design S-parameters (a) 13C at 75MHz (b) 1H at 298MHz.

designed initially to operate at 131 MHz .

The novelty of this paper is in (i) introducing new T/R switches based on microstriplines couples that proofed better performance in heat dissipation and handling high power compared to the classical couplers [25] (ii) compacting the size of the switch by 50% compared to the initial design, with the advantage in using the switch with half the number of the multichannel-single resonance RF coils (iii) designing a novel dual tuned switch that handle two frequencies signal to a dual resonance RF coil, at the same time and without tuning during operation. This proposed design has the advantage in using the switch with half the number of the multichannel-dual resonance RF coils.

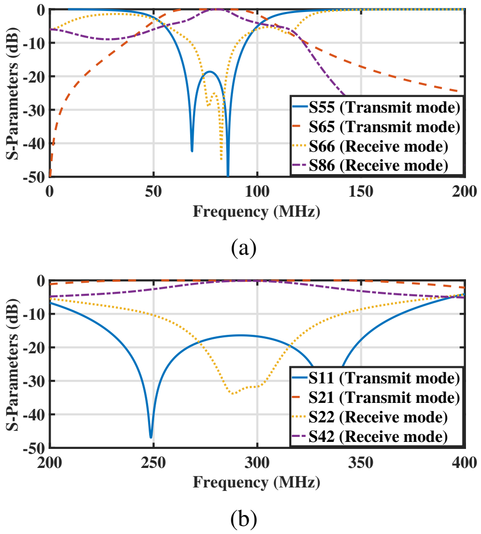
IV. The Simulation Results

A. *The Results of The Dual-Tuned Double-Coupler Switch*

The performance of the first dual-tuned 1H/13C T/R switch (without compacting) that is shown in Figure 2, has been verified using electromagnetic simulation for S-parameters as shown in Figure 6. During transmit mode, good matching for the 1H signal at port 1 (S11$\simeq$-18dB) and the 13C signal at port 5 (S55$\simeq$-25dB) has been achieved. Moreover, low insertion loss between ports 1&2 (S21$\simeq$-0.3dB) and ports 5&6 (S65<-0.2dB) has been achieved for the 1H and 13C amplifiers-coils delivered signals, respectively. During receive mode, good matching for the 1H RF coil signal at port 2 (S22$\simeq$-34dB) and for the 13C RF coil signal at port 6 (S66$\simeq$-30dB) has been achieved. In addition to that, low insertion loss between ports 2&4 (S42$\simeq$-0.3dB) and ports 6&8 (S86<-0.2dB) for the 1H and 13C coils-receivers signals have been achieved, respectively. The isolation between the inner and outer coupler is around 70 dB. In addition, the isolation between the amplifier port and the receiver during transmit mode is 62 dB and 70 dB for 1H and 13C couplers, respectively. This design has an insertion loss lower than that achieved by other switches, where 1.2dB was revealed for for the X-nuclei [22], and 1dB for the 1H [23].

B. *The Results of The Compact Dual-Tuned Double-Coupler Switch*

The S-parameters of the compacted switch is shown in Figure 7. In this design, the proposed dual tuned switch has been compacted in size to half, from 240mm × 220mm to 120mm × 110mm. The pi-shaped technique from transmission line theory is used. During transmit, good matching for the 1H signal at port 1 (S11$\simeq$-16dB) and the 13C signal at port 5 (S55$\simeq$-19dB) has been achieved. Moreover, low insertion loss between ports 1&2 (S21$\simeq$-0.3dB) and ports 5&6 (S65<-0.25dB) has been achieved, for the 1H and 13C amplifiers-coils delivered signals, respectively. During receive, good matching for the 1H RF coil signal at port 2 (S22$\simeq$-32dB) and for the 13C RF coil signal at port 6 (S66$\simeq$-25dB) has been achieved. Moreover, the insertion loss between ports 2&4 (S42$\simeq$-0.5dB) and ports 6&8 (S65<-0.6dB) has been achieved for the 1H and 13C coils-receivers delivered signals, respectively. The isolation between the inner and outer



(a)

(b)

Fig. 7. The compact first dual tuned switch during transmit and receive for (a) 13C at 75 MHz, and (b) 1H at 298MHz.

coupler is around 60 dB. In addition, the isolation between the amplifier port and the receiver during transmit mode is 62 dB and 67 dB for 1H and 13C couplers, respectively.

C. The results of the Dual-Tuned Single-Coupler Switch

In this design, a dual tuned 1H/13C switch is introduced to handle the signal to/from dual resonance 1H/13C RF coil. The switch is first designed to resonate at both 131MHz and 393MHz, as shown in Figure 8(a). The first (131MHz) and second (393 MHz) harmonics of the designed coupler are then shifted by the shunt capacitors to 75 MHz and 298 MHz, as shown in Figure 8(b) . During transmit, good matching at the power amplifier port 1 (S11≃-11.5 dB and -13dB) has been achieved for 1H and 13C frequencies, respectively. Low insertion loss between the power amplifiers and the dual-resonance coil ports 1&2 (S21≃-0.8 dB and -0.27 dB) has been achieved for 1H and 13C frequencies, respectively. During receive, good matching at port 2 (S22≃-19 dB and -15dB) has been achieved for the 1H and 13C frequencies respectively. Further, low insertion between the coil and receiver ports 2&4 (S42≃-1.2 dB and -0.8 dB) for 1H and 13C frequencies, respectively. In addition, the isolation between the amplifier port and the receiver during transmit mode is 62 dB at 1H and 13C frequencies.

V. Conclusion

In this paper, two designs of dual tuned 1H/13C T/R switches have been designed to serve 1H/13C RF coils working independently and in dual resonance at 7 Tesla MRI. Both switches based on microstriplines topology which is promising in heat dissipation and handling more power to/from the coils. The first switch has been designed with two concentric MSLs couplers on the top and bottom of the switch. This switch is used to deliver two signals of 1H and 13C frequencies to/from 1H and 13C RF coils, independently. Using one switch with two RF coils has the advantage of reducing the number of T/R switches to half the number of RF coils. A pi-shaped technique from transmission line theory is used to reduce the dimension of each dual tuned switch of the first type by 50%. This reduction in size is promising in using a reasonable area for the T/R switches when they are used near to multichannel RF coils. The second switch has a novel design with a single MSL coupler on the top and bottom of the switch. This switch is used to deliver a dual resonance signal (of 1H and 13C frequencies) to/from a dual resonance 1H/13C RF coils. Our proposed dual tuned T/R switch is a promising solution whenever multichannel dual resonance RF coils are required.

***Abstract*—Living biological tissues in plants, fruits and flowers possess considerably high permittivity and electrical conductivity over wide microwave frequency spectrum. Plants, being immobile, are continuously exposed to electromagnetic radiation emitted from cell tower antennas. As a consequence, plants are expected to absorb quite a large amount of incident electromagnetic energy over multiple frequency bands. Different global and national regulatory bodies have put limits on maximum permissible electromagnetic exposure to restrict absorption in humans and minimize related health risks. However, electromagnetic energy absorption in plants along with associated physiological and molecular effects has not been considered in these guidelines. Plants, in general, possess higher surface area while compared to humans or other living objects. In particular, flowers own reasonably high surface to volume ratio and consequently dissipate quite high amount of electromagnetic energy in a relatively less tissue mass. Hence, this paper aims at estimating specific absorption rate data for a hibiscus flower model at 947.50 MHz and 1842.50 MHz. Linearly polarized plane waves at those two frequencies impinge on the hibiscus flower model in separate simulations as per the International Commission on Non-Ionizing Radiation Protection guidelines. Maximum local point, averaged over 1g contiguous tissue and whole body averaged specific absorption rate data at those two frequencies are significantly different than the data reported earlier at 2450 MHz – indicating, the nature of dependence of specific absorption rate data on frequency of irradiation, incident field strength and dielectric properties of constituent flower tissue.**

***Keywords*—conductivity, hibiscus, permittivity, ICNIRP, electromagnetic radiation, specific absorption rate**

I. Introduction

With the increased use of different wireless communication systems, estimating electromagnetic energy absorption rate in human phantoms is now a standard practice for protecting human health [1-7]. Electromagnetic energy absorption rates in human phantoms are estimated and measured primarily due to near-field radiation from cell phones, wearable or implantable radio frequency devices. However, electromagnetic energy absorption rate estimations in different plant and fruit models have also been undertaken in recent time [8-13] – as the constituent tissues possess reasonably high dielectric properties [8-15] and moreover, plants are being continuously exposed to mobile tower radiations in far-field. The radiated power density in far-field or equivalent electric field strength, due to emission from antennas installed on mobile towers, is governed in accordance with the prescribed global or national electromagnetic regulatory guidelines [16-19]. Therefore, electromagnetic energy absorption rates estimation in different plant, fruit and flower models is absolutely necessary as per the global and national guidelines [8-13]. Electromagnetic energy absorption rate is quantified in terms of specific absorption rate (SAR) – i.e. the rate of electromagnetic energy absorption by a biological object when microwave radiation impinges on the same. SAR is in general averaged over point mass, 1g tissue mass, 10g tissue mass or the whole body mass as prescribed in protocol. Mathematical expression for point SAR is $\sigma|E|^2/2\rho$ – where, σ represents electrical conductivity of tissue, E represents peak value of internally developed electric field strength and ρ represents tissue density [13].

It should be noted that electromagnetic energy absorption rate estimations in typical flowers haven't been performed

Table I: Dielectric properties and tissue density of hibiscus flower [12]

Tissue	Density (Kg/m^3)	Frequency (MHz)	Permittivity	Loss Tangent
Hibiscus Flower	644.50	947.50	43.53	0.279
		1842.50	42.33	0.221

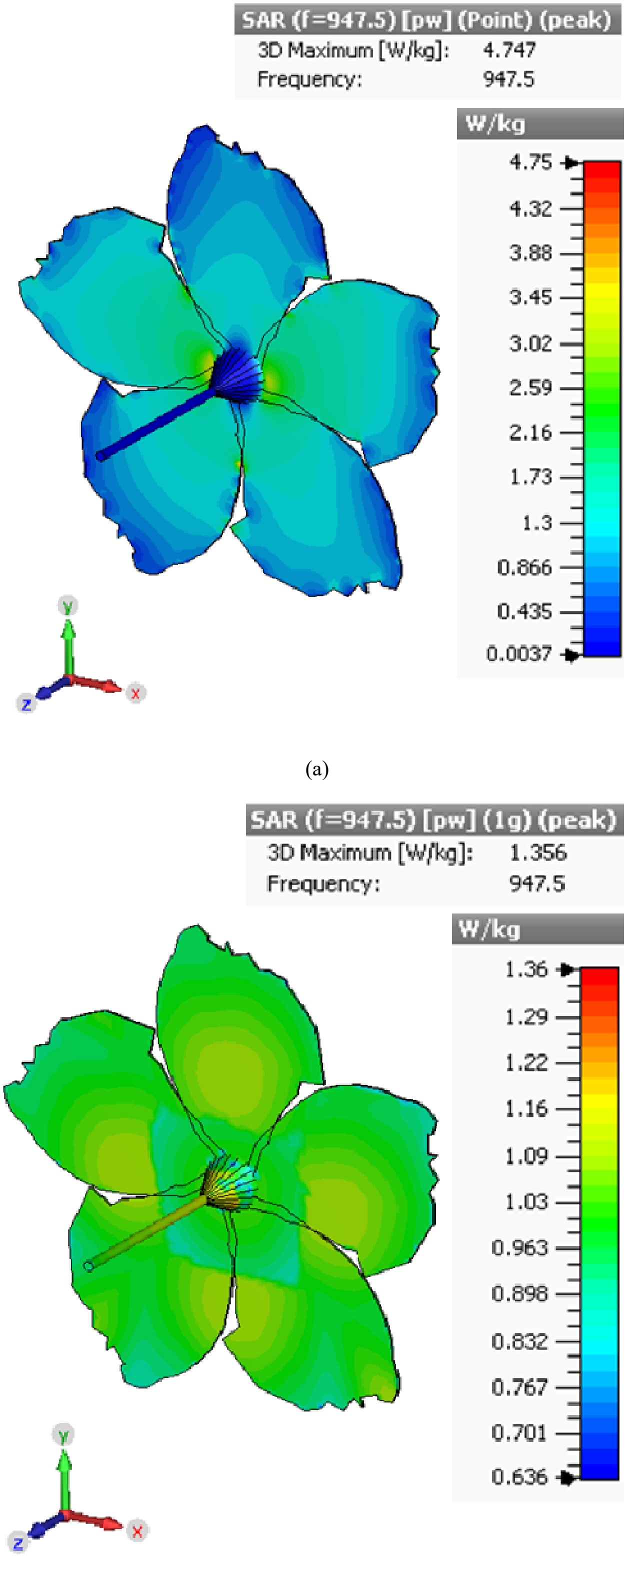
Table II: ICNIRP prescribed reference electromagnetic regulatory limits for public exposure zone [16]

Frequency (MHz)	Maximum permissible power density (W/m^2)	Equivalent peak E-field (V/m)
947.50	4.7375	59.77
1842.50	9.2125	83.34

earlier except one or two selective cases [12-13]. Broadband dielectric properties measurement of hibiscus flower tissue and subsequent SAR data assessment only at 2450 MHz was reported in a recent article [12] – but, SAR data estimations at other important telecommunication frequency bands such as 900 MHz and 1800 MHz downlink bands weren't reported for the designed hibiscus flower model. Hence, this article extends that work by estimating maximum local point SAR (MLP SAR), 1g averaged SAR (1g SAR) and whole body averaged SAR (WBA SAR) data at 947.50 MHz and 1842.50 MHz respectively. All SAR data have initially been planned to be simulated for a plane wave incidence with plane wave equivalent field strength specified as per electromagnetic regulatory guidelines prescribed by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) [16].

II. SAR Simulation Technique

The typical hibiscus flower model reported earlier in an article has been used here for SAR simulation in CST Microwave Studio 2016 [20] – moreover, frequency dependent dielectric properties at 947.50 MHz and 1842.50 MHz along with the measured tissue density data have been taken from the same published article [12]. The typical hibiscus flower model contains five petals along with a twig and possesses total mass of 2.30g – the same is illustrated in Fig. 1. The broadband dielectric properties (i.e. permittivity and loss tangent) of hibiscus flower tissue have been reported to be measured using the open ended coaxial probe technique; moreover, the tissue density characterization technique has also been outlined in the same article [12]. The dielectric properties at 947.50 MHz and 1842.50 MHz along with the measured tissue density are tabulated in Table I. Plane wave with linear polarization propagating along z-axis and electric field variation along x-axis impinges on the designed flower model at above mentioned frequencies in two different simulation environments as per the ICNIRP guidelines [16]. ICNIRP prescribed maximum permissible reference power densities in public zone are different at 947.50 MHz and 1842.50 MHz – detailed data have been tabulated in Table II [16]. Time domain solver in CST Microwave Studio 2016 has been employed to simulate SAR data [20]. Complex geometry, high permittivity and significant loss tangent of the designed flower model are the prime reasons to choose time domain solver for proper



(a)

(b)

Fig. 2. (a) Point SAR distribution on three dimensional surface of the typical hibiscus flower model due to plane wave (linearly polarized) irradiation at 947.50 MHz as per ICNIRP guidelines [16] (b) 1g SAR distribution on three dimensional surface of the typical hibiscus flower model due to plane wave (linearly polarized) irradiation at 947.50 MHz as per ICNIRP guidelines [16] meshing of the structure [13] – this solver is developed based on a computational method known as Finite Integration Technique [21-22]. Spatial distance of one wavelength in the tissue material has been segmented into 20 parts and the flower model has been discretized with hexahedral meshes of different sizes. Next, four perfectly-matched-layers (PMLs), each possessing 0.0001 reflection coefficient, have been used in absorbing boundary during SAR simulations. All open (add space) boundaries have been set very close to the structure so that the plane wave excitation can be placed as close as possible. Then, -40 dB inverse transformation accuracy has been set to obtain frequency domain characteristics from the time domain results (after steady state energy criterion is satisfied). MLP SAR, 1g SAR and WBA SAR data have been simulated at 947.50 MHz and 1842.50 MHz respectively using IEEE/IEC 62704-1 protocol with an average cell mass of 0.00034g.

III. Simulated SAR Results and Discussions

Simulated SAR data at 947.50 MHz and 1842.50 MHz are of significant values – moreover, SAR values at 1842.50 MHz increase by a large scale (3 to 4 fold) as illustrated in Table III. Simulated MLP SAR and 1g averaged SAR distributions on the three dimensional surface of the hibiscus flower model at 947.50 MHz (as per ICNIRP regulations) are illustrated in Figs. 2(a) and 2(b) respectively. To be specific, MLP SAR values are 4.75 W/Kg and 19.12 W/Kg respectively at 947.50 MHz and 1842.50 MHz – an increase of 4 fold. This increase in SAR value is due to multiple reasons. Firstly, wavelength gets shorten at higher frequency resulting in more number of electric field peaks within the hibiscus flower model [12-13]; Secondly, maximum permissible incident field strength significantly increases at 1842.50 MHz compared to 947.50 MHz – as a consequence, SAR value also increases [12-13]. In addition, dielectric properties of hibiscus flower also alter with frequency and this further contributes in altering SAR value with frequency [12]. However, it should be noted that earlier published SAR data at 2450 MHz for the same hibiscus flower model are of higher values while compared to the present reported SAR data at 947.50 MHz and 1842.50 MHz – and the reasons are obvious and have been discussed above [12].

Even at a particular frequency, SAR distribution on three dimensional surfaces of the hibiscus flower model possesses a wide spatial variation – as observed in Figs. 2(a) and 2(b) respectively. The hibiscus flower model contains regions with relatively higher SAR values near the junction of the petals and the twig; moreover, moderately high SAR values are also noted near the sharp edges of the petals – these observations resemble with the earlier reported SAR distribution at 2450 MHz [12]. It is so because strong charge accumulation takes place near sharp edges of any arbitrary shaped lossy dielectric biological object – consequently, higher electric field strength develops locally at regions with concentrated charge distribution resulting in increased SAR value near sharp edges of the flower structure [12-13]. Thus, increased point SAR values near sharp edges can have localized consequences and therefore spatial SAR averaging over 1g or larger mass can overlook this real scenario – therefore not recommended [12].

Table III: Simulated SAR results for the typical hibiscus flower model at 947.50 MHz and 1842.50 MHz

Frequency (MHz)	Peak E-field (V/m)	SAR averaging mass (g)	Max SAR (W/Kg)
947.50	59.77	Point	4.74682
		1	1.35591
		WBA	1.02422
1842.50	83.34	Point	19.1214
		1	4.82687
		WBA	3.39038

Simulated SAR results at 947.50 MHz and 1842.50 MHz shouldn't be further underestimated by averaging over 6 or 30 minutes of time duration – it is so as flowers in plants get continuous electromagnetic irradiation throughout their lifespan [12-13]. Here, reported SAR data have been noted for plane wave irradiation with linear polarization i.e. wave propagation along z-axis and electric field variation along x-axis. But, simulated SAR data can definitely alter if the direction of wave propagation or the polarization alters – as the designed flower structure is not symmetric along all axes and SAR data significantly depends on geometry of the biological object [11].

IV. Conclusions

There are a number of international and national electromagnetic regulatory organizations across the globe and ICNIRP is one of those – these electromagnetic guidelines are of wide contrast and prescribed reference power density limits at public zone differ a lot [13, 16-19]. Here, all simulated SAR data have been reported for ICNIRP public exposure guidelines – however, simulated SAR data would alter in case other electromagnetic regulatory guidelines are considered [13, 16-19]. Prescribed reference power density level as well as expression for point SAR changes proportionately with the square of electric field magnitude – the initial parameter is correlated to the square of incident electric field magnitude whereas SAR depends on square of developed internal electric field magnitude. SAR values, due to simultaneous exposure at multiple frequencies, add up in real scenarios and thus the concern is further raised [13]. Moreover, estimated SAR values would increase many folds in case occupational scenarios are taken into account [16].

Simulated SAR data can be treated as initial reference for practical SAR measurement in future – however, custom made phantom model, equivalent dielectric liquid, design of electric field probe along with its calibration are some of the challenges to be dealt with. To conclude, significant SAR values in hibiscus flower model insist to investigate biological effects of long duration as well as short span electromagnetic exposure on plants, fruits and flowers.

***Abstract*—this paper derives extended three-stage recursive identification algorithm of MISO for (CARARMA) systems. Based on The decomposition technique, four subsystems are obtained and the parameters of each subsystem are identified. Some model validation methods are computed to measure the model value and Akaike's Final Prediction Error Criterion (FPE) is used to verify the selection of system order. The algorithm has a high computational efficiency because the covariance matrices dimensions become small in each subsystem. Finally, this algorithm effectiveness is demonstrated in simulation example**.

Keywords*— *parameter estimation, decomposition technique, model validation, covariance matrix, Final Prediction Error Criterion

I. Introduction

System identification has important effect on control theory, optimization, state filtering, modern control and other fields [1-4], deals with issue of designing mathematical models of dynamic systems from the true data for the input and the output of the system [5-7]. Parameter estimation is significant for system identification and system modeling [3, 8], and there are many Parameter estimation algorithms in the literature. For instance, LS algorithms, the auxiliary model based identification algorithms and gradient based algorithms [9, 10]. LS methods can be divided into two classes. First class can be used for offline identification and is called iterative identification methods; another can be used for online identification and is called recursive identification methods. RLS method considers important development which has made the LS algorithm one of the very important and largely used for real-time implementations. RLS method can be used only for Auto – Regressive model (ARX). for other models, such as, autoregressive moving average model(ARMAX) or controlled autoregressive autoregressive moving average (CARARMA) model, RLS method cannot be used. One such algorithms that deals with these types of models in system identification is multiple-stage algorithms [8] and the basic idea is based on the decomposition technique that can convert the main identification issue into small sub issues, which are simpler to solve[11]. For instance, Yao and Ding derived Two-stage least squares based iterative identification algorithm for controlled autoregressive moving average (CARMA) systems [12]. This work proposes extended three-stage recursive identification algorithm of MISO for (CARARMA) systems. The decomposition technique is used as the basic idea and thus the covariance matrices dimensions of each subsystem become small and computational efficiency of the proposed algorithm become high. This paper is structured as follows. Section 2 introduces multi-input single-output CARARMA system and its identification model is given. Extended three-stage recursive identification algorithm for MISO CARARMA systems is derived in Section 3. Section 4 presents model validation and order selection. In section 5, a simulation example is given to demonstrate the efficacy of this algorithm. Finally, the conclusions are given in section 6.

II. Problem Formulation

In this work, MISO system, linear, time-invariant, discrete-time system, described by (CARARMA) model [13] as shown in fig. 1 is considered and given as

$$A(z)y(k) = \sum_{j=1}^{2} B_j(Z)\, u_j(k) + \frac{D(z)}{C(z)} v(k) \qquad (1)$$

where

$u_j(k)$, $j = 1, 2$, $y(k)$ are the inputs, output of the system and $\nu(k)$ is the white noise with $m = 0$ and $\sigma^2 = 1$ [9]. $A(z), B_j(z), C(z)$and $D(z)$ are polynomials as [8]:

$$A(z) = 1 + a_1 z^{-1} + a_2 z^{-2} + \cdots + a_{n_a} z^{-n_a} ,$$

$$B_j(z) = b_{j1} z^{-1} + b_{j2} z^{-2} + \cdots + b_{jn_j} z^{-n_j} ,$$

$$C(z) = 1 + c_1 z^{-1} + c_2 z^{-2} + \cdots + c_{n_c} z^{-n_c} ,$$

$$D(z) = 1 + d_1 z^{-1} + d_2 z^{-2} + \cdots + d_{n_d} z^{-n_d} ,$$

First, the inner variable is defined as

$$w(k) = \frac{D(z)}{C(z)} v(k), \qquad (2)$$

Thus, equation (1) can be rewritten

$$A(z)y(k) = \sum_{j=1}^{2} B_j(z)\, u_j(k) + w(k). \qquad (3)$$

Or

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$$y(k) = -\sum_{i=1}^{\mathrm{n_a}} a_i y(k-i) + \sum_{j=1}^{2}\sum_{i=1}^{n_{b_j}} b_{ij}\, u_j(k-i) + w(k) (4)$$

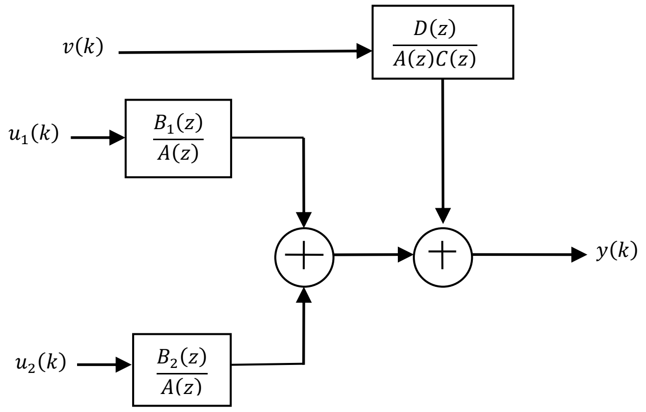

Fig. 1. The MISO (CARARMA) system.

It can be described in a linear regression form as

$$y(\mathrm{k}) = {\varphi_1}^T(k)\theta_1 + {\varphi_2}^T(k)\theta_2 + {\varphi_3}^T(k)\theta_3 + w(k) \quad (5)$$

Where

The information vectors are [8],

$$\varphi_1(\mathrm{k}) = [-\mathrm{y}(\mathrm{k}-1), -\mathrm{y}(\mathrm{k}-2), \dots, -\mathrm{y}(\mathrm{k}-\mathrm{n_a})]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_a}},$$

$$\varphi_2(\mathrm{k}) = [\mathrm{u_1}(\mathrm{k}-1), \mathrm{u_1}(\mathrm{k}-2), \dots, \mathrm{u_1}(\mathrm{k}-\mathrm{n_1})]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_{b_1}}},$$

$$\varphi_3(\mathrm{k}) = [\mathrm{u_2}(\mathrm{k}-1), \mathrm{u_2}(\mathrm{k}-2), \dots, \mathrm{u_2}(\mathrm{k}-\mathrm{n_2})]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_{b_2}}},$$

The parameter vectors are

$$\theta_1 := [\mathrm{a_1}, \mathrm{a_2}, \dots, \mathrm{a_{n_a}}]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_a}},$$

$$\theta_2 := [\mathrm{b_{11}}, \mathrm{b_{12}}, \dots, \mathrm{b_{1n_1}}]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_{b_1}}},$$

$$\theta_3 := [\mathrm{b_{21}}, \mathrm{b_{22}}, \dots, \mathrm{b_{2n_2}}]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_{b_2}}},$$

In addition, equation (2) can be rewritten

$$w(k) = [1 - C(z)]w(k) + D(z)v(k)$$

$$= -c_1 w(k-1) - c_2 w(k-2) - \dots - c_{n_c} w(k - n_c) + d_1 v(k-1) + d_2 v(k-2) + \cdots + d_{n_d} v(k-n_d) + v(k) \quad (6)$$

And it can be written in a linear regression form as

$$w(k) = {\varphi_4}^T(k)\theta_4 + v(k) \quad (7)$$

Where

$$\varphi_4(\mathrm{k}) = [-\mathrm{w}(\mathrm{k}-1), -\mathrm{w}(\mathrm{k}-2), \dots, -\mathrm{w}(\mathrm{k}-\mathrm{n_c}), \mathrm{v}(\mathrm{k}-1), \mathrm{v}(\mathrm{k}-2), \dots, \mathrm{v}(\mathrm{k}-\mathrm{n_d})]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_c+n_d}},$$

$$\theta_4 := [\mathrm{c_1}, \mathrm{c_2}, \dots, \mathrm{c_{n_c}}, \mathrm{d_1}, \mathrm{d}, \dots, \mathrm{d_{n_d}}]^{\mathrm{T}} \in \mathbb{R}^{\mathrm{n_c+n_d}},$$

Finally, equation (7) is substituted into equation (5) [14], $y(k)$ can be written as [6]

$$y(k) = {\varphi_1}^T(k)\theta_1 + {\varphi_2}^T(k)\theta_2 + {\varphi_3}^T(k)\theta_3 + {\varphi_4}^T(k)\theta_4 + v(k) \quad (8)$$

$$= \varphi^T(k)\theta + v(k).$$

$$\varphi^T(k) = [{\varphi_1}^T(k)\ {\varphi_2}^T(k)\ {\varphi_3}^T(k)\ {\varphi_4}^T(k)] \in \mathbb{R}^{\mathrm{n}},$$

$$\theta = \begin{bmatrix}\theta_1\\ \theta_2\\ \theta_3\\ \theta_4\end{bmatrix} \in \mathbb{R}^{\mathrm{n}}, \quad \mathrm{n} = \mathrm{n_a} + \mathrm{n_{bj}} + \mathrm{n_c} + \mathrm{n_d}$$

Equation (8) is the identification model of MISO (CARARMA) system, it includes parameter vector θ that contains all parameters of the system to be identified [15].

III. Extended Three-Stage Recursive Identification Algorithm

Extended three-stage recursive identification algorithm is based on the decomposition technique as the basic idea and thus multiple-input single-output (CARARMA) System is decomposed into four subsystems.

Four intermediate variables are defined as,

$$y_1(k) = y(k) - {\varphi_2}^T(k)\theta_2 - {\varphi_3}^T(k)\theta_3 - {\varphi_4}^T(k)\theta_4, \quad (9)$$

$$y_2(k) = y(k) - {\varphi_1}^T(k)\theta_1 - {\varphi_3}^T(k)\theta_3 - {\varphi_4}^T(k)\theta_4, \quad (10)$$

$$y_3(k) = y(k) - {\varphi_1}^T(k)\theta_1 - {\varphi_2}^T(k)\theta_2 - {\varphi_4}^T(k)\theta_4, \quad (11)$$

$$y_4(k) = y(k) - {\varphi_1}^T(k)\theta_1 - {\varphi_2}^T(k)\theta_2 - {\varphi_3}^T(k)\theta_3, \quad (12)$$

From (9)–(12), equation (8) can be decomposed into four sub-identification models [8],

$$y_i(k) = \varphi_i^T(k)\theta_i + v(k), \quad i = 1,2,3,4. \quad (13)$$

These includes the parameters vectors $\theta_1, \theta_2, \theta_3$ and θ_4 [12].

Then, four criterion functions are defined as,

$$J_i(\theta_i) := \sum_{j=1}^{k} [y_i(j) - {\varphi_i}^T(j)\theta_i]^2, \quad i = 1,2,3,4.$$

Let the partial derivatives of $J_i(\theta_i), i = 1,2,3,4$ with respect to θ_i be zero

$$\left.\frac{\partial J_i(\theta_i)}{\partial \theta_i}\right|_{\theta_i = \hat{\theta}_i(k)} = -2\varphi_i(j)\sum_{j=1}^{k}[y_i(j) - {\varphi_i}^T(j)\hat{\theta}_i(k)]$$

$$= 0, \quad i = 1,2,3,4. \quad (14)$$

Let $\hat{\theta}(k) := \begin{bmatrix} \hat{\theta}_1(k) \\ \hat{\theta}_2(k) \\ \hat{\theta}_3(k) \\ \hat{\theta}_4(k) \end{bmatrix} \in \mathbb{R}^n$ be the estimate of $\theta = \begin{bmatrix} \theta_1 \\ \theta_2 \\ \theta_3 \\ \theta_4 \end{bmatrix} \in \mathbb{R}^n$

Minimizing the criterion functions and as a result, RLS algorithm can be obtained for computing $\hat{\theta}_i(k)$:

$$\hat{\theta}_i(k) = \hat{\theta}_i(k-1) + L_i(k)\big[\big(y_i(k) - \varphi_i{}^T(k)\hat{\theta}_i(k-1)\big](15)$$

$$L_i(k) = P_i(k-1)\varphi_i(k)[1 + \varphi_i{}^T(k)P_i(k-1)\varphi_i(k)]^{-1},$$

$$P_i(k) = [I - L_i(k)\varphi_i{}^T(k)]P_i(k-1),$$

$$P_i(0) = p_0 I, \;\; i = 1,2,3,4$$

The equations from (9)–(12) are substituted into equation (15) with $= 1,2,3,4$, obtains

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4 - \varphi_1{}^T(k)\hat{\theta}_1(t-1)\big] \quad (16)$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4 - \varphi_2{}^T(k)\hat{\theta}_2(k-1)\big] \quad (17)$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_4{}^T(k)\theta_4 - \varphi_3{}^T(k)\hat{\theta}_3(k-1)\big] \quad (18)$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\hat{\theta}_4(k-1)\big] \quad (19)$$

Equations (16) – (19) include the unknown parameter θ_i $i = 1,2,3,4$. The Replacement of the unknown θ_i in (16)–(19) with their estimates $\hat{\theta}_i(k-1)$ is the solution:

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\;\big[y(k) - \varphi_2{}^T(k)\hat{\theta}_2(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1) - \varphi_1{}^T(k)\hat{\theta}_1(k-1)\big]$$

$$= \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \varphi^T(k)\hat{\theta}(k-1)\big],$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \varphi_1{}^T(k)\hat{\theta}_1(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1) - \varphi_2{}^T(k)\hat{\theta}_2(k-1)\big]$$

$$= \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \varphi^T(k)\hat{\theta}(k-1)\big],$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\big[y(k) - \varphi_1{}^T(k)\hat{\theta}_1(k-1) - \varphi_2{}^T(k)\hat{\theta}_2(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1)\big],$$

$$= \hat{\theta}_3(k-1) + L_3(k)\big[y(k) - \varphi^T(k)\hat{\theta}(k-1)\big],$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\big[y(k) - \varphi_1{}^T(k)\hat{\theta}_1(k-1) - \varphi_2{}^T(k)\hat{\theta}_2(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1)\big],$$

$$= \hat{\theta}_4(k-1) + L_4(k)\big[y(k) - \varphi^T(k)\hat{\theta}(k-1)\big],$$

$\varphi_4(k)$ includes the unknown noise terms $w(k-i)$ and$v(k-i)$, and thus these estimated parameters cannot be generated based on the above algorithms in (16)–(19). Replacing $w(k-i)$ and $v(k-i)$ with their estimates $\widehat{w}(k-i)$ and$\hat{v}(\mathrm{k}-\mathrm{i})$ is the solution, and obtain

$$\hat{\varphi}_4(k) := [-\widehat{w}(k-1), -\widehat{w}(k-2), \ldots, -\widehat{w}(k-n_c), \hat{v}(k-1), \hat{v}(\mathrm{k}-2), \ldots, \hat{v}(\mathrm{k}-\mathrm{n_d})]^T \in \mathbb{R}^{n_c+n_d}.$$

$$\hat{\varphi}(k) := \begin{bmatrix} \varphi_1 \\ \varphi_2 \\ \varphi_3 \\ \hat{\varphi}_4 \end{bmatrix} \in \mathbb{R}^n.$$

Now, equation (5) can be written as,

$$w(k) = y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3,$$

And $\qquad v(k) = w(k) - \varphi_4{}^T(k)\theta_4,$

The estimated $w(k)$ and $v(k)$can be computed by

$$\widehat{w}(k) = y(k) - \varphi_1{}^T(k)\hat{\theta}_1 - \varphi_2{}^T(k)\hat{\theta}_2 - \varphi_3{}^T(k)\hat{\theta}_3$$

$$\hat{v}(k) = \widehat{w}(k) - \hat{\varphi}_4{}^T(k)\hat{\theta}_4$$

Thus, extended three-stage recursive parameter estimation algorithm for computing the estimated parameters $\theta_1, \theta_2, \theta_3$ and θ_4 of CARARMA model is obtained as

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k1)\big], \quad (20)$$

$$L_1(k) = P_1(k-1)\varphi_1(k)[1 + \varphi_1{}^T(k)P_1(k-1)\varphi_1(k)]^{-1}, \quad (21)$$

$$P_1(k) = [I - L_1(k)\varphi_1{}^T(k)]P_1(k-1), P_1(0) = p_0 I_{n_a}, (22)$$

$$\varphi_1(k) = [-y(k-1), -y(k-2), \ldots, -y(k-n_a)]^T \in \mathbb{R}^{n_a}, \quad (23)$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k-1)\big], \; (24)$$

$$L_2(k) = P_2(k-1)\varphi_2(k)[1 + \varphi_2{}^T(k)P_2(k-1)\varphi_2(k)]^{-1}, \quad (25)$$

$$P_2(k) = [I - L_2(k)\varphi_2{}^T(k)]P_2(k-1), P_2(0) = p_0 I_{n_1}, (26)$$

$$\varphi_2(k) = [u_1(k-1), u_1(k-2), \ldots, u_1(k-n_1)]^T \in \mathbb{R}^{n_1}, \quad (27)$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\big[y(k) - \hat{\varphi}^{\mathrm{T}}(k)\hat{\theta}(k-1)\big], \; (28)$$

$$L_3(k) = P_3(k-1)\varphi_3(k)[1 + \varphi_3{}^T(k)P_3(k-1)\varphi_3(k)]^{-1}, \quad (29)$$

$$P_3(k) = [I - L_3(k)\varphi_3{}^T(k)]P_3(k-1), P_3(0) = p_0 I_{n_2}, (30)$$

$$\varphi_3(k) = [u_2(k-1), u_2(k-2), \ldots, u_2(k-n_2)]^T \in \mathbb{R}^{n_2}, \quad (31)$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\big[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k-1)\big], \; (32)$$

$$L_4(k) = P_4(k-1)\hat{\varphi}_4(k)\left[1 + \hat{\varphi}_4{}^T(k)P_4(k-1)\hat{\varphi}_4(k)\right]^{-1}, \quad (33)$$

$$P_4(k) = \left[I - L_4(k)\hat{\varphi}_4{}^T(k)\right]P_4(k-1), \mathrm{p}_4(0) = p_0 I_{n_c+n_d}, \quad (34)$$

$$\hat{w}(k) = y(k) - \varphi_1{}^T(k)\hat{\theta}_1 - \varphi_2{}^T(k)\hat{\theta}_2 - \varphi_3{}^T(k)\hat{\theta}_3. \quad (35)$$

$$\hat{v}(k) = \hat{w}(k) - \hat{\varphi}_4{}^T(k)\hat{\theta}_4. \quad (36)$$

$$\hat{\varphi}_4(k) = \begin{bmatrix} -\hat{w}(k-1), -\hat{w}(k-2), \ldots, -\hat{w}(k-n_c), \\ \hat{v}(k-1), \hat{v}(\mathrm{k}-2), \ldots, \hat{v}(\mathrm{k}-\mathrm{n_d}) \end{bmatrix}^T \quad (37)$$

$$\hat{\upvarphi}(\mathrm{k}) \coloneqq [\upvarphi_1^{\mathrm{T}}(k), \upvarphi_2^{\mathrm{T}}(k), \upvarphi_3^{\mathrm{T}}(k), \hat{\upvarphi}_4^{\mathrm{T}}(k)]^T \in \mathbb{R}^{\mathrm{n}}, \quad (38)$$

$$\hat{\theta}(k) := \left[\hat{\uptheta}_1^{\mathrm{T}}(k), \hat{\uptheta}_2^{\mathrm{T}}(k), \hat{\uptheta}_3^{\mathrm{T}}(k), \hat{\uptheta}_4^{\mathrm{T}}(k)\right]^T \in \mathbb{R}^n. \quad (39)$$

IV. MODEL VALIDATION AND ORDER SELECTION

A. *Model validation*

Model validation is a fundamental part of simulation model development, and generally implemented in parallel with the model design process [16]. There are many validation methods in the literatures and in this section, some criteria's will be studied [5]:

1. *Root-mean-square error*

RMSE is the predominant statistical methods [17] and it has widely been used in evaluating the accuracy of the model [18]**.** RMSE is computed as follows [19]:

$$RMS - Error = \sqrt{\frac{\sum_{i=1}^{N}\left((\hat{y}_i - y_i)\right)^2}{N}} \quad (40)$$

2. *The Cross-Correlation Test*

the estimated residual is used with the input sequence u(k), to develop a test and check the independence between the residual and the input. The cross-correlation matrix is given by

$$\hat{R}_{\epsilon u}(\tau) = \frac{1}{N-\tau}\sum_{k=\tau+1}^{N} \hat{\epsilon}\left(k, \hat{\theta}\right)u\left(k-\tau, \hat{\theta}\right)^T \quad (41)$$

if the cross-correlation function is approximately zero, then, the model is perfect [20]**.**

B. *Model order selection*

Akaike's Final Prediction Error (FPE) Criterion is used in this work for the model order selection and is defined as:

$$FPE = \left(\frac{1}{N}\sum_{k=1}^{N} e^2(k)\left(\frac{1+(n/N)}{1-(n/N)}\right)\right) \quad (42)$$

Where

N is the number of samples, n is the number of model parameters, V is the residuals variance and is computed as [21].

$$V = \left(\frac{1}{N}\sum_{k=1}^{N} e^2(k)\right) \quad (43)$$

V. SIMULATION RESULTS

An example is provided in this part to evaluate the capability of this algorithm. Consider the following MISO for (CARARMA) systems,

$$\mathrm{A(z)y(k)} = \sum_{\mathrm{j=1}}^{2} \mathrm{B_j(Z)\,u_j(k)} + \frac{\mathrm{D(z)}}{\mathrm{C(z)}}\mathrm{v(k)}$$

$$\mathrm{A(z)} = 1 + 0.65\mathrm{z}^{-1} + 0.85\mathrm{z}^{-2},$$

$$\mathrm{B_1(z)} = -0.15\mathrm{z}^{-1} - 0.25\mathrm{z}^{-2},$$

$$\mathrm{B_2(z)} = 0.18\mathrm{z}^{-1} - 0.28\mathrm{z}^{-2},$$

$$\mathrm{C(z)} = 1 + 0.7\mathrm{z}^{-1},$$

$$\mathrm{D(z)} = 1 + 0.4\mathrm{z}^{-1},$$

$$\uptheta = [\mathrm{a_1, a_2, b_{11}, b_{12}, b_{21}, b_{22}, c_1, d_1}]^{\mathrm{T}},$$

$$= [0.65, 0.85, -0.15, -0.25, 0.18, -0.28, 0.7, 0.4]^{\mathrm{T}},$$

The inputs $\{u_1(k)\}$, $\{u_2(k)\}$ are generated as a white sequence with $m = 0$ and $\sigma^2 = 1$, while $n(k)$ is generated as a Gaussian white noise with $m = 0$ and $\sigma^2 = 0.20^2$. First, RMS-Error and the cross-correlation test are used for evaluating the validation of the model. Fig. 2 shows root mean square errors versus all sequences (k). This figure demonstrates that, RMS-Error become smaller as the sequence increases, which indicate that the model accuracy is high, in addition, the correlation between the residual and one of the inputs sequences is showed in fig. 3. The figure shows that, the values are very low (the model is typical).

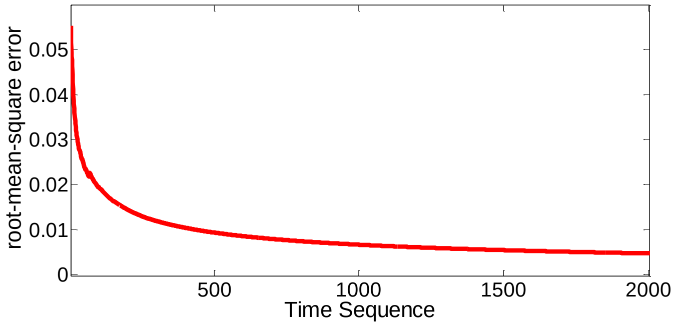

Fig. 2. Root mean square errors versus time sequences

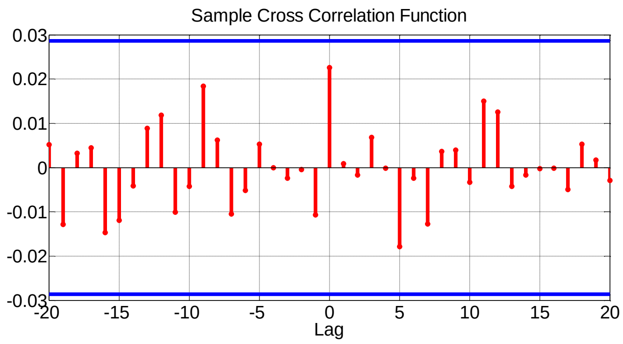

Fig. 3. Cross-correlation between the residual and one of the inputs sequences

Fig. 4 shows the true output and the estimated output of three-stage RLS algorithm and extended three-stage RLS algorithm. Window from n =1080 to n =1100 has been taken for more clarification as shown in Fig. 5,it shows that the estimated output of extended three stage RLS algorithm very close to the true output compared with the estimated output of three stage RLS algorithm, that means, the effectiveness of this algorithm is high. This conclusion has been confirmed by computing and plotting the residual of extended three-stage RLS algorithm and three-stage RLS algorithm as illustrated in Fig 6.

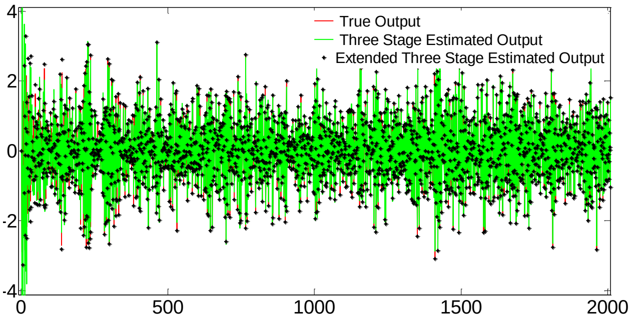

Fig. 4. The true output and the estimated output of three-stage RLS algorithm and extended three-stage RLS algorithm

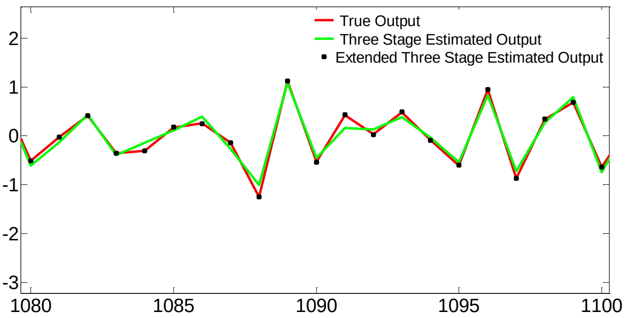

Fig. 5. Window from n =1080 to n =1100 of the true output and the estimated output of three-stage RLS algorithm and extended three-stage RLS algorithm.

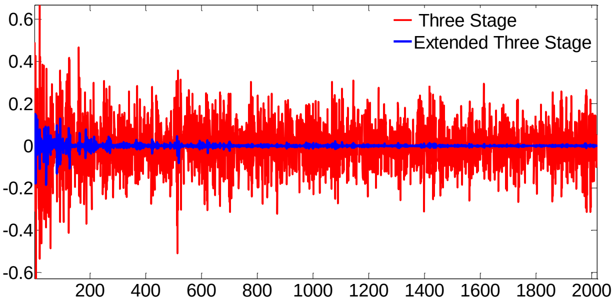

Fig. 6. Residual of three-stage RLS algorithm and extended three-stage RLS algorithm.

FPE is calculated from one to five models as shown in next figure, and as we have supposed, the second order system is the best model order

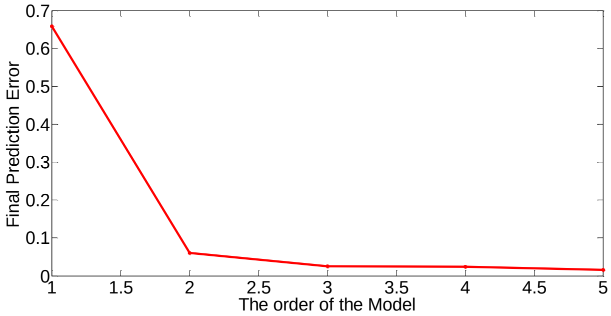

Fig. 7. FPE versus model order

Finally, Root-mean-square error of three-stage RLS algorithm and extended three-stage RLS algorithm versus the sequences is shown in Fig. 8.

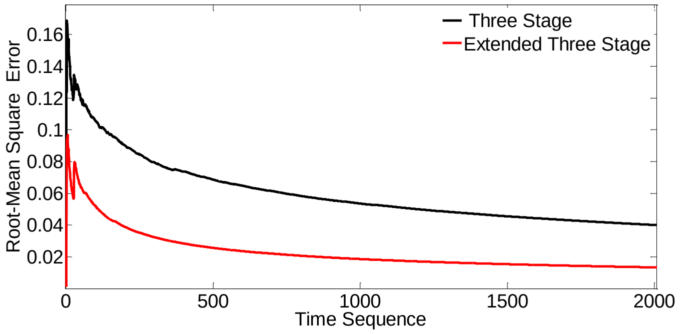

Fig. 8. Root-mean-square error of three-stage RLS algorithm and extended three-stage RLS algorithm versus the sequences.

The figure illustrate that extended three-stage RLS algorithm is more accurate than three-stage RLS algorithm.

VI. CONCLUSIONS

This paper studies extended three-stage recursive identification algorithm for multiple-input single-output (CARARMA) systems. The results show that the proposed extended three-stage RLS algorithm is more accurate and require less computational load compared with three-stage RLS algorithm.

***Abstract*—This paper explores the relationship between a person's demographic data, age (IV1), gender (IV2), ethnicity (IV3), and political ideology (IV4), and the risk of him/her falling prey to Mis/Disinformation attacks (DV). Participants (n=161) were subjected to the Fake News and deepfake test (15-item). The main data analysis tool employed by this study is multiple linear regression. Important findings of the study include the revelation of the disparity in the performance of the subjects from the underrepresented groups against those who are not. This paper further confirms that an increase in age is a risk for being Disinformed. The predictive model further reveals the profile of a most likely Disinformation victim. The intended target audiences of this paper are policymakers, social scientists, and tech companies.**

Keywords—Fake News, Misinformation, Disinformation, Polarization, Risk

I. Introduction

The pervasiveness of fake news in the digital world has been unparalleled. A number of social networking sites such as Facebook and Twitter allow users and entities alike to create and/or share content in their respective spaces. A particular type of content in these sites is news and journalistic information. More than being able to share content on these sites, information users consume such crucial information from these media, and as such, the integrity of contents is of crucial importance.

On the other side of the spectrum, misleading information had been long existing in the same environment, persisting and mixed with the legitimate news with the intent to deceive users due to several varying reasons and inspirations, primarily political and conspiracy induced. Ultimately, the information consumer has the personal responsibility to decide which of these are factual and which are misleading [1]. Thus, highlighting the ability to detect misinformation with the existing information descriptors, i.e., the contextual clues, is of extreme importance.

With social media feeds consisting of virtually unlimited information, the question comes down to what constitutes a user's judgment of a content's legitimacy. An instrumental set of conditions, i.e., demographic and socioeconomic factors, have long been attributed to the decision-making of users [2][3]. The effects of these on a user in the detection of fake news functions are investigated. The underlying main research question of this paper is "How does a user's demographic attributes influence his ability to detect misinformation?". The basic defense of a user against the risk to the vulnerability of detecting misinformation is condensed into the proper use of using descriptors to recognize fake news when it is spotted, and as such, the contribution to the existing literature of this study will include the methodology used to empirically observe this risk.

The significance of this study is built upon the argument that proper recognition of misinformation is always a precursor phase to combatting the ecosystem of fake news in any space, including social networking sites. All existing solutions be it of any type of technological structure and design, relies first on the detection of an existence of misleading contents [4]. Other pragmatic implications of the results of this study are the increased accuracy in the calculation of risk in humans exposed to fake news campaigns through demographic profiling. From this point, campaigns of awareness to properly recognize fake news can be more focused to the more vulnerable group(s), as revealed by this study. The main output of the study is a predictive model that reveals the projected risk profile of the vulnerable targets of disinformation attacks. This paper will (1) discuss the literature highlighting the disinformation and each demographic factor, (2) discuss propositions and a model for building the predictive model, (3) provide the methodology for conducting the study, (4) share the findings and limitations of the study, and (5) highlight the future research.

II. Literature Review

A. Disinformation and Age

Craik et al. (1986) [5] proposed the reasoning that a user's information perception is dependent on his/her age. This is due to the fact that the mental capacity of a person undergoes many changes and development from infancy to adulthood. However, after reaching a theoretical peak age— this then progresses to decline up to the point of demise. Nelson (1998) [6] further explored this proposition and later revealed that one of the many strands in the development of this constant change is the evolution of a bias based on subjective and personal beliefs. In particular, [5][7] further developed the exploration of belief bias and how it plays a huge part in age and information perception. Two of the findings highlighted two important points: Younger adults, i.e., late teens or early

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

twenties to their thirties, performed more accurately and faster than older adults, i.e., past forty in logical and arithmetic tests. On the contrary, the study revealed that older adults performed better than their younger counterparts on exams involving the establishment of logical inferences from sequential arguments. Ding et al. (2019) [8] explained that logic tends to counteract with beliefs in subjects with varying age groups.

Corollary findings [9] have firmly linked age differences in belief bias, its dynamics, and how it paves the way to misinformation. The study found out that belief bias, more predominantly in older subjects, results to more resistance in a user's position when presented with logical evidence should it be contradicting with their beliefs. The potential for widespread dissemination of misinformation, [10] has examined the individual-level characteristics associated with sharing false articles during the 2016 US presidential campaign and has found a strong influence of age, which persists after controlling for partisanship and ideology: Information consumers over 65 shared nearly seven times as many articles from fake news domains as the youngest age group. Furthermore, this documents that ideology and age were associated with sharing activity as the dependent variable. The independent function of age is strongly observed in: Holding constant ideology, party identification, or both. Age, when separated among the variables, holds a strong influence wherein older consumers were more likely to share fake news than respondents compared with the next-youngest group, 18-29 years of age. This gap in the rate of fake news sharing between those defined by age categorization oldest category and youngest category is notably wide.

Concluding Proposition 1: Existing studies predominantly link stronger correlation to older subjects in the dissemination of misinformation compared to their younger counterparts. Among the age groups, the range of younger adults, 18-29, tends to have lesser documented acts of propagating misleading contents. The prominent cause of these having stemmed from belief bias.

B. Disinformation and Political Ideology

Political leaning is a motivational force to humans. It can inspire or compromise one into performing great atrocities, acts of courage, and kindness. Humans can even sacrifice lives—all in the name of an abstract belief system [11]. When political views function as a predictor, a magnitude of evidence shows that the effect of this to quite a number of users is quite different. The confirmation bias in its form compels users to consider unverified content to be still considered as factual. In extreme cases—even when content is verified to be untruthful is still considered factual by a user with stronger confirmation bias [12].

Generally, there are two partisan divisions, the right, which is highly partisan, while those on the left, which is more objective in their coverage [13]. This results in an asymmetrical media environment [14]. It is in a human's inclination to defend one's ideologies from information that conflicts with his political point of view, the negativity bias. This hypothesis of confirmation bias suggests that conservatives react to threats with greater negativity and motivated information processing than their liberal counterparts [15]. And time has yet again shown that anyone—regardless of political affiliation displays an internal informational processing when confronted with information that contradicts their point of view—resulting in a distinct perception [16]. This biasing effect becomes more obvious when objectionable political information relates to a position that one takes comfort in [17][18]. The negativity bias hypothesis appears such that people will react to threats by defending their ideological in-group and core ideological values when challenged.

Together, these results suggest that a politically natured group will respond to the basic psychological threats with the affirmation of important and salient values to them [15]. Disputes will arise when those holding differing political views collide—which are usually ubiquitous and deep-seated, which can often be followed on common, recognizable lines. Understanding the correlation of distinct political orientations is probably a prerequisite for managing political disputes, which are strongly tagged as a source of the incorrect perception that can then lead to misinformation campaign wars [19]. The cause of this social conflict is backed not just by political dimension but also in a multitude of dimensions in which opposing groups differ from each other in terms of several positions-from tastes in art, explanation of the sciences, up to the tendency to pursue a new type of information, almost always the variability in political ideologies of users may have caused it [20].

Alongside this, an understanding of the cause of its persistence and how it affects information consumption must be central to their themes [21]. Works by [21][22] attempted to first detect if a specific content is politically inclined and challenged the leanings of media contents to better understand fake news in a politically polarized mainstream media by investigating linguistic differences in the discussion of the topic by left- and right-leaning news sources. The study revealed that political leanings tend to employ non-neutral words, with the right inclined to more aggressive while the left inclined to put more emphasis on compassion.

With fake news garnering increasing public attention, a systematic literature review by [4] examined the way broader media environment and people in it may have caused or be damaged by disinformation. Technological studies provide that media sources used discernibly different language and catered for a specific consumer when discussing contents—underscoring a fundamental difference in definitions and portrayals of any issue, and how this ignites a frequent focus on each other, presumably in the spirit of blaming the other for a raised problem [21]. These works are all but the first steps towards identifying the descriptive differences between news sites' varying views in their discussions of a given subject.

Concluding Proposition 2: Existing studies reveal that politics and governance act as a motivator for political acts of a number of information users. Enabled by confirmation bias & negativity bias, this instantiates the creation and spreading of misleading news that highlights the political partisan and discredits the others.

C. Disinformation and Ethnicity

Cross-sectional studies [23][24] argued that ethnicity should be included as a demographic control variable in the assessment of the widespread problems in social sciences. The reason is that present findings with insights from most domains relevant to attitude formation, i.e., stereotyping literature, strongly bridges the potential role of ethnicity and perceived similarity.

Leighley et al. (2009) [25]'s underlying assumption is that the differences in ethnicity between groups may contribute to the homogeneity of culture in organizations. In developing nations, often characterized by a high level of ethnic diversity, concerns arise that groups with heterogeneous values, norms, and attitudes—the broad set of traits that can be referred to as culture—may be unable to agree on policies, the provision of public goods, and the broader goals of society [25]. Each of these traditions reflects a variety of viewpoints on the persistence of ethnic and cultural identities and a wide range of theories on the factors that gave rise to both ethnic and cultural differentiation.

One may not simply look away from the evidence consistent with a synthesis of both views: ethnicity is indeed associated with fundamental differences in values, attitudes, and preferences, including information consumption [26][27][28]. However, the reverse may not be true such that culture is the dependent variable which may not be attributed exclusively to ethnicity. Disinformation campaigns highlight non-specific trajectories on samples that are based on ethnicity variations. This accounts for the economically, and political biases that may help establish the link between culture and ethnicity. The complex relationship between ethnicity and culture in relative terms of fake news propagation had so far remained missing from the economics literature on ethnic heterogeneity.

Nelson (1979) [29] had undertaken a longitudinal study that documented the effects of socioeconomic status (SES), particularly ethnicity, on political participation. As consensus has grown on the role of socioeconomic status, other factors, like ethnicity, have been most of the time prioritized only to secondary in terms of importance. Variations in levels of participation can be traced, in part, to differences in ethnic political culture, and the web is no exception. Ethnicity has a more significant effect than socioeconomic status on levels of participant political culture.

The dynamics in which ethnicity might influence the understanding of social and political information retrieval in a rapidly evolving environment are of emerging concern. Fridkin et al. (2006) [30] recommended that future researchers give more serious attention to this ethnic factor. More studies will fill this gap especially focusing on the quantitative research on the relationship between ethnicity and culture that correlates to an individual's ethnolinguistic identity as a predictor of his norms, values, and preferences [30]. More than looking at the individual participant's ethnicity, the holistic view of the group composition should be taken into consideration—the diversity.

Concluding Proposition 3: The existing studies highlight the degree of overlap between ethnicity through culture and how it creates the attitude of an individual in his social identity in the information environment can all be traced to ethnicity as a potent determinant of civil conflict and public goods, in this case, misinformation. Furthermore, ethnicity is revealed to be a smaller part of a bigger determinant, diversity, that affects information flow on social networks.

D. Disinformation and Gender

Pennycook et al. (2018) [31] & Giacopassi et al. (1986) [24] revealed that weaponized disinformation campaigns and endemic online violence against gender minorities exist. Resources [32] that identify the demographics display consistent affinities to understanding how this phenomenon affects our democratic process to its propagation.

Social media environments are only beginning to grapple with the unintended affordances of their features and are not held accountable by regulatory governing bodies, which should serve as watchdogs and advocates—and gender as a variable, appeared from that. With gender as the issue i.e., variable—international nonprofits, academic institutions, and philanthropic investors see online threats as a form of social injustice and not a concern for democracy and national security. A new kind of authoritarianism seeks to push minority groups aside and halt progress on their rights by controlling social media channels, attacking the press, and limiting freedom of assembly and expression—and gender plays a firm role in this [33].

The support for gender-inclusive social web communication is deteriorating for certain minorities including women, and LGBTQIA+ communities. Belhadjali et al. (2017) [34] shows it's critical to analyze the role gender plays, consciously or unconsciously, for the promotion of more gender-inclusive and harmonious democracies—yet the convergence of gender, democracy, disinformation, and information technology remains understudied. Female politicians who are prolifically wielding social media as a way to overcome underrepresentation and connect with their constituencies—wherein a survey of female politicians from over 100 nations found that more than 85 percent of them use social media and particularly Facebook, with younger legislators being the most active—highlights the need in understanding whether online platforms are a level playing field for political engagement, or replicate the same biases as traditional media outlets [35][36].

Marwick (2017) [37] extracted data from leaders in different industries from the arts and sciences across multiple varying leanings, countries, and regions of the world, reviewed over 100 works of literature, and produced an analysis to identify gender trends in politics and information dissemination on the web in the United States. The research concluded that social media seem to provide some female candidates with an increased ability to promote their "brands" and level the engagement field, exposing that females are able to generate more followers, likes, and user engagement than their male counterparts.

On the other side of spectrum, there is a massive magnitude of evidence [38][39][40] that shows how women leaders and minority activists are often targets of online attacks, harassment aimed at making these personas seem irrelevant. Female politicians around the world expressed the sentiment of how a huge fraction of them having seen demoralizing images of them spread through an information environment or digital medium. The massive spread of gender-charged disinformation campaigns—ranging from mockery to even death threats—transcends into the physical world. Often, attacks come from armies of politically motivated trolls and bots. Stahl (2006) [41] shows that in a political party—female candidates are targeted more often than male candidates by fake news accounts with the explicit intention of halting certain gender-minority from actively engaging in the information medium. When fake news is aimed at certain gender-based communities, the whole information medium produces a bias through an attempt to control the users who can contribute to the ecosystem of information.

Concluding Proposition 4: Gender inclusiveness and equal participation is a precursor towards an actively participatory democracy that allows social media to be utilized effectively to bring all, regardless of gender, closer to government. The need to examine gender as an enabler or otherwise in a participatory environment, including the phenomenon of disinformation, is the very reason why academic institutions, civil society groups, and philanthropists who aim to protect and foster democratic values have a responsibility to look into the gendered dimension of fake news and online violence against gender-minority in politics.

III. Methodology

Figure 1 below describes an overview of the study's methodology. Note that the data collection device is the fake news test.

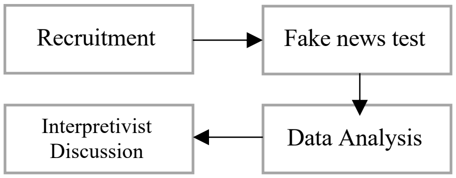

Fig. 1. Block Diagram of Methodology

A. The Population

The survey was opened for an undergraduate class of Introductory in Informatics during the period September 1, 2020, to December 7, 2020. Of the 234 eligible and invited students to take the optional survey, 168 responded. Declared majors and concentrations of subjects are varying, including but not limited to cybersecurity, computer science, informatics, economics, communications, sociology, business administration, accounting, and physics. The age range of subjects is from 18 to 25.

B. Data Collection

A preliminary survey questionnaire that extracts demographic data from each participant was asked. To force the users to select an option, all of these fields are required—by default leaving it empty will prevent one from proceeding to the next item.

To associate the above demographic data to the risk of being disinformed, the users are then later given the fake news test devised by Caramancion (2020) [42] based on the Ecosystem Theory of Disinformation [43]. The test displays a content to a user and explicitly asks for a response if it is legitimate or illegitimate. Furthermore, the fake news test includes screenshots of *deepfakes* which then prompts the users to evaluate if it is legitimate or otherwise.

C. Data Analysis

General descriptive statistics and grade distribution were used to establish the baseline of measures of the results for the dependent variable. This is generally to get an overview of the population's performance. To answer this paper's research questions, the independent variables considered are the demographic data of each participant, i.e., age (in range), political leaning, gender, and ethnicity.

These IVs are then associated with the performance of each participant as their score on the fake news test and will serve as the dependent variable for all of the IVs stated before. To perform this analysis, a multiple linear regression was employed as the main analysis technique of this paper. Dummy coding was employed before loading the IVs to the model. No violation in the assumptions exists, including normality, multicollinearity, and homoscedasticity. Finally, an interpretivist approach was employed by the author to give possible explanations of the results.

D. Controls and Limitations

The survey was deployed in blackboard and is strictly timed so as to mimic the actual stimuli environment of browsing a social media feed. The whole survey was timed 60 minutes and will auto-submit after the timer has elapsed, although, as per the item analysis, the average user typically completed the assessment in 5 to 10 minutes. The range of user attention span per content as revealed by Facebook Research is varying from 1.7 seconds to 12 seconds. The themes of the questions are all relevant to the national affairs within the United States. Backtracking was prohibited to disallow any modification of answers to earlier questions.

Among all the participant responses, seven attempts were incomplete, i.e., the user opened the assessment but left the survey unanswered, leading the timer to expire and automatically submit their attempts. These responses were removed from the aggregate data.

IV. Results

A. Overview

Table 1 displays the general descriptive statistics of the regression results in aggregate form. Table 2 presents the model information of the predictive model alongside the Durbin-Watson's test. Table 3 highlights the coefficient of the predictors alongside the collinearity diagnostics. Table 4 presents the details of the regression model, including coefficients and their respective statistical significance.

V. DISCUSSION

Discussion 1: An Increase in Age is the Biggest Risk Factor of Disinformation

The regression model suggests that the higher the age of the subjects, the higher their risk of being disinformed. Subjects with an age range of 25 to 34 score less than their younger counterparts. Furthermore, subjects with age range 35 to 44 scored significantly lower. The optimum age of subjects that scored the highest were 18 to 24, followed by the age group below 18.

Discussion 2: Females Appear to be at More Risk Compared to Males

The regression model suggests that, on average female participants score lower, 1.54 less, compared to the male subjects. Although, among all the demographic factors, gender appears to be the least statistically significant. It should also be further noted that the sample ratio of male-to-female is 95:66.

Discussion 3: Asians, African Americans, Hispanics, and Latinos all have a Bigger Risk of being Disinformed

Interestingly, the predictive model confirmed that the historically underrepresented ethnic group that appeared to garner the lowest score are the Asians, followed by African American subjects, and then the Hispanics and Latinos.

Discussion 4: American Indians and White Subjects have Lower Risk of being Disinformed

The regression model further revealed that American Indians and Alaskan Natives scored the highest, implying their skill in disinformation detection. The ethnic group that follows from this are the Caucasian/White.

Discussion 5: Political Parties Outside the Outside the Major Parties have Bigger Risk of being Disinformed

The regression model suggests that subjects who self-identify as Democrats tend to recognize Disinformation and Deepfakes most accurately. This is followed by those who self-identify as Independent, followed by Republicans. The group who performed the least are the subjects who has Political Affiliation that's Something Else.

VI. Conclusion And Future Works

This study was incepted with the hope of reducing the instances and impact of disinformation on information consumers. The resulting output is a predictive model that uses the demographic factors – a. age, b. gender, c. political ideology, and d. ethnicity as independent variables. The model is based on the interaction among these variables in a given population.

With Caramancion (2020)'s work as inspiration, the first part of the experiment revealed the accuracy of individuals in detecting fake news in a social media feed. The results are then aggregated and analyzed to establish a correlation based on their respective predictors.

Findings are the result of the subject's empirical measure from the experiment mapped out against the four preceding factors. Based on the scores of the subjects, these findings revealed the profile with the weakest ability to detect misinformation, prompting to result in the research question of this study being explicitly answered. The distinct parts of the result, i.e., regression coefficients, are then compared with one another to search for behavioral patterns that revealed the profiles who a. At most risk to be misinformed, b. those who can accurately detect Fake News.

This study lays the foundation in assessing a person's participation in the persistence of Disinformation on the digital space. The ability of technological advances to combat disinformation through detection is learned through training. One practical area for future research is the applications of different style of cyber awareness/education in shielding these individuals against disinformation—therefore highlighting the importance of strengthening the user's capability in recognizing misleading contents against legitimate ones. The variations in the results highlight the need for variations in education. Future studies may enhance the predictive model developed in this paper by injecting more socioeconomic factors as independent variables and through a consistent and incremental validation of the subjects in a longitudinal research. Finally, a population of bigger size may be considered to better reflect the domain attempting to measure.

Abstract—**Channel coding for the 5th generation (5G) wireless communication system has to fulfill diverse requirements arising from new machine type communication (MTC) services. The 5G-MTC applications can be classified into two categories: Ultra-Reliable Low-Latency Communications (URLLC) and massive Machine-Type Communication (mMTC). Polar code and Low-Density Parity Check (LDPC) code are among the most advanced channel coding techniques known today that have the potential to be used in the 5G. The main objective of this paper is to evaluate the error correction performance of Polar and LDPC coding schemes in the case when short to medium information block lengths are transmitted, as it is often in mMTC and URLLC scenarios. These codes are evaluated in terms of both Block Error Rate (BLER) and Bit Error Rate (BER). Simulation results show that Polar codes exhibit a much better error correction capability compared to the LDPC codes for short block lengths, while they have a comparable performance at medium block length.**

Keywords—5G-MTC, LDPC, Polar codes, mMTC, URLLC.

I. Introduction

With the rapid development of wireless communication technology, the 5th generation (5G) has received considerable attention and emerged as a more advanced way in telecommunications [1]. Compared to the fourth-generation (4G) wireless systems, 5G has been designed not only to enhance mobile broadband (MBB) applications but also to support new services centered on machine type communications (MTC) [2], [3].

Machine-type communication (MTC) is one of the main communication paradigms for a wide range of emerging services that enables devices to interconnect wirelessly with minimal or without human intervention, the main usage scenarios of 5G-MTC are [4]: massive MTC (mMTC) and mission-critical MTC (mcMTC) also known as ultra-reliable low-latency communications(URLLC). As the term speaks for itself, mMTC is about providing wireless connectivity to a large number of machine type terminals, with low costs and extremely low energy consumption [5]. While URLLC, is about communication with a high level of reliability (e.g., 99.999%) and low latency in the order of 1ms or less [6]. Recently, numerous researches have been performed to meet the challenging requirements of these scenarios such as research on the field of channel coding.

Channel coding is one of the most prominent and critical subjects in today's wireless communication systems. The goal of channel coding is to protect the information from noise and interference encountered in the transmission through the channel and this is achieved by using a channel encoder and decoder. The former introduces redundancy in a controlled manner in the transmitted information sequence, while the latter exploits this redundancy to detect and correct errors on the receiver side.

The recent interest in channel coding schemes for the 5G has directed to polar codes and LDPC codes [7]. For the Enhanced Mobile Broadband (eMBB) scenario, LDPC code has been chosen for the data channels and Polar code has been adopted for the control channels [8]. As for URLLC and mMTC use cases, research on efficient coding schemes is still ongoing. The candidate coding schemes considered for 5G networks are Turbo code, LDPC code and polar codes [9]. However, Turbo codes are not recommended to use for MTC scenarios since it exhibits a poor performance when information block length is small. Besides, the complexity of Turbo codes is much higher than other modern coding schemes [10]. LDPC has come out as one of the major channel coding contender for 5G [11]. While recent investigations [12] demonstrated that Polar codes outperform modern coding schemes without any sign of error floor, Furthermore, they have the lowest system complexity among the competitive codes that might be used in 5G systems which render them preferred for 5G mMTC/URLLC use cases [13].

In order to achieve the requirements of the mMTC and URLLC, the selected channel coding scheme should have the capability to support short information blocks with low computation complexity, low latency and very good error correction performance to provide higher reliability. Hence, This paper mainly focuses on error correction performance of 5G channel coding schemes namely Polar code and LDPC code for short and medium information block lengths(64<K<1024) in the context of mMTC/URLLC scenarios. However, there are other parameters needed to be taken into account to determine the appropriate coding technique for URLLC and mMTC use cases. The considered codes are evaluated and compared in terms of BLER and BER over an Additive Gaussian Noise (AWGN) channel.

Our paper is organized as follow. In Section II, we briefly introduce the 5G channel coding techniques namely: LDPC codes and Polar codes. BER and BLER simulations results of the discussed codes are provided in SectionIII. Finally, we provide conclusion in Section IV

II. PRELIMINARIES OF CHANNEL CODES

In this section, LDPC and Polar coding schemes are briefly introduced, respectively.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

A. LDPC codes:

In 1962, R. Gallager introduced a family of error correction codes, called Low-Density Parity Check (LDPC) Codes [14]. But they were then largely forgotten. LDPC codes were rediscovered by Mackay in 1996 [15] and, since then, they have been applied in numerous communications systems. As the name implies, they are characterized by a sparse parity check matrix H, where sparse means that most of the entries are zero. An example of H is the following:

$$H = \begin{bmatrix} 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix} \qquad (1)$$

LDPC code can also be described by a graph, called tanner or bipartite graph. [16], which is composed of Check nodes (CNs) and the Variable nodes (VNs). In the Tanner graph, variable node i is connected to check node j, whenever h_{ij} of H is non-zero, as illustrated in Fig. 1.

Recently, research on LDPC codes has been oriented on quasi-cyclic (QC) LDPC code. The 5G LDPC code belong to the class of QC-LDPC codes, where two base graphs are defined [17].

The LDPC decoding can be implemented by using Sum-Product(SP) algorithm, but it suffers from high complexity. This complexity can be greatly reduced by using the min-Sum algorithm (MSA)[18]. In order to increase the convergence speed of MSA, Layered Min-sum algorithm was proposed [19].

B. Polar codes

Polar code [20], invented by Arikan in 2008, is a special class of error correcting codes that can provably achieves the channel capacity. Polar codes exploit a novel concept called channel polarization, which converts the transmission channel into virtual channels of different capacities. In the limit of infinite block-length, it can be shown that channels become either perfectly noiseless or very noisy. Polar codes are then constructed by only using the noiseless channels for transmitting information while freezing the inputs of all other channels to known values.

The encoding of Polar code with code length N ($=2^n$, $n \geq 1$) is performed using the generator matrix obtained from the polar transform. The generator matrix G_N can be written as:

$$G_N = F^{\otimes n}, \quad F = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \qquad (2)$$

Where $F^{\otimes n}$ denotes the n^{th} Kronecker power of F. The encoding is a process to obtain the encoded bits x $=\{x_1, x_2, \ldots, x_N\}$ through x = u G_N=u $F^{\otimes n}$ for a given source vector u = $\{u_1, u_2, \ldots, u_N\}$. The source vector u consists of the frozen bits and information bits. Fig.2 shows the polar encoding for N=4.

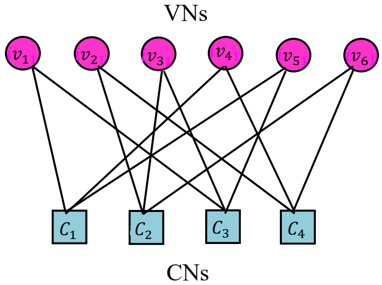

Fig.1. Tanner graph for LDPC Code.

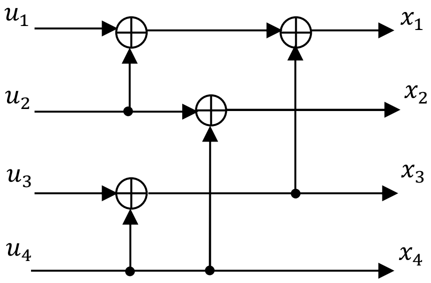

Fig.2. Polar encoder for N=4

The decoding of polar code can be achieved by a Successive Cancellation (SC) algorithm. Unfortunately, Polar code under standard SC algorithms [20] is rather unsatisfactory at short blocklengths. For this reason, Successive Cancellation List (SCL) decoder has been introduced in [21] to mitigate these problems. The performance of the SCL decoder can be further improved by concatenating them with a Cyclic Redundancy Check (CRC) codes (CRC-SCL), where the outer CRC code is used to determine a valid codeword within the list of candidates at the end of the aforementioned decoding process (SCL) [22].

III. SIMULATION RESULTS

The performance of LDPC and polar codes are evaluated for information block lengths of K= 64,128, 256, 512 and 1024 bits with code rate R=1/3. The evaluations are performed in terms of BLER/BER vs. SNR using Binary Phase shift keying (BPSK) for modulation and the channel considered is AWGN. The results are given in below figures from Fig.3 to Fig.7.

In our simulation, we have considered LDPC code based on the 5G specifications [17] and layered min-sum algorithm with 15 iterations was used in the decoder. CRC-SCL algorithm with list size L=8 and CRC of length 16 is used to decode Polar code.

From Fig. 3 and Fig. 4, it is clear that the performance of Polar code is superior to that of LDPC code for short information block lengths (K $\leq$ 128), in both BER and BLER. The performance gain of Polar code against LDPC code is around 1 dB for k=64, and 0.65 dB for k=128 at BLER=10^{-4}.

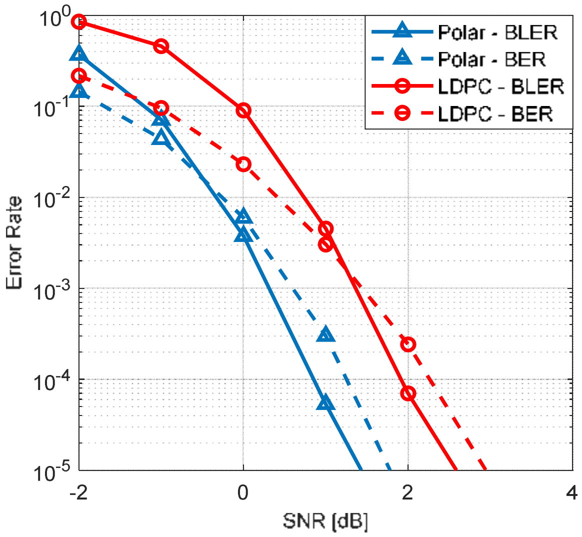

Fig.3. BER and BLER Performance of channel codes for K = 64 bits and R=1/3.

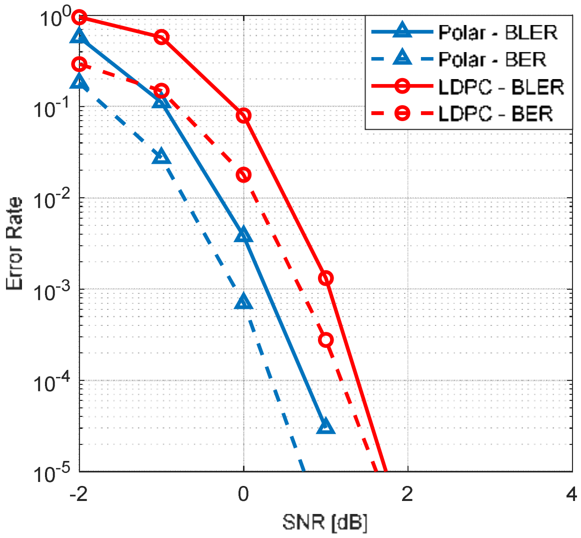

Fig.4. BER and BLER Performance of channel codes for K = 128 bits and R=1/3.

Furthermore, it can be seen from the results that as the code length increase, the performance gain of polar codes over LDPC codes decreases. As shown in Fig.5, Polar codes perform slightly better than LDPC in BER, while the performance of LDPC come close to the performance of the polar code in BLER at this information block length (K=256).

We can see from Fig. 6 and Fig. 7, that LDPC code has comparable performance as that of polar code at information bit length of K=512 and K=1024. We also observe that the performance of LDPC is around 0.15 dB better than the Polar code at BLER=10^{-4} for K=1024. So, it is concluded that at short block lengths polar code offers the best error correction performance, while LDPC and Polar offer similar performance at moderate information block length.

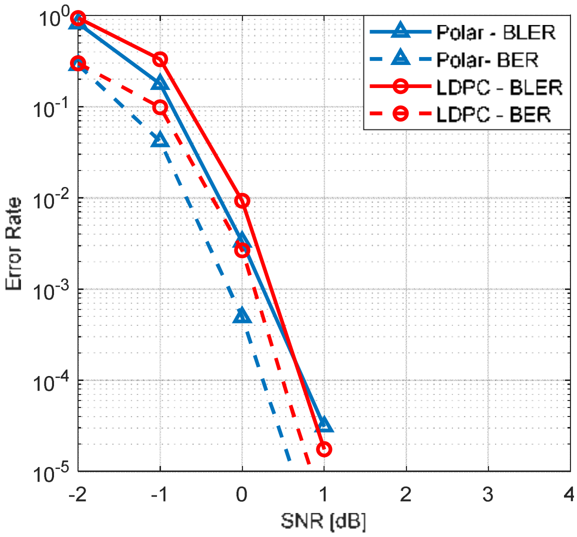

Fig.5. BER and BLER Performance of channel codes for K = 256 bits and R=1/3.

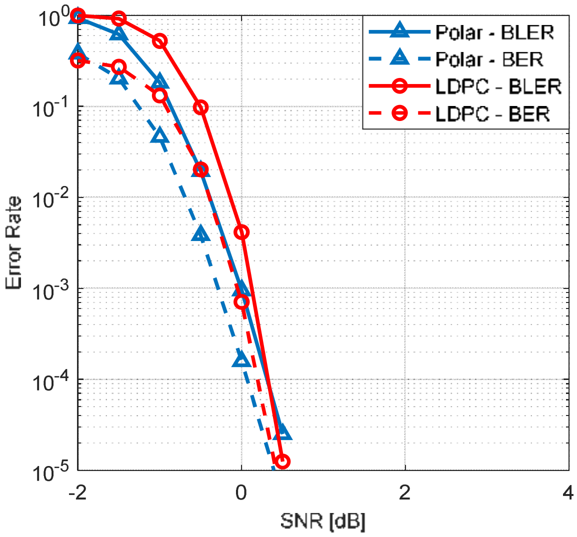

Fig.6. BER and BLER Performance of channel codes for K = 512 bits and R=1/3.

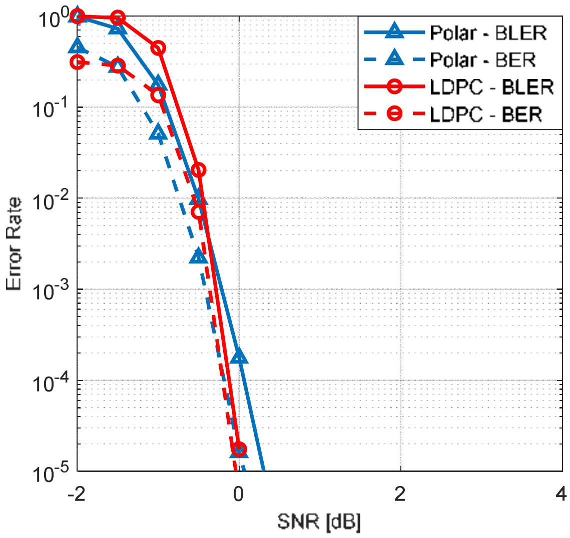

Fig.7. BER and BLER Performance of channel codes for K = 1024 bits and R=1/3.

IV. CONCLUSION

This paper has presented the error correction performance evaluation of LDPC code and polar code for short to medium information block lengths (K ≤ 1024) at a code rate of 1/3 under URLLC and mMTC scenarios. AWGN and BPSK are considered as the communication channel and modulation scheme, respectively. From the results, it is observed that the performance of Polar code with CRC-SCL decoder is better than that of LDPC codes for short information block lengths. While at medium information block length they show a comparable performance. Consequently, it can be said that Polar codes are a promising channel coding scheme in such scenarios.

***Abstract*—This paper presents a research in progress mobile application recommendation system for mobile data plan. With the vast amount of mobile data plan available, students must put a lot of effort in finding a mobile data plan that is the best value for money or the best for their heavy usage needs. Thus, paper proposes a recommendation system to aid students in the selection process of a mobile data plan. Further, hybrid filtering will be applied in the development process of this system to recommend a few suitable mobile data plans.**

***Keywords*—Recommendation System, Hybrid Filtering, Mobile Data Plan, MDLC**

I. Introduction

In recent years, telecommunication using mobile phones are entangling to everyone's daily life. The use of mobile phone is not mainly used for telephone conversation, but it has also been used mainly: (1) for text messaging and (2) surfing the net via the use of mobile data provided by the mobile telco operators. The demand for a better use of mobile data is increasing enormously as the usage of a more stable and fast mobile data is increasing due to various use and complex usage the mobile devices among users. Among the usage of mobile phone via the use of the mobile data are internet surfing, video streaming, downloading, and mobile learning mainly among students. Mobile learning is a learning process using various mobile gadgets, and it is transforming the learning environment by allowing students to participate in an asynchronous, and ubiquitous mode [1]. The extensive implementation of mobile learning has resulted in students relying on the usage of their personal mobile data in order to gain access to extensive learning materials[2]. Thus the demand for students in getting the best mobile data plan is vital [3].

The structure of this paper is as follows. The following section will highlight previous studies on the topic of interest. Following that, the recommendation technique relating to the topic of interest will be presented. Next the methodology and system architecture of the project will be presented. Finally, future works of this project will be presented.

II. Literature Review

Previous studies has highlighted that: (1) the use of mobile phone in learning enables student to communicate easily and better with their fellow lecturers, and (2) it also helps students to exchange information and study materials [4-7]. However, other related studies on mobile learning has highlighted that this kind of learning creates financial strains on students as they stressed the need of having a better mobile data plan in order to fully utilize the purpose of mobile learning [8].

The demand for the usage mobile data plan has risen over the years and are driven by several factors, among which: (1) mobile data fixed rates, (2) how easily it connects to laptops (3) online gaming (4) the ability to watch videos while on the go and (5) educational purposes [5, 9]. As for a student, the demand for a good and reliable mobile data plan from a mobile telco provider is vital, as students use extensive mobile data in for their mobile learning process [10]. Furthermore, every student needs: (1) the lowest mobile call rate, (2) uninterrupted mobile service, and (3) mobile data plan at the best price [11].

Over the years, there has been a great amount of mobile data plan available, and students have to put a lot of effort in finding the most suitable mobile data plan. Furthermore, is has also been suggested the implementation of a recommendation mobile data plan system in order to help users (i.e. students) to choose the best available mobile data plan [12, 13]. As such by creating a recommendation system, it would help minimize the information overload in a personalized way (i.e., for students) thus it would be also beneficial not only for the end user, but for the mobile telco provider as the would get more information about the users need. A recommendation system is a specific information

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

filtering system which ranks the existing information base on specific user conditions. Further, the outcomes from a recommendation system would rank the information based on specific filtering technique.

III. Filtering Technique

Recommender systems are software applications which is designed to provide suggestions that could be of interest a User [14, 15]. Further, each recommender application is base on certain technique. The following sub section will highlight and briefly explain three main filtering technique which are widely highlighted in previous research, mainly the: (1) content base, (2) collaborative filtering (CF), and (3) hybrid.

A. Content base filtering

Content base filtering is a technique base on the assumption of a user and several users personal interests. If a user intertest in a particular topic of interest remains the same for a few days, thus it can be said that the user's topic of interest will remain the same for the near future. In a web surfing scenario, a user will tend to search the same topic of interest. Thus, the content base filtering technique will only show those information related to a user's topic of interest and similar users with the same topic of interest. [16-18]. Figure 1 below refers to content base filtering.

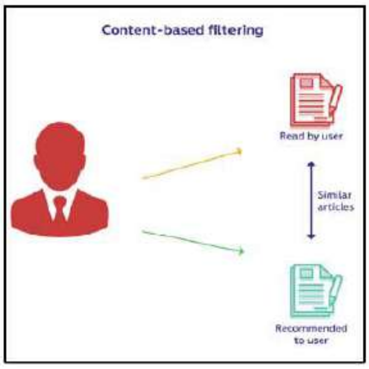

Fig. 1. The content base filtering technique

B. Collaborative filtering

This technique uses the idea of spreading news, word of mouth, people's option, and reviews [11, 15]. This filtering technique then filters and sorts based on similarity them accordingly to help users make decisions[13, 16]

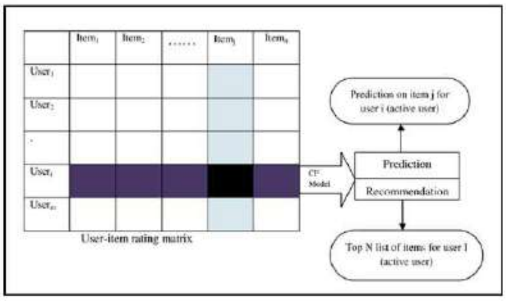

Fig. 2. Collaboarative filtering

C. Hybrid filtering

This technique (Figure 3) combines both filtering techniques mention in the above sub sections. The outcome of this technique is based on the users topic of interest combined with other information such as previous reviews, option and spreading news [17].

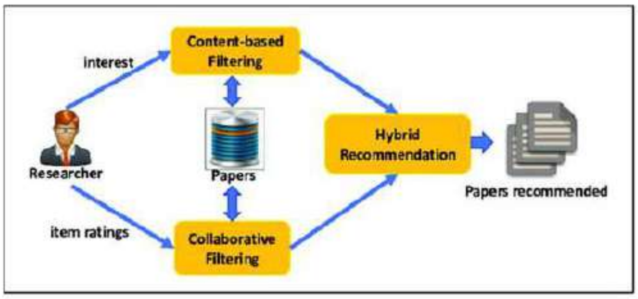

Fig. 3. Hybrid Filtering

IV. Methodology

The proof of concept of the proposed system in this project will be using the Multimedia Development Life Cycle (MDLC) methodology [19] (figure 4). A well-developed methodology plan will save time, money, and multiple modifications. The MDLC activities concentrate on technological aspects of the product development [20]. The MDLC consists of: (1) conceptualization phase, (2) development plan phase, (3) preproduction phase, (4) production phase, (5) postproduction phase and (6) documentation phase. Each of this phase will be briefly explained in the following sub sections.

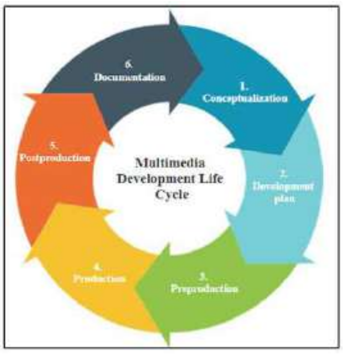

Fig. 4. Multimedia Development Life Cycle (MDLC)

A. Conceptualization

This phase constitutes of the categorization of domain stage. This project will be categorized into three main domain: (1) information – to be given to the users, (2) filtering – base on certain criteria, and (3) outcome – providing the best recommendation to the user.

B. Development

This phase constitutes the development of the system architecture for the mobile application. The system architecture for this system will be explained in the next section.

C. Preproduction

In this phase, the mobile application is coded. This application will be using several tools such as jquery. mobile-1.0 as the platform, Adobe Dreamweaver CS5, and XMAPP control panel v.3.1.0

D. Production

In this phase, all the functional requirements of the prototype mobile application will be analyzed and tested to obtain user feedback.

E. Postproduction

In this phase, further testing will be conducted, using scenario base testing and black box testing.

F. Documentations

In this phase, proper documentation and deployment of the mobile application will be conducted.

V. Proposed System Architecture

The system architecture (figure 5) is the conceptual model that describes a system's structure, behaviors, and more opinions [21]. In the Multimedia Development Life Cycle process, serves as the key milestone. The goal of the activities of system architecture is to define a comprehensive solution based on logically connected and compatible principles, concepts, and properties. Further, the system architecture has features and properties that satisfy, the problem or opportunity expressed by the system specifications and principles of the development life cycle which is then implemented by technology.

The activities presented in Figure 5 defines a thorough project outcome solution based on the logically associated and compatible standards of the proposed project. The outcome of this data plan recommendation system implementation comes from several data plans from any telecommunication company that users would choose to access the internet connection. This project would be using the website's triplet and metadata files as a database in the data plan recommendation system. This data plan recommendation system would be using the hybrid filtering technique. This proposed project implements hybrid filtering technique. This technique combines the user topic of interest and other similar reviews focusing on the same topic of interest. Furthermore, the hybrid technique also utilizes other users reviews to provide the best possible recommendation [17, 21].

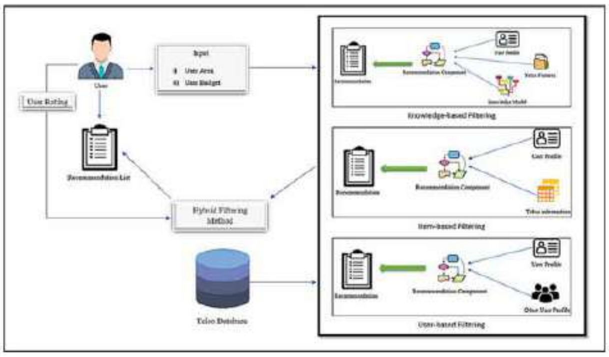

Fig. 5. System architecture

The system architecture will also help to prioritize conflicting goals. In the early stages of a research project system, the system architecture ensures that a design strategy can create an appropriate framework. Furthermore, the design risks and several mitigation plan can also be recognized early especially in the construction process by designing efficient architecture. Functional requirements, including software coding standards, instruments, and platforms, are also determine in the system architecture. Hence, it will ensure success in proposed project and it also gives the right technological solutions.

VI. Future Works

Numerous telco providers offer affordable and reasonable data plans which best suits students. However, for students the selection of a good data plan is vital, as students mostly uses extensive mobile data in their daily usage especially for their mobile learning.

The propose recommendation system opens new ways for customized knowledge and information to be retrieved from the Internet. It also aids to mitigate the issue of information overload, by using the recommendation systems. This is because users (i.e., students) are only interested in those information that are is necessary for their usage.

Further, this work in progress paper has highlighted several filtering techniques which can used by the recommendation system. The proposed mobile data plan recommendation system will be using the hybrid filtering technique, as this technique is a complete technique focusing on a user's interest and other users' reviews. It is hope that this project will inspire and serve as a guide to develop other recommendation system.

Metal Oxide Surge Arrester: A Tool for Lightning Stroke Analysis

M. Shaban
Dept. of Electrical and Electronic Engineering
Loughborough University, UK

***Abstract*— Surge arrester is used to protect the equipment of electrical transmission and distribution systems from the effects of lightning and switching overvoltage. They are very much reliable devices which can work for decades without causing any problems provided they are properly designed, configured, and maintained. This paper examines the effects of lightning strokes in an electrical network and analyzes two different frequency dependent models of metal oxide surge arrester following the IEEE standards. The objective is to create a suitable model of tower which considers the propagation of surge, the footing resistance and the two types of air-gap leaders. It is found that, with the identification of overvoltage, the rate of failure of a substation could be determined. This is done through a comprehensive study that uses different strategies among the one available in literature. It was also found that all the strategies generated a similar transient overvoltage. It was observed that the range of values obtained could be considered as complying with the standards.**

Keywords: Lightening Stroke; Frequency Dependent Model; Electrical Tower; Surge Arresters; Transient Overvoltage

I. INTRODUCTION

In transient studies, the models are usually different from the classic models which are often used in power systems study. All lines, including the span of lines, towers, cables, and surge arresters, are expected to be frequency dependent (FD). A transformer is also expected to be a very peculiar model because in higher frequencies, the most important parameter is the surge capacitance of the primary and the secondary winding of the transformer. Similarly, all the equipment of a sub-station is expected to be modeled using stray capacitance [1]. The lines and spines in a sub-station are very short; therefore, to simulate this system, a precise step should be taken within a short time.

The equipment in the 420 kV system normally has a standard lightning impulse withstand level of 1425 kV. Hence, according to the IEC standards on insulation coordination [2, 3], the highest occurring voltage in the case of a non-self-restoring insulation in operation should stay below this value by a factor of 1.15, i.e., it should not exceed 1239 kV. Nevertheless, the lightning impulse protection level of 823 kV offers enough protection.

Several significant factors can cause the voltage at the terminals of the equipment to be protected to take on a considerably higher value. When inductive voltage drops; it discharges currents higher than the nominal discharge current and provides separation effects through traveling wave processes between the terminals of the arrester and the equipment to be protected. The latter phenomenon must be considered when planning the optimal location of an arrester [4]. It is, therefore, possible to increase the energy absorption capability of the arrester bank to the extreme values by connecting, normally, up to 100 metal oxide columns in parallel [5]. Despite, there are many other options for optimizing the necessary investment against the power supply quality by protecting only part of the towers, part of the phases, or by choosing less expensive arresters of low energy absorption capability based on an arrester failure risk analysis [6].

Lightning faults are of two types: the flashovers, mainly single-phase, following a screen failure and caused by direct hitting to the phase conductors and the back flashovers, which can occur when the lightning strike hits a tower or the ground wire. In this case, the potential at the top of the tower rises significantly and can exceed the dielectric strength of the insulators string [7-9].

Recently, the polymeric ZnO surge arresters have been developed and have been put into operations on transmission lines to limit the overvoltage based on their characteristics. A significant number of surge arresters of lines are in service today and there is a high demand for them at different voltage levels [10-13]. A study, aimed at improving the performance of transmission lines in the face of constraints, requires the modeling of the element of each line considering the effect of the frequency [14].

This paper uses the modified model of surge arresters recommended by the IEEE [15, 16] to examine the phenomenon and effect of lightening stroke on a designed surge arrester. This dynamic model is used to evaluate a lightning overvoltage protection. A lightning overvoltage is generated by using Cigre (International Council on Large Electric Systems) I-surge model on top of the tower. The resulting shape of the overvoltage and its magnitude are computed at two different points. The simulations are repeated with various parameters and with two types of surge arresters (FD model and ZnO model.

The simulations are performed with the popular transient software known as Alternative Transient Program (ATP), which itself is a revised version of the Electromagnetic Transient Program 3.1 (EMTP-RV).

II. SURGE ARRESTER MODELLING

Normally, a surge arrester is modelled using ZnO arrester which is in a nonlinear library of the ATP Draw. In its data function, the rating voltage of a surge arrester and the desired

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

voltage rating are computed together. A surge arrester cannot be simply considered as a nonlinear resistor as it is in the EMTP library. Rather, it must be modified as described in the IEEE working group 3.4.11 [17]. After the modification, it becomes a frequency dependent (FD) model of a surge arrester and gives much better response for lightning transients as compared to the simple model present in the library of the ATP Draw. The frequency dependency is built by the RL and the RLC filters as shown in Fig. 1.

In this case, two surge arresters are used: one at the primary level of a transformer and the other at the secondary of a transformer. Table 1 shows the characteristics of the surge arresters. A surge arrester should be modelled in line with these characteristics. Most of the times, a manufacturer might provide these standard values.

The values of *R0, L0, C0, R1,* and *L1* are given in the IEEE working group. The formulae for calculating these values are given below:

- *L1 = 15 d/n uH*
- *R1 = 65 d/n ohms*
- *L0 = 0.2 d/n uH*
- *R0 = 100 d/n ohms*
- *C = 100 n/d pF*

Where "*d*" is the estimated height of the arrester (in meters), which is 0.56 m. "*n*" is the number of columns of the arresters in parallel which is only one in this case. The circuit shown in Fig. 1 is converted into a sub-circuit, which is shown in the form of horizontal lines in Fig. 2. All the values of the parameters are defined in the mask.

I-surge is taken from the library of sources and connected with the arrester to verify it. The scope is used to measure the voltage. In the I-surge source itself, we can measure the voltage and waveform options of the current. After running the simulation, the current output is generated using the scope view command in the software.

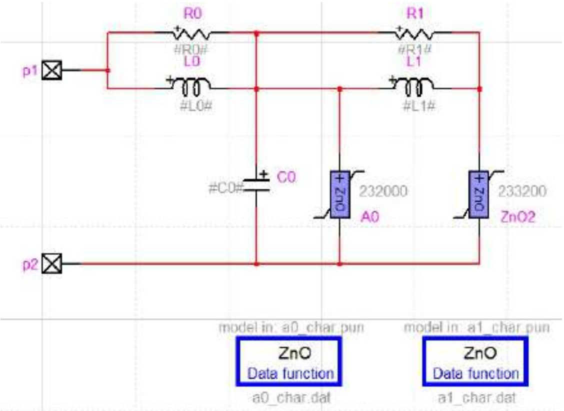

Fig. 1. HV Surge arrester.

TABLE I. SURGE ARRESTER CHARACTERISTICS.

	High Voltage Side	Medium Voltage Side
Rated Voltage	36 kV	12 kV
Continuous operating Voltage	30.04 kV	10.02 kV
Nominal Discharge Current	8/20 us, 10 kA	8/20 us, 10 kA
Residual Voltage at Nominal Current	116.6 kV	40 kV

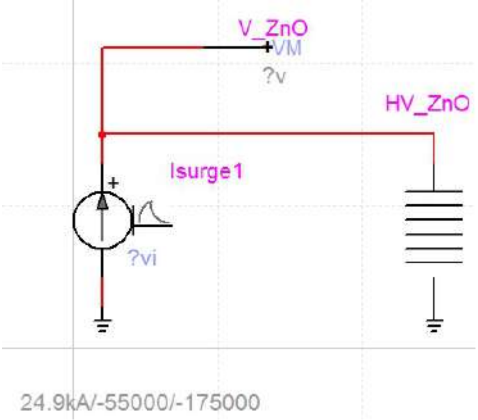

Fig. 2. HV Arrester energization.

It is observed that the pulse is same as defined by the standard shown in Fig. 3 and the voltage generated because of this current and the current itself are compared in Fig. 4. The maximum voltage is identified using the delta cursor command in scope view and calculating the residual voltage at the nominal current, which is the same as described in Table I by the standard.

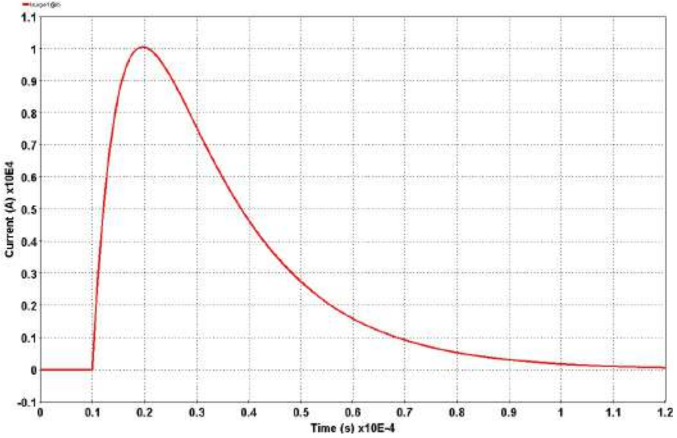

Fig. 3. Impulse defined by standard.

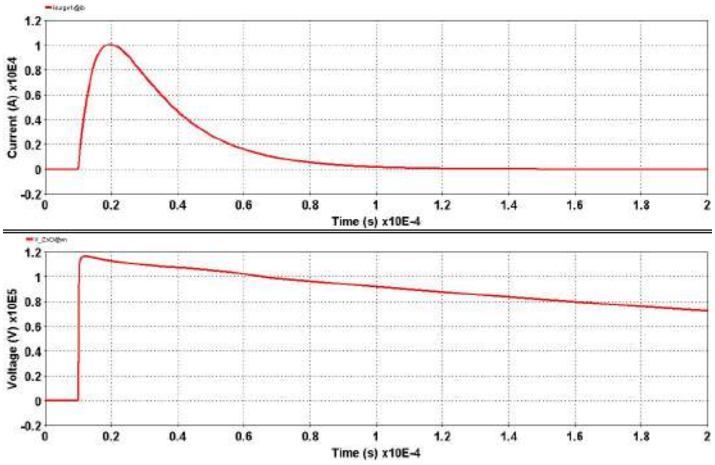

Fig. 4. Impulse and voltage at source.

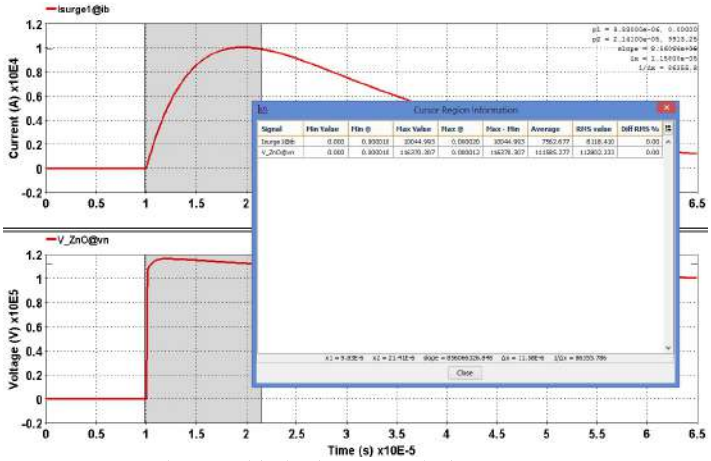

Signal	Min Value	Min @	Max Value	Max @	Max - Min	Average	RMS value	Diff RMS %
Isurge1@ib	0.000	0.000018	10044.993	0.000020	10044.993	7562.677	8118.430	0.00
V_ZnO@vn	0.000	0.000018	116270.307	0.000012	116278.307	111585.277	112802.333	0.00

Fig. 5. Residual voltage at nominal current.

Fig. 5 shows the maximum value of the residual voltage at the nominal current on the high voltage side of arrester. This maximum voltage is in line with the acceptable standard. Therefore, the desired surge arrester that can be used in the network for the study of lightning is successfully modelled.

III. THE ELECTRICAL TOWER

When lightning strikes on the tower, there will be surge inside the tower with a reflection. Therefore, it is important to model a tower which considers reflection, especially, towers that are taller than 50 m. Towers are generally considered as an ideal single conductor-distributed parameter (CP model in EMTP-RV) [18]. However, more complex models are needed for consideration when towers are taller than 50 m. The surge impedance for the proposed conductor can be calculated using equations (1) and (2).

$$Z_{surge} = 60 \ln\left(\cot\left(\frac{1}{2}\tan^{-1}\left(\frac{R_{avg}}{h_1 + h_2}\right)\right)\right) \tag{1}$$

While

$$R_{avg} = \frac{r_1 \times h_2 + r_2\left(h_1 + h_2\right) + r_3 \times h_1}{h_1 + h_2} \tag{2}$$

R_1 = Tower top radius (m),

R_2 = Tower midsection radius (m),

R_3 = Tower base radius (m),

h_1 = Height from base to midsection (m),

h_2 = Height from midsection to top (m).

The propagation velocity in the towers is estimated at 80 % of the speed of light [19]. The CP line can represent each section of the tower. For the branch, only inductance can be used if they are short in length. The CP line can be used as well; however, it depends on the length of the branch. Fig. 6 shows how the case is going to be as the first step for an electrical network.

For the length of 20 m, 3 m, 3 m, and 4.65 m, CP lines are used for each section of the tower while inductors are used for the branches. The air-gap leader for supporting the phasor and the footing resistance could also be used. As for the resistance, because of the ionization of the soil, the footing resistance changes with the value of the current at a certain point. Thus, in low currents, a constant footing resistance is used and when the current becomes higher, the resistance changes according to the equation (3).

For footing resistance, the control resistance in nonlinear library is used. In this controlled resistance, we input the values of admittance and the current. There are two types of resistances possible here, either the constant or one which depends on the current, thus, at this point, the input selector is used. If the input selector pin is 1, then the resistance will be constant, and the second input is the function of the resistance which depends on the current. This is how the footing resistance is built.

$$R_i = \frac{R_o}{\sqrt{1 + \left(\frac{I}{I_g}\right)}} \tag{3}$$

R_o – footing resistance at low current and low frequency, i.e., 50 or 60 Hz [Ω].

I – Stroke current through the resistance [kA].

$I_g = \dfrac{\rho.E_0}{2.\pi.R_0{}^2}$ - limiting current to initiate sufficient soil ionization [kA].

ρ - Soil resistivity [Ω m].

E_o – is the soil ionization gradient, recommended value: 400 [kV/m].

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

After building the footing resistance, the air-gap leader is to be considered, for which there are two different models that can be used.

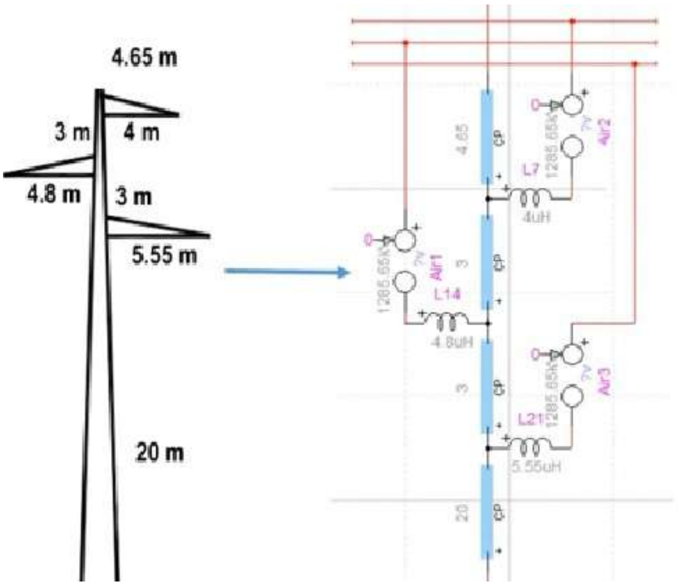

Fig. 6. Electrical tower in EMTP.

A. Disruptive Effect Model

The first one is called disruptive effect model [20]. Flashover occurs when the equation (4) becomes true.

$$\int_{t_o}^{t}\left(\left|V_{gap}(t)\right|-V_0\right)^{k} dt \geq D \qquad (4)$$

-t_o is the time point at which V_{gap} becomes greater than V_o. When the voltage V_{gap} goes below V_o the integral is reset.

The gap is an ideal open switch before the flashover, and it becomes an ideal closed switch after the flashover. The gap remains closed after the flashover until the control signal becomes greater than zero, in which case it will reset (open) the gap. Fig. 7 shows the disruptive effect model along with the ground resistance.

The disruptive effect model with the same equation can be found in the switch library with the name, airgap. The same airgap is used for all three phases. The purpose of the input to the airgap is to reset it after the flashover so we insert zero as an input. This means that it will never reset itself. After this, the stray capacitance between the tower and the phase is used because every stray capacitance has an influence when dealing with high frequencies. The typical value for the capacitor is 80 *pF*. After making all the connections, a sub-circuit was produced creating the tower in EMTP-RV.

B. Air Gap Leader

This is even more advanced model that is why the simulation time will be higher and the simulation will be slow when this type of air-gap is used [21] and it is shown in Fig. 8. This model is not in the library but exists in the examples with the name airgap leader, which is a valid example of this airgap. The same tower is used but only the replacement of the disruptive model with this air-gap model is done as shown in Fig. 9.

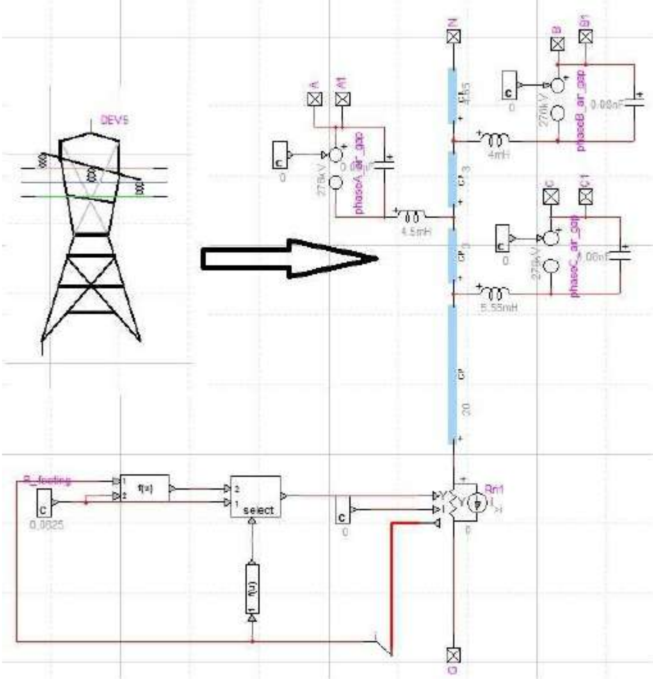

Fig. 7. Disruptive effect model along with ground resistance.

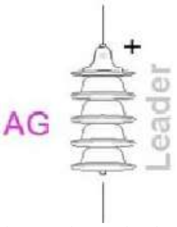

Fig. 8. Air gap leader.

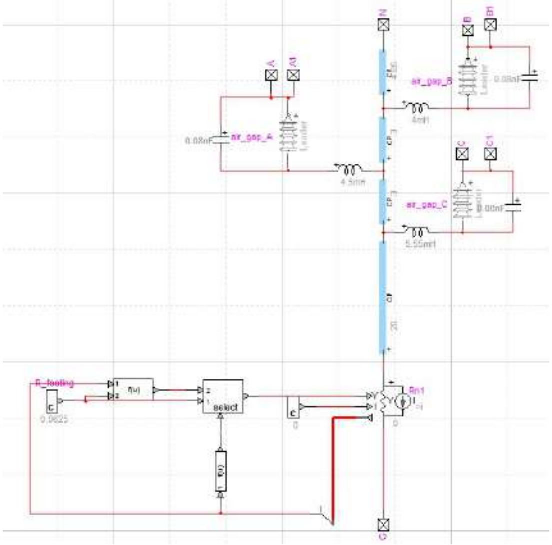

Fig. 9. Airgap model along with ground resistance.

IV. THE ELECTRICAL NETWORK

In this section, each span of the tower where the lightning strike can occur is modelled. The FD model of the line is used and will copy the tower that was built using the first airgap i.e., the disruptive effect model. The line data case is used to enter the date for FD lines. Four conductors (three phases and one neutral) were used with the 300 m length for each. The lightning will strike on the tower and there is going to be a back flashover, so tower should be modelled in a way such that there is no back flashover after the last tower modelled. After the lightning strikes, there will be a reflection between towers. Something should be done after the last tower so that there will be no reflection. Therefore, to get rid of the undesirable reflection, a very long line of 100 km was placed which is presumably transposed. There will then be a voltage source of 64 kV connected using BUS.

To model a substation, every element should be modelled e.g.
Circuit Breakers (CB): 2*50 *pF*
Capacitive voltage transformers (CVT): ~4400 *pF*
Current transformers (CT): 200-800 *pF*
Power transformer: 1-6 *nF*

Fig. 10 shows the detailed circuit diagram drawn in EMTP-RV using cables, lines, and a transformer. Many examples of the typical capacitance values for a lot of equipment are explained in Annex B IEEE C37.0111-2011. However, the preferred data is the one provided by the manufacturer especially, for the transformer. When one uses a short cable to connect the tower with a substation, it can be modelled with RL. One can then connect the surge arrester with all three phases and these surge arresters can be grounded using another small cable.

For the cables going through a substation, the CP model must be used for the cable lengths which are more than 50 m which will reproduce the propagation. Therefore, there is no need to use the FD model for short cable lines because it can create some convergence problems. When the CP model for a 50 m cable was used that connects the phases with a CVT and model CVT with a capacitor with a value of 4400 *pF*, the transformer used is three phase YgD+30º. However, in fact, the transformer is not valid for a high frequency because it has a lot of high value inductance; and in high frequencies, the inductances are like open circuit.

Here, the stray capacitance becomes important, and the values of the stray capacitance were taken from [22] which are 5 *nF*, 15 *nF*, and 20 *nF*. For the lightning, the Cigre current source was used from the sources library and was connected to one of the towers. In the data case of the current source, the data like starting and ending time of the lightning strike was inserted. The subsequent strikes could also be observed by adding current sources in parallel and by changing the starting time.

After running the simulation, the observed parameters were the voltage at the top of the tower, current through the airgap, voltage within the substation, and the energy through the surge arrester. For the simulation, the time-step was small for the lightning, i.e., 0.005 *us*; and the simulation time was 300 *us*. The simulation was very slow, and, during the event, energy was plotted through a deterministic approach.

V. RESULTS AND DISCUSSION

While considering the weather forecast, one can determine the worst lightning strike that could occur. When the overvoltage is identified, the probability of the equipment failing, considering this voltage, can be calculated. This facilitates the determination of the rate of failure of the substation. Fig. 11 shows the waveform of the energy through the surge arresters.

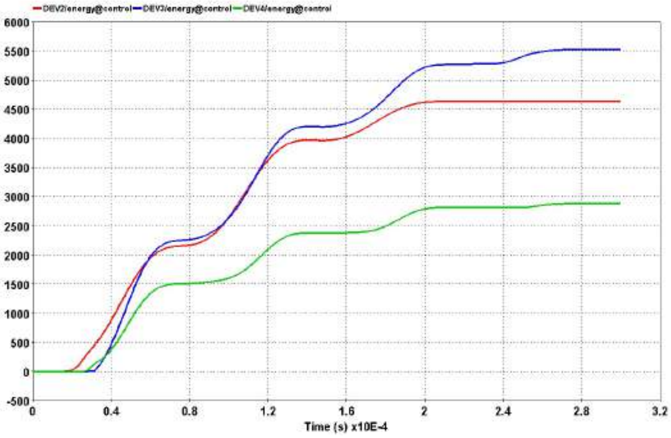

Fig. 11. Energy through surge arresters.

Similarly, the voltage at the top of the tower and on the substation is observed in Fig. 12. It was seen that the voltage was smooth at the substation because of the surge arrester.

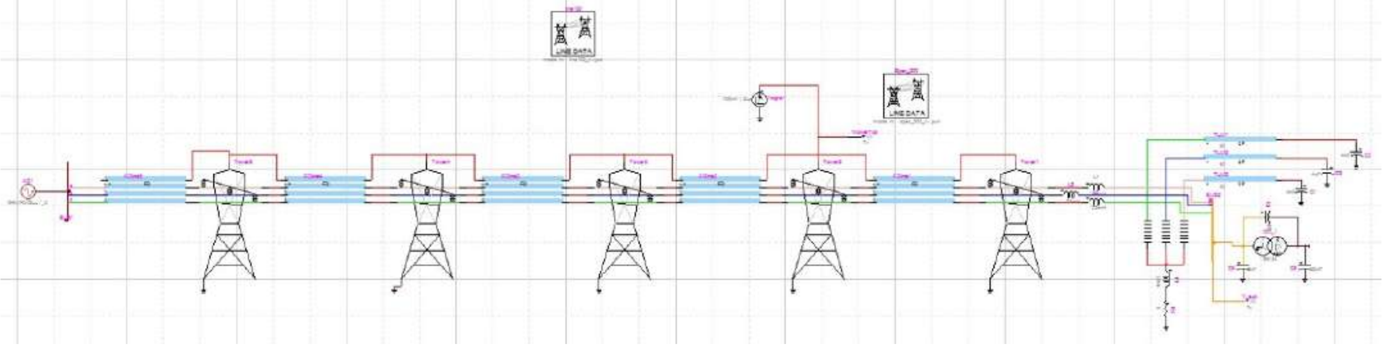

Fig. 10. Electrical network using cables, lines, and towers.

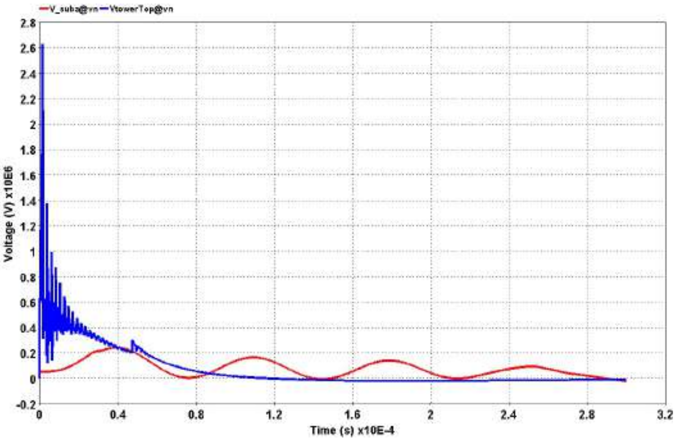

Fig. 12. Voltage at tower top and at substation.

VI. CONCLUSION

This paper modelled the surge arrester according to the IEEE standard to investigate the lightening stroke effect on different surge arresters and is suitable for all types of overvoltage studies. The calculation of energy during the event is a deterministic approach and can be used for weather forecast. Therefore, the worst lightning strike can be determined in advance. It is concluded that with the identification of overvoltage, the rate of failure of a substation could be determined.

Nonetheless, the obtained results indicate that the lightning current (amplitude) and the tower footing resistance must be considered in the study of lightning protection. A major part of the surge current was dissipated through the ground. This study shows that several alternatives that can improve line performances and ensure compromise between these alternatives must be considered. It is recommended that the secondary protections should also be made as the improvement of the transmission line performances alone does not ensure complete protection of a power system.

***Abstract* - This paper presents a predictive model to potentially identify high-risk COVID-19 infected patients based on easily analyzed circulatory blood markers. These findings can enable effective and efficient care programs for high-risk patients and periodic monitoring for the low-risk ones, thereby easing the hospital flow of patients and can further be utilized for hospital bed utilization assessment. The present machine learning-based SV-LAR model results in a high 87% f1 score, harmonic mean of 91% precision, and 83% recall to classify COVID-19, infected patients, as high-risk patients needing hospitalization.**

Keywords – COVID-19, SARS-CoV-2, pandemic, patient outcomes, machine learning models

I. INTRODUCTION

COVID-19 is a new disease for which effective treatment is still awaited. It was declared a pandemic by World Health Organization (WHO) on March 11, 2020 [1]. As of January 28, 2021, more than 100 million people have been affected by this infection causing more than 2 million fatalities [2]. Global health care now faces unprecedented challenges with the widespread and rapid human-to-human transmission of SARS-CoV-2 and high morbidity and mortality with COVID-19 worldwide [3].

COVID-19 patients get worse quickly and aggressively.
In addition to high transmissibility SARS-CoV-2 infection it is also characterized by fever, dry cough, weakness, headache, dyspnoea, and loss of smell and taste in the early stages, which are common symptom of cold and flu [4]. The early onset of common symptoms can rapidly change to acute respiratory distress syndrome (ARDS), acute cardiac injury, cytokine storm, coagulation dysfunction, and multi-organ failure if the disease is not resolved, resulting in patient death [5]. Early studies showed that COVID-19 patients with comorbidity may lead to poor prognosis, increasing the risk of severe illness from COVID-19. Among laboratory-confirmed cases, patients with any comorbidity yielded poorer clinical outcomes than those without [6]. Several studies have been conducted to find a correlation between pre-existing medical conditions and their impact on COVID-19 prognosis.

In a meta-analysis by Wang et al, Hypertension, diabetes, Chronic obstructive pulmonary disease (COPD), cardiovascular disease, and cerebrovascular disease were found to be the major risk factors for patients with COVID-19 [7]. Several risk factors that led to the progression of COVID-19 pneumonia were identified, including age, history of smoking, maximum body temperature at admission, respiratory failure, albumin, and C-reactive protein [8]. Given the virtually unstoppable global trend of SARS-CoV-2, together with the high prevalence of comorbidities worldwide, the combination of these two conditions poses greater clinical, societal, and economic burdens to healthcare systems [9].

Until now the source of the pathogenesis of the COVID-19 remains unclear, and no specific treatment has been recommended for coronavirus infection except for meticulous care. The world is ready to receive the vaccines as approved worldwide, but the threat continues with mutating strains of the virus. Therefore, the need for a better solution for providing care to those who absolutely need it and to predict the future requirements for better planning and management for better patient outcomes, continues. In

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

several articles, researches have indicated the need for better hospital management by early identification of patients requiring hospitalization and possible further triage [10].

In another attempt to decode the comorbidity-related risks in COVID-19 patients, Zhao et al. developed a logistic regression-based classification model to predict two primary outcomes of admission to the intensive care unit (ICU) and death. The risk score model yielded accuracy with an Area under the curve (AUC) of 0.74 ([95% CI, 0.63–0.85], p = 0.001) for predicting ICU admission and 0.83 ([95% CI, 0.73–0.92], p<0.001) for predicting mortality for the testing dataset. This model was developed and internally validated using data from the COVID-19 persons under investigation (PUI) registry of 4997 patients from a major academic hospital (Stony Brook University Hospital) [11] in New York. Another finding was that the mortality group uniquely contained cardiopulmonary parameters as top predictors.

In another study aimed to clarify high-risk factors for COVID-19, researchers used Multivariate Cox regression to identify risk factors associated with the progression of the disease. Univariate and multivariate analyses showed that comorbidity, older age, lower lymphocyte count, and higher lactate dehydrogenase at presentation were independent high-risk factors for progression. A novel scoring model, named CALL [12], with an area under the receiver operating characteristic curve (ROC) of 0.91 (95% CI, .86–.94) was established to help clinicians better choose a therapeutic strategy.

Elisa Grifoni et al, tested the predictive power of the CALL score in an Italian COVID-19 population admitted to hospital from 12 March to 20 April 2020 and consisting of 210 patients. Their findings concluded that the CALL score is a good prognosticator for in-hospital mortality but not for progression to severe COVID-19 in their settings [13].

In another statistical analysis regarding the associations between increased cardiac injury markers and the risk of 28-day-all-cause death of COVID-19 patients in the Chinese population, the 5 myocardial biomarkers (high-sensitivity cardiac troponin I, creatine phosphokinase)-MB, N-terminal pro-B-type natriuretic peptide, creatine phosphokinase, and myoglobin) were found to be significantly prognostic of COVID-19 mortality [4].

Baseline patient characteristics, laboratory markers, and chest radiography can predict short-term critical illness in hospitalized patients with COVID-19, with an internally validated AUC = 0.77 using a logistic regression-based risk model developed by Steven Schalekamp, et al [14]. In another study, Zhou et al. validated a nomogram including 6 predictors: age, respiratory rate, systolic blood pressure, smoking status, fever, and chronic kidney disease. The model demonstrated a high discriminative ability in the training cohort (C-index = 0.829), which was confirmed in the external validation cohort (C-index = 0.776). In addition, the calibration plots confirmed good concordance for predicting the risk of ICU admission [15].

In another study, a regression analysis showed that C-reactive protein (CRP) was significantly associated with aggravation of non-severe COVID-19 patients, with an area under the curve of 0.844 (95% confidence interval, 0.761–0.926) and an optimal threshold value of 26.9 mg/L [16]. In a Spanish study, COVID-19 patients with normal levels of lymphocytes or mild lymphopenia, imbalanced lymphocyte subpopulations were early markers of in-hospital mortality [26].

Despite several initiatives aimed at containing the spread of the disease, countries are faced with unmanageable increases in the demand for hospitalization and ICU beds [18]. The health care system globally, has been stressed and stretched to its limit. In order to help in patient triage, several attempts have been made to discover early predictors of COVID-19 disease progression and spread. Identification of such factors that predict complications of COVID-19 is pivotal for guiding clinical care, improving patient outcomes, and allocating scarce resources effectively in a pandemic. Medical resource allocation assessments should be based on a risk/benefit approach considering the intensity of transmission, the health system's capacity to respond, other contextual considerations (such as upcoming events which may alter transmission or capacity) and the overall strategic approach to responding to COVID-19 [25] in each specific setting.

We think that it requires agile decision-making based on ongoing situational assessments at the most local administrative level possible. We propose a predictive machine learning model that identifies a potential high-risk patient from the COVID-19 patient population based on blood based circulatory markers. These predictions would help the administrators to make provisions for the scarce 'hospital beds. Consequently, the model can help in providing better public health and social measures to alleviate patient care during the pandemic time thereby improving patient outcomes at large.

II. MATERIALS AND METHODS

A. The Dataset

We have used data published on a public forum , that of Hospital Israelita Albert Einstein, at São Paulo, Brazil [19]. The dataset contains records of patients that were tested for COVID-19 using SARS-CoV-2 Reverse transcription polymerase chain reaction (RT-PCR) and additional blood tests between the 28th of March 2020 and 3rd of April 2020. All data were anonymized following the best international practices and recommendations. The full dataset released included 5,644 individual patients' clinical test results that were standardized to have a mean of zero and a unit standard deviation. It provided information of patient hospitalization into three types of wards in the hospital, such as regular ward, semi-intensive care unit, and intensive care unit as depicted in Fig 1.

The information of patients admission to various wards in the hospital was used to create the target variable for the current problem statement. Hospitalization is needed by patients needing extra care and monitoring due to health

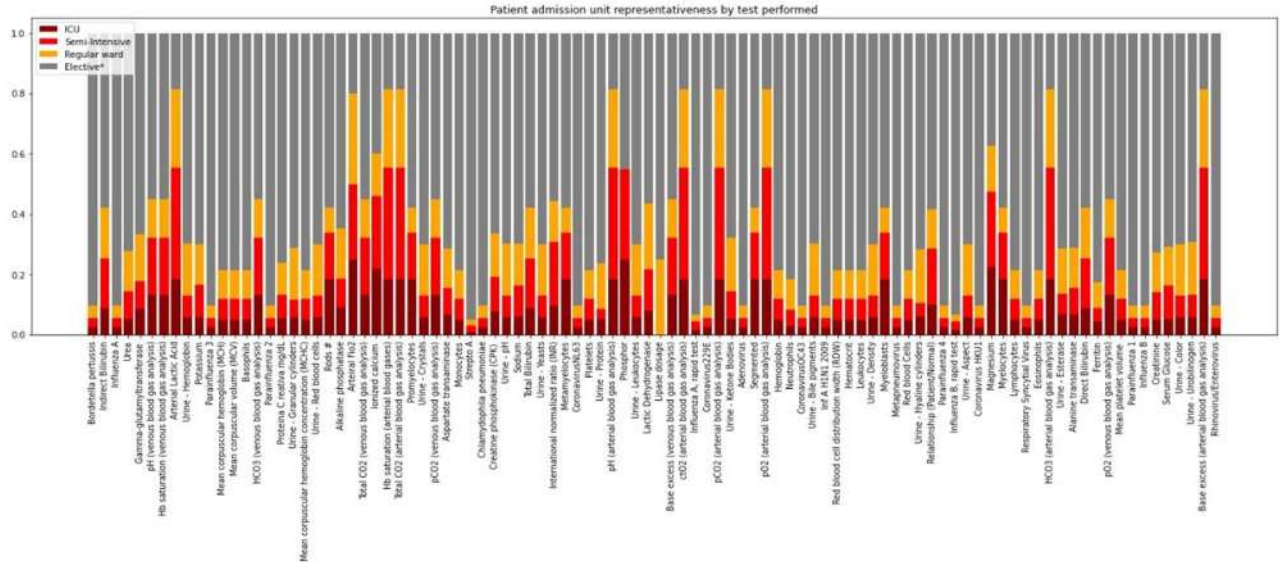

Fig.1. Distribution of patient admission into the three hospital wards across various tests performed

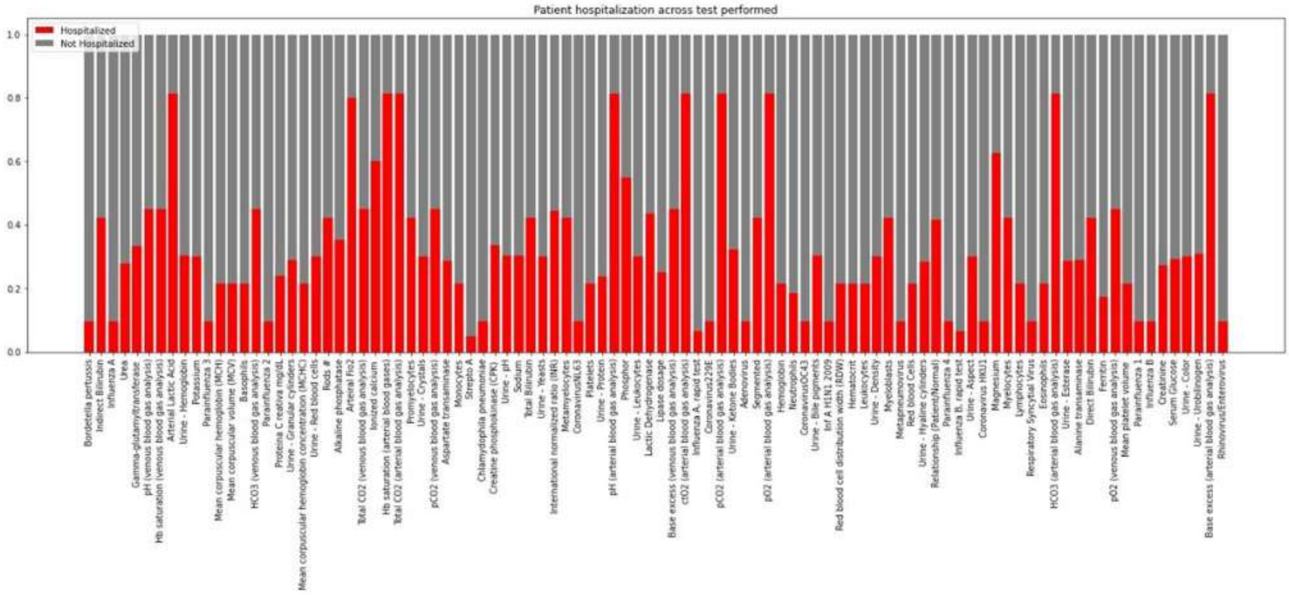

Fig.2. Distribution of hospital admission across various tests performed

who despite being infected do not need hospital admission constitute the low-risk patient population. This formed the basis of the binary classification and the target label for classification of patients {needing hospitalization in any of the hospital wards = 1, no hospitalization needed = 0} for the current objective. The distribution as per figure 1 above was therefore transformed to look like Fig 2 below.

As the current hypothesis is set around blood analysis, we have carefully selected features of routine blood analysis only. Parameter related to patient age was not considered in order to avoid any age related bias in the present analysis. Tests pertaining to viral or bacterial infections other than SARS-CoV-2 were also dropped. It is our objective to find blood based markers to identify high-risk patients and therefore features related to routine urine analysis were also dropped from the current model. Blood gas analysis either on venous blood or arterial blood is also not included in the current analysis. Largely because the blood samples are required to be tested in a 30 minute window or need a cold supply chain [19]. It is our intent to find markers that eases the hospital workload during the pandemic and therefore it is counterintuitive to include tests that need immediate attention and hospital setting to give good results.

It is for this reason that the working dataset for the model building exercise includes test parameters form a simple blood workup, keeping in mind that the sample could be collected form patients’ home environment and not necessarily in the hospital setting. Fig 3 presents the frequency of each test performed amongst the blood analysis related parameters considered for the model building, in the select dataset of 558 patient records tested positive for SARS-CoV-2.

For the purposes of our research we extracted records of patients that were tested positive for the RT-PCR test for the ongoing COVID-19 infection. Our working dataset consisted 558 records of patients infected with COVID-19 from the whole of 5644 patient records. The target variable is the hospital admission class amongst the extracted records. Following our research question we formulated the hypothesis that we were to test -

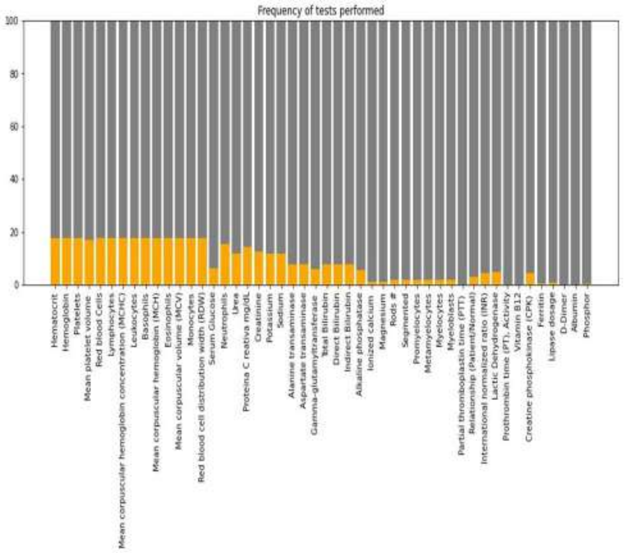

Fig.3.Percent blood analysis done on Covid positive patients

H0: There is no correlation between blood analysis of a COVID positive patient and his/her hospitalization

H1: There is a correlation between blood analysis of a COVID positive patient and his/her hospitalization

B. Model building

We started model building after data processing. The working data had missing values and columns with all null values. Features with more than 95% missing values were dropped and remaining missing values were imputed with the mean. We started with simple linear algorithms such as logistic regression, ridge classification and elastic net, and moved on to non-parametric algorithm such as Nearest Neighbours Classifier and Gaussian Naive Bayes classification. We also used tree based algorithms like decision tree classifier and extra tree classifier. Multiple ensemble techniques like random forest classifier, bagging classifier, adaboost classifier were also used to model the target label with select features of the prepared dataset. We used scikit learn library of machine learning algorithms [20]. Based on our findings, we propose the SV-LAR model for our 2-class (SARS-CoV-2 positive induced hospitalization or not) classification. The proposed model uses voting classifier ensemble based on logistic regression, random forest and adaboost classifier. The working dataset also has class imbalance. Only 10 % labels of the working dataset are positive class of hospitalised COVID positive patients, in the three available hospital wards. We have used SMOTE (Synthetic Minority Oversampling Technique) on the training data to deal with the class imbalance by upsampling the positive class [21].

C. Model performance measures

The performance of the model is expressed in terms F1 score, precision and recall. As we attempt imbalanced classification problem F1 score metric becomes more relevant. It is a measurement that considers both precision and recall to compute the score that can be interpreted as a weighted average of the precision and recall values. High F1 score (closer to 1.0) is desirable in our model. Precision is determined by the number of correctly labeled annotations divided by the total number of annotations added by the machine-learning annotator. It indicates how accurately the model has labelled the two classes. Another metric, recall specifies how many mentions that should have been annotated by a given label were actually annotated with that label. A recall score of 1.0 means that every mention that should have been labeled as entity type A was labeled correctly. In this imbalanced healthcare dataset high scores for precision and recall are desirable for an ultimate high f1 score [23, 24].

III RESULTS AND DISCUSSION

A. Evaluation

The proposed SV-LAR model of the COVID-19 infected patients produces a classification f1-score of 87%. With precision at 91% and recall at 83%. The confusion matrix is presented in the figure below.

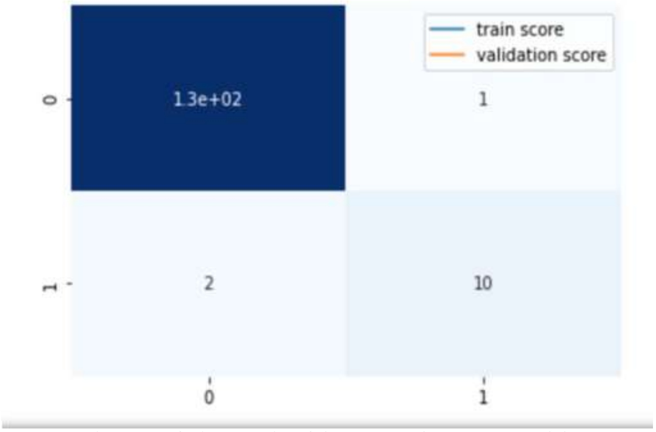

Fig.4. Confusion matrix of the proposed SV-LAR model

To the best of the authors knowledge, it is the first study to report a predictive machine learning model with high precision and recall for the triage of high-risk COVID-19 patients using simple blood exams. As per our findings, it would be possible to identify high-risk COVID-19 patients with more than 83% sensitivity and 91% specificity based on blood analysis alone. While the majority patients are asymptomatic, about 10% patients need hospitalisation. Our solution can enable healthcare professional, segregate potential high-risk patient in need of high degree of hospital care based on simple and cheap blood analysis and monitor them closely.

TABLE 1 CONFUSION MATRIX OF SV-LAR MODEL

	precision	recall	f1-score	support
0	0.98	0.99	0.99	128
1	0.91	0.83	0.87	12
accuracy			0.98	140
macro avg	0.95	0.91	0.93	140
weighted avg	0.98	0.98	0.98	140

If RT-PCR and blood analysis samples were to be taken from residence (as this service is available in India, and possibly in other countries as well), many patients can save a trip to the hospital emergency rooms thus saving time for both the hospital staff and themselves. This model can surely help in managing the pandemic related patient flow effectively and efficiently. Also, this will extend care 'as needed' by each patients' condition, where a high-risk patient is not sent home and a 'not at risk' patient is managed quickly without risking unnecessary hospital visit. Thus our model ensures using available resource where needed and thereby improves patient outcomes and hospital's healthcare burden as well.

B. Proposed solution for patient management

Once our model is deployed in healthcare setting it will enable quick movement of patients and help manage hospital resources more effectively. The suspected patients take a SARS- CoV2-RT-PCR test and simultaneously give blood samples for analysis. If tested positive for COVID-19 infection their blood result is tested through the pretrained SV-LAR model.

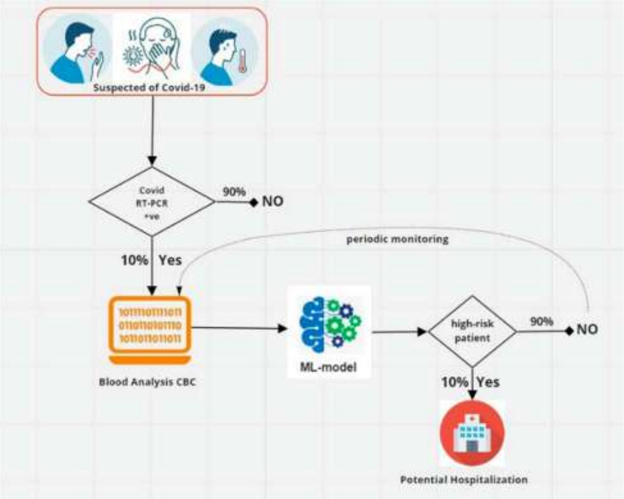

Fig.5. Envisioned patient flow using SV-LAR model

The model predicts their risk of hospitalization. If the patient belongs to high-risk class, the he/she should be tested for other tests like blood gas analysis and should be admitted upon physician approval. If the patient is deemed not at high-risk he/she should be sent back with periodic blood workup. The blood samples should be periodically analysed and tested through the SV-LAR model for risk assessment. This will enable healthcare staff to monitor each patients' development effectively.

IV. CONCLUSION

By the simple intervention of machine learning model (SV-LAR) with f1-score of 87%, the identification of a potential high-risk patient can be performed easily. The differential costs of tests required to the prediction is also underwhelming. SV-LAR model can be used to benefit healthcare workers by identifying about 10% high-risk COVID-19 patients from the increasing COVID-19 patient population. The precision of the model is a high 91% and 83% recall for the positive class. Simply put, 83 out of 100 high-risk patients can be identified correctly using this model and can be taken into hospital care for further treatment.

SV-LAR model is potentially fastest way to triage COVID-19 patients into high-risk and low-risk groups. Not only that, it enables to monitor patients via simple, non-expensive, quick, robust and minimally-invasive blood analysis. The identified high-risk patient population can then be put through more tests and procedures and can be treated accordingly. The low-risk patients, on the other hand, can be remotely monitored for any change in the patients' prognosis via the same model.

Our proposed model can be utilised globally. It relies on basic blood analysis, which is the most simple and established diagnostic service readily available in the healthcare system of any nation. This enables improved management of pandemic agnostic of the socio-economic standing of the nation.

An additional positive impact is related to hospital and patient flow management. It allows patient journey to be monitored from a distance providing better isolation of COVID-19 patients. Given that blood samples could be drawn periodically and analysed away from hospital emergency rooms, it allows ERs to work more efficiently despite the pandemic.
A limitation of our study however, is that not every patient hospitalized needs ICU. Due to the lack of data we could not segment the ICU needing patients from hospitalization requirements. As more data is collected and made available we can further refine the model. We believe that as more data will be incorporated in the model its performance and reliability will increase.

At this point, the model is developed from data available from patient emergency room visits from one hospital only. The model remains to be tested across geographies and hospitals for increased robustness. So far we have utilised only machine learning algorithms and not used deep learning algorithms to train the data. One of the reason was the size of the information available. As the available dataset was small we restricted our approach to include machine learning models. It is known that neural networks and deep learning algorithms work better on large datasets or else they tend to overfit. The performance of the model in larger datasets remains to be seen both using proposed machine learning algorithm and transferring similar approach in deep learning algorithms.

***Abstract* -- Deaf & mute people communicate usually in Sign Language with each other. Although the sign-language is very well known among these people it's quite unknown by other people. An attempt is made in this project to bridge the communication gap for the people who don't know Sign Language. The sign language used is the American Sign Language Lexicon Video dataset for this project which can be further extended to different languages. The dataset was in video format so a dominant frame extraction algorithm that would extract the dominant images from the video was used to create an as-per-requirement dataset. We found a lot of work had been already done on finger-spellings recognition but since finger-spellings make it much more complicated in actual time we thought of moving ahead with rather identifying words. The work was completed on a Computer Vision's State-of-the-art model based on Deep Learning that helped in achieving the completion of the task at instance level classification making the recognition task to a better identification at pixel-level which in-turn helps in achieving better results. An attempt has been made here to employ the latest method to make the computer learn sign languages that are independent of a person's complexion, lighting conditions, and orientations.**

Keywords-- Key-Frame Extraction, Deep Learning, Computer Vision, Instance Segmentation, American Sign Language Lexicon Video Dataset, Object Detection based SOTA model.

I.INTRODUCTION

This project demonstrates the ability to bridge the communication gap between the autistic-mute individuals and regular individuals in order to bring about a meaningful social impact and foster a sense of unity amongst the disabled by using the power of Artificial Intelligence. The aim was to develop an efficient system that can improve the lifestyle conditions for the autistic mute and hopefully contribute to the greater whole. Disability figures in India have risen about 30% in the previous decade, with about 20.3% of people having movement disabilities, 18.9% having hearing impairments. A major study published in 2018 of five sites in India found that 9.2% of children aged between 2-5 years and 13.6% of the children aged between 6-9 years had at least one of seven neurodevelopmental disorders (vision impairment, epilepsy, neuro motor impairment including cerebral palsy, hearing impairment, speech and language disorders, autism spectrum disorders and intellectual disability[27]. The number of impaired people has recently reached about 400 million and therefore extensive research and studies have been accelerated in order to ease the means for communication amongst the disabled. Currently the communication between the autistic mute community and non-autistic mute takes place with an expert interpreter which becomes inconvenient as well as expensive since human learning and expertise in the subject is involved. Aiming to create a ground of equal opportunity is the foremost objective of this approach. A lot of work has already been carried out in this domain , a lot of them referring to Fingerspelling Recognition.

To a dated back research, the concept of gesture recognition proposed by Junji Yamato et al. [6] included Time-Sequential models which used Hidden Markov Models. HMM increases the computation complexity with a very complex logic to encompass in a program. A variety of visual techniques were discussed which mentioned the use of gloves that simplifies the further processing parts, or skin colour based algorithms which typically aims to bring the hand colour as a feature extraction process or finger detection which tries to detect gestures based on the number. of fingers closed or open, as proposed by Saba Joudaki et. al. [1]. The techniques again have huge computation demands. A Real-time American Sign Language Letters Recognition was proposed by Authors, [2] Xinyun Jiang et. al., which used PCA for feature extraction and then a One-vs-One SVM classifier was used to classify the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

gestures [2]. But only a limited number of gestures can be trained since with larger datasets, SVM takes a longer time to converge. One method proposed using Haar Cascades for sign language feature extraction and then using CNN, proposed by Sanket Kadam et. al. [3]. Again Haar Cascades adds an increasing computation which is a template matching algorithm. Another development made was the use of depth maps in fingerspelling recognition. Depth map was basically created from a depth sensing device which basically used the Microsoft Kinect Camera, proposed by Byeongkeun Kang et. al. [4]. This camera shows up different colour scales depending on the distance from the camera. This helps in providing additional information in feature extraction but again the depth map needs to be extensively created. A similar approach was specified previously as well that used MLRF model thereby classifying the finger spellings which is a very lightweight model used for reducing memory consumption as well as boost up speed, proposed by Alina Kuznetsova et. al. [5]. The technique was implemented on a rotation- position- and scaling- invariant features extracted from the images. A very simple arrangement was proposed by Thad Starner et. al. [7] that established usage of desk and wearables. This requires the signer to be sitting at a desk or using a wearable that actually sees the sign from the same angle as the signer would see it, again the proposed uses HMM for modelling. A different feature extraction was proposed by Ariya Thongtawee et. al. [8] that would include different techniques like number of white pixels at the edge of the image, finger length from the centroid point, angle between fingers of first and last frame. This method exhaustively uses a very strong feature extraction algorithm to gain the idea of a gesture at the very approach possible. A different technique for feature extraction was proposed by M.M. Islam et. al. [9] that uses K-Convex Hull which has multiple complex algorithms which introduces due latency and computational complexities. A paper proposed vision based features extraction using kurtosis and PCA, by M.M. Zaki et. al. [10].The paper proposes the use of a 3D motion sensor which is a palm-sized Leap motion sensor which was then an economical option to Cyberglove or Microsoft Kinect & the features thus extracted were classified using K-NN and SVM. The depth image technology used by C.Dong et.al. in [12] uses depth comparison to extract features and a Random Forest as well as a constrained link angle algorithm to exactly classify the gesture into a finger spelling. Another visual based feature extraction technique that was used was SURF which is an Image Processing algorithm, was proposed by C.M. Jin et. al. [13] for feature extraction which then was forwarded to SVM for classification. A different idea was proposed which converted sign language to text and speech, proposed by V.N.T. Truomg et. al. [14] was based on Haar-Cascade algorithm and pattern matching to classify the gesture. A dynamic Sign language detection technique based on Sign Language Trajectory and Key Frame extraction [15] was proposed by Yufei Yan et. al. It uses Joint Point Weight Assignment of Hand Trajectory that helps in recognition of two hand gestures keeping a view that two points brings two different information at a time. Then DTW (Dynamic Time Warping) is used to classify the gestures. A further refined algorithm was proposed [16] by Murat Tskiran et. al. which converted the image from RGB to YCbCr space which was then forwarded to skin colour detection algorithm and then hand detection using K-convex hull algorithm. This method proves computationally intensive and then uses CNN to classify the gestures. A paper on Indian Sign Language [17] by Sajanraj T D et. al. proposed a technique called CLACHE for feature extraction. This led to extraction of Region of Interest and then using R-CNN, the gestures were classified. A very complex set of algorithms [18], proposed by Archana S. Ghotkar et. al. used HSV and YCbCr colour model, Haar-like features, adaptive skin colour model, location, angle, velocity & motion pattern P2-DHMMS which seems in itself quite tedious to achieve, puts a very complex combinations of algorithms with a requirement of heavy computation power. Use of CNN was done based on a simple Skin Segmentation and Image category classification is proposed in [19] by Shadman Shahriar et. al. which uses bounding box for feature extraction. Another proposal [20] by Helen Cooper et. al. was using the HOG, DTW & Kalman filters to extract features and then uses HMM and CNN which is quite simpler as compared to the previous mentioned algorithms.

In our approach, we propose a simple and yet an effective method of pixel level segmentation, which was the basic idea for using the model. The concept of semantic/instance based segmentation was thus a better solution and it could be understood by asking these questions to classify the approach into 4 major categories:

1. *Semantic Segmentation*:

Given an image, could we classify each pixel as belonging to a particular class?

2. *Classification+Localization:*

Could we also get the location of the said object in that image by drawing a bounding box around the object?

3. *Object Detection:*

In a real-world setting, we don't know how many objects are in the image beforehand. So can we detect all the objects in the image and draw bounding boxes around them?

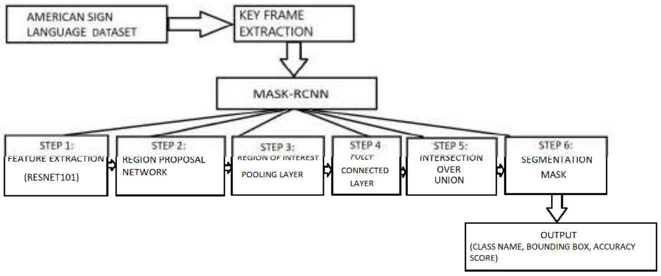
4. *Instance Segmentation:*

Can we create masks for each individual object in an image? It is different from semantic segmentation. How? Let's say we're looking at an image then we won't be able to distinguish between the two objects of the same class using semantic segmentation procedure as it would sort of merge both the objects together. We hence intend to do this pixel level segmentation by using a State-of-the-art(SOTA) instance based segmentation in a single architecture that throughputs a pixel level accuracy in detecting gestures. Our model gives a high accuracy output as the algorithm makes sure that we not only have a classification of the object of interest with a bounding box but also an instance based segmentation of the image. The dataset used for our approach is the American Sign

Language Lexicon Video Dataset designed by Stan Sclaroff, Carol Neidle, Vassilis Athitsos, J.Nash, A.Stefan, Q.Yuan, A.Thangalli [21]. In the consequent sections, we will map out a step by step procedure and the workings of our architecture.

II. MATERIALS AND METHODS

The detailed model architecture and its procedure are given as follows:



AMERICAN SIGN LANGUAGE DATASET
KEY FRAME EXTRACTION
MASK-RCNN
STEP 1: FEATURE EXTRACTION (RESNET101)
STEP 2: REGION PROPOSAL NETWORK
STEP 3: REGION OF INTEREST POOLING LAYER
STEP 4 FULLY CONNECTED LAYER
STEP 5: INTERSECTION OVER UNION
STEP 6: SEGMENTATION MASK
OUTPUT (CLASS NAME, BOUNDING BOX, ACCURACY SCORE)

Fig.1 Model Architecture

A. *Data Acquisition and Pre-processing*

American Sign Language Lexicon Video[24] data was leveraged for building the model. The dataset used here was in a video (.mov) format, which contains over 3300 signs, each sign represented from a different angle. Some of the lingual annotations included in the dataset are the start and end times of a sign, start and end hand labels, etc. For supporting computer vision tasks and recognition of sign languages, the dataset had numeric IDs for every sign, and every sign is represented in a video sequence with a calibrated camera. Out of the total set of gestures, forty distinct gestures were used to train the model using a total of 667 images, out of which model was trained on 551 images and tested the model on 116 images. All images were extracted to a size of 640*480 pixels since the movements were distinctive enough for this particular pixel size. Using a reasonable pixel size also helped in a faster training procedure with reduced computational complexity.

B. *Key-Frame Extraction*

C. *Mask RCNN Model*

Mask RCNN algorithm has been leveraged for building the model. Features extraction, classification, instance based segmentation is a part of single architecture. Mask RCNN is a widely used Computer Vision algorithm classified as State-of-the-art model for object detection on providing maximum accuracy while at the same time providing pixel level accuracy. The Mask-RCNN model, built on the top of ResNet101 architecture, feeds on images provided by Key-Frame

Key Frame Extraction algorithm was used as a data pre-processing step which generates unique key frames from the American Sign Language dataset that was pre-recorded.[22]. The fact that the Key frame extraction algorithm was used was that it was a pre-processing step, it helped us segregate only the frames of interest and it helped us speed up the process of frame retrieval. Key frame extraction played a pivotal role in order to process real time videos which added up to the efficiency of our model architecture. The following steps detail the Key Frame Extraction algorithm:

Step 1:

To find the difference between two consecutive frames in terms of edges so as to find significantly different frames that define different action

For each video frame k = 1 to N

- Read frame Vk and Vk+1
- Obtain the gray level image for Vk and Vk+1
  - Gk = Gray image of Vk
  - Gk +1 = Gray image of Vk +1
- Find the edge difference between Gk and Gk + 1 using the Canny edge detector.
  - Let diff(k) be their difference.
  - dif(k) = summation of i,j (Gk - Gk + 1) where i, j are row and column index.

Step 2:

Compute the mean and standard deviation

Step 3:

Compute the threshold value

- Threshold = M + a*S , where a = constant

Step 4:

Find the key frames for k = 1 to (N-1)

- If diff(k) > Threshold then,
- Write frame Vk +1 as the output key-frame

extraction, and serves as the core algorithm for our model architecture. Although this algorithm was computationally intensive, the underlying working of being highly selective in choosing the features right from the first stage provided a headway in accuracy and a trade-off to higher resource usage while at the same time solved the problem for vanishing gradients.

Once major features were found having high probable objects within, these were brought on a uniform scale by means of ROI pooling and then further classified into the gesture list available beforehand along with position of the hands. This was refined via IoU to extract even richer images and finally giving the rich extracted images to the segmentation mask in order to throughput an instance based segmentation. This gave the model a high accuracy output as the Mask RCNN model went through a series of steps in order to make sure that classification of the object with a bounding box as well as instance based segmentation of the image.

The workflow of the Mask RCNN model is as follows: -

1. *Feature Extraction*

ResNet (Residual Networks), a classic neural network algorithm, a winner of the ImageNet challenge held in 2015 was used as a backbone for our project. It allowed training on extremely deep neural networks while being able to efficiently solve the problem of vanishing gradient at the same time. It has 101 blocks in it, each block contains a convolution layer, activation layer as Relu, followed by a convolution with a skip connection as the latter adds input directly to the output of the previous convolution layer which is commonly known as a *'Residual Block'*. With Python and Keras library, the Resnet101 architecture which was readily available in pre-trained mode was implemented for creation of the model

2. *Region Proposal Network*

It was basically used to determine whether a specific region has an object in it or not, if it did not find an object in certain features, it eliminated those features and considered only the features which hadan object in it. It returned the candidate bounding boxes.

3. *Region of Interest*

Region of Interest was found in order to extract even more richness to the existing image. Region of interest determined how an image could contain a specific region with more information in them. The region obtained from RPN was of different sizes, thus pooling layers was used to bring them to the same size.

4. *Fully Connected Layer*

These regions were forwarded to a Fully Connected layer to predict the bounding boxes and class labels.

5. *Intersection Over Union*

For all the predicted regions, we computed the intersection/union (intersection over union). Condition: If IoU is >= 0.5, then consider the region as ROI & if not, then exclude the region.

6. *Segmentation Mask*

Once the ROI was found w.r.t. the IoU values, we added a mask branch to the existing architecture. This gave the segmentation mask for each region that contained an object (element wise segmentation). It also returned a mask of size 28*28 for each region which was then scaled up for inference. This was the final step, which gave a class label of the gesture in an image, a bounding box around the gesture in that image, and an instance based segmentation of the objects in that image.

III. RESULTS

Training losses and validation loss is shown below that explains the model's losses which is inclusive of the bounding box loss as well as the classification loss that gives an idea about how the losses are improvised.

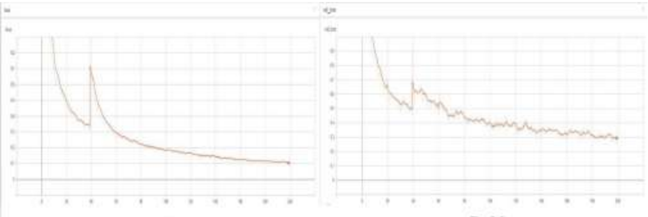


Fig. 2.1

Fig. 2.2

Fig.2.1 is the plot of training loss whereas Fig. 2.2 is the validation loss. The losses graph is loss vs. epoch graph

SGD(Stochastic Gradient Descent) was the optimizer in use because it has faster convergence as compared to adam or other optimizers due to the fact that a paper[26] claims the following — "We observe that the solutions found by adaptive methods generalize worse (often significantly worse) than SGD, even when these solutions have better training performance. Again gradient clipping is used to reduce any issues of exploding gradient.

To ensure the model does not overfit there were some different strategies which were used. One basic strategy was to use weight decay regularizer[25] achieving then state-of-the-art results reported:

"…and weight decay of 0.0005. We found that this small amount of weight decay was important for the model to learn. In other words, weight decay here is not merely a regularizer: it reduces the model's training error"

In terms of hyperparameter tuning the model used was pre-trained on COCO-dataset hence the model was tuned on few hyperparameters which included learning rate & weight decay. For the purpose of optimization the learning rate was tuned from 0.01 to 0.0001 whereas for the purpose of regularization the weight decay was tuned from 0.01 to 0.001. All the hyperparameters tuned where tuned specifically for this use case and are the result of experimental tuning to improve the results.

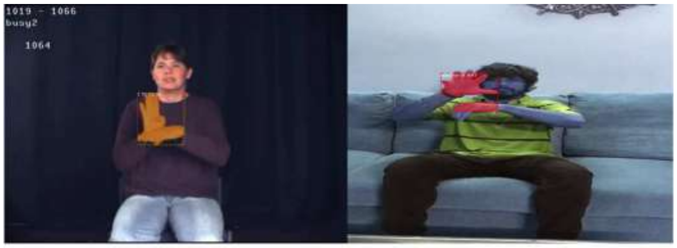

Fig. 3.1 Fig. 3.2

Fig.3.1 is from the validation set which informs us about the validation score of the model and in order to test if the model works accurately with different lighting conditions and orientation. in Fig. 3.2. we tested the model by having a person perform the sign language, in this case 'Advise'.

The basic evaluation procedure of any Object Detection(Semantic Segmentation as well) model proceeds with a term known as mAP(mean Average Precision). The reason behind using this was because Object Detection was localizing multiple objects in a single image. In order to calculate how each object was identified in each image as well as how near to real description the prediction was, this was not used. As per the use case, the majority of the signs were single handed signs which is why the concept of object detection stood redundant. Hence, the idea was to use the same metric of Object Localization which is IoU but averaging over all the images IoU's helped in detecting how good is the performance of the model on the entire validation set, hence introduced average IoU. An average IoU of ~95% was achieved on the train set whereas ~90% was achieved on the validation set

IV. DISCUSSION AND CONCLUSION

Algorithms used before like Skin Detection Algorithm: Skin Region Detection, Feature Extraction: K-Convex Hull Algorithm, Classification: Convolutional Neural Network are not used in place of Key-Frame extraction because former mentioned techniques had multiple disadvantages. Skin Detection Algorithm would not intelligently detect skin regions according to dynamic lighting conditions and was only as good as it is trained. The other, otherwise widely used, K Convex Hull Algorithm suffered from slow recursion, overhead of the repeated subroutine calls, required excessive memory for storing intermediate results of sub- convex hulls, unable to control and guarantee sub-problem size resulting in sub-optimum worst-case time performance. Also the underlying 'Divide and Conquer' algorithm was not ideal if the points to be considered were too close to each other. Instead the Key-Frame extraction algorithm retained information with lesser images and was independent of the input condition like light, skin region, cloth color etc. which were all taken care of as these would remain the same through the gesture hence these would sbe summarily neglected for extracting the features.

The Mask R-CNN takes care of various steps inside its architecture all the way from extracting features in the first step, determining if that extracted feature consists of an object or not in the second step in order to ensure that only those features with objects in it are processed for the next step and then it brings all the features consisting of objects to the same size in the third step by using Region of Interest pooling layer and further classifying the image with a bounding box in the fourth step. It then passes on the classified images along with their bounding boxes to intersection over union to extract instance based segmentation.

To prepare the training data quickly, A better tool is required for automating the frame annotation process, which if fed with initial geometry of a target object, may decide what possible shapes the target object can have, i.e. for fingers, gaps (hull) between the fingers having relation between their lengths/breadth and with that of palm as given, then the auto-annotation will correctly contour the hands in any posture and can give additional output of hand rotation angles which may serve as additional input feature.

The first version of our model detects ASL from recorded video as real time video could not be processed due to technical constraints like limited GPU, free memory on Google Colab. Also its code intensive being on TensorFlow 1.0x platform. VMWares give us sufficient access to resources but even that has certain limits. YOLO can be tried in place of Mask-RCNN provided the constraints are met.

Since the project does not serve the masses, getting investors to up-scale the project can get tricky. However, the promising nature of the project can rope in players soon if a solution which integrates a full end to end product comes up which has a well-designed, user-friendly interface and runs on slower hardware and can work even without internet connection.

An attempt can be made to train the model on a Mobile NET architecture with the features learnt from the current model. The new Mobile app size model will do the same task. Secondly a bi-directional LSTM model can be built to frame multiple gestures into a grammatically correct sentence which then can be converted to speech and in another form as per the customer requirement – this will increase the business scope of the model and its application.

***Abstract*--This paper presents a solution to Traffic monitoring and analysis at Indian toll plazas. In some of the areas, the work is done on Vehicle detection and localization, vehicle registration detection, and character recognition and vehicle make classifier (Currently concentrated on Indian Cars only). Accurate detecting and localizing of objects in computer vision has always been a core problem, to the rescue of which Tensor Flow Object detection API comes with implementations provided by RCNN family (Basic RCNN, Fast RCNN, and Faster RCNN) and Single-shot detection models. Experimenting over a range of models from Faster RCNN with inception v2, SSD MobileNet, and SSD inception v2 for vehicle and vehicle registration number detection problem we got higher accuracy with Faster RCNN with inception v2 for RMS Prop optimizer. For the detected vehicle registration number, we used an SVM-based multiclass classifier. A custom image dataset is used to train the model. The vehicle make classifier is implemented with VGG16 and the dataset was selected to contain only Indian cars.**

Keywords—Vehicle Detection, Vehicle registration number, Faster RCNN, VGG16 and SVM

I. Introduction

India has a huge web of highways all over the country connecting cities and states together. Road transportation being the most widely used mode of commuting and transporting goods from one city or state to other city and state. A need of monitoring and analysis of traffic at Indian roads is of paramount importance to civil and military surveillance for use of development and security-based decisions. Also, the derived insights could be a source of input to help find solutions to wide variety of problems a commuter face.

Indian traffic at toll plazas is very complex and critical with a diversified volume of vehicles likes of bikes, cars, trucks, and buses running on road at any given time of the day. Causes a wide variety problem of which congestion being most common on Indian toll plazas. The maintenance of these highways is very important to keep the connectivity intact.

Toll Plazas or toll booths are special counters build on highways to collect tax from the general population using the highway for commuting. This tax is basically to retrieve the cost to build and maintain the highway. So, it a usual scenario of getting a huge congestion of traffic where everybody is lined up to pay the taxes before they move ahead.

As a result of these congestion, it not only causes delays to commuters but also adds to loss of fuel and productive time. On a larger scale to observe the impact can be as large as impacting the economy negatively. Also, the kind of pollution caused in scenarios of traffic congestion is tremendous impacting environment.

II. Motivation of Work

Spending hours at toll plaza in heavy traffic is very common in India and people do complain of waiting long before they are able to pay and pass the toll booth. As per the toll rules of NHAI [1] there is a max of 3 minutes waiting period for every vehicle to be able to pay and pass the toll booth and if this time exceeds beyond 3 minutes due to congestion, delay by toll booth authority or any other similar reasons should be allowed a free passage without a fee.

A necessity of monitoring of the toll booth functioning and scenario identification of congestion help us find better solutions of several problems at toll booths.

III. Related Work

Our proposed solution targeted few of the milestones on which past work done. A vision-based vehicle identification system providing solution of object extraction [16], object tracking, occlusion detection and segmentation, and vehicle

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

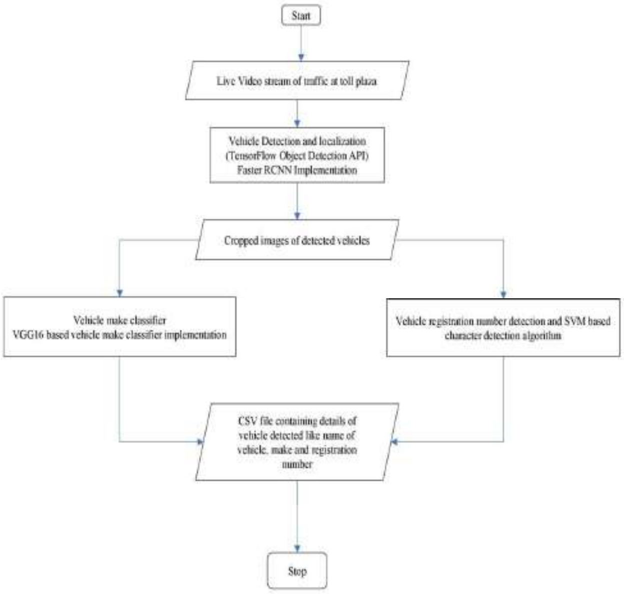
classification. In situations where vehicles on the road may occlude each other, their trajectories may merge or split and to handle this they developed three processes: occlusion detection, motion vector calibration, and motion field clustering. Finally, the segmented objects were classified into seven different categorized vehicles [2].

Object Detection solution based on TensorFlow's Object Detection API being a promising technique providing ability to build and deploy image recognition software. Object detection technique not only classifies and recognizes objects of interest in images but also localizes them and marks them with bounding boxed around them. Solution mostly focuses on detecting harmful objects like threatening objects for which they got Tensor flow Object Detection API to train model and have used Faster R-CNN algorithm for implementation [3].

Region-based convolutional neural network for real-time hand gesture recognition. A Faster region-based convolutional neural network (Faster-RCNN) with Inception V2 architecture was used. Their solution observed average precision, average recall, and F1- score by training the model with a learning rate of 0.0002 for Adaptive Moment Estimation (ADAM) and Momentum optimizer, 0.004 for RMSprop optimizer. A better result of precision recall and F1-score values were attained with ADAM optimization algorithm after evaluating over custom test data [5].

IV. Our Proposed system

Proposed solution is an integration of models trained to help achieve objectives like vehicle detection on live video streams, Vehicle counting, Vehicle model type classification and vehicle registration number detection.



Start
Live Video stream of traffic at toll plaza
Vehicle Detection and localization (TensorFlow Object Detection API) Faster RCNN Implementation
Cropped images of detected vehicles
Vehicle make classifier VGG16 based vehicle make classifier implementation
Vehicle registration number detection and SVM based character detection algorithm
CSV file containing details of vehicle detected like name of vehicle, make and registration number
Stop

Fig 1. Solution Workflow

The above figure shows the workflow followed in our solution. We started with detection and localization of our desired objects which are different types of vehicles and form distinguishing boundaries for the located objects into video frames and cropping the detected objects to be stored locally and used for further processing in outlaid milestones.

In Object Localization we detect where the object is situated, and Object detection involves detecting multiple objects in an image. In Object detection, we break down the original image into multiple images and perform Object Localization on each part. Extracted image parts are called ROI (Region of Interest) / Anchor Boxes/ Priors. To solve the problem of classification and regression (localization), we have different models which uses different approaches such as R-CNN uses 'Selective Search' to extract ROI's. Fast-RCNN also uses Selective Search but extract ROIs from Feature Map. Faster R-CNN uses Region Proposal Network (RPN) to extract ROIs and in SSD, we (humans) provide the ROIs using multiple grids and anchor boxes (or priors). Allow CNN to look at different ROIs to see if there is an object in the ROI and what is their bounding box.

Constructing a true Deep Learning model with ability to precisely localize and detect multiple objects in same image is always a core challenge with traditional computer vision and hence TensorFlow Object detection API an open-source solution built on top of TensorFlow makes it bit easy to construct, train and deploy Object detection models. So, for object detection we used TensorFlow Object detection API's one of the powerful tools to help us achieve the objective detection milestone and use algorithm for implementation.

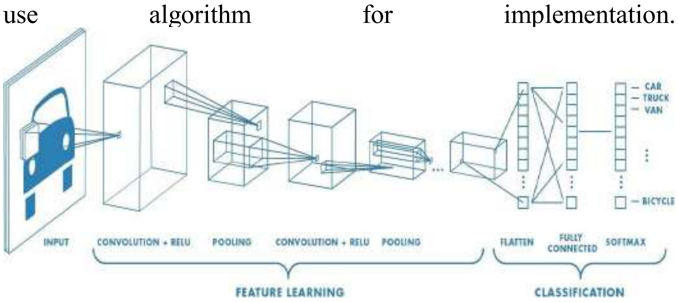


Fig 2. CNN Architecture

Input image applied with a layers of convolution layers (with RELU activation function) Max pooling layer to concise the derived feature maps by extracting the max values of the feature map values to concentrate on the main features of detected objects. The output of pooling layer then flattened feature map then passed through fully connected Neural network layers. SoftMax activation enables to do multi-class classification.

For the detected vehicles in multiple video frames using Faster RCNN implementation it became a challenge to monitor the moving vehicles and hence we applied a naming logic to address the detected objects and monitor them in subsequent frames. A combination of location directory, a counter to track number of cropped images, class index id, class index name and object id were used as components to form a name for the detected vehicles.

A unique object id talked about is derived via Centroid tracking algorithm are given in the derived name space which is then saved in csv format and finally merging all csv for detailed analysis. such as counting number of vehicles etc. Centroid tracking algorithm relies on the Euclidean distance between:

- Existing object centroids (i.e., objects the centroid tracker has already seen before).
- New object centroids between subsequent frames in a video.

Further to the processing in the solution the detected vehicles with bounding boxes are cropped and used for vehicle make classification and vehicle registration number detection. K. Simonyan and A. Zisserman [4] from the University of Oxford in the paper "Very Deep Convolutional Networks for Large-Scale Image Recognition" proposed VGG16 convolutional neural network. We used VGG16 based image classifier for identifying the make of detected vehicles in first stage of our system.

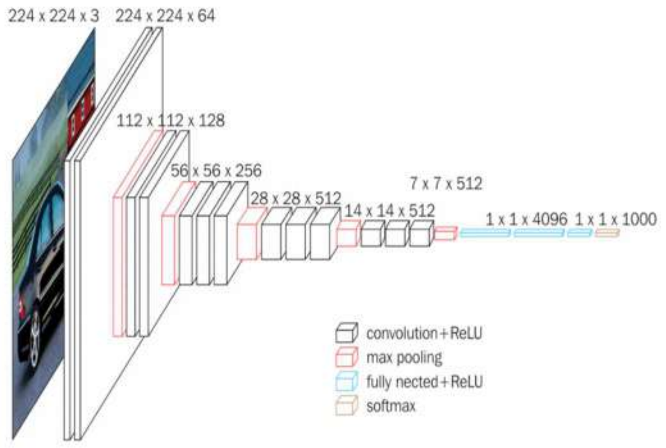

Fig 3. VGG16 CNN

The same cropped image of object detection stage of our system was used as an input for vehicle registration number detection. A background subtraction achieved with Otsu Thresholding. Background subtracted Images were then subjected to segmentation where each character was further predicted with an SVM based character recognition algorithm.

Histogram
Global Thresholding (v=127)
Original Numper Plate Ima
Histogram
Otsu's Thresholding
Gaussian filtered Image
Histogram
Gaussian + Otsu's Thresholding

Fig 4. Background Subtraction (Otsu Thresholding)

Finally, the output of all these models is clubbed to form a CSV file with insights like Vehicle counts, Vehicle registration number, Vehicle make classification description along with timestamp showing the date and time. This insight then redirected over dashboard for live monitoring and further analysis.

With all the data collected via the above workflow can be conducted to help in different domains of interest.

- Traffic inflow at toll plazas to extract busiest day, week of the month, busies hour of the day etc.
- Toll collections stats and each vehicle service time monitoring.
- Security insights with Vehicle registration number detection and vehicle model type detection.

V. Algorithms

A. SVM based Character Recognition

The hypothesis function h is defined as:

$$h(x_i) = \begin{cases} +1 & if\ w.x+b\geq 0 \\ -1 & if\ w.x+\ b<0 \end{cases} \qquad (1)$$

The point above or on the hyperplane will be classified as class +1, and the point below the hyperplane will be classified as class -1. Computing the (soft margin) SVM classifier amounts to minimizing an expression of the form,

$$\left[\frac{1}{n}\sum_{i=1}^{n} max\left(0,1-y_i(w.x_i-b)\right)\right]+\lambda\left|\left|w\right|\right|^2 \qquad (2)$$

We focus on the soft-margin classifier since choosing a sufficiently small value for lambda yields the hard-margin classifier for linearly classifiable input data.

B. Faster R-CNN

Replaces the selective search method with region proposal network (RPN) which makes the algorithm faster time/Image – 0.2 second.

$$\text{IoU} = \frac{\text{Anchor} \cap \text{GroundTruth}}{\text{Anchor} \cup \text{GroundTruth}} \qquad (3)$$

$$\text{IoU} = \frac{\text{A} \cap \text{Gt}}{\text{A} \cup \text{Gt}} \begin{cases} > 0.5 = \text{Object} \\ < 0.5 = \text{No Object} \end{cases} \qquad (4)$$

Computing the Intersection over Union is dividing the area of overlap between the bounding boxes by the area of union.

In the numerator we compute the *area of overlap* between the *predicted* bounding box and the *ground-truth* bounding box. We are keeping the threshold value of 0.5.

The denominator is the *area of union*, or more simply, the area encompassed by *both* the predicted bounding box and the ground-truth bounding box.

Dividing the area of overlap by the area of union yields our final score — *the Intersection over Union.*

$$\text{IoU} = \frac{\text{A} \ \cap \text{Gt}}{\text{A} \ \cup \text{Gt}} \begin{cases} > 0.5 = \text{Object} \\ < 0.5 = \text{No Object} \end{cases}$$

VI. System Environment setup

A. Hardware

TABLE.1. HARDWARE COMPARISON

Machine Type	CPU Processor	GPU	RAM	Clock speed
Machine 1 - Asus vivo book-max A541uv	Intel® Core TM i3 7100U	Nvidia 920MX	12GB	2.4GHz
Machine 2 - Acer Predator Helios 300	Intel® Hexacore Intel i7 9750	Nvidia RTX 2060	16GB	2.6Ghz

B. Dataset

TABLE.2. DATASET DETAILS

Models	Dataset	Train Images	Testing Images	Number of classes	images /classes
Vehicle detection Model	Google image dataset v4, Custom images	701	180	6	145 approx.
Vehicle registration number detection model	Google image dataset v4, Custom images	2000	376	1	2376
Vehicle Make classifier	Google Custom images using labelImg	689	272	17	60 approx.
SVM Character recognition (0-9 digits, 26 alphabets)	Google Custom images using labelImg	1260	180	36	40 per character

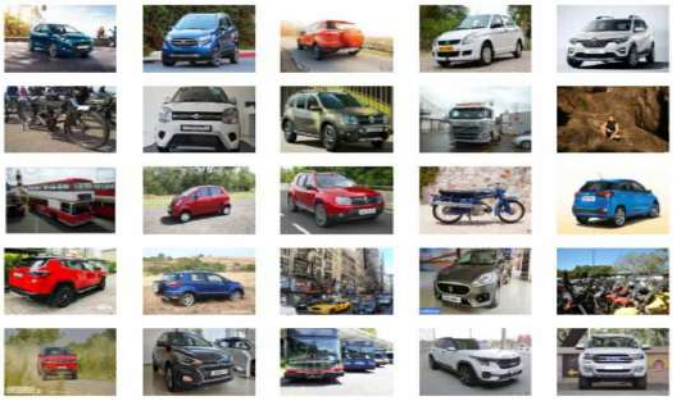

Fig 5. Actual dataset for Object detection and make classifier

These images for object detection were taken to ensure that they have the desired vehicle class covering major portion of the image with a wide variety of vehicle orientation like middle/close range in front of the camera, middle/close range in the left, close/middle range in the right, and far range to enable the model to learn better. The images sizes vary from 300*300 to 1000*1200 pixels. Several instances of a same vehicle are included with different bounding hypotheses. Also, few images of multiple classes like Car, Bus or Truck and person was included to enable the model to learn various weights from such perspective. We included around 120-150 images per class and the classes were – Car, Truck, Bus, Rickshaw, bike and Person.

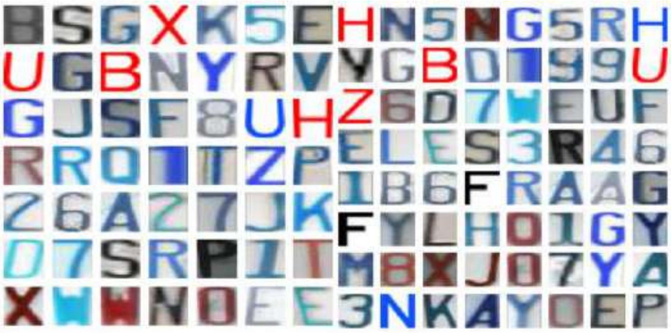

Fig 6. Character recognition dataset

For vehicle registration detection we used images with vehicle registration numbers covering the entire image size. To add diversity, we included Indian plus foreign registration number plates and multiline number plates to enable our model to learn them better. The selected images were of size 20*20 pixels for SVM based character recognition model.

At this moment our solution only considers the class Cars for Vehicle make classification for which we used google images of Indian car models like Honda Amaze, Hyundai i10, Suzuki Wagon R, Suzuki Swift etc. Images ranging from 300*300 to 1000*1200 pixels majorly coving the entire image size. The Cars were selected to have wide variety of vehicle orientation like middle/close range in front of the camera, middle/close range in the left, close/middle range in the right, and far range to enable the model learn better.

VII. Results & Discussion

A. False detection results

For vehicle registration detection the model detected the flashlights as vehicle registration number.

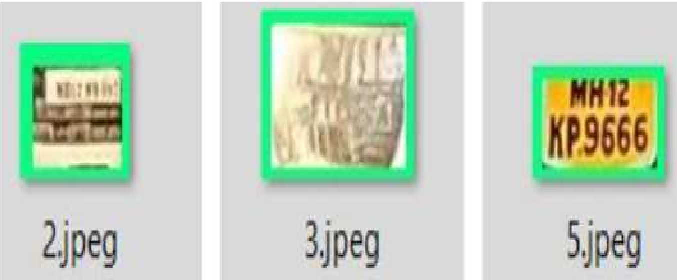

Fig 7. False detection of vehicle registration number

B. Results of Evaluation

For object detection we use the concept of **Intersection over Union** (IoU). IoU a Jaccard index-based computes intersection over the union of the two bounding boxes; the bounding box for the ground truth and the predicted bounding box. So, a value of 1 would be perfect overlap.

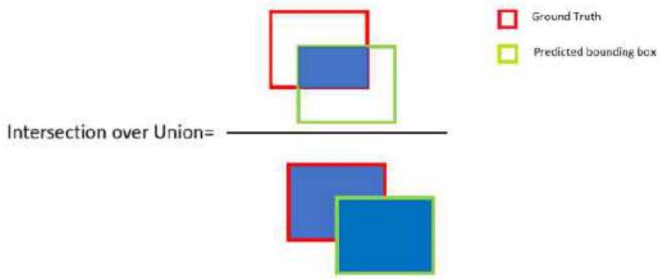

Fig 8. Intersection over Union

With a threshold value the prediction can be expressed as positive or negative. Let us say IoU threshold is set to 0.5, in that case:

- if IoU ≥ 0.5, classify the object detection as True Positive (TP).
- if IoU < 0.5, then it is a wrong detection and classify it as False Positive (FP).
- When a ground truth is present in the image and model failed to detect the object, classify it as False Negative (FN).
- True Negative (TN): TN is every part of the image where we did not predict an object. This metrics is not useful for object detection, hence we ignore TN.

Set IoU threshold value to 0.5 or greater. It can be set to 0.5, 0.75. 0.9 or 0.95 etc.

C. Losses

$$L(\{\text{pi}\},\{\text{ti}\}) = \frac{1}{N_{cls}}\sum_i L_{cls}(p_i,p_i^*) + \lambda\frac{1}{N_{reg}}\sum_i p_i^* L_{reg}(t_i,t_i^*) \qquad \textbf{(5)}$$

i *= index of an anchor box in an mini batch*
pi *= probability of object being present in given ith index anchor box predicted by model*
p*i *= object being present in given ith index anchor box specified in the Label (1= positive anchor, 0=negative anchor)*
ti *= predicted bounding box for object being present (only for positive anchor and do not care for negative anchor)*
t*i *= ground truth of bounding box for ith positive anchor*
Lclassification *= classification loss for object present or not*
Lregression *= regression loss for bounding*
{pi} *= output of classification layers*
{ti} *= output of regression layers*

As referred in earlier section object detection deals with two objective viz classification and localization classification deals with whether object is present or not whose loss function is given by 1/Nclases * Lcalsification (pi,p*i) . Localization deals with regression loss given by λ 1/Nregression*Lregression(ti,t*i).Here , 1/Nclases and 1/Nregression is used to normalize and is weighted by a balancing parameter λ used for balancing the trade of between the two losses. Nclasses is equal to mini batch size here we have taken 64, normalized by the number of anchor locations (i.e., Nregression ~ 2, 400). Regression box losses are only calculated against the positive anchor boxes.

D. Final Model outcome

The trained models are tested over the test samples and their performance is evaluated for a few parameters such as precision, recall and IoU.

TABLE.3. EVALUATION METRICES

Objectives	**Models used**	**Metrices**		
		Avg. Precision	**Avg. Recal**	**Avg. F1 Score**
Object detection	FasterRCNN-InceptionV2	0.453	0.678	0.543
	SSD_MobileNet_V2	0.352	0.453	0.3961
	SSD_InceptionV2	0.384	0.461	0.418
Vehicle number plate detection	FasterRCNN-InceptionV2	0.749302	0.689	0.7177
Vehicle Model type detection	VGG16	0.481	0.514	0.496

VIII. CONCLUSIONS

While experimenting with a few models used for vehicle detection and vehicle registration number detection and make classifier the results observed as Faster RCNN with Inception v2 and VGG16 proved to having considerably better precision, recall and F1 scores and higher accuracy against other counterparts. Table 3 gives a tabular description of all the evaluation metrices.

Faster RCNN with inception v2 model is trained for 12000 epochs with momentum optimizer 0.09 and learning rate 0.00002.

Dhaka, Bangladesh
imtiaz@diit.edu.bd

***Abstract*—Algorithm is an efficient way to solve issues or minimizing efforts in an existing system by imposing new technique or rules on the existing system. Technology creates new platform or elements by which a vast majority of business growing and new idea or algorithm can be more effective if one can attain the algorithm on its system. Online e-commerce platform is increasing and due to COVID-19 the world has been mostly depending on it. Customer always expects fastest delivery when customer uses online platform and the eagerness of customer's expectation always impacts on online platform. In the thought of fastest delivery for the manufacturer or B2C oriented business a fastest shipping algorithm has been proposed where the algorithm will use the dataset of its existing system and will calculate the shortest path to find the nearest located outlets. It will gradually support the manufacturers or brands by identifying the nearest distance outlets for fastest delivery of products and at the same time it will minimize the efforts of work, time and cost.**

Keywords—Dataset based Algorithm, Dijkstra's Algorithm, E-commerce, B2C, Fastest shipping, Allocating nearest supplier.

I. Introduction

Strategies changes in accordance with the technological innovation where new methods always get the priority for solving critical situations. Algorithms are the way where the new possible solution for a problem can be stated. E-commerce business is developing rapidly and due to the COVID-19 people mostly depends on e-commerce. As people more depends on e-commerce so the shipping issues also arise at the same time. How to ship a product in the fastest way from the seller that are mostly identical issues nowadays for getting good reviews of the system.

Multiple sellers can sell the same product as the brand can allow multiple sellers but multiple sellers won't be in the same address or districts or states. Amazon is one of the top e-commerce platforms where multiple sellers can sell the same product as sellers have the authorization to sell the same product and for that, they normally get the approval from the brand and use the brand or manufacturer labelled UPC to list their items. Ali Express is another popular platform where the same products can be sold by multiple sellers.

A product price is distinct for all customers where the brand has rules to sell the same product. How a seller can understand how they will get the order as many of the seller using the same links and same prices. Sellers draft thinking is that they need to put discounts so that they can generate sales. Although sellers can think we can get sales by getting positive reviews and feedbacks. Algorithms will help the platform owner or the brand to find out who will ship the products and who will get the customer order.

Fastest shipping is one of the important factors to keep customers faith in e-commerce. In the fastest shipping way how a seller will be selected from the pool as multiple sellers selling the same products are the key concerns in this paper. As e-commerce has the priority of giving the opportunity to have multiple sellers to use the same platform and the same manufacturer or brand can have a different physical warehouse or showroom.

Algorithms implementation is a possible solution for the fastest shipping and allocating who will ship the products means from whom the product will be purchased. If one brand has multiple storefronts in different places and if the brand uses one e-commerce for its online platform then the algorithm will help them by defining from which place the product will be shipped. At the same time the algorithm if successfully implemented in software or in machine learning it will automatically predict the fastest warehouse or storefronts from where the fastest shipment is possible.

Building an efficient algorithm is necessary to sorting out these issues as it can help the platforms owner or brand owner to achieve more success in regards to the fastest shipment. The main aim of this paper is to create an algorithm which can be the best fit for both popular e-commerce platform like Amazon, Ali express, eBay etc. as well as for the manufacturer or brands. After implementing these algorithms they can have faith that their system or procedures offer the fastest shipment to their customers.

II. Background Analysis

An algorithm is a finite sequence of well-defined, computer-implementable instructions, typically to solve a class of problems or to perform a computation [1][2]. Algorithms are always used for giving solution for specific issues which can be implemented with any languages. It can be used for calculating, data processing, sorting complex problems etc. An algorithm can be expressed or can be executed in a finite set of time or space and it is a well-defined formal language [3].

Shipping collision issues for multiple shipments with four simulation schemas have been proposed [4]. Multiple researchers focus on how to design an effective model for the marine shipment procedure. A Morphing Evolutionary Algorithm has been proposed which will effectively subside the manual works and the performance improvement is 11.67% [5]. Shipping collision and manual works always delay the shipping performance and hence customer gets dissatisfied.

Consumers are the key to e-business and the fastest shipping is necessary to get the reliability or faith of consumers. Consumer adaption of online shipping a vital issue for study and consumers intention depends on it to buy online [6]. Consumer's faithfulness depends on the timely shipping or delivery of a product. For that many models have been imposed or proposed for the fastest delivery [7]. Shipping methods or timely shipping is a great key to become successful in the e-commerce sectors.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

In Amazon, a product can be sold by multiple sellers where they can use the same product links for selling [8]. A product of Amazon has been checked and finds the similarity that it has multiple sellers who are using the same product link for selling their products [9]. As multiple sellers use the same product link for selling their products so that an algorithm needs to identify which seller will get the priority for getting an order. The algorithm will help the platform owner to detect the identical and logical seller who will get the priority.

An observation has been taken into account of a renowned brand named "UGG". It has multiple stores in the USA and Canada where it uses the same online platform to get online sales and running its e-commerce sector [10]. UGG has multiple stores so that they can do the fastest shipment in the USA and Canada based on customer addresses. Definitely, an algorithm can help them find the fastest delivery to its customers so that no manual works needs to notify the outlets manually.

III. Gap or Current Methodology Analysis

Giant platforms like Amazon have their own recommendation or learning algorithms by which they can predict or assign sellers for a specific order. As multiple sellers sell the same product, they must have their own way to determine the sellers with some specific criterion. For brands or manufacturers who don't have any specific parameter to select the method for those, an algorithm can be introduced and by observing these issues a novel algorithm approach has come to a solution that others can implement on their portal.

UGG brands have many outlets in the USA but not in all the states [10]. New York, California, New Jersey etc. states have their outlets but Colorado State doesn't have their outlets. When a customer from Colorado states tries to purchase a product from them then it will be time-consuming for an admin to find the nearest outlets to ship that customer's product. In this parameter, if an algorithm can be implemented properly on its website like Amazon so that the manufacturer can easily notify the outlets that are located in the nearest state. After notifying the outlets will start shipping the product on their own and shipment will be fastest.

There is a number of consecutive ways to ship a product to the customer like by Air, by Parcel or Transport services. One can say that each state has its own Airports and Air shipment services then why should one need to implement the algorithms. The main focus of the proposed novel algorithm is to ship the products to the customer with less time and cost minimization on the shipping. Air shipment cost is pretty high but if the system with the implemented algorithm can show the nearest possible outlets with fewer charges and the fastest shipment then customers will be satisfied as well as the physical works will be reduced.

The manufacturer can have their own warehouse for the online orders, where they likely to keep all the products that they are intended to ship to the customers from online. Expenditure on the warehouse normally high and the shipment procedure from the same warehouse can rigorously follow the same rules like shipment time to consumers, shipment costs to consumers, return policies to the consumer etc. The approached algorithm can help the manufacturers to maximize their sales through each outlet and warehouse expenditure will be low and manpower will be less than in previous.

IV. Proposed Algorithm

UGG brand has a list of outlets in nineteen states in the USA [10] where the country has in total of 50 states [11] [12]. Customers from other states can use the UGG vendor website as a medium for their purchase and customers always expect to get the order as soonest as possible. It must be noted that customers from the same states where the stores are located can order through the portal as well and at that time customers order will directly check their state located outlets first.

In the proposal, a platform needs to be introduced or need to be implemented or if the manufacturer already has an online ERP (Enterprise resource planning) [13] software they can use it. Cloud inventory management software tool like the Finale Inventory software [14] can be used by the manufacturer or the manufacturer can build their own portal where they can easily locate which outlets has which products, colors or sizes. As the tool finale inventory has the features to obtain the store name for each different quantities or items [14] so that the manufacturer can easily locate and can grab their updated store database from the software each time when an order normally placed by the customer. Finale Inventory has the option to download the manufacturer's products product database and it's normally come as a CSV file [15].

Small manufacturers who are still in the development process can use the software for their products inventory, POS, accounting etc. and at the same time they can use the proposed algorithm for their fastest and automated tasks to assign outlets for shipping to the online customers. Manufacturers like UGG, Ray-ban, CK etc. can have their own tool but their tools need to have the product's location so that the products lookup database can be easily trained in the algorithm process. An important factor that needs to be noted that the finale inventory has the POS (Point of Sales) [16] so that when an item physically sold by the outlets the system will automatically deduct that quantity from their database so that the proposed system will always get the accurate score for pointing the exact outlets for the shipment process.

A. Datasets for the proposed Algorithm

The algorithm needs data for the successful operation and the structure of an algorithm depends on which data algorithm will work. For the proposed algorithm two datasets will be needed for the successful operation.

a) Imported Products Dataset

"Products imported dataset" can be imported from the ERP (Enterprise resource planning) software [13] or can be imported from the Finale Inventory web tools [15]. It must have the products name, style no, color name, sizes, availability, location of the product etc. The location of the product is mandatory as the outlet's names normally are used in this column. This dataset can be downloaded in a timely manner so that each time when order placed it will be automatically downloaded for utilizing through the system using the algorithm. The orientation of the dataset table can look like below where one product's secondary data has been listed in table I:

TABLE I.

Item ID	Style no#	Product Name	Color	Size	In stock	Location	State Name
120001	1016222	CLASSIC MINI II BOOT	Black	7 US	10	Citadel, Tanger	California
120001	1016222	CLASSIC MINI II BOOT	Black	7 US	5	Orlando	Florida
120001	1016222	CLASSIC MINI II BOOT	Black	7 US	2	Riverhead	New York
120002	1016222	CLASSIC MINI II BOOT	Black	8 US	10	Chicago	Illinois
120002	1016222	CLASSIC MINI II BOOT	Black	8 US	5	Premium	Nevada
120003	1016222	CLASSIC MINI II BOOT	Chestnut	7 US	2	Seattle	Washington

TABLE II.

State name	California	Connecticut	Florida	Georgia	Hawaii	Illinois	.....	N^{19th}
Alabama	1381.45	1851.01	7910.78	10661.75	7655.61	1252.03	....	-
Alaska	909.83	1057.84	9057.76	9380.39	7545.86	474.66	....	-
Arizona	1614.01	2035.94	8372.03	10680.27	7137.65	977.77	....	-
Arkansas	1808.23	2139.70	8970.02	10438.87	6691.20	715.39	....	-
California	1	478.82	8317.62	9320.27	8411.70	1273.96	....	-
Colorado	2452.26	2724.71	9529.71	10547.76	5992.89	1216.34	....	-
…..	....	....	....	....	....	....	....	-
N^{50th}	-	-	-	-	-	-	-	-

The products name on the website must be the same as the system software has. The table above has the product that is used as an example of the product table dataset [17]. Two different outlet's names have been addressed in the table to give an explanation that those outlets have the same product but they can have quantities in a random order like Citadel has 7pcs and Tanger has 3pcs. When any of those outlets have been sold out then one outlet name will show in the location column. It has been also noted that when an online order comes to an outlet then the outlet will deduct the order quantity from that outlet's POS in-stock quantities. The idea behind the above table is mostly appropriated with the Finale Inventory Software [15] as the dataset of the software are same. If any state outlets don’t have quantities for a specific product it won't show available in this dataset whether if other state outlets have products for the same product then their available stock will show in the dataset.

b) Dataset of distance from each state

Each of the states has a specific distance from the other states in the same country and very rarely the distance from each other matches exactly. But each state contains a number of cities, where the cities have different distances between each other. In this paper, the distance between the states only measured and the dataset has been prepared to have one(1km) distance when the distance of the same state will be calculated. Let's say "X" state distance from the 'X" state distance is one(1km). One can put the distance from the same state as zero (0km) but if one wants to train the dataset to different AI or Machine Learning algorithms then value one (1km) will be good for finding the shortest path. The dataset table will contain 19 states name on the column and on the row, there will be 50 states name. As the manufacturer UGG has outlets in 19 different states in the USA [10] and the country USA has in total 50 states [11][12]. Distance from each state is calculated in kilometers (km) and the distance was found from the web portal named "Distance from to" [18].

B. Algorithm

- Order id and the details of the order will be acknowledged
- From the order the "customer's lived state name" and "item/product id" will be picked out
- Whether the customer's state name matches with any of the states that are on the 1st column of the dataset of distance from each state which must be checked
- If the customer state name matches with the state name that is on the dataset of distance from each state, then an array will be created for the shortest path order to each state from the customer state name by using the "Dijkstra's algorithm" which will use the dataset of distance from each state.
- It will check whether the located nearest state has the ordered product id or not by checking the in-stock quantity column of the dataset of imported products.
- If the located state outlet has quantities of the ordered item/product id, then the outlet will be notified and an order will be placed for that outlet.

If more than one store located in that state outlet has the same product then it will randomly choose one outlet from the imported products datasets where normally the outlet names are listed.

- If the mapped state doesn't have the product id or quantities, then it will look into the shortest path state array for the next state name and will move to step 4.
- If the state name doesn't match with the 1st column of the dataset of distance from each state then it will be marked as an international address and the international shipping team will be notified.

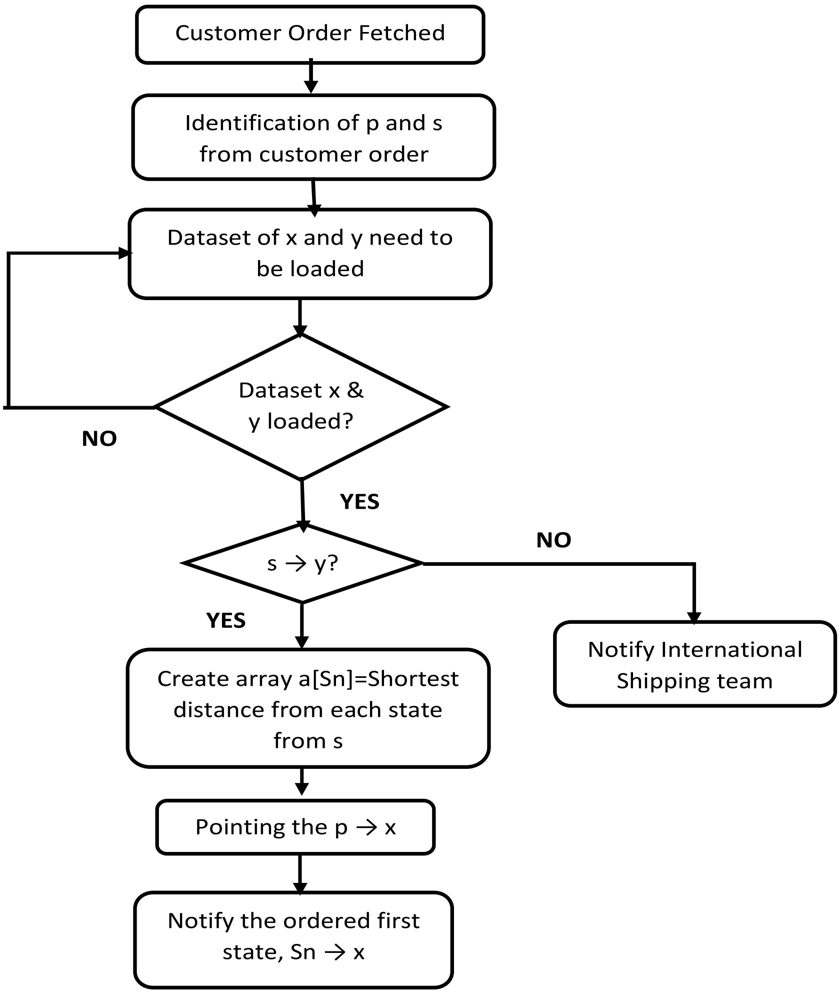
C. Pseudocode

The Pseudocode of the proposed algorithm are listed below:
Let's say the order dataset has the below properties,

```
Customer Order Dataset {
    Customer-name ();
    Customer-address ();
    Product details ();
    Paid amount ();
}
Let's take,
Imported Product dataset = x;
Dataset of Distance from each state = y;
State name from customer-address () = s;
Item-id from customer ordered product details () = p;
s ←customer-address ();
p ← product-details ();
algorithm (x, y) {
    If {
        s → y;
        For each state in y, create the ordered shortest path array from s using Dijkstra's Algorithm:
        a = [Sn]
        for each state Sn of a[Sn]:
            p → x;
            notify the ordered first Sn →x;
    }
    else{
        notify the international shipping team.
    }
}
```

D. Flowchart

The flowchart of the proposed algorithm are given below:



Customer Order Fetched
Identification of p and s from customer order
Dataset of x and y need to be loaded
Dataset x & y loaded?
NO
YES
s → y?
NO
YES
Create array a[Sn]=Shortest distance from each state from s
Notify International Shipping team
Pointing the p → x
Notify the ordered first state, Sn → x

Fig. 1. Flowchart of the proposed algorithm

V. The complexity of the Proposed Algorithm

The proposed algorithm has complexity in some criterion as it depends on the dataset that needs to be fetched by the algorithm. Some of the errors that one can face when trying with the algorithm are listed below:

A. *Outlet allocation*

By observing the dataset of imported products, it shows that one specific state's multiple outlets can have the same product and there are not any specifications on how many quantities each outlet owns. For this issue, the outlets will be chosen randomly but if a customer order a big amount like 10pcs but the one state's none of the outlets has that amount of quantity, then there will be bugs. The algorithm will be well suited for customers like Amazon where normally a customer doesn't order more than 2-3pcs at a time.

B. *Multiple items of an Order*

A customer placed an order which has multiple items like the customer ordered a shoe and a top. The algorithm can solve the multiple items of that order by taking each of the ordered item id's at once to use them through the algorithm. But still, there is one order id for that order so that multiple different outlets will be notified for the same order. As the algorithm needs to do the same tasks twice so that it will be time-consuming as well.

C. *Cloud Service*

The algorithm will work when an order will be placed on the website or in the system so that from the ordered data the algorithm will start manipulating to identify the potential outlets for shipping the order. Cloud server needs to use for the ideal operation of the algorithm. One can do that in their desktop system but for the fastest manipulation cloud will be much better.

D. *Dataset Loading Issues*

The algorithm mainly depends on two specific datasets, those are the "imported products dataset" and "the dataset of distance from each state". The dataset of distance from each state can be loaded once as this dataset won't having any changes but the "imported products dataset" always changed in a manner that the outlet's physical sales will be deducted and new items can be adjusted to the outlets so that if dataset won't be loaded properly every time then wrong outlet's will be notified.

VI. Open Challenges

The proposed algorithm has built with the idea for fastest shipping to the consumers when a manufacturer can use the same website for selling its products where there can be a number of outlets in different states in a country. It will be very identical if one manufacturer can implement this algorithm to their web portal where a cloud server will be the most appropriate for executing the algorithm. Though it has some limitation or challenges for implementing or issuing the algorithm, it will be good for practicing the algorithm and necessary steps can be taken when facing more issues or the issues that listed in this paper. The machine learning approach will be the best fit for the proposed algorithm, as the idea behind the algorithm has the initialization to work with two specific datasets. Machine learning techniques will be a challenge to implement and if someone can build any other edition for this algorithm, it will be taken into account. As the algorithm proposed by observing the complexity, cost, time for a manufacturer for running an e-commerce portal, more new features can be taken into account for more effectiveness of the proposed algorithm.

VII. Conclusion

The goal of the algorithm normally minimizes the tasks or time that take earlier a good amount of time and algorithm performs or normally creates for some specific issues. In this paper the algorithm that proposed are created mainly for the B2C platforms where a manufacturer can easily flourish their online business by allocating different owned outlets for the shipping. Customer always wait for the products arrival and in that circumstance the algorithm will find the shortest distance outlets and that allocated outlets will be the candidate for shipping the products if only it has the available stock. By implementing the proposed algorithm manufacturer won't then have to think for the physical warehouse for keeping the online orders quantities and it will help them by minimizing the cost and time. As outlet's person can do the shipment and can maintain the whole system so that manpower will be less. The manufacturer can also notice how their physical outlets sales and how much outlets have in stock so that supply chain management will be more accurately.

***Abstract*— Our study aims to predict the requirement of isolation beds, oxygen beds, and Intensive Care Unit (ICU) beds in both government and private hospitals for COVID-19 patients in Telangana, India. Using epidemic modeling and time series analysis techniques, we can predict the future daily COVID-19 cases and active cases from historical data of confirmed COVID-19 cases. From the historical data analysis, we can also establish the pattern of hospitalized cases from active cases and also the pattern of various categories of bed occupancy numbers. The pattern is represented by minimum, maximum and average percentages. We have observed the second wave of COVID-19 in many European countries and is spreading more rapidly than the first wave. In India, we must be prepared to address the second wave as it might be more rampant since the lockdown is eased in most of the cities. Since traveling and gatherings are getting back to normal, significantly larger population might be susceptible and would need immediate hospitalization. We presented a process/methodology to estimate bed occupancy numbers from the prediction of COVID-19 positive and active cases using modified Susceptible-Infected-Recovered (SIR) model for the contagion and FB-Prophet model for time series analysis. We used official data from the Government of Telangana bulletins for the COVID-19 pandemic up to December 31st, 2020 for our process/methodology. SIR modeling is more intuitive and explainable but requires a lot of trial and error and assumptions. The FB-Prophet prediction process is simple and accuracy is also better compared to SIR modeling.**

I. INTRODUCTION

COVID-19 is an infectious disease known to cause severe acute respiratory syndrome Coronavirus 2 (SARS-CoV-2). The World Health Organization (WHO) has declared the novel Coronavirus (COVID-19) as a global pandemic on 11th March 2020.

In India, the first positive case of COVID-19 was detected on 30th January 2020, in Kerala. The Government of India implemented a complete nationwide lockdown on 24th March 2020 for 21 days, and was continued until 31st May 2020 [12]. The purpose of the nationwide lockdown was to contain the spread of the COVID-19 disease so that the Government could scale up the production of the testing kits for COVID-19 and personal protection equipment (PPE) for the health workers and build extended health infrastructure to accommodate more COVID-19 patients [1][6]. On 3rd June, in India, 952 dedicated COVID hospitals with 1,66,332 Isolation beds, 21, 393 ICU beds, and 72,762 Oxygen supported beds were available. 2,391 dedicated COVID Health Centers with 1,34,945 Isolation beds; 11,027 ICU beds and 46,875 Oxygen supported beds have been operationalized [1].

In the state of Telangana, the first positive case of COVID-19 was detected on 5th March, 2020. As on 11th January 2021, the total positive cases in Telangana are 2,90,008 wherein 60.64% of males and 39.37% of females were affected. There are 281 dedicated COVID hospitals consisting of 4,330 ICU beds and 8,428 Oxygen beds [7].

By now, the world has been made aware of the impact COVID-19 had on the societies and their healthcare systems. Already at the start of the first wave of the pandemic, it became apparent that the capacity of hospital beds could come under great pressure. The morbidity of COVID-19 drastically increased the demand for hospital beds.

Disasters typically come with a sudden influx of unforeseen patients, which almost instantly pushes the boundaries of a hospital's capacity. Lack of bed capacity further increases that burden [2][3][4].

In order to prevent such overflow, in India, on 24th March 2020, a strict lockdown was imposed due to COVID-19 wherein there were only 519 confirmed cases across the country. After 53 days of nationwide lockdown, on 16th May 2020, the confirmed cases shot up to 85,950 in India [13]. In this timeframe, it was observed that the growth rate of the cases had slowed down by 6th April, to the rate doubling every 6 days, and by 18th April [15], to a rate doubling every 8 days. Lockdown 2.0 was imposed between 15th April 2020 till 3rd May 2020. During Lockdown 3.0 and 4.0 until 30th May 2020, the Government segregated all the districts into three zones based on the spread of the virus- green, red and

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

orange - with applied relaxations [13]. Due to this nationwide lockdown over a period of time by means of quarantine, social distancing, hand washing, closure of educational institutions, curfews, wearing a mask etc, the influx in hospitals had decreased comparatively. On 30th May 2020, the Government announced that the lockdown would be lifted from then on, except for the containment zones wherein the lockdown continued till 30th June 2020. From 1st June 2020 till 31st January 2021, there were 8 unlock measures imposed each month which were focused on how restrictions should be eased in a phased manner.

A fragile equilibrium needs to be found between reserving a sufficient number of beds for COVID-19 cases, while also providing sufficient beds for regular, necessary care which cannot be delayed. In order to achieve such balance, predictive models can play an important role, to predict the number of needed beds that should be allocated to the pandemic. We therefore set up forecasting models to predict on each day the needed capacity for different bed types using cases and beds data of Telangana State from Aug 2020 to Nov 2020.

II. MATERIAL

The data is obtained from Telangana Covid19 Healthcare Bulletins [7] from Telangana Government’s website. The daily bulletins available from 1st August, 2020 onwards have information about the number of daily positive cases, total accumulated cases, recovered cases, deaths, active cases, home quarantined cases, total beds in government and private hospitals in the states and how many beds are occupied daily in various categories of beds: regular, oxygen and ICU. From these bulletins, we have collected data from 1st, August, 2020 to 30th, November, 2020 and did analysis on the data.

III. ANALYSIS

A. *Positive, Recovered and Active cases*

Fig.1 shows the daily positive cases and recovered/deceased cases between 1st August, 2020 to 30th November, 2020. The dips in the numbers were observed during Sundays and holidays where the number of tests done were low. The peak number of positive cases around 3000 were during the 4th week of August, 2020.

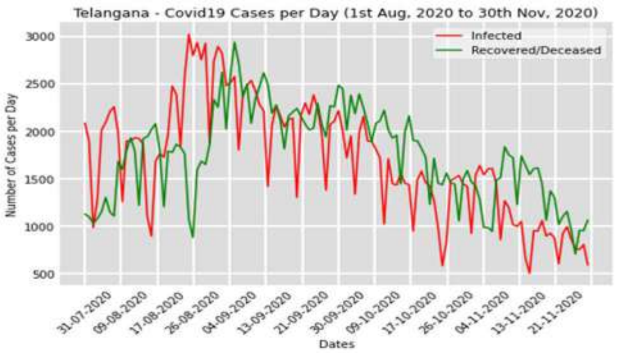

Fig. 1. Daily positive and recovered/deceased cases

Fig.2 shows total accumulated positive cases and recovered/deceased cases. The total positive cases were around 270000 and total recovered cases were around 260000 on the last day of November. There were a total 1460 deaths during the same time [7]. The total active cases reached a maximum of around 32994 during last week of Aug, 2020.

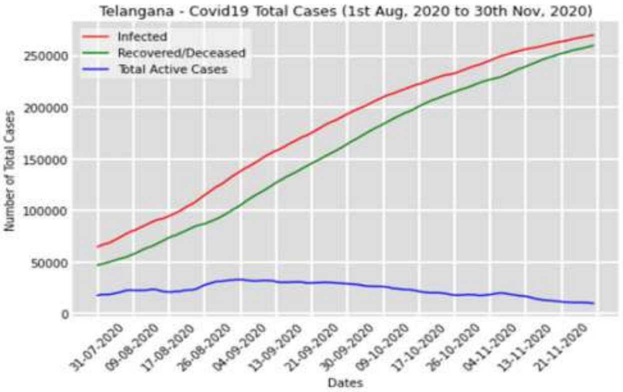

Fig. 2. Cumulative positive, recovered/deceased and active cases

B. *Primary and Secondary contacts testing*

Fig.3 shows the number of primary contacts and secondary contacts tested daily. More numbers of primary contacts are tested. The testing numbers increased during August.

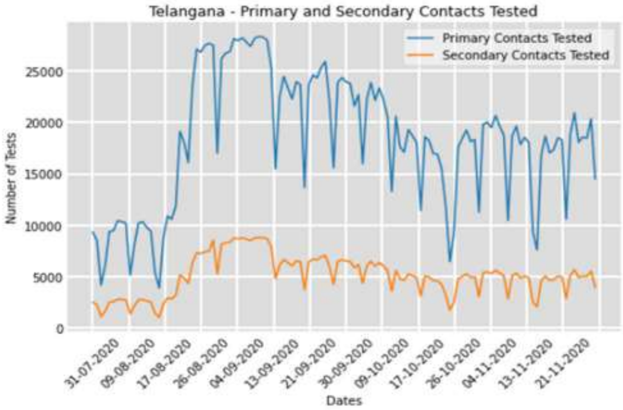

Fig. 3. Primary and Secondary Contacts Testing

C. *Active, Home Isolation and Hospitalized cases*

Fig.4 shows the graph total active cases, total home isolation cases and total hospitalized cases.

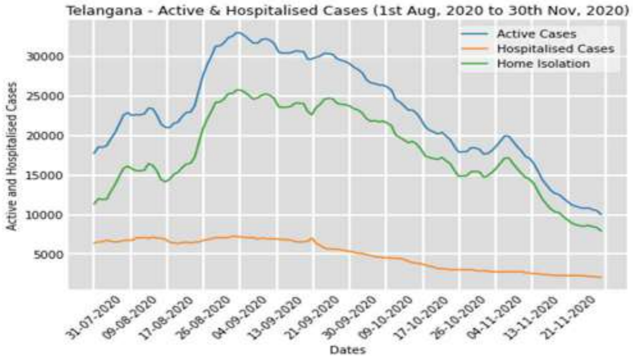

Fig. 4. Total active, home isolated and hospitalized cases

Hospitalized cases are obtained from subtracting the home isolated cases from total active cases. Maximum hospitalized cases were around 7250 during the first week of Sep, 2020.

D. *Various categories beds occupancy numbers*

Fig.5 shows the graph of total beds occupancy numbers of various kinds of beds. The beds are categorised as regular, oxygen and ICU beds. These beds are available in both government and private hospitals. There were around 17000+ beds in both private and government hospitals as on the last day of Nov, 2020. Out of those beds 8500+ were of government and 8500+ were of private. There were 3600+ regular beds, 8500+ oxygen beds, 4800+ ICU beds. Private hospital oxygen beds are occupied most followed by government hospital oxygen beds. As per the protocol/general nature of precautions to be followed, most asymptomatic cases are home quarantined. Symptomatic cases or cases with comorbidities will be referred for hospitalization. Out of all the hospitalized cases, mild symptomatic cases without comorbidities and young age are given regular beds. Old age and cases with comorbidities are given oxygen beds. Very severe cases will be allotted to ICU beds.

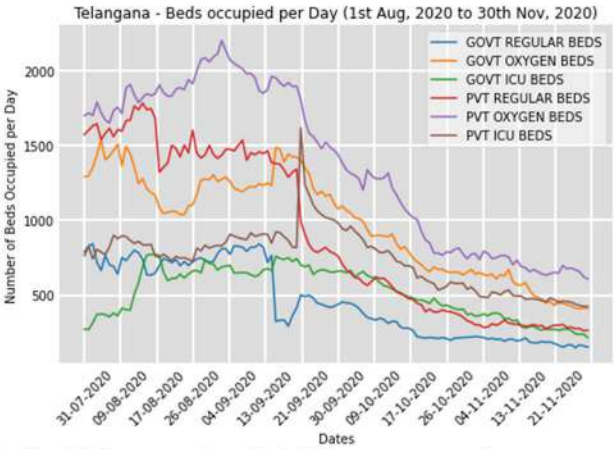

Fig. 5. Various categories of beds daily occupancy numbers

Fig.6 shows the percentage of beds occupancy with respect to total beds.

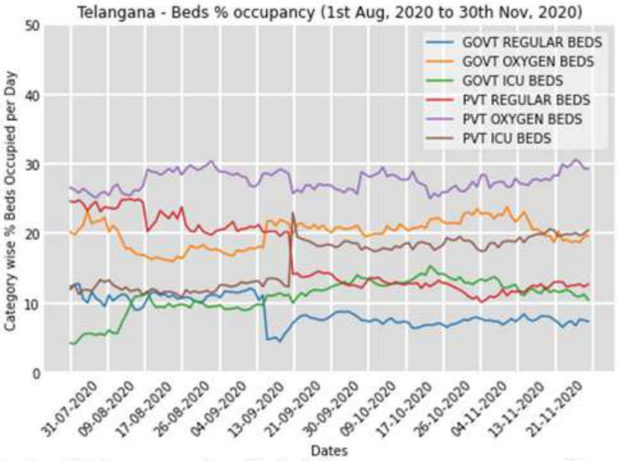

Fig. 6. Various categories of beds daily occupancy percentages with respect to total beds occupied

Private oxygen beds occupancy percentage was between 25 to 30%. Initially private regular beds occupancy percentage was between 20 and 25%, but later that percentage came down to around 10%. The government oxygen beds percentage was varying between 15% to 25%. All other categories of beds occupancy percentages were below 15%.

E. Relationship between active cases and beds occupancy

Fig. 7 shows the approximate relationship (which is estimated from the beds occupancy data) between number of active cases and the beds occupancy pattern.

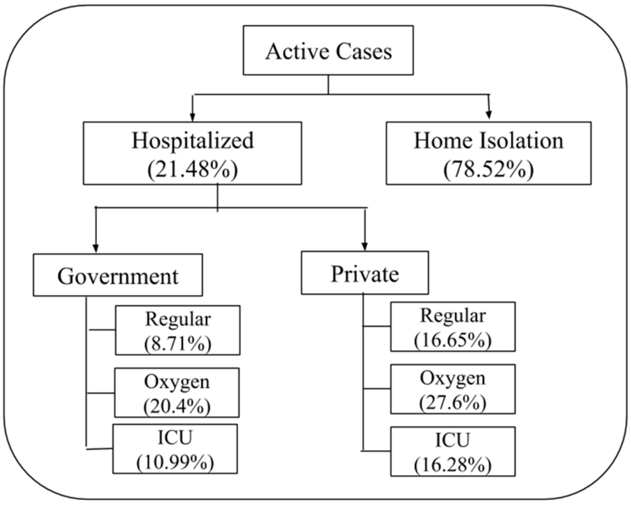

Fig. 7. Estimation Flow chart of Average beds occupancy numbers from number of active cases

Maximum, minimum, average percentages of home isolation, hospitalization and various categories of beds information are given in Table.I.

TABLE I. BEDS OCCUPANCY PERCENTAGE AND THEIR RELATIONSHIP

Percentages	Min	Max	Avg
% Home isolation cases wrt Active Cases	63.8%	86.15%	78.52%
% Hospitalized cases wrt Active Cases	13.85%	36.20%	21.48%
% Govt regular beds wrt Hospitalized Cases	4.46%	12.79%	8.71%
% Govt oxygen beds wrt Hospitalized cases	15.97%	23.85%	20.4%
% Govt ICU beds wrt Hospitalized cases	4.12%	15.35%	10.99%
% Pvt regular beds wrt Hospitalized cases	10.14%	24.95%	16.65%
% Pvt oxygen beds wrt Hospitalized cases	25%	30.62%	27.60%
% Pvt ICU beds wrt Hospitalized cases	10.80%	35.53%	16.28%

IV. METHODOLOGY

From the above analysis, we can conclude that if we have information about the number of active cases, then we can estimate the number of hospitalized cases and further estimate the number of various categories of beds required.

A. Positive, Recovered and Active cases

To estimate the number of beds we shall estimate the number of active cases. The number of active cases are estimated from the number of cumulative positive cases and the number of cumulative recovered cases plus the number of deceased. According to protocol each confirmed case is considered active for 14 days and is quarantined and declared recovered after 14 days unless it is a critical case. As recovery rates are very high, we can consider that most of all confirmed cases will get recovered after 14 days. This gives us the formula for estimating the active cases. Number of active cases is derived by subtracting the number of recovered cases (including number of deceased cases) from the number of cumulative positive cases 14 days ago.

So we formulated the following method for estimating the number of various categories of beds' requirement in future by predicting the number of positive cases and number of active cases.

1) Using the SIR/SEIR model, predict the number of positive cases daily P(t) for the next n number of days from existing data.
2) Using the SIR/SEIR model, predict the number of removed (recovered/deceased) cases daily R(t) for next n number of days from existing data.
3) Accumulate the number of positive cases and removed cases daily PC(t), RC(t) for next n number of days from existing data.
4) Calculate the number of active cases using the formula : AC(t) = PC(t-13) - RC(t). This formula is verified using existing data.
5) Calculate the number of hospitalized cases HC(t) as percentage of Active Cases AC(t). All hospitalized cases require beds. So the total beds requirement is HC(t).
6) Calculate various categories (regular, oxygen, icu (govt, pvt)) of beds as percentage of Total Beds HC(t).

We used the SIR model in our case to predict the number of positive cases and number of recovered cases. We also experimented with Time Series analysis and prediction models like ARIMA and Facebook (FB) Prophet.

B. SIR modeling

In the SIR model [8], there are 3 compartments: Susceptible(S), Infected(I) and Recovered or Removed(R). Susceptible individuals (S) become infected and move into the infected class (I). After some period of time [16] infected individuals recover and move into the recovered class (R). The corresponding equations are given by

$$\frac{dS}{dt} = -\beta . I . \frac{S}{N} \tag{1}$$

$$\frac{dI}{dt} = \beta . I . \frac{S}{N} - \gamma . I \tag{2}$$

$$\frac{dR}{dt} = \gamma . I \tag{3}$$

where S, I and R, are the numbers of susceptible, infected, and recovered individuals in the population. Suppose the unit of time we are considering is days, then

β is the transmission/infection rate and βSI represents the number of susceptible individuals that become infected per day.

γ is the recovery rate and γI is the number of infected individuals that recover per day;

1/γ is the infectious period i.e. the average duration of time an individual remains infected.

An important quantity of any disease model is the reproductive number, R0, which represents the average number of secondary infections generated from one infectious individual. For the SIR model,

$$R0 = \beta N / \gamma \tag{4}$$

where N=S+I+R is the total (constant) population size.

C. ARIMA - Time Series Analysis

Autoregressive Integrated Moving Average (ARIMA) is a simple, flexible and performs well in forecasting tasks [10]. Individual components are AR, I and MA. The AR part simply speaks about autocorrelation using the past data to explain current data. Autocorrelation tries to find out how many lags/periods of time will best predict the current numbers. The 'I' refers to using differencing to attain stationary. Stationary means the statistical properties of the time series such as the median, variance and correlation remain stationary over time. When forecasting a value using a forecasting model, there will be a delta between prediction and the actual value. The MA part can be thought of as a collection of these error terms. These error terms can be incorporated to factor in random fluctuations/irregularities when making our forecast [10].

D. Facebook (FB) Prophet - Time series analysis

An interesting alternative to forecasting problems is using fb-prophet [9] that makes the task of forecasting more accessible and easier to carry out. The great part of fb-prophet is that it automatically detects change points in time series and allows us to factor in hourly, daily, weekly, monthly, yearly trends and even allows us to factor in changes of trends during pre-defined holidays to make our forecast more accurate. Best model can be obtained from turning on weekly seasonality and setting seasonality mode as multiplicative [10]. The forecasted value reveals both the trends, the upper and lower bound forecasts. Prophet is based on decomposable (trend+seasonality+holidays) models. This works best with the time series data that have clear seasonal effects [11]. FB Prophet is strong in dealing with missing data, capturing the shifts in the trend and large outliers. The Prophet framework has its own special data frame to handle time series and seasonality data easily [11],

E. SIR Model - Data fitting

The data collected from Telangana dataset are organized in the form of time-series where the rows are recorded in time (from August to November, 2020), and the three columns are, the total cases I_t, number of infected individuals I and deaths D. Consequently, the number of removals R can be estimated from the data by R = I_t - I - D.

We tried to fit the data to the SIR model by trial and error and visual inspection. The parameters: initial susceptible population, infection rate (beta) and recovery rate (gamma) are adjusted manually through trial and error to fit the data as best as possible to obtain the result graph as shown in Fig.8.

In the graph shown in Fig.8, the red line is actual active cases following the infection curve obtained from the SIR model approximately. The SIR model is used to simulate the susceptible, infection and removed cases from 1st July, 2020 for next 500 days until mid-December, 2021. From Fig.8 we can observe that the infection cases will reduce to zero by March-April, 2021, if there are no second wave of infections.

If there are any new waves of infections, with new data we can adjust the model parameters and fit the data to get a new SIR model, which we can use for predictions.

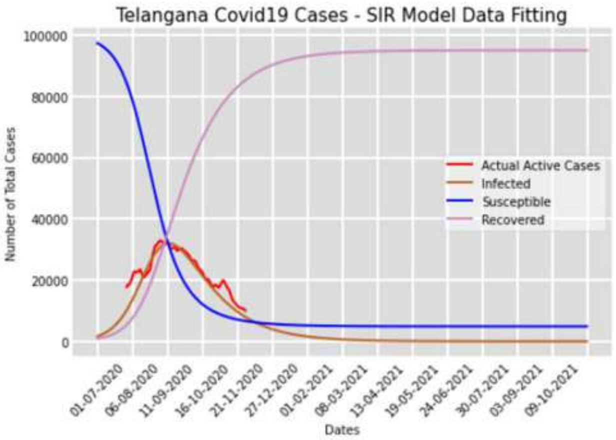

Fig. 8. Active cases data fitting with SIR modeling

The beta (infection/transmission rate) and gamma (recovery/removal rate) varies as shown in Fig.9.

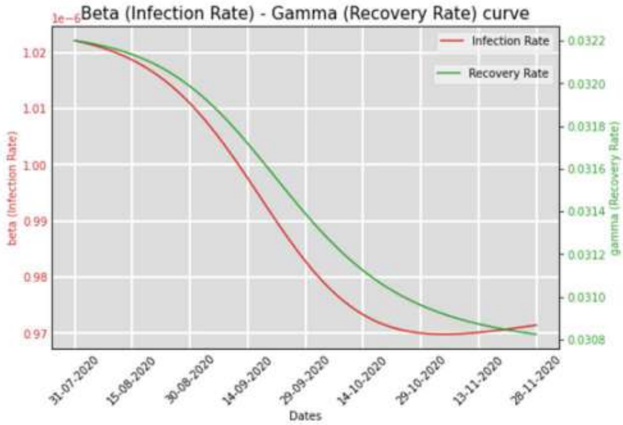

Fig. 9. Telangana Infection and Recovery Rates of SIR Model

V. RESULTS

We can use the SIR model to predict the number of active cases for every day for the next n number of days and from the number of active cases, we can predict the number of hospitalized cases and total number of beds and in turn predict the number of various categories of beds required using the average percentages obtained from existing data which was given in Table. I.

A. *Predicting Active and Hospitalized cases*

Fig.10 shows the number of active cases predicted from the SIR model from 1st December, 2020 to 30th April, 2021. The number active cases predicted for 1st December, 2020 was around 7500+ decreased to around 150+ for 30th April, 2021. Hospitalized cases which are calculated as the percentage of active cases, decreased from 1600+ to 30+ during the same time.

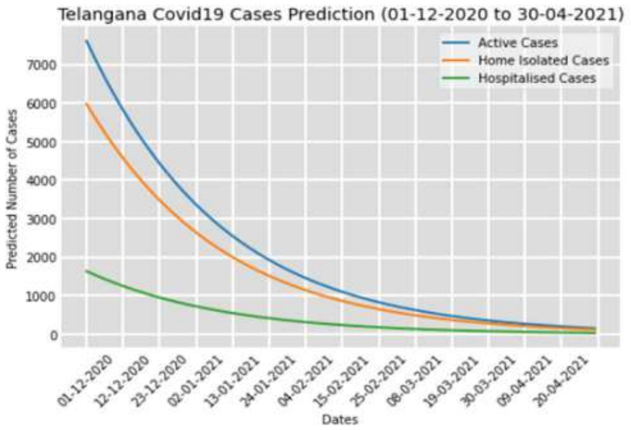

Fig. 10. Active and Hospitalized Cases Prediction from SIR Model

B. *Predicting various categories of beds*

Fig.11 shows the predicted number of various categories of beds from 1st December, 2020 to 30th April, 2021. Private Oxygen beds are generally utilised most and their number has decreased from 450+ beds to single digits.

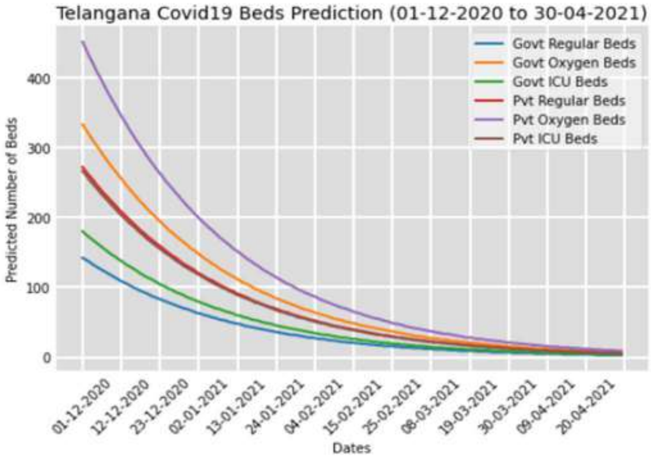

Fig. 11. Number of various categories of beds prediction from total hospitalized cases obtained from SIR Model

C. *Predicting daily positive cases using FB-Prophet*

We also used FB-Prophet for predicting daily positive cases and their trend along with their lower and upper bound as shown in Fig.12.

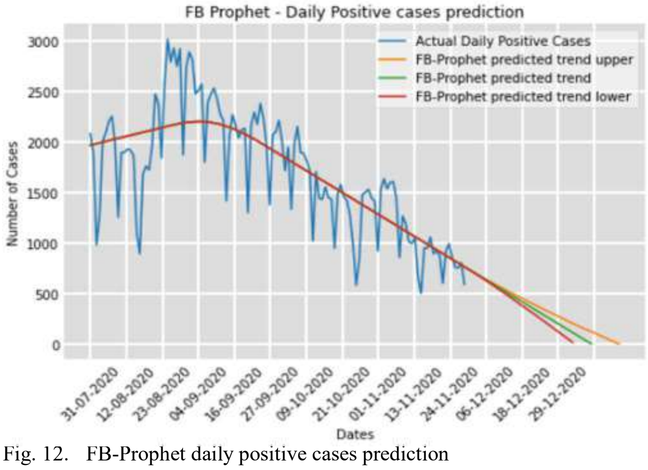

Fig. 12. FB-Prophet daily positive cases prediction

D. *Predicting total active cases using FB-Prophet*

Fig.13 shows the FB-prophet prediction of total active cases and their trend along with their lower and upper bounds

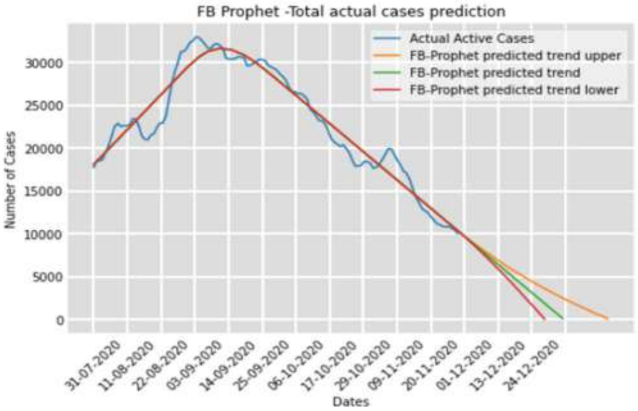

Fig. 13. FB-Prophet total active cases prediction

E. *Accuracy metrics for Predictions*

We used data from 1st Aug, 2020 to 30th Nov, 2020 as training dataset and 1st Dec, 2020 to 23rd Dec, 2020 as test dataset.

SIR Model, ARIMA and FB-Prophet active case predictions and their RMSE values for train and test datasets are shown in Table II.

TABLE II. ACTIVE CASES PREDICTIONS - RMSE VALUES FOR SIR AND FB-PROPHET

Data Set	***SIR RMSE***	***ARIMA RMSE***	***FB PROPHET RMSE***
Train Dataset	3126.61	1887.60	1512.85
Test Dataset	1773.69	14441.98	1611.52

SIR modeling is more intuitive and explainable, but requires a lot of trial and error and assumptions. The FB-Prophet prediction process is simple. The root mean squared error (RMSE) of FB-Prophet predictions is less and more accurate. So FB-Prophet predictions can be used for quick and accurate prediction of daily COVID-19 positive and active cases.

VI. DISCUSSION AND CONCLUSION

Based on Historical data and predictive analysis done so far we have observed that existing government and private hospital beds are sufficient to handle all hospitalized COVID19 cases. Highest occupancy is observed in the Oxygen bed category in both government and private set up.

We have observed second waves in many European countries [14] and the proposed predictive analysis can be used to understand hospital beds availability in future if a second wave occurs in India. This analysis can be applied to analyse hospital beds availability in other states in India.

SIR modeling can be used with extra parameters to simulate lockdown effects, surges, comorbid conditions, festivals/congregations, elections, environmental factors like pollution and weather conditions, air travel restrictions, food habits etc., to approximately predict the infection spread scenarios and be prepared with adequate healthcare infrastructure.

The FB-prophet model also can be used for time series analysis for predicting positive cases more accurately with inclusion holidays, special days etc.

As the vaccination started in India and there is no second wave observed except in a few cities, let us hope present healthcare infrastructure in the country is enough.

***Abstract*—The overhead crane systems are important heavy-duty machines that are widely used, especially in construction and industry sectors to transport and lift heavy loads. This paper introduces the mathematical modeling of a 3-D overhead crane. The Euler-Lagrange equation is utilized to extract the dynamic equations of the crane system. The obtained nonlinear crane model has been linearized by applying the feedback linearization technique. Then, a PID controller has been developed and implemented to the obtained linearized crane model. The parameters of the designed PID controller have been tuned by implementing the Differential Evolution (DE) algorithm which significantly improved the performance of the PID controller. The simulation results have been performed using MATLAB/SIMULINK platform. The obtained simulation results clearly showed the impact of applying the Differential Evolution (DE) technique to tune the PID controller gains which provided better performance compared to the manually tuned PID controller gains.**

***Index Terms*—overhead crane, dynamics, PID control, feedback linearization, differential evolution**

I. Introduction

Overhead cranes have extensive use in industry for transportation of heavy loads. To guarantee safe and systematic functioning of the gantry crane, proper design and control is a must. Therefore, several studies were conducted to study the dynamic behavior and control of such system. In order to design a proper control scheme for the crane, the correct dynamic model must be in hand. Many researchers have studied the over head crane system in attempts to optimize it's operation. Among the previous studies, modeling and control of a three-dimensional overhead crane is introduced in [1], where, a new dynamic model of the crane is derived based on a newly defined two-degree-of-freedom swing angles. A decoupled control scheme based on the dynamic model, linearized around the stable equilibrium, is proposed for anti-swing control. It is reported that, the decoupled scheme guarantees not only rapid damping of load swing but also accurate control of crane position and load hoisting for the practical case of simultaneous traveling, traversing, and slow hoisting motions, which was also proven by experiments. Other modeling techniques were carried out such as solid modeling and finite element analysis [2]. Linear controller such as Proportional Derivative (PD) was proposed in [3], the uncertainty in the crane dynamics was compensated by radial basis function neural networks (RBF). Many nonlinear control techniques were attempted, in [4] saturation control approach was used to control a two degree of freedom overhead crane as to control the horizontal position. Sliding mode control [5], [6] was also used to control overhead grane. In addition, partial feedback linearization technique was used to improve the response of a nonlinear controller [7]. LasSalle's invariant set theorem was utilized to develop nonlinear coupling control laws to overhead crane [8]. In [9] Backstepping with sliding mode control was designed for 3D overhead crane, the mathematical model was developed by lagrangian principal. A fuzzy based control laws using inertia theorem was implemented in [10], another enhance fuzzy method was used to minimize the dead zone problem effect. A fuzzy technique in conjunction with proportional derivative (PD) controller was adopted [11]. Fuzzy logic with feedforward-feedback controller was proposed in [12].

In [13], a 3-D crane modeling and control utilizing Euler-Lagrange state-space method and anti-swing fuzzy logic is proposed, where, the mathematical model of the system is deduced. Using laboratory stand and Simulink® environment the state-space representation for that model is introduced and explored. The acquired control design was analyzed & simulated, and the performance was compared with available encoder-based system supplied by the 3-D crane maker Inteco®. In addition, an anti-swing fuzzy logic control has been built and tested. Achieved control strategy is compared with the available anti-swing PI controller planned by the three-dimensional crane producer Inteco®. 5 DOF control strategies are designed, assessed and compared with the various load masses.

Also Artificial intelligence techniques have its share in controlling and stabilizing overhead crane, A particle swarm optimization technique was used to tune the parameters of model predictive control (MPC) [14]. A cuckoo search algorithm was used to model overhead crane using radial basis function neural networks with aid of membrane communication mechanism [15].

II. The 3-D Overhead Gantry Crane System

The three-dimensional overhead crane under investigation with its payload is pictured in Fig. 1, where L represent the

[1] Earlier known as Amin A. Mohammed

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

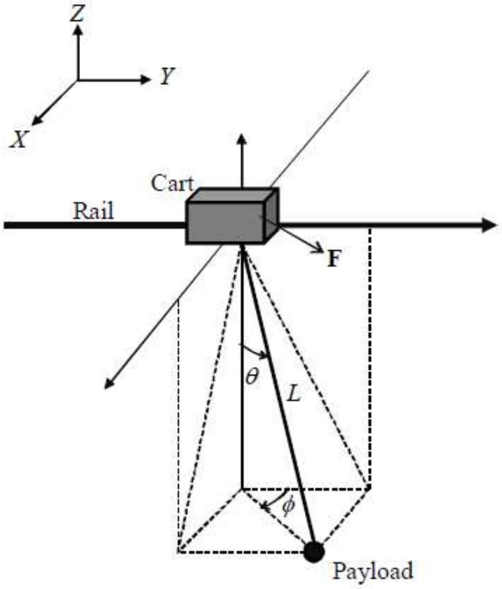

Fig. 1. Representation of the three-dimensional overhead crane.

length of the rope, θ & ϕ the swing angles of the rope, and F is the cart drive force. To simplify the analysis, the payload and the cart are regarded as point masses. The cart friction force and the tension force that may lead to an elongation in the rope are ignored.

III. Crane Dynamic Model

The dynamic model of the 3-D overhead crane system which is essential for control is formulated based on Euler-Lagrange equation [16]. To apply Lagrange equation, first the kinetic energy and the potential energy associated with the system must expressed [17]. As shown in Fig. 1, the position vectors for rail, cart and payload are given by:

$$r_r = [x, 0, 0]$$

$$r_c = [x, y, 0]$$

$$r_p = [x + L\sin\theta\sin\phi, \quad y + L\sin\theta\cos\phi, \quad -L\cos\theta]$$

where y and x denote the cart locations in Y- and X-directions correspondingly.
The system entire kinetic energy is a contribution from the cart, rail, and payload, as given bellow:

$$T = T_{rail} + T_{cart} + T_{payload} \tag{1}$$

Where

$$K_{rail} = \frac{1}{2}m_r\dot{r}_r^2 = \frac{1}{2}m_r\dot{x}^2$$

$$K_{cart} = \frac{1}{2}m_c\dot{r}_c^2 = \frac{1}{2}m_c(\dot{x}^2 + \dot{y}^2)$$

$$K_{payload} = \frac{1}{2}m_p\dot{r}_p^2 + \frac{1}{2}J\dot{\phi}^2 + \frac{1}{2}J\dot{\theta}^2$$

After substituting for r_p and simplifying, the total kinetic energy becomes:

$$\begin{aligned} T =& \frac{1}{2}(m_r + m_c + m_p)\dot{x}^2 + \frac{1}{2}(m_c + m_p)\dot{y}^2 + \\ & m_pL\cos\theta\sin\phi\dot{x}\dot{\theta} + m_pL\sin\theta\cos\phi\dot{x}\dot{\phi} \\ & + m_pL\cos\theta\cos\phi\dot{y}\dot{\theta} - m_pL\sin\theta\sin\phi\dot{y}\dot{\phi} \\ & + \frac{1}{2}(m_pL^2 + J)\dot{\theta}^2 + \frac{1}{2}(m_pL^2\sin^2\theta + J)\dot{\phi}^2 \end{aligned} \tag{2}$$

where g is the gravitational acceleration and J symbolizes the payload's moment of inertia. The potential energy on other hand, is only resulting from the payload, and is given by:

$$V = v_{paylaod} = -m_pgL\cos\theta \tag{3}$$

The Euler-Lagrange equation is given by [18]:

$$\frac{d}{dt}\left[\frac{\partial K}{\partial \dot{q}_i}\right] - \frac{\partial K}{\partial q_i} + \frac{\partial V}{\partial q_i} = Q_i, \quad i = 1, 2, 3, 4 \tag{4}$$

Where q_i and Q_i are the generalized coordinate and the associated generalized force.
The state and control vectors are defined respectively, as:

$$q = \begin{bmatrix} x & y & \theta & \phi \end{bmatrix}^T$$

$$Q = \begin{bmatrix} f_x & f_y & 0 & 0 \end{bmatrix}^T$$

In which f_x and f_y denote the control inputs for the motion in the X- and Y-direction. Out of Equation (4) a set having four equations is achieved for $i = 1, 2, 3, 4$, that is:

$$\begin{aligned} \frac{d}{dt}\left[\frac{\partial K}{\partial \dot{x}}\right] - \frac{\partial K}{\partial x} + \frac{\partial V}{\partial x} &= f_x \\ \frac{d}{dt}\left[\frac{\partial K}{\partial \dot{y}}\right] - \frac{\partial K}{\partial y} + \frac{\partial V}{\partial y} &= f_y \\ \frac{d}{dt}\left[\frac{\partial K}{\partial \dot{\theta}}\right] - \frac{\partial K}{\partial \theta} + \frac{\partial V}{\partial \theta} &= 0 \\ \frac{d}{dt}\left[\frac{\partial K}{\partial \dot{\phi}}\right] - \frac{\partial K}{\partial \phi} + \frac{\partial V}{\partial \phi} &= 0 \end{aligned} \tag{5}$$

From the equation set (5), the dynamic model of the crane can be expressed in matrix (compact) form [19]:

$$M(q)\ddot{q} + C(q, \dot{q})\dot{q} + G(q) = Q \tag{6}$$

where the matrices $M(q) \in R^{4\times4}$, $C(q, \dot{q}) \in R^{4\times4}$ symbolize the inertia and Centripetal-Coriolis terms as shown in equations (7, 8).
And $G(q) \in R^4$ is the gravity vector defined as:

$$G = \begin{bmatrix} 0 & 0 & m_pL\sin\theta & 0 \end{bmatrix}^T$$

Since the inertia matrix $M(q)$ is symmetric and positive definite, it's inverse must always exist [20], thus, from the matrix equation in (4), we can write:

$$\ddot{q} = M(q)^{-1}(Q - C(q, \dot{q})\dot{q} - G(q)) \tag{9}$$

$$M(q) = \begin{bmatrix} m_r + m_p + m_c & 0 & m_p L \cos\theta \sin\phi & m_p L \sin\theta \cos\phi \\ 0 & m_p + m_c & m_p L \cos\theta \cos\phi & -m_p L \sin\theta \sin\phi \\ m_p L \cos\theta \sin\phi & m_p L \cos\theta \cos\phi & m_p L^2 + J & 0 \\ m_p L \sin\theta \cos\phi & -m_p L \sin\theta \sin\phi & 0 & m_p L^2 \sin^2\theta \end{bmatrix} \tag{7}$$

$$C(q,\dot{q}) = \begin{bmatrix} 0 & 0 & -m_p L \sin\theta \sin\phi\dot{\theta} + m_p L \cos\theta \cos\phi\dot{\phi} & m_p L \cos\theta \cos\phi\dot{\theta} - m_p L \sin\theta \sin\phi\dot{\phi} \\ 0 & 0 & -m_p L \sin\theta \cos\phi\dot{\theta} - m_p L \cos\theta \sin\phi\dot{\phi} & -m_p L \sin\theta \cos\phi\dot{\phi} - m_p L \cos\theta \sin\phi\dot{\theta} \\ 0 & 0 & 0 & -m_p L^2 \sin\theta \cos\theta\dot{\phi} \\ 0 & 0 & m_p L^2 \sin\theta \cos\theta\dot{\phi} & m_p L^2 \sin\theta \cos\phi\dot{\theta} \end{bmatrix} \tag{8}$$

Moreover, the payload swing angles with respect to XZ-plane, θ_y and with respect to YZ-plane, θ_x can be expressed as follows, by direct project of the appropriate side of Fig. 1:

$$\theta_x = \tan^{-1}(\tan\theta \sin\phi), \qquad \theta_y = \sin^{-1}(\sin\theta \cos\phi) \tag{10}$$

IV. Controller Design

A. Feedback Linearization and PID Control

The essential idea of feedback linearization technique is it to define a control law in such a way that we cancel the nonlinearities in the model and end up with a linear differential equation for error command, and then use the linear control design techniques. This technique sometimes called computed torque control [18], [19], and it has been applied successfully in robotics [17].

Rewrite the model given in Equation (6):

$$M(\theta)\ddot{\theta} + C(\theta,\dot{\theta})\dot{\theta} + g(\theta) = \tau \tag{11}$$

The next task is to develop a PID controller as shown in equation (12), to the dynamic model. A supplementary state variable is required to address the integral part of the PID control. It is defined by ξ, and its derivative with respect to time is $\dot{\xi} = \tilde{\theta}$.

$$\tau = K_P\tilde{\theta} + K_I \int \tilde{\theta} dt + K_D\dot{\tilde{\theta}} \tag{12}$$

Thus, the PID control law could be represented by the below system [20]:

$$\tau = K_P\tilde{\theta} + K_I\xi + K_D\dot{\tilde{\theta}} \tag{13}$$

$$\dot{\xi} = \tilde{\theta} \tag{14}$$

The closed-loop equation's is found by introducing the control law τ of (13) to the crane dynamics (11), i.e.

$$M(\theta)\ddot{\theta} + C(\theta,\dot{\theta})\dot{\theta} + g(\theta) = K_P\tilde{\theta} + K_I\xi + K_D\tilde{\theta} \tag{15}$$

$$\dot{\xi} = \tilde{\theta} \tag{16}$$

As a function of state vector $\begin{bmatrix}\xi^T & \tilde{\theta}^T & \dot{\tilde{\theta}}^T\end{bmatrix}^T$, equations (15-16) could be expressed as:

$$\frac{d}{dt}\begin{bmatrix}\xi \\ \tilde{\theta} \\ \dot{\tilde{\theta}}\end{bmatrix} = \begin{bmatrix} \tilde{\theta} \\ \dot{\tilde{\theta}} \\ \ddot{\theta}_d - M(\theta)^{-1}[K_P\tilde{\theta} + K_I\xi + K_D\dot{\tilde{\theta}} - C(\theta,\dot{\theta})\dot{\theta} - g(\theta)] \end{bmatrix} \tag{17}$$

$\tilde{\theta} = \dot{\tilde{\theta}} = 0$ at the equilibrium, hence $\theta = \theta_d$.
Therefore equation (17) gives:
$[\xi^T \quad \tilde{\theta}^T \quad \dot{\tilde{\theta}}^T] = [\xi^* \quad 0^T \quad 0^T]$, where

$$\xi^* = K_I^{-1}[M(\theta_d)\ddot{\theta}_d + C(\theta_d,\dot{\theta}_d)\dot{\theta}_d + g(\theta_d)]$$

$$\frac{d}{dt}\begin{bmatrix}\theta_d \\ \dot{\theta}_d\end{bmatrix} = \begin{bmatrix} \dot{\theta}_d \\ M(\theta_d)^{-1}[\tau - C(\theta,\dot{\theta})\dot{\theta} - g(\theta)] \end{bmatrix} \tag{18}$$

B. Differential Evolution

Differential Evolution (DE) is renowned as an effective global optimizer. In this study the main objective is to reduce the settling time and the overshoot. DE starts with a population of NP possible solutions labeled $X_{i,G}, \quad i = 1, ..., NP$, where i an index represents the population of a given generation and G represent such generation. The performance of DE relays on three major operations, namely, mutation, followed by generation or reproduction and selection.

The central idea of DE is a new strategy for producing vectors of trial parameter . By summing the weighted difference vector among two population members to a third one, DE produces new parameter vectors. If the obtained vector gives a lower objective function than an old population member, the newly produced vector substitutes the vector that was compared with. Moreover, the best parameter vector is evaluated for every generation as to keep track of the advance of the procedure [22].

In this case the initial population is indiscriminately selected, in a range of 0 to 200, for the three gains of the controller $K_P, K_I, \quad$ andK_D. With original population (Np) and generation $(Ng\ )$ sizes of 20, cross over (CR) and mutation (F) factors of 0.5. The (gross) objective function is constructed as follows:
$OF = 0.5 \times (OF1 + OF2)$ where OF_1 and OF_2 represent the individualistic objective functions for maximum overshoot and settling time.

V. Results and Discussion

In the present analysis, the nominal values of the parameters are taken as $m_p = 0.73kg$, $m_c = 1.06kg$, $m_r = 6.4kg$, $L = 0.7m$ and $J = 0.005kg.m^2$ [21]. The acceleration gravity g is taken as $9.8m/s^2$.

The optimized PID controller parameters obtained using DE are: $K_p = diag(200, 200, 200, 200)$, $K_D = diag(22.28, 22.28, 22.28, 22.28)$, and $K_I = diag(111, 111, 111, 111)$, the achieved results are discussed below.

The obtained results with and without DE algorithm are compared as detailed below. There is a high overshoot and settling time for the position of the cart as shown in Figs. 2-3 in case of manual tuning. However, those high overshoot and settling time have been reduced significantly with the turned PID parameters using DE algorithm. Besides, the rise time has been significantly reduced as detailed in Table I and Table II with excllent improvement in the (absolute) peaks. This clearly highlight the usefulness of applying DE algorithm to turn the parameters of the PID controller.

On the other hand, the settling time for angular displacements is relatively high for the case of manual turning as displayed in Figs. 4-5. Yet, with the help of DE algorithm, the settling time has been dramatically reduced which once again confirm the superior of DE algorithm over the manual approach. Detailed response characteristics for the angular displacement (θ) are provided in Table III, where the rise time was reduced by around 10 times, overshoot was totally removed, and the peak was reduced by around 20%. Similar info are shown in Table IV for the angular displacement (ϕ), where; the rise time, settling time, overshoot, and peak were reduced.

Finally the control signals for the case of manual tuning and optimized tuning are shown in Figs. 6-9 (for comparison only as they're predetermined already). High control signals are required in case of DE algorithm as to achieve rapid responses, which could be cited as a pitfall against DE, however, it is realistic in light of the immediate response that was obtained. On the other hand, very small control inputs are needed in case of manual turning which is penalized by poor and late responses.

VI. Conclusion

The dynamic model of a 3-D gantry crane including rope length and payload has been developed using the Euler-Lagrange method.

A nonlinear PID control, base on the feedback linearization technique is proposed. The obtained results, include some oscillation, however, by using DE to tune the controller parameters, better results are achieved. The achieved results with DE implementation have greatly reduced the settling time and the maximum overshoot compared with the manual tuning case. Conversely, the control associated with DE algorithm are relatively high compared with the other case.

Abstract— Field Programmable Gate Array (FPGA) Memories are synchronous pipelined circuits that rely on the distribution of the clock to achieve the timing requirements. The density of FlipFlops (FFs) are higher in such designs. This paper discusses a novel method and algorithm for reducing the simultaneous switching current demand to address IR hotspots by the staggered placement of these FFs. The higher current demands from a small section of high resistive Power Distribution Network (PDN), is redistributed to other unused sections of the Network. This approach improves the performance of clock network distribution by reducing the clock insertion delay and max skews. Application of proposed algorithm reduces IR-drop by 32.5% and improves clock insertion delay by 36.5%.

Keywords— Dynamic IR- drop, Power Distribution Network (PDN), dynamic current reduction, scan chain, Place and Route (PNR), Clock Tree Synthesis (CTS), FlipFlops (FFs)

I. Introduction

As the complexities of integrated circuits have increased, the power consumption during the circuit test also has grown drastically. Also, the power consumption during the scan testing is higher than the power consumed in normal operation due to the increased switching activity. Excessive test power consumption can lead to dynamic IR-drop which in turn degrades the circuit performance and may lead to functional failure.

For system-on-chip (SoC) designs, FFs are the major building blocks in terms of PPA (Power, Performance and Area). For test purposes, these FFs are hooked into scan chains. Several studies are done on Hold time failures caused by clock skews [1-4]. Traditionally, hold time failures are caused by clock skew from different clock branches, different clock domains or clock jitter, drift, etc. [5].

To improve test run time, the scan chain is partitioned into smaller chains [6]. There are several scan-FFs in each of these chains. During test mode, all scan FFs change state or toggle simultaneously. At each active edge of the clock, every FF captures the incoming data and sends it to the next stage. Also, the CTS targets all the FFs for zero clock skew, so all FFs would switch at the same time. Every active edge of the clock triggers the switching current of all the FFs. Therefore, the peak current demands are synchronous to the clock for the active edges which attribute to a higher on-die IR-drop.

There are mainly two types of supply voltage degradation: (1) Static IR-drop, which is observed when a Power/Ground supply network is considered as a resistive network with DC supply current sources; (2) Dynamic IR-drop, which is caused by switching current in Power/Ground network.

Various cell placement and design floor-planning-related methods have been proposed to restrict supply voltage reduction. Prior works demonstrated different approaches for IR-drop modeling and optimization. IR-drop modeling is very beneficial, particularly for the larger, chip-level designs, which usually have a longer turnaround time to complete the IR-drop analysis.

We compared recent works [7,8,9] in Table 1. Bhamidipati et al. proposed an algorithm to simultaneously reduce the peak current and the intensity of IR hotspots by scheduling useful skews [9]. This technique is useful for reducing peak current demands of timing non-critical cells. Also, this method does not consider clock insertion delays of targeted FFs. Insertion of power staples is a new technique for improving PDN robustness in sub-10nm technologies. Heo et al. introduce an approach to improve power staple insertion at post-placement in [8]. Power staples are short pieces of metal shorting multiple adjacent Power rails, to mitigate the IR-drop. This approach is suitable for designs with less routing congestion. Kahng et al. introduce the first IR-drop aware placement engine in [7]. They present a greedy algorithm to find optimum NP-hard placement of cells to reduce IR-drop. They formulated IR-drop (Voltage) as a function of supply currents and study the distribution of current to each cell to locate the ideal placement to reduce IR-drop. For each cell's peak current, the worst voltage degradation is approximated by a log-sum-exp function and integrated into the objective function. The solution to the NP-hard problem is large in numbers and time-consuming process as greedy search algorithms are not linear but polynomial in time. The polynomial search for a big design at advanced technology nodes can increase the run time almost exponentially.

TABLE 1. IR-Drop Optimization: Previous Works Vs Our Work

Ref. Work	*Design Step*	*Target*	*Method*	*Improve Clock insertion delay*
[7]	Place-Opt	Peak Current Reduction	Cell Movement	NO
[8]	Place-Opt	PDN Resistance Reduction	Staple Insertion	NO
[9]	CTS	Peak Current Reduction	Useful Skew Scheduling	NO
Our Work	Place-Opt	Dynamic IR-Drop	Cell Movement	YES

These methods [7,9] suppress the peak current demands, but they cannot avoid local IR-drops, particularly in the scan test modes, where the peak current demands are

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

synchronous to the clock for the active edges which attribute to a higher on-die IR-drop. Such demands can be very high if the successive FFs have the opposite data stored and placed together in close vicinity.

In our previous work [10], we demonstrated a novel method of FFs clustering to improve the clock insertion delay of FPGA memories. These delays are highly impacted by the big wirelengths inside the Semi-Custom FPGA memories, which limit the operating frequency of the designs. Dynamic IR-drop hotspots result from instantaneous large current drawn in a local region. For test purposes, these clustered FFs are hooked into scan chains.

In this paper, we demonstrate a deterministic linear search algorithm to minimize the local dynamic IR-drop caused by high-density FFs clustering. Unlike NP-hard, our approach is to simplify the search by targeting only a finite number of searches to meet the specifications of design, rather than finding the most optimum solutions. Our proposed approach is to distribute the high current demand from a small section of the Power Distribution Network to the unused [less utilized] sections without disturbing the clustering approach discussed above. This technique not only reduces the formation of local IR hotspots but also proves to be very effective in maintaining the clock skews. This solution is easy to plug into the mainstream physical design Clock Tree Synthesis (CTS) step. Application of proposed algorithm reduces IR-drop by 32.5% and improves clock insertion delay by 36.5%.

II. Power Distribution Network & Dynamic IR-Drop

A Power Distribution Network (PDN) is a stitched network of Power/Ground metal straps to deliver stable supply voltages from PG pads to all the circuit devices in a design. Fig. 1 shows a typical PDN with (a) PG pads, providing the ideal reference voltages (VDD and GND), (b) PG Metal Straps, connecting to PG pads through high metal layer, (3) via stacks, connecting PG meshes with lower-level metal, and (d) Standard Cell PG rails, connecting to PG pins of standard cells in low metal layers from which Standard Cell pins can be accessed.

Construction of a typical PDN in advanced geometry nodes where 16 or more metal layers exist, starts with building M0 rails to which the power and ground pins of standard cells are connected. M0 rails are altered between Standard cell rows, hence these are separated by the height of standard cells. Due to an increase in the current and power density at the advanced technology nodes, the M0 rail alone may not be strong enough to meet IR-drop and Electromigration (EM) requirements.

So, to mitigate these limitations, M2 rails are routed in parallel to M0 rails. The higher-level metal straps are routed perpendicular and parallel alternatively to distribute the current evenly. These straps are connected to the immediate lower metal layer at each cross-intersections by using a via-stack. The size of the via-stack needs to be chosen carefully; larger via-stacks reduce the resistive IR-drop, but consume more routing resources and cause congestion. Upper Metal [M8 and above] layers are progressively made wider to evenly distribute the current across the design. These upper metal layers have less resistivity and introduce very little impact on IR-drop. Lower metal layers in 7nm such as M0/M1 rails and corresponding vias have a higher resistivity.

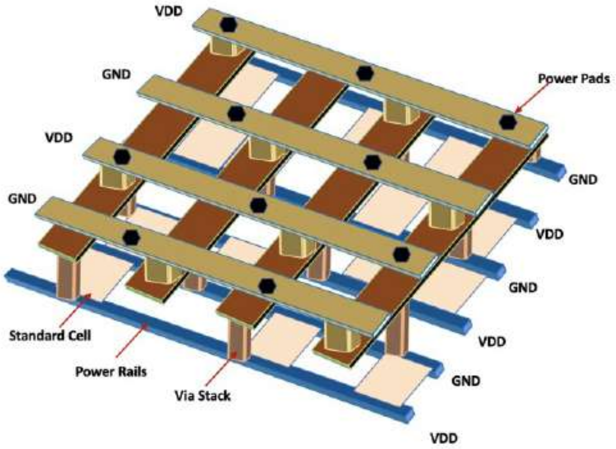

Fig. 1. Typical PDN construction

IR-losses are the ohmic voltage drop on the power grid which depends on the metal layers sheet resistances [11]. In 7 nm technology, the spectrum of metal layer resistivity is large, from the top lesser resistive layers to the bottom higher resistive layers (M0-M3). The chart in Fig. 2 shows the normalized sheet resistance with respect to M0 for each layer of 7 nm node technology. Metal 0 and Metal 1 are more frequently used by standard cells to connect signals and power supplies. The section of PDN which connects the power supply to these cells with M0 and M1 is the major contributor of IR-drop.

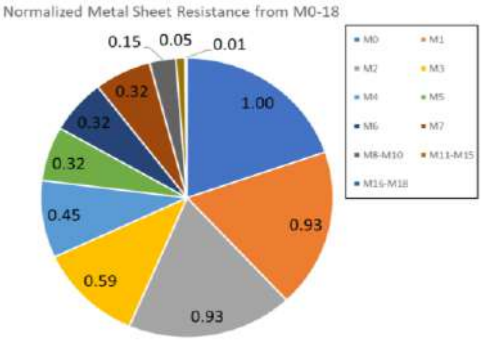

Fig. 2. Normalized distribution chart of Sheet Resistance

III. Problem Statement

The goal of our work can be defined in 2 steps:
(1) Automate the clustering of critical path FFs within a physical bound: The task is to identify the critical timing paths based on the functionality of the sub-blocks. The placement bounds are estimated and defined based on the number of FFs associated with the sub-blocks. This approach reduces the clock insertion delays of targeted FFs.
(2) Dynamic IR-aware placement adjustment of these FFs to minimize the Engineering Change Order (ECO) during high current switching operation such as scan testing: Defining the target IR-drop constraints, max displacement constraint, dynamic IR-report for every targeted sub-block, with the objective of cell moment to reduce IR-hot spots without degrading the clock insertion delay. These displacements also reduce the local routing congestions.

IV. Our Approach

Placing cells to minimize static IR-drop has been proven to be NP-hard [Ref- Supply voltage degradation aware analytical placement]. The solutions to the NP-hard problems are large in numbers. NP-hard problems are solved using a greedy search algorithm that is not linear but polynomial in time. Usually, PDN is designed with a nominal set of wire widths and pitches for different metal layers and then optimized to meet the allowed **IR-drop budget** based on the targeted designs. Our proposed approach is to convert the cell placement search into a deterministic linear search. We only target to achieve the specified IR-drop budget, rather than using greedy search to find the most optimal placement. We focus the optimal placement search within the targeted bounds which is broken into smaller unit bins. We further constrained our cell placement search within standard cell rows of these placement bounds. Every bin is also targeted to have a predefined checker-board patterned FF placement for staggering the FFs. We also derived a predefined IR-drop target budget. This approach transforms the search algorithm to be deterministic and linear rather than greedy.

A. *Automation of placement bounds for critical sub-blocks and CTS control options*

Using placement bound constraints, we physically cluster the placement of all the FFs of the timing critical sub-block. Our previous work [10] shows an improvement in clock-to-out for the targeted sub-block by 36% and in max skew by 39%. In this paper, we propose an automated method to generate the physical bounds. Clock grouping options for related FFs of sub-blocks within the bounds were also applied for reducing clock insertion delays and clock skews.

B. *Defining the target Bin*

To simultaneously reduce the peak of dynamic current surge and intensity of IR hotspots, we break the placement bounds into smaller bins as Placement Units [PU] Fig. 3. The most resistive section of the PDN is the M0-rail and the via stack that connects the M1 metal straps. Considering that the M0-rails and Via0 are highly resistive, they are the highest contributing elements to the formation of high-IR regions. Therefore, if the current, which is demanded through each lower level via stack could be lowered, the intensity of IR hotspots could be greatly mitigated. To mitigate the higher resistivity of lower-level metal layers, we define a single bin to cover vertical M1 pitch (VDD to VDD). This is the minimum distance between Via0 in M0 - VDD or GND power rails. The current drawn from any section of PDN is directly proportional to the number of cells connected.

C. *Acceptable IR-drop target budget calculation*

The calculations for determining an acceptable IR-drop target is based on the following assumptions [12] [for typical 7 nm SoC and nominal Voltage ($V_{nominal}$)= 0.925V power supply]:

i. A standard cell library characterized to $V_{nominal}$ ±10%

ii. Variation within Voltage Regulator $V_{nominal}$ ±2%

iii. 18.5 mV of IR-drop from the Voltage Regulator to the SoC.

Based on the .LIB characterization data, it is clear that the SoC PDN must maintain at least 0.8325 V (0.925V – 10%) to all the standard cells. Also, the worst-case voltage delivered from the Voltage Regulator is 0.9065V (0.925V – 2%). So, the acceptable IR-drop target can be easily determined by subtracting the voltage requirement from the voltage supplied:

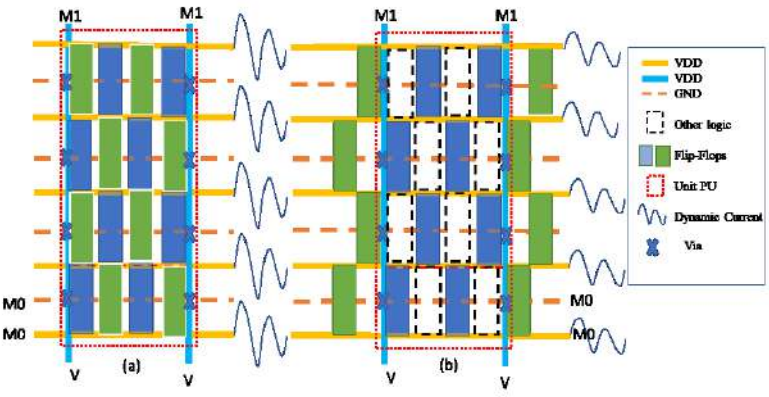

Fig. 3. Unit Placement Bins (a) before, (b) checkerboard pattern

$$\delta = (V_{Supply\_Regulator} – 2\%) – (V_{nominal} –10\%) – 18.5mV$$

$$= 0.9065V – 0.8325V– 18.5mV = 55.5 mV$$

[δ is Total IR voltage drop target budget on VDD and VSS]

D. *The checkerboard pattern for FF placement and Dynamic current simulations*

We propose a checker-board pattern for spacing and placing the cells to reduce the number of cells connected to M0 between M1 pitch Fig. 3. In 7nm, scannable FFs are usually double-height cells to provide easy access to additional scan-related pins, so our targeted bin is extended to cover several rows of scannable FFs. For proper spacing and placement of the cells in a checkerboard pattern, the number of FFs within the M1 pitch is kept equal to the number of rows of FFs inside the bin.

We also constrained the maximum displacement distance of the FFs to be within ±M1 pitch to minimize the impact on clock insertion delay of FFs due to displacement. [Horizontal displacement range of the Unit Scan [-x_{Δ},x_{Δ}] = ±M1 pitch]. Circuit level simulations including 4x4 FFs and RC modeling of the M0/M1 inside the bin before and after the displacement shows a 41% reduction in dynamic current fig. 4. With this reduction, we concluded that the constrained $\pm x_{\Delta}$ is sufficient enough to achieve the IR-drop target budget δ.

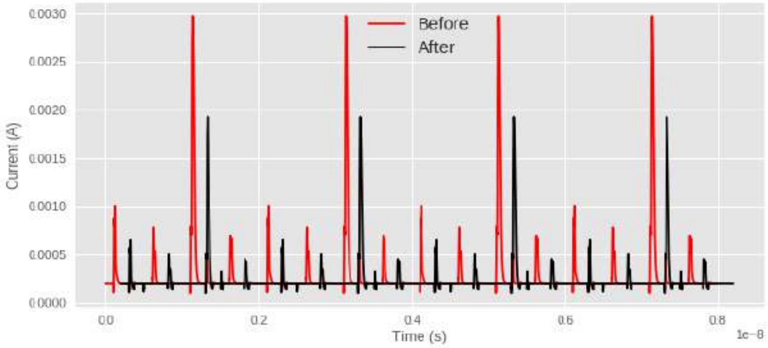

Fig. 4. Dynamic current simulations before and after displacement

E. Explanation of Algorithm

The following pseudo-code provides a detailed description of the algorithm used to implement the proposed solution. The flow can be defined in these steps:

(1) Defining a targeted list of functional modules for improved clock insertion delay. This list is fed into the **prepare_bound** function. For each functional module, a list of origins in the form of Cartesian (X, Y) locations is defined to place placement bounds.

(2)For each functional module, the **commit_bound** function is called. This function has multiple tasks: (a)Bound area is defined as a function of the total number of FFs with 50% extra margin to compensate the push out for checker-board patterned placement. (b) These bounds are further divided into an equal number of rows and columns of the unit bin (PU), (c) Deriving Bbox (Bounding box) of placement bounds based on the number of rows and columns of unit bins, (d) Extracting coordinates of each unit bins for traversing within the bounds, (e) Each unit bin is also further divided into the placeable FF units of 4x4, (f) Co-ordinates of these placeable FF units are also extracted, (g) Create a collection of each placeable units of every bin(PU) in the placement bound.

(3) Placement bound is created from (2) (a),(c)

(4) place opt and legalization

(5) (a)For each row of the collection created in (2)(g), the rows are traversed and placed FFs are staggered in a checkerboard pattern. (b) In case of all the placeable FF units are occupied, row over-flow is applied to continue the displacement of the FFs to the next row.

(6) Legalize placement.

TABLE 2. NOTATIONS

Term	Definition
B	Set of placement Bounds in design
b_k	K^{th} placement Bound of set B
b_{kW}/b_{kH}	Width & Height of b_k
PU	Unit Placement Box
PU_w /PU_H	Width & Height of one PU PU_w =P_{M1} & PU_H = 4*2*S_h
S_h	Site Row (Standard cell Row) Height
FF_W	Width of Unit Scan FF
FFh	Height of Unit Scan FF (Double Height Cells) =2* S_h
N_{FF}	Number of Unit Scan FF inside b_k
P_{M1}	Horizontal Pitch of M1 (Vertical) Power track inside PDN P_{M1} is an Integer multiple of FF_W
a, a_loc	Matrix [N_R x N_C] of PUs inside Bound, corresponding locations
b,b_loc	Matrix [r_p x r_q] of Placeable Unit Scan FF inside PU, corresponding locations
[-x_Δ, x_Δ]	Horizontal displacement range of the Unit Scan FF. χ_Δ= f(P_{M1}) or χ_Δ= f(FF_W)
Ab_k	Area Needed of b_k to have 50% Utilization = 2*[N_{FF}* FF_W*2* S_h] = N_R*N_C
MODE[i]/Origin[i]	List of functional modules/List or targeted origins of Bounds
ab	Collection of origins of each placeable FF units row-wise throughout a placement bound

```
prepare_bound () {
//List Functional Modules targeted for improved clock insertion delay
|    set MODE_[i] ← [READ_path1, READ_path2, Write_path] //defining
|     set Origin_[i] ← [{ll_x1, ll_y1}, {ll_x2, ll_y2}, {ll_x3, ll_y3}]
|      For [i=1; i<sizeof [MODE_[i]]; i++],

   set Bbox for $b_k$, bbx1= $[\{\chi_{llb}, y_{llb}\}, \{\chi_{urb}, y_{urb}\}]$
      //Setting Bbox for bound $b_k$, deriving Cartesian X and Y locations
7:$\sum Orig_{PU}(R_i, C_j)$ ← $\sum_{\substack{0\leq R_i \leq N_R \\ 0\leq C_j < N_C}} [\{\chi_{llb} + C_j * PU_w\}, \{y_{llb} + R_i * PU_H\}]$
      //Derive origin for each element of matrix a, as $f(PU_H)$
      //Cartesian X location and $f(PU_W)$ for Cartesian Y location
8: create_matrix =a_loc; dimension = {$N_R$, $N_C$}
      // Assign all the Cartesian origin of each PU to another matrix
9: create_matrix =b; dimension = { $r_p$, $r_q$ } → $\begin{pmatrix} p_3 q_0 & \cdots & p_3 q_3 \\ \vdots & \ddots & \vdots \\ p_0 q_0 & \cdots & p_0 q_3 \end{pmatrix}$
     // Each element of matrix a is further divided into placeable FF units
     //(4x4)

10: create_matrix =b_loc; dimension = {$r_p$, $r_q$}
     // Assign all the Cartesian origin of each PU to another matrix
11: create a collection
        $set\ ab = \begin{pmatrix} R_N C_0 \begin{pmatrix} p_3 q_0 & \cdots & p_3 q_3 \\ \vdots & \ddots & \vdots \\ p_0 q_0 & \cdots & p_0 q_3 \end{pmatrix} & \cdots & R_N C_N \begin{pmatrix} p_3 q_0 & \cdots & p_3 q_3 \\ \vdots & \ddots & \vdots \\ p_0 q_0 & \cdots & p_0 q_3 \end{pmatrix} \\ \vdots & \vdots & \vdots \\ R_0 C_0 \begin{pmatrix} p_3 q_0 & \cdots & p_3 q_3 \\ \vdots & \ddots & \vdots \\ p_0 q_0 & \cdots & p_0 q_3 \end{pmatrix} & \cdots & R_0 C_N \begin{pmatrix} p_3 q_0 & \cdots & p_3 q_3 \\ \vdots & \ddots & \vdots \\ p_0 q_0 & \cdots & p_0 q_3 \end{pmatrix} \end{pmatrix}$

  //get the origin of each placeable FF unit row-wise throughout bound $b_k$
12: a) create bound $b_k$ ← $\binom{\in[FF]}{bbx1}$
    //create_placement bound
    b) apply CTS grouping options
13: run incremental place_opt & legalization

14: For each row of $R_{ab}$ {
        get the origin of all placed cells

     $rearrange\ FF$
     $\rightarrow \begin{cases} \text{If } R_{ab} \text{ is even} \rightarrow (C_0 q_0, C_0 q_2, \dots, C_N q_0, C_N q_2) \\ \text{If } R_{ab} \text{ is odd} \rightarrow (C_0 q_1, C_0 q_3, \dots, C_N q_1, C_N q_3) \\ \text{displacement range} \rightarrow [-x_\Delta, x_\Delta] \end{cases}$
15: for a row overflow

$rearrange\ FF\ ext \begin{cases} R_{ab} + 1\ (If\ R_{ab} \text{ is even} \rightarrow (C_0 q_0, C_0 q_2, \dots, C_N q_0, C_N q_2) \\ R_{ab} + 1\ (R_{ab} \text{ is odd} \rightarrow (C_0 q_1, C_0 q_3, \dots, C_N q_1, C_N q_3) \end{cases}$

16: legalize placement
}
```

V. EXPERIMENT RESULTS

Our proposed dynamic IR hot-spot and clock insertion delay reduction technique was tested on selected sub-blocks of the FPGA Semi-custom Memory design at 7nm technology node with 0.925V power supply. The following EDA tools are adopted to construct our experimental flow: The Synopsys IC Compiler II (ICC-II) [13] was utilized for Design planning, PDN construction, cell placement, CTS, and routing. The proposed flow script is written in TCL language, which is the native scripting language in ICC-II's shell. The IR-drop is calculated using Ansys Totem [14]. Static timing analysis is reported by PrimeTime [15].

A. IR hot spot reduction

Fig. 5 reflects the effectiveness of our proposed algorithm in reducing IR hot spots. In this figure, the IR map of FPGA Semi-custom Memory design before and after the application of the proposed algorithm is illustrated. We targeted to apply the algorithm on 3 functional modules of the design. As demonstrated, the IR hot- spots of Placement Bounds (b1, b2, and b3) are completely mitigated. In the map, the Red color denotes voltage drops above 60mV and the Yellow color denotes voltage drops below 60mV.

In Fig. 6, the top 10 bins are sorted based on the voltage degradation within each placement bound. The 3D plot contains the normalized Cartesian location of bins in (X, Y), and Z represents the IR-drop in mV. Voltage drops before and after applying the proposed algorithm are captured. The worst IR-drop is improved by ~32.50%. For all 3 Placement Bounds, we achieved the IR-drop target budget [δ] of 55.5 mV. Table 3 captures the IR-drop improvement for all the targeted sub-blocks.

B. Impact of clock insertion delay and timing

Table 3 illustrate that after applying our proposed algorithm, the clock insertion delay is reduced by ~36%. This kind of FFs placement also ensures the reduction of local skew within a specific functional module. Such placements also reduce the overall wirelength and loads from clock distribution networks. Results also indicate that the proposed algorithm has a very minimal impact on the timings of each sub-blocks.

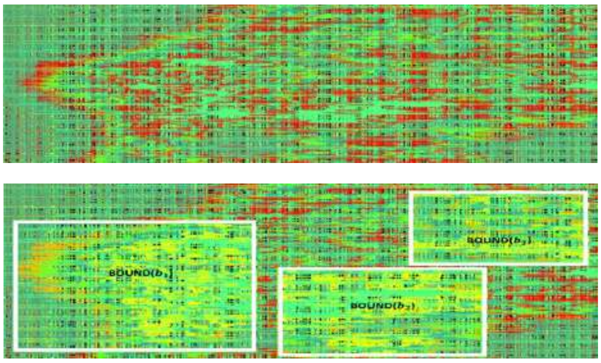

Fig. 5. IR hotspot maps before (Top) and after (Bottom) the application of the IR-mitigation technique.

VI. CONCLUSION

This paper presents a novel dynamic IR-drop optimization flow to eliminate IR hotspots along with the improvement of clock insertion delays. Our proposed approach is to convert the cell placement search into a deterministic linear search. We targeted to achieve the specified IR drop budget, rather than using greedy search to find the most optimal placement. Cell movement can be predicted accurately by the proposed model, and the proposed optimization scheme can mitigate IR-drop in quality and quantity without timing degradation. We acknowledge that the proposed algorithm has a limitation in reducing the hotspots located around macros, within the narrow channels, or around the chip boundary. These hotspots cannot be fixed by cell movement but can be mitigated by local PG augmentation, cell swapping, or decap cell insertion, etc. Our future work will be targeted to address these limitations.

Abstract— **In the framework of creating a digital ecosystem of commercial real estate objects, the main problem is the formation of a digital environment for managing all components of engineering systems that ensure the vital activity of the real estate object.**

The aim of this work is to develop a system for accounting for mutual settlements for electricity consumed on the basis of a distributed ledger using blockchain technology. To assess the effectiveness of the system a simulation model was built using AnyLogic system. Based on the model the system architecture was designed and a software application of the distributed ledger was developed.

Keywords— Blockchain technology, distributed ledger, simulation model, software application

I. Introduction

The electricity market in Russia, like in Europe, is changing dynamically. New energy sales companies are emerging that actively compete with each other for consumers. This competition is especially intensified in the retail electricity market. For organizations involved in the operation of real estate, the tasks of energy management and management of relationships with energy sales companies are extremely relevant. The use of smart contracts based on blockchain technology is becoming a serious competitive advantage for an energy company.

The blockchain is a technology that allows us to conduct transactions peer-based unified network (P2P network, peer-to-peer). Transactions of this type assume that each member of the network can carry out a transaction directly with any other member of the network without the involvement of a third-party intermediary [1]. The data chains are stored in a decentralized manner in a distributed ledger on the participants' devices. A distributed ledger is a distributed database that is stored on the device of each of its participants.

The advantage of this technology is that it has no governing body. It was precisely the absence of intermediaries in this system that aroused keen interest in it.

Lacking a controlling intermediary, the system must be distinguished by another idea: database security. With this in mind, each piece of information entered into this database is reviewed by independent contributors. The technology ensures the security of transactions, has confirmation of the authenticity of data and identity. If someone wants to transfer data, then he must be authenticated, and, as a result, a record of the input / transfer of data will be saved. The data participating in the blockchain is almost impossible to change if there is no access to the keys. The risk of a data breach is unlikely at this stage.

Due to its high degree of security and autonomy, the technology has become popular primarily in the financial industry [2]. The participants themselves check the authenticity of transactions; no third-party regulator is needed.

Energy industry is a promising area for using blockchain technology [3]. In particular this technology can find application at the stage of energy sales. For example, electricity can be sold either directly to consumers or through an independent utility company, and the technology under consideration could enable a utility company or a major supplier to bill consumers directly based on readings recorded on the blockchain.

Typically, electricity suppliers process a huge number of customer requests which undoubtedly affects the speed of decision-making, not to mention careful control over the supply process [4]. Blockchain technology can also be used in this process.

Along with billing for consumed energy blockchain technology can be seen as the backbone of energy logistics processes and metering of consumed electricity.

At the moment there are several well-known companies on the market that provide their services in the development and implementation of blockchain technology in energy companies.

These companies are:

- LO3 Energy and their TransActive Grid project, which is the decentralized open source platform for applications. Built-in tools allow you to measure the level of generation and consumption of electricity in real time, along with other indicators. Despite the fact that the project is under development, its first demo version is currently working in Brooklyn (USA) [5].
- Energy Blockchain Labs – was founded in 2016, the laboratory, together with other companies, is working on projects aimed at developing energy Internet technologies based on blockchain technology and solving problems in the field of generation, consumption, trade and energy management [6].
- Grid Singularity is a green blockchain company that is spearheading the development of an open, decentralized energy data exchange platform under the auspices of the Energy Grid Foundation (EWF) [7].

Now the Russian energy system consists of a small number of large participants between whom there are strong ties and direct communication with the state and vertical integration make the system inactive. Recently, the transition from a continental level to a smaller one (for example, urban or regional) is beginning to take on more and more economic meaning. Such a campaign can serve as

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

a solution to the problem of energy supply to remote territories (for example, the development of renewable energy sources in the Far North). Blockchain technology will ensure the most effective interaction between the buyer and the electricity seller and sell electricity not only without a trade margin and additional costs, but also change its cost depending on production volumes and needs [8].

As a rule, companies engaged in the operation of real estate process a huge volume of data from contracts and customer orders which undoubtedly affects the speed of decision-making. In addition parameter monitoring for energy engineering systems and processes is required. Blockchain technology can be effectively used for solving these tasks. Along with billing for energy consumption blockchain technology can be seen as the basis of energy logistics processes and measuring the amount of electricity consumed [9]. The aim of this work is to develop a system for accounting for mutual settlements for electricity consumed on the basis of a distributed ledger using blockchain technology.

II. FUNCTIONAL MODEL OF THE DISTRIBUTED LEDGER

To design the functional model of a distributed ledger of contracts for electricity consumers of real estate objects we used UML notation [10].

A distributed ledger consists of two types of nodes: a member and a manager. Each of them uses its own software. All actions in the network, such as registration of a new participant, execution of a contract for the supply of electricity to a real estate object, payment of consumed electricity are performed with the participation of the control unit. We will build functional models of operations in the network of the distributed ledger of contracts for the supply of electricity. The node acting as a buyer of electricity, generates a request with the contract data from its side and signs them with a digital signature for identification. The entire data request is signed to protect against changes.

Having received the application the control node checks the data for validity: the ownership of the digital signature and the terms of the electricity purchase agreement. If inaccuracies are found, it is sent for processing to the sender's node. After verification, the control node sends an application to the seller node when it appears on the network. The seller node checks the terms of the contract and, if agreed, carries out the formation of the contract on its part and signs it with a digital signature. Information protection is organized at the same level as at the buyer's site.

The second part of the contract from the seller node (electricity supplier) is sent to the managing node. The control node checks it and forms a block of two parts of the contract and information from the register about the previous block. And also signs it with a digital signature. For the signature, information such as the data of the contracts of both parties, the hash sum of the previous block and the digital signatures of the parties to the transaction are used, thereby the digital signature of the control node protects the entire block.

After that, the received block is sent to all network participants.

Main part is an algorithm for executing a transaction and checking its validity. This algorithm is presented on Fig.1.

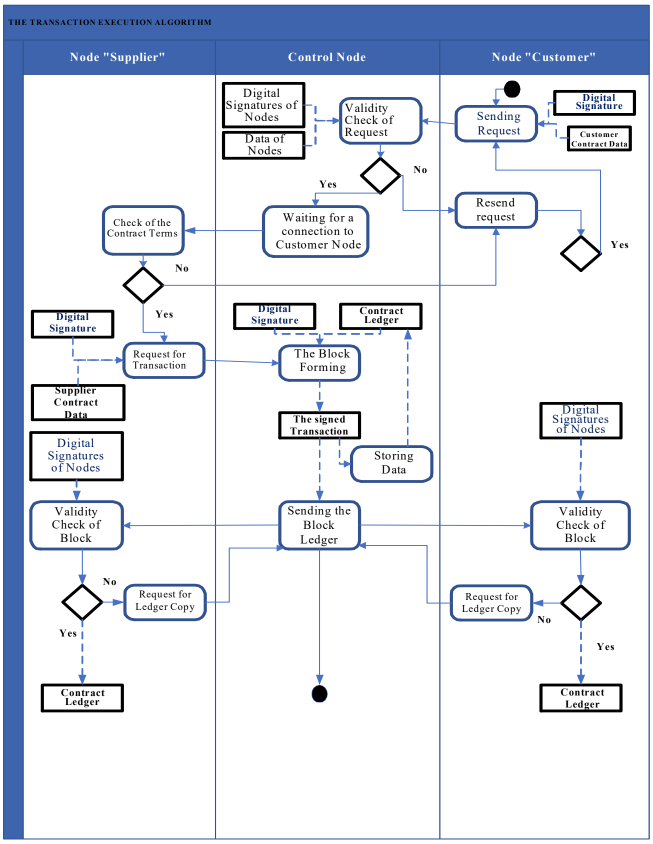

Fig. 1. FLOWCHART OF THE TRANSACTION EXECUTION ALGORITHM

III. MATHEMATICAL MODEL OF THE DISTRIBUTED LEDGER

The model of a distributed ledger is based on the client-server architecture. Additional tasks are performed on the server: identification, request verification, processing and generation and sending of a request error message. To achieve the reliability of our distributed ledger network we proposed additional application servers that will replace the failed main server. To develop a distributed ledger network we use model is based on Petri-Markov net [11].

Let’s consider Petri-Markov net which is presented on Figure 2.

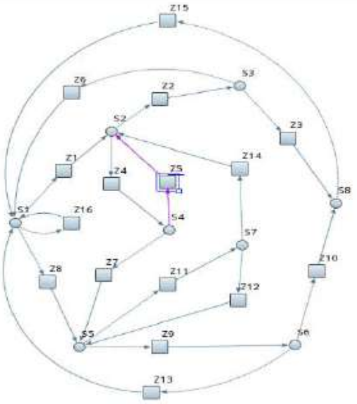

Fig.2 PETRI-MARKOV NET MODEL FOR THE DISTRIBUTED LEDGER

In this model $\{s_{1(s)}, ..., s_{j(s)}\}$ is the set of positions, $Z = \{z_{1(z)}, ..., z_{j(z)}\}$ is the set of transitions. Position S_1 - receipt of a request from the client, S_2 - operational state of the main server, S_3 - the ability to process the request by the main server, S_4 - inoperative state of the main server, S_5 - operational state of the backup server, S_6 - the ability to process the request by the backup server, S_7 - inoperative state of the backup server, S_8 - communication with the database server. Transition $\boldsymbol{Z_1}$ - client request to the main server, $\boldsymbol{Z_2}$ - user identification on the main server, $\boldsymbol{Z_3}$ - access to the database server from the server software, $\boldsymbol{Z_4}$ - failure of the main server, $\boldsymbol{Z_5}$ - operating state of the main server, $\boldsymbol{Z_6}$ - message from the main server about the impossibility of processing the request, $\boldsymbol{Z_7}$ - request transmission to another server, $\boldsymbol{Z_8}$ - client request to the backup server, $\boldsymbol{Z_9}$ - user identification on the backup server, $\boldsymbol{Z_{10}}$ - access to the database server from the backup server software, $\boldsymbol{Z_{11}}$ - failure of the backup server, $\boldsymbol{Z_{12}}$ - operating state of the backup server, $\boldsymbol{Z_{13}}$ - message from the backup server about the impossibility of processing a message, $\boldsymbol{Z_{14}}$- sending a request to another server, $\boldsymbol{Z_{15}}$ - sending processed data to clients, $\boldsymbol{Z_{16}}$ - preparing to receive new data.

According to the proposed Petri-Markov model one can only judge the attainability of states; for a complete assessment of the characteristics of the chosen algorithm, we need to build a simulation model.

IV. Computer Simulation Results

We used AnyLogic 8.3.3 as a simulation tool. It is a universal tool for simulation modeling [12]. The program has a modern graphical interface, is cross-platform and can run on Windows, MacOS and Linux.

The constructed simulation model of the interaction between the client and the control node in the AnyLogic program is shown in Figure 3.

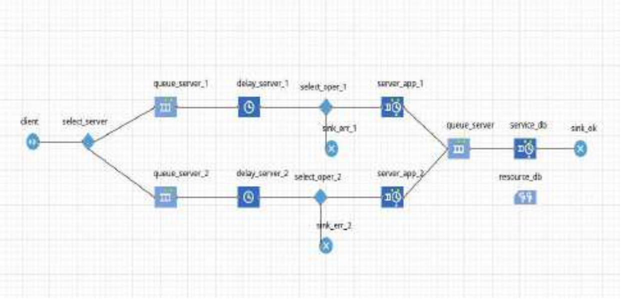

Fig.3 THE SIMULATION MODEL OF CLIENT INTERAGTION WITH THE MANAGING NODE

In this model are presented:

- client - a request from the client program.
- select_server - simulate the failure of the primary server and redirect the request to the backup.
- queue_server_1 and queue_server_2 - queue of requests to the primary and backup servers, respectively.
- delay_server_1 and delay_server_2 - delay for processing a request on the primary and secondary servers, respectively.
- select_oper_1 and select_oper_2 - simulation of operation processing, error content in the request to the primary and backup servers, respectively.
- sink_err_1 and sink_oper_2 - simulates the server response about an error when executing a request to the primary and backup servers, respectively.
- server_app_1 and server_app2 - simulation of transaction processing by the program on the primary or backup server, respectively.
- queue_server - database server queue.
- server_db - modeling the process of processing a transaction request on the database server.
- resource_db - placing transactions into the database.
- sink_ok - simulation of a response to the client about the successful completion of the operation.

We use this model to test the operability of the distributed register of contracts with electricity consumers of real estate objects. Model parameters: probability of failure of the main server - 0.20, latency on the server when processing a request from the client, and latency for applying a transaction on the database server - 75 msec. The rate of requests is measured by the number of requests per second.

The result of performing computer experiments is shown in Table 1.

Test	Request Rate (quantity/msec)	Number of Requests	Application Server Queue (quantity)	DataBase Server Queue (quantity)
1	1	10026	0	0
2	14	10836	1	1
3	20	10543	3	1
4	30	10344	47	1

TABLE I. COMPUTER SIMULATION RESULTS

According to the data obtained as a result of the computer simulation we can conclude that all requests are guaranteed to be served at a high intensity of their arrival in the network. You can also see that with a low intensity of requests the queue does not exceed one request, which means that requests with such an intensity will be processed without waiting in the queue.

When the request rate is more than 20, a sharp increase in the queue length begins, which affects performance.

V. Development of a Smart Contract System for Electricity Suppliers

To store the ledger on all nodes and user information on the control node, the SQLite DBMS was chosen. Each copy of the ledger, as well as user information, is available in single-user mode of the program installed on the node. The data in the SQLite database is stored in one file and when accessing them, direct access is used, this increases the speed of reading and writing.

The SQL language is used as the interface for interaction between the user applications and the DBMS.

To develop the software the C ++ programming language was chosen using the Qt cross-platform library. The Qt library which represents many dynamic link libraries is written in C ++. Its main advantage is cross-platform, that is, the written code can be used to create an application on any supported platform: Windows, Linux, Android, iOS, WindowsPhone, Embedded Linux and many others. Qt Creator was chosen as the development environment, it is the standard development environment for programs using the Qt library and comes in the same package with it.

Figure 4 shows a class diagram for a distributed ledger.

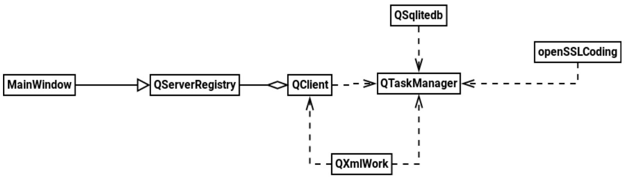

Fig.4 THE CLASS DIAGRAM FOR DISTRIBUTED LEDGER

A distributed ledger is made up of blocks combined into a chain (blockchain) that protects its integrity. The blocks themselves are provided with a digital signature which can be used to identify each of the parties who signed the Contract.

To access the distributed ledger the user uses a private key which is used to sign the block with a digital signature. This key is unique and its theft will not pose a threat to existing blocks in the distributed ledger but it can be used to sign new contracts without the knowledge of its owner, therefore, the storage of this key should be organized by each user of the distributed ledger network individually and convenient for him. The password itself is not stored on the computer only its hash is stored for verification.

In addition to the distributed ledger the control node stores confidential information about users registered on the network, as well as signature data [13]. Confidential user information is used by the control node as user verification; registration and storage is best organized according to the scheme shown in Figure 5. The same applies to a piece of information on a digital signature namely the private key.

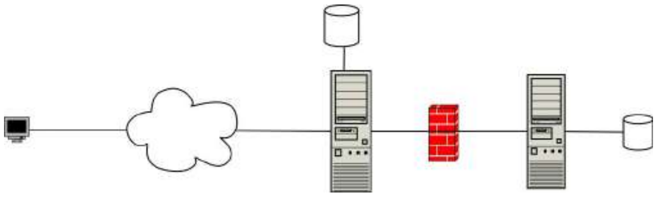

Fig.5 DATA PROTECTION SHEME ON THE CONTROL NODE

All external requests to the server with protected data are restricted by the firewall. Requests are accepted and sent only to the server of the control node which is located in the same local network. Requests for information are limited and can be in the form of true or false which makes it impossible to obtain information if you have access to the local network.

VI. Conclusion and Future works

Blockchain technology has already found wide application in the financial sector and is just beginning to develop in the energy industry, in particular in the electric power industry [14]. The following main advantages of using the technology in question in this industry were highlighted:

- Decentralized storage of transactional data will have a positive impact on the level of protection of this data and will allow for greater independence from the authority performing the centralized administration function.
- The use of blockchain technology will simplify the procedure for making payments using cryptocurrencies, digitalizing contracts, verifying transactions, managing digital content and executing trade operations.
- The technology under consideration will allow the exclusion of third-party intermediaries from the business model previously involved in it.
- Blockchain technology will provide an opportunity for consumers who are also electricity producers and have generating capacities (for example, solar panels and wind generators) at their disposal to sell the electricity they generate not only to their neighbors, but also to the operators of the electrical network. With this approach the purchase price of electricity by electricity grid operators will depend only on production volumes and will not include a trade margin.
- Through the use of blockchains all transactions will be executed in real time and the final settlement will be made only on the basis of the volume actually consumed. This will contribute to the fact that the operators of the electric network no longer need data for making mutual settlements.

The solution to design the distributed ledger of contracts between electricity consumers at real estate objects and electricity suppliers has been presented in this paper. The model of a distributed ledger is based on Petri-Markov networks. To assess the performance of the distributed ledger model at various queries intensities, an original computer simulation algorithm was proposed using the AnyLogic software. When the distributed register of contracts is transferred to the production phase real data will be compared with the simulation results.

The proposed model is based on a closed distributed ledger, in which there is a control node that performs the functions of a network administrator. In the future it is necessary to develop the resulting model and abandon the control node as an administrator in favor of a hybrid model, in which anyone can become a network participant without a lengthy and complex registration and data verification procedure. This will make it easier to use and increase the number of network participants.

Another area of research is the development of a solution that would integrate the transmission of data on consumed electricity using the Internet of Things technology into a smart contract system built using a distributed ledger.

***Abstract*—Resistive infrared detectors arrays (bolometers) may show interferences between devices. Such interferences called crosstalk, or more specifically sneak path, reduce the signal quality, causing reading errors. This work proposes an interesting alternative solution to avoid sneak paths in bolometers arrays. The idea is to use simple diodes in series with the detectors, so all possible sneak paths are grounded and the detectors are only trigged when the diodes were conducting. Test were conducted in purely resistor arrays and diode-resistor arrays. The target resistance of one element was set to 105 kΩ. For both isolated devices and matrix devices elements, the target resistance was achieved, indicating that the sneak path effect has been avoided. So, this solution, in addition to improving the signal quality, is also a simpler construction when compared with transistors switches solution, requiring less metal levels, since no tracks are required to activate the transistor.**

***Index Terms*—bolometer; crosstalk; sneak path; resistor; diodes; infrared; detectors; array**

I. Introduction

The goal of this work is to analyze the signal interferences that occur in bolometric detectors arrays, and to propose an innovative solution to avoid the so called sneak path problem.

Bolometric detectors are made of resistors whose resistance varies with temperature when influenced by electromagnetic radiation, and one of their applications is the generation of thermal images.Thermal images are generated from a detector array whose thermal surface distribution contrast is observed as a function of time [1].

The term ”focal plane array” (FPA) refers to a set of individual image detector elements (”pixels”) located in the focal plane of an image system. Although the definition may include one-dimensional arrays, as well as two-dimensional (2D) arrays, it is often applied to the latter ones [2]. This work is focused on 2D arrays.

Fig. 1 shows a three-dimensional array connections scheme used in bolometer FPAs. The sneak path problem can be observed in this kind of arrangement.

A. The Sneak Path Problem

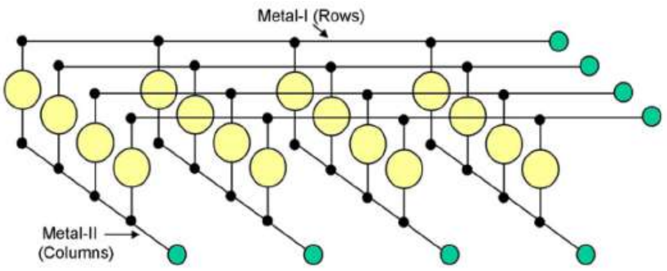

Fig. 1. Schematic diagram showing metals rows and columns connection scheme [3].

The sneak path problem can be described as a crosstalk interference between adjacent cells caused by the sneak path current. This is an undesired effect and may cause signal misinterpretations [4], [5], as shown in Fig. 2.

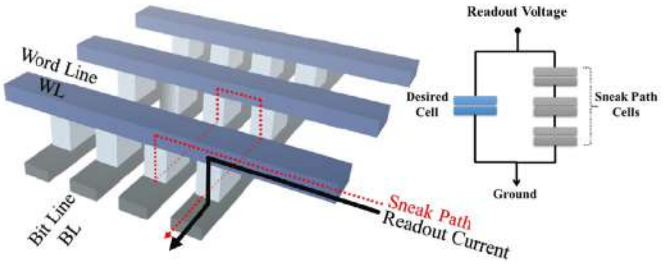

Fig. 2. Representation of sneak path cells and sneak path current in a array cell [6].

As can be seen in Fig. 2, the sneak path problem occurs when one element is addressed and other elements form a parasitic circuit in parallel. This parasitic circuit provides an undesired current pathway, since this current activate not only the addressed device, but also all other adjacent elements, leading to a signal misinterpretation.

Many solutions have been presented to solve the sneak path problem, including solutions based on transistors, diodes, volatile switches and non-linear devices [7].

The most common solution to solve sneak path problems in bolometric FPAs is the use of transistors in series with each detector. Memristors arrays technology devices have been using diodes as a popular way to solve the addressing problems, due to its simplest structure and easy manufacturing

This work was supported by Brazilian agencies CAPES (process nº BEX 1006/14-1) and CNPq (process nº 153630/2012-4).

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

processes [7].

As shown in Fig. 3, a diode is added to each memory cell producing a new diode and a memristor cell (1D1M). The sneak path problem is one of the main difficulties when building memories with three-dimensional design [6]

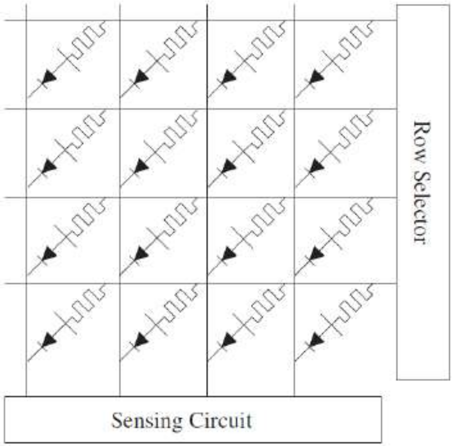

Fig. 3. Simple memory array with a diode in series with a memristor for each memory cell [5].

As can be seen in Fig. 4 the unaddressed diodes cells end up being reversed polarized, and do not conduct current, preventing the electrons from flowing in unwanted paths.

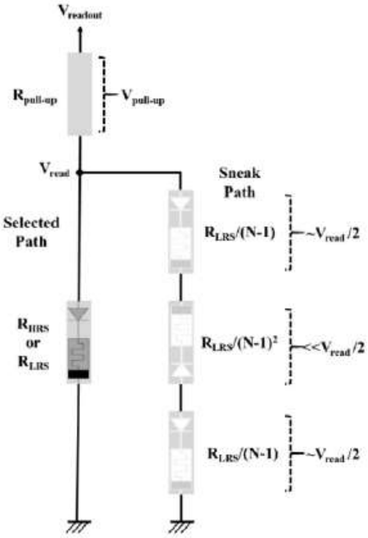

Fig. 4. Equivalent circuit of the 1D1R selection device [6].

The proposal in this work is to adapt the memristor diode solution for bolometric FPAs. Such solution is presented in [8]. Many works have been found in the literature having applications in memristors and pressure detectors [9], but none with any implementation in bolometric detectors.

II. Proposed Solution

The circuits are assembled in the configuration of NxN arrays, and the elements are read through row and column addressing. In order to test for the sneak problem effect, two different projects were fabricated and tested. Purely resistive elements and resistor diode elements. For purely resistive arrays with identical elements, it is possible to calculate the resistance measured between any pair of X (vertical) and Y (horizontal) wires by (1).

$$R_{eq} = R(\frac{2N-1}{N^2}) \tag{1}$$

Where:

N: Number of elements on the side of the square array.

A: Elements resistance.

Equation (1) was obtained by circuit analysis.

So for arrays composed of 100 kΩ resistors and using (1), one may find the value on any addressed element, as shown in the table I.

TABLE I
Calculated Resistances

Array	Resistance
Isolated Device	100 kΩ
2x2	75 kΩ
3x3	55,55 kΩ
4x4	43,75 kΩ
8x8	23,43 kΩ

As already mentioned, the solution proposed in this work have a diode added to each resistor producing a new cell of a diode and a resistor (1D1R). The advantages of this proposal are:

- Reduced manufacturing processes, since a diode is much simpler than a transistor.
- Reduction of metal levels, since no connections are required to power the transistor drives.
- Increased density sensors in the DIE.

An important observation is that in this work the detectors array and the sensing circuit are fabricated separately.

A. Implementation

Initially an electrical simulation was performed for both purely resistive elements and for 1D1R elements. Then the simulated arrays were implemented using a printed circuit board (PCB) and commercial devices (100 kΩ ± 5% and IN4148 diodes). In order to easily check the circuit configuration setup, electrical measurements were performed in both circuits by applying a DC voltage (HP3245A) and measuring the current using a standard multimeter (HP3458A).

After the measurements with the PCB, an integrated circuit (IC) design was started using the XFAB XC06 technology (Fig. 5). The manufactured IC was designed having an array 8x8 of resistors, an array 8x8 of 1D1R elements, and some isolated resistors and diode for testing purposes. Where used RPOLYH resistors (high resistive poly0 resistor) of 100 kΩ, and DP diodes.

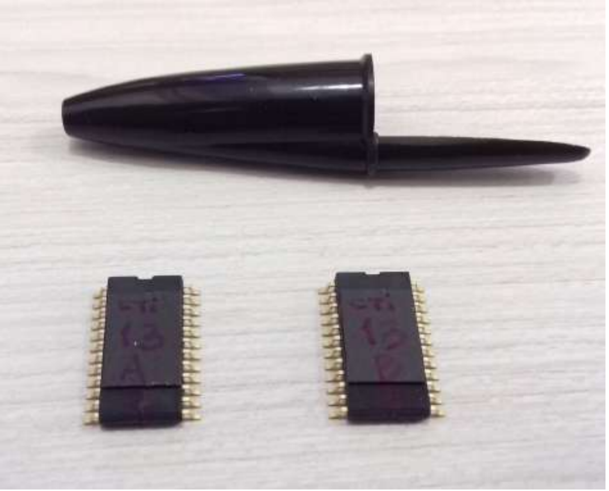

Fig. 5. fabricated ICs.

III. Results and Discussion

A. Electrical Simulations Results

Fig. 6 shows the IxV curves for an isolated resistor and arrays of 2x2, 3x3 and 4x4 elements. These values are i agreement with the results presented in table I.

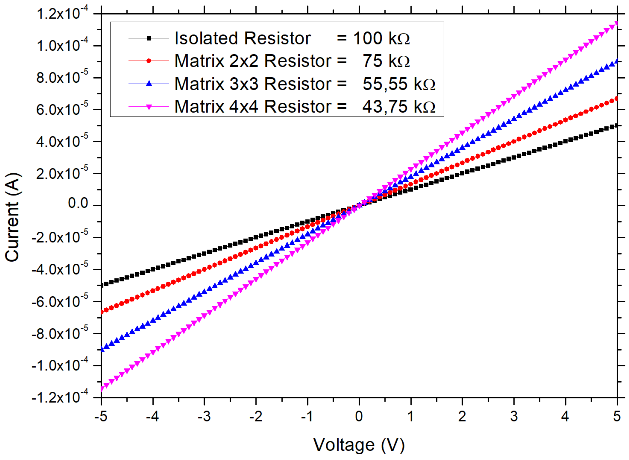

Fig. 6. Current vs Voltage of the simulated resistor arrays.

The simulated IxV curves for arrays with 1D1R elements are shown in Fig. 7. As expected, all values presented are practically identical, indicating that the “diode” solution have worked, avoiding sneak paths on devices that were not the measurement subject. The diode operation can be observed since all curves have a zero current value (diode leakage current in order of nA) in the negative voltage range and start to rise at about 0.3 V, reaching a linear operation at 0.7 V.

B. Electrical Measurements in PCB Arrays

The IxV curves for the PCB resistor arrays are shown in Fig. 8. These values are also in agreement with the results presented in the simulations and in table I.

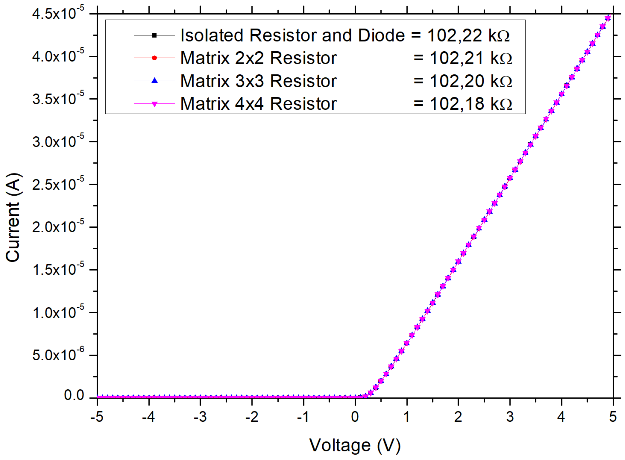

Fig. 7. Current vs Voltage of the simulated 1D1R arrays.

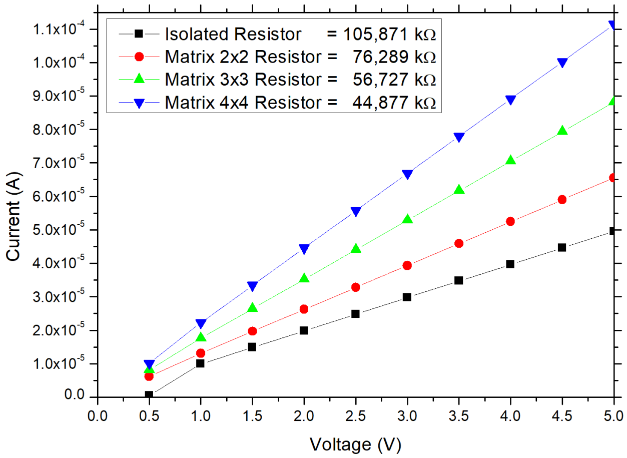

Fig. 8. Current vs Voltage of PCB resistor arrays.

The IxV curves for the PCB arrays of 1D1R elements are shown in Fig. 9. They are all overlapping indicating the effectiveness proposed by the diodes solution, resulting in no sneak paths problem.

C. IC simulations results

The IC design was performed using Cadence tools. The simulated IxV curves for the isolated devices are shown in Fig. 10. The isolated resistor have presented a 100 kΩ, as designed, for both negative and positive voltages. On the other hand, the 1D1R element has null value up to approximately 0.7 V and a resistance value close to 100 kΩ, as expected for a resistor diode configuration.

An interesting result can be observed in Fig. 11. For the IxV curve of 8x8 arrays, a device suffering from sneak path

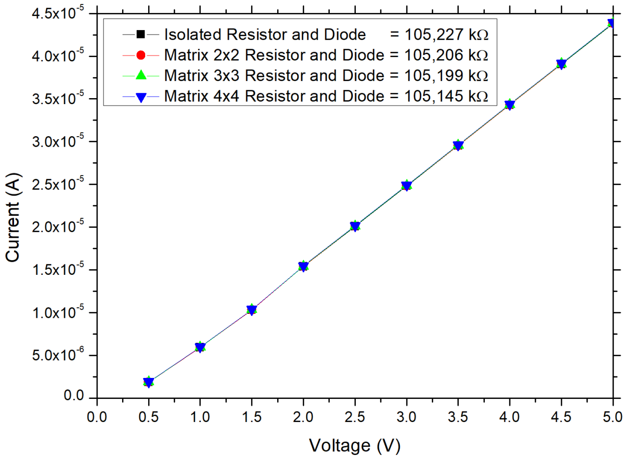

Fig. 9. Current vs Voltage of the PCB 1D1R arrays.

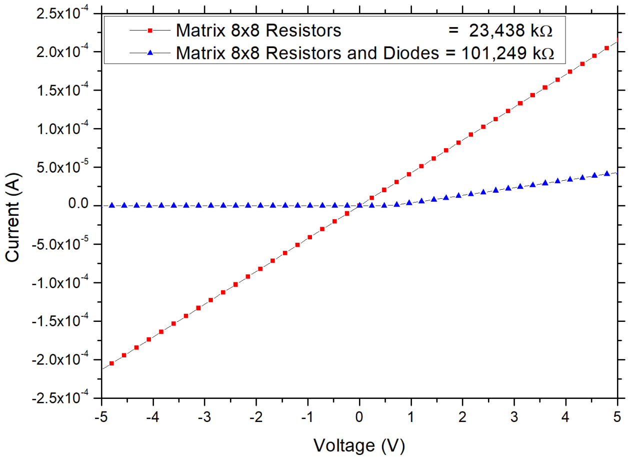

Fig. 11. Current vs Voltage of the 8x8 array simulated in Cadence

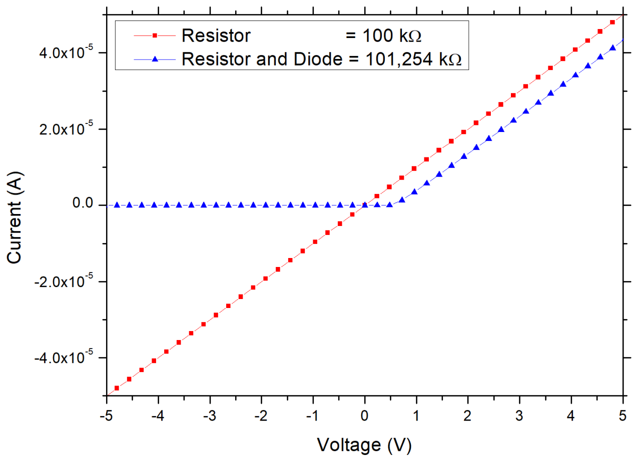

Fig. 10. Current vs Voltage of the isolated device simulation

problem, should present a resistance of about 23 kΩ, as pointed out in table I. As one can see, this value was reached for the resistor element array. Nonetheless, the cadence layout simulation for 1D1R elements have presented approximately 100 kΩ value and a resistor diode like curve, again, proving that the diodes were efficient in canceling the sneak paths.

D. IC Fabricated Measurements

Since all measurements and simulations have indicated so far that the solution proposed was indeed efficient, a IC measurement was performed. The chip was packaged and a test bench was designed for IxV measurements. The IxV curves measurements for the isolated devices are shown in Fig. 12. The curves follow almost in parallel, indicating a very close resistance value. The offset between the curves is due to the use of the diodes. Both numbers are in agreement with the designed target resistance value.

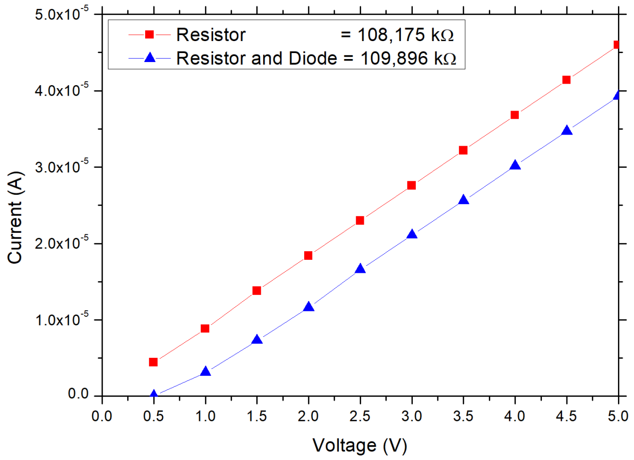

Fig. 12. Current vs Voltage of isolated devices fabricated inside the IC.

The IxV curve of 8x8 arrays, shown in Fig. 13, have presented misleading results for the 1D1R element. For the resistor array the expected 23 kΩ resistance value was obtained. In the other hand, due to lack of a guard ring for grounding the diodes, a non-expected behavior was achieved in the 1D1R elements.

As a summary, tables II, III, IV and V show all resistance values obtained through simulations and measurements. All implementations presented consistent results, except for the 1D1R elements of the IC 8x8 matrix. It was expected that the 8x8 1D1R IC array presented a similar value as the isolated resistor diode device, which did not happen, differing from all previous results. It was used the XFAB XC06 technology

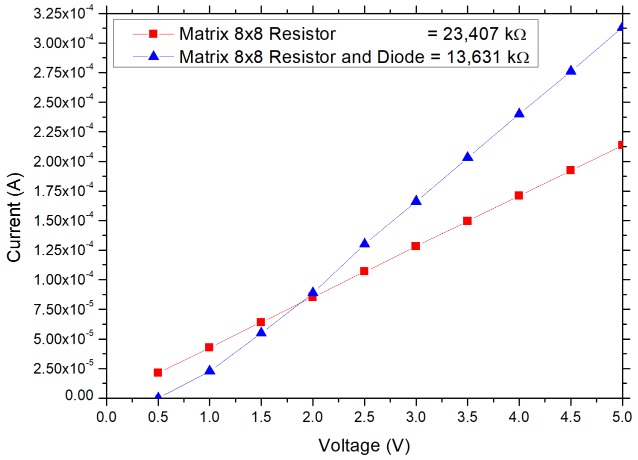

Fig. 13. Current vs Voltage of array 8x8 fabricated inside the IC.

that requires (mandatory) guard ring for grounding procedures. Since this requirement was not verified by the DRC, unfortunately the proper grounding has not been done. Some more testing were performed and it was possible to observe that, since some diodes are not properly grounded, they may conduct during the measurements. Therefore a future work the IC is being designed with guard rings.

TABLE II
RESISTANCES 1

Array	Calculated R	Simulation R	Simulation RD
Isolated Devices	100 kΩ	100 kΩ	102,22 kΩ

IV. CONCLUSION

In this work, sneak paths between resistive elements of bolometric FPA were analyzed. The goal of this work is to overcome the signal interferences that occur in bolometric detectors arrays, proposing an innovative solution to avoid this problem. For this purpose, isolated and arrays elements were designed, simulated, manufactured in PCB and fabricated trough IC design. Through the measurements of arrays made up of resistors, it was possible to clearly demonstrate the sneak paths effect. The proposed solution efficiency was demonstrated in the diodes resistors arrays. All electrical simulations and measurements performed in the PCB design have confirmed the effectiveness of the proposed solution. Tests were conducted in purely resistor arrays and diode-resistor arrays. The target resistance of one element was set to 105 kΩ. For both isolated devices and matrix devices elements, the target resistance was achieved, indicating that the sneak path effect has been avoided. However, for the ICs, it was expected that the 8x8 1D1R IC array presented a similar value as the isolated resistor diode device, and the same did not happen. This fact arises from the lack of a guard ring for grounding the diodes. Nonetheless, it was presented an effective solution that, in addition to improving the signal quality, is also a simpler construction when compared with transistors solution, requiring less metal levels, also avoiding sneak path problems at all.

TABLE V
RESISTANCES 4

Array	IC R	IC RD
Isolated Devices	108,175 kΩ	109,896 kΩ
8x8	23,407 kΩ	13,631 kΩ

***Abstract*—The decline of human physical ability with aging is an important factor to consider as to athletic performance evaluation. Physiological factors or real-world performance data have been used to build mathematical models. Marathon is a sports event attracting more and more participants. However, due to the limitation of field size, the race organizers usually must qualify each athlete for certain events based on age and gender. We use statistical and machine learning models for analyzing the Boston Marathon results to delineate the decrease in elder athletes' endurance performance. We also apply the transfer learning model on the mobile activity tracking social media platform Strava to classify beginners or professional athletes using performance data and applying sentiment classification to athletes' comments. Our results may provide valuable insights for athletes, coaches, and governing bodies for athletics.**

***Index Terms*—Machine learning, Statistics, Sport, Natural language processing**

I. Introduction

The change of endurance performance with aging is an interesting topic. It applies to the world-class athletes competing at the highest level, such as the Olympics and World Championship events. Also, it has drawn more and more attention from the general population with the popularity of road racing, cycling, and triathlon events [1]. For example, according to the "2018 U.S. Running Trends Report", near 18.3 million registrants entered road race events in 2017 [2]. We may expect a gigantic number of participants in all endurance events worldwide, which indicates a thriving industry of recreational endurance competition. Many of these athletes have passed their best physiological period for endurance performance. However, they still strive for excellence in their performance to the best of their ability. Understanding the change of human physical ability may provide important information to evaluate elder athletes' performance and guidance on how to manage expectations and design training programs for them. For instance, World Masters Athletics (WMA) adopts statistician Alan Jones' Age Grade Tables to make race performance of all ages comparable across the board. Fig. 1 and 2 show excerpts from World Masters Athletics (WMA) Running Age-Grade Tables by Alan Jones (https://github.com/AlanLyttonJones/Age-Grade-Tables). The table calculates the age-grading factor as the current world record of an event divided by the current world best time of each age in that event. The age-graded time of an athlete can be presented as the race time multiply by the age-grading factor of certain age and event [3]. The age grading system calculates athletes' race times as the percentage of the current world record times of corresponding age and gender, which gives a normalized scale to assess competitiveness.

Fig. 2. Excerpts from World Masters Athletics (WMA) Female Running Age-Grade Tables by Alan Jones. The table calculates the age-grading factor as the current world record of an event divided by the current world best time of each age in that event. The age-graded time of an athlete can be presented as the race time times the age-grading factor of certain age and event

Researchers have been exploring the underlying mechanisms of decline in endurance performance with aging from the perspective of human physiology [4] [5]. The main components include exercise economy, lactate threshold, maximal aerobic capacity, *et cetera* [6]. A comprehensive literature review systematically summarized the physiological factors responsible for the change of endurance performance with aging, for instance, age-related decrease in maximal oxygen

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

uptake (VO2max), maximum heart rate (HRmax), stroke volume, arteriovenous oxygen difference, active muscle mass, type II muscle fiber size, and blood volume [7]. Another recent review examined the contributions of vascular senescence to the degeneration of endurance and physical ability in the more senior population [8]. A pioneer 22-year longitudinal study revealed a significant decline of VO2max in a group of fifty-three former elite distance runners [9]. Although VO2max has been regarded as a poor indicator for endurance performance and one of the most misused physiological parameters [10], this work provided a valuable perspective of how aging may affect the human body. A more informative set of results would present measurements at multiple time points during the investigation period and backed up by relatively larger sample size. An investigation of oxygen uptake at the anaerobic threshold (VO2AT) in elite mountain runners showed that a significant decrease of VO2AT began after 49 years old [11].

Interestingly, a study about the effects of aging on indoor rowing performance revealed gender differences – while the decline with aging displayed a linear relationship in women, a biphasic model was more appropriate to fit the data collected from male subjects [12]. Later, an article showed that from age 25 to 85, women's performance in stationary rowing declined twice as faster as men's [13]. Another study investigating the change of swimming performance with aging demonstrated gender difference in swimming events of some distances [14]. These results suggested that it would be imperative to differentiate genders while evaluating the physiological effects caused by aging and build a robust data model. Moreover, an analysis of top Masters performance in athletics, swimming, rowing, cycling, triathlon, and weightlifting demonstrated that aging might affect various sport events differently [15]. Noticeably, an interview study explored the non-physiological factors that may account for the changes of performance with aging, such as psychological factors [16]. Their research suggested that analyzing physiological data may not provide a complete picture of aging's effects on sports performance.

As recreational endurance activities have been in blossom for many decades, a large amount of data is constantly being generated, which is characterized by the properties of big data – volume, variety, and velocity. In a study in 2012, they analyzed the top ten performances of each group based on age and gender in the New York City Marathon (1980-2009) [17]. The authors found out that despite the decline of aging performance, the race results within each age group had been improving. They attributed this trend to the overall increase of participation of master athletes in endurance sports, better training facilities, and a higher spirit of competitiveness. Although their study revealed a trend in a relatively long period, the top ten athletes' results could not well represent the broader population. Given this trend, analyzing current data is very helpful to disclose valuable patterns. Here, we propose to leverage the vast amount of data from recent race results to build a statistical model that can unveil the mathematical relationship between endurance performance and age. Our model can be applied to predict athletes' future performance and for the athletic governing bodies and race organizers to set and/or revise age-group categories and qualifying standards. For example, how do we properly define different athletics divisions: junior, open, masters based on statistics instead of just conventions. Additionally, as a reference, professional athletes and coaches must plan their careers accordingly since they want to reach the peak of their career before the decline of physical ability begins.

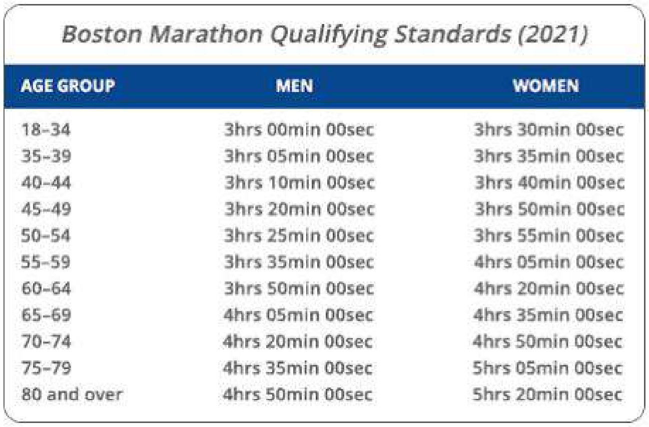
The user friendly applications that records activities during the exercise can be a valuable source of numeric and textual data [18] [19] [20], [21]. These applications create social media platforms where athletes can share their sport activities. It is important for these applications to provide reliable health information to prevent possible injuries for beginner athletes, especially while they are aging. Expert misinformation detection systems can enhance trust and reliability of health information which is provided by smart devices and applications [22] . Extraction of reliable textual information about the trail and body health in smart devices is a critical feature in creating safe environment for athletes [23].

II. Research design and data collection

Researchers can adopt two approaches, cohort study or cross-sectional study, to investigate the effects of aging on endurance performance. There are both advantages and limitations for these two approaches, which are discussed in detail below.

A. *Cohort study*

A cohort study design tracks the race performance of athletes for a relatively long time. The researchers evaluate the change of race performance and/or physiological parameters with aging. Those studies have been usually focusing on elite athletes. For example, a French group analyzed the data collected from individual athletes' careers in track and field and swimming events in three decades (from 1980 to 2009) and the ranking of chess players [24]. They discovered a relationship between performance and age. There are limitations in the design of cohort study when it comes to exploring the change of human physical abilities with the aging process. First of all, although performance data collected from elite athletes and world records may be considered an excellent representation of true human abilities at the highest level, the data are limited by sample size. Secondly, most professional athletes may only have a very short span of career during their peak phase. After they retire, they are no longer competing or competing at the level of efforts they used to be. Hence, we may not be able to collect data during a time window that is wide enough to demonstrate human ability change with aging. Moreover, even when they are at their peak phase, their performances may fluctuate because of other reasons instead of aging, such as prolonged injuries or illness, changes of training methods or coaches, adjustments to diet *et cetera*. Those factors may greatly affect the accuracy of the mathematical models; especially consider the relatively small sample size.



Boston Marathon Qualifying Standards (2021)

AGE GROUP	MEN	WOMEN
18-34	3hrs 00min 00sec	3hrs 30min 00sec
35-39	3hrs 05min 00sec	3hrs 35min 00sec
40-44	3hrs 10min 00sec	3hrs 40min 00sec
45-49	3hrs 20min 00sec	3hrs 50min 00sec
50-54	3hrs 25min 00sec	3hrs 55min 00sec
55-59	3hrs 35min 00sec	4hrs 05min 00sec
60-64	3hrs 50min 00sec	4hrs 20min 00sec
65-69	4hrs 05min 00sec	4hrs 35min 00sec
70-74	4hrs 20min 00sec	4hrs 50min 00sec
75-79	4hrs 35min 00sec	5hrs 05min 00sec
80 and over	4hrs 50min 00sec	5hrs 20min 00sec

Fig. 3. 2021 Boston Marathon Qualifying Standards [25]

B. *Cross-sectional study*

Researchers can investigate the race result data from different age groups in certain events for the approach of a cross-sectional study. The most prominent advantage of cross-sectional study design is leveraging the massive amount of data being generated. Millions of recent race results become available each year containing the performance and biographical data, from which we can build the performance-age model. Moreover, sampling from the general population may provide insights into the physical abilities at all levels, making the model more meaningful when applied to different groups. Apparently, on the other hand of the coin, data from recreational athletes may not reflect the true physical abilities because, unlike professional athletes who choose athletics as their careers, recreational athletes may lack the desire to compete and prepare for competing to their maximal potential. To overcome this problem, we need to select the relatively competitive events that host participants who are willing to train and compete to their true absolute abilities.

C. *Boston Marathon and Its Qualifying Standards*

Established in 1897, Boston Marathon is the oldest marathon and one of the world's most prestigious road racing events. Each year, around 30,000 runners all over the world compete in this race. The most notable feature of the Boston Marathon is enacting strict qualifying standards for their entrance procedure. Fig. 3 shows the Boston Marathon qualifying standards for men and women. The qualifying standards are set for each 5-year age and gender group. The times set in the qualifying standards have been adjusted many times during the last few decades to fit the race's capacity. In the recent years, the registration of the Boston Marathon opens at the beginning of September. Marathon performance on a certified course from the previous year can be used to qualify this race. Due to the limitation of field size, meeting the qualifying standard does not guarantee a race entry; it simply grants registration eligibility. The race organizer, Boston Athletic Association (BAA), ranks the athletes after the registration window is closed. Applicants with faster qualifying times are selected to enter the race first until the field has been filled up. This athlete selection procedure results in different cut-off qualifying times in practice each year. Implementing the entrance procedure with dynamic qualifying times guarantee the most competitive field of the race is assembled. For our purpose, race results from Boston Marathon may serve as excellent data set to build a performance-age relationship model. First of all, given near 25,000 data points produced per year, Boston Marathon race results have a large enough sample size to build reliable models. These data come from athletes of various, but relatively competitive, levels, not just a few world-class elite athletes. Models built upon these data are representative, and therefore may have broader applications. Secondly, the competitive field assembled at Boston Marathon ensures that race performance is evidence of athletes' real physical abilities. Thus, our model may demonstrate individuals' true physical limitations in different age and gender categories.

D. *Data Collection*

The 2017 Boston Marathon result data were used for our analysis, which contained 26,410 instances. The data set included the following attributes: bib number, name, age, gender, city, (US and Canada) state, country, citizenship, each 5-kilometer split time (from 5 to 40 kilometers), pace (time per mile), official time, overall place, gender place, division place. Also sport activities were colleted from Strava API [26]. Strava [19] is an application recording activity data during exercise.

III. Approach and Method

Regression models (median finish time versus age for males and females, respectively) were built to fit the Boston Marathon result data. The models might use different mathematical relationships to fit the data, such as linear, second, third-degree polynomial, and exponential regression. Then 10-fold cross-validations and statistical tests were performed to evaluate the models. The best fitting models were chosen and visualizations of the models were presented.

Clustering was used to reveal the reasonable age group separations. The official result data set contained the split time at each five-kilometer checkpoint from 5 to 40 kilometers. So, the latter split time contained the redundant information from previous ones. The data set was transformed into eight five-kilometer intervals to remove the redundancy. K-means clustering algorithm was applied to the instances containing the following attributes: age, overall place, eight five-kilometer split times. The data were scaled and centered. The clustering results were displayed with two dimensions, age and overall place.

IV. Results

A. *Linear and Polynomial Regression Model*

Fig. 4 and Fig. 5 showed the change of median finish times (male, and female athletes) with ages. From 20 to 70 years old, runners' finish times seemed to go exponentially slower. In the following steps, the 20 – 70 years old male

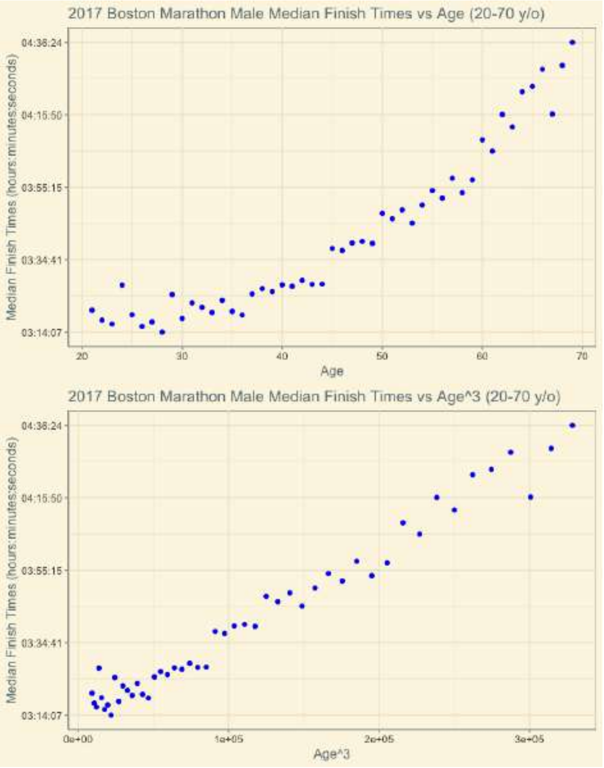


Fig. 4. Male 20 – 70 years old runners' finish times at 2017 Boston Marathon were plotted against ages and the cubic ages. The latter plot suggested a third degree polynomial regression model.

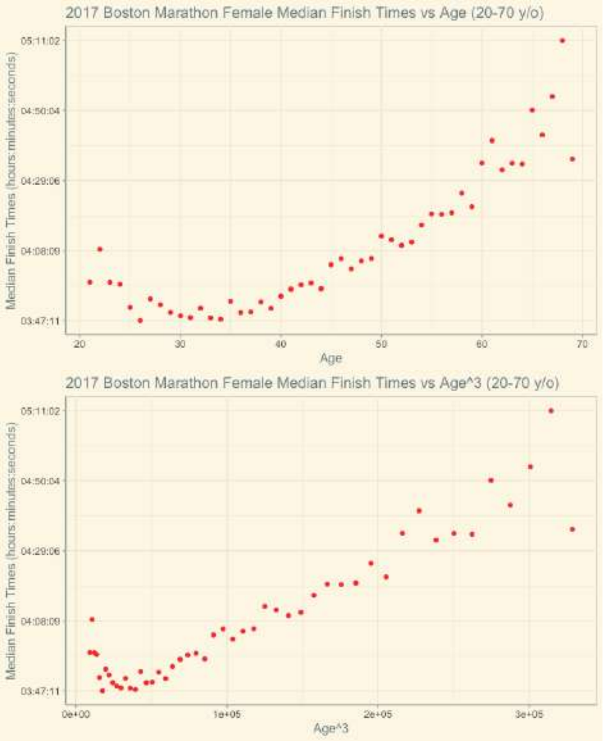

Fig. 5. Female 20 – 70 years old runners' finish times at 2017 Boston Marathon were plotted against ages and the cubic ages. The latter plot suggested a third degree polynomial regression model.

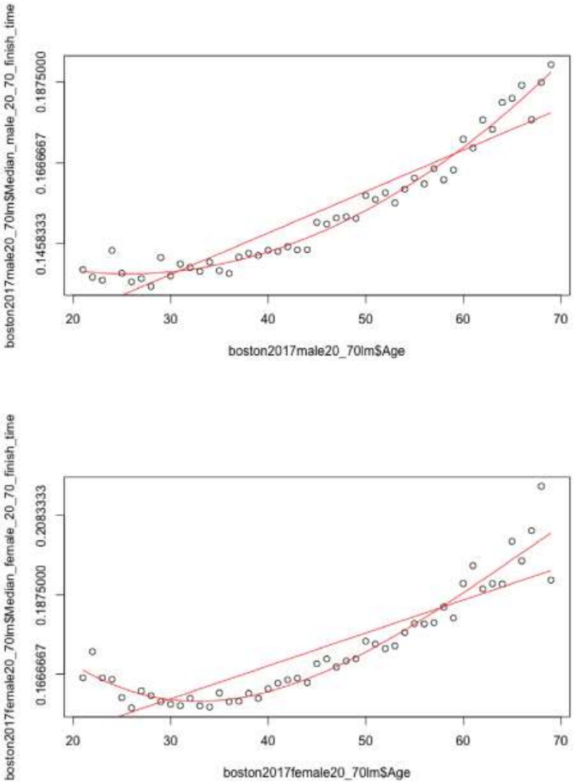

Fig. 6. The comparison of simple liner regression models and a third-degree polynomial regression models. The plots visually demonstrated that the latter ones fitted the data better for both male and female data. (Upper panel: Male; Lower panel: Female)

and female runners' median finish times were plotted against ages and the cubic ages, respectively. Apparently, the median finish times had a linear relationship with the cubic ages, which suggested a third-degree polynomial regression model (Fig. 6). Both simple linear regression models and third-degree polynomial regression models were built. ANOVA test was used to compare the two models. The results showed that a third-degree polynomial regression model fitted the data significantly better than a simple linear regression model. 10-fold cross-validation of the third-degree polynomial regression demonstrates a perfect fit (Fig. 7). Taken together, the analysis of 2017 Boston Marathon result data demonstrated that the athletes became slower as they aged, and there was an apparent third-degree polynomial relationship between runners' finish times and ages.

B. Clustering

The process of aging and the corresponding change of athletic ability may display different rates during different phases. Intuitively, we can sense the apparent physical changes caused by hormone levels, including the onset of puberty and menopause of women. However, the effects of hormone level alteration on athletic performance may take time to occur. Moreover, hormone level change is certainly not the only reason to explain everything in terms of aging. Mathematical

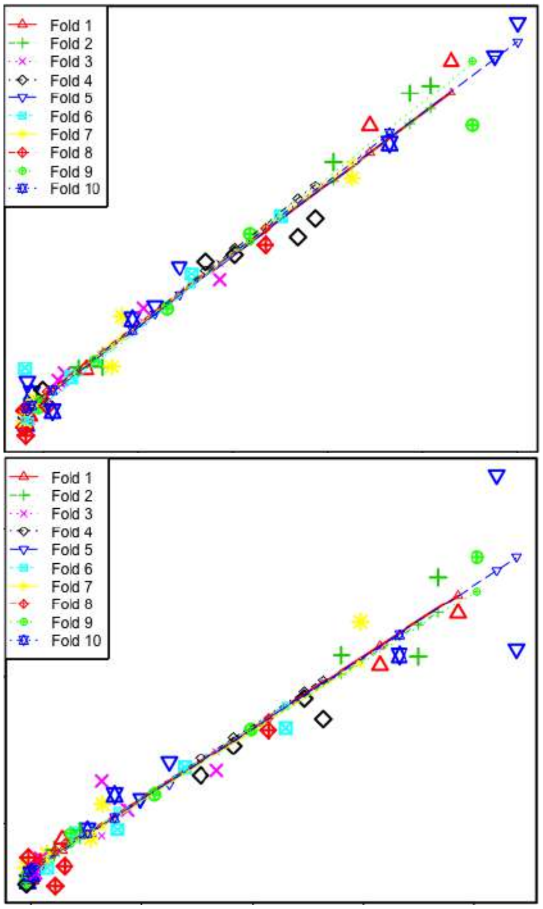

Fig. 7. 10-fold cross validation of the third-degree polynomial regression model demonstrates perfect fit and prediction (Upper panel: Male; Lower panel: Female).

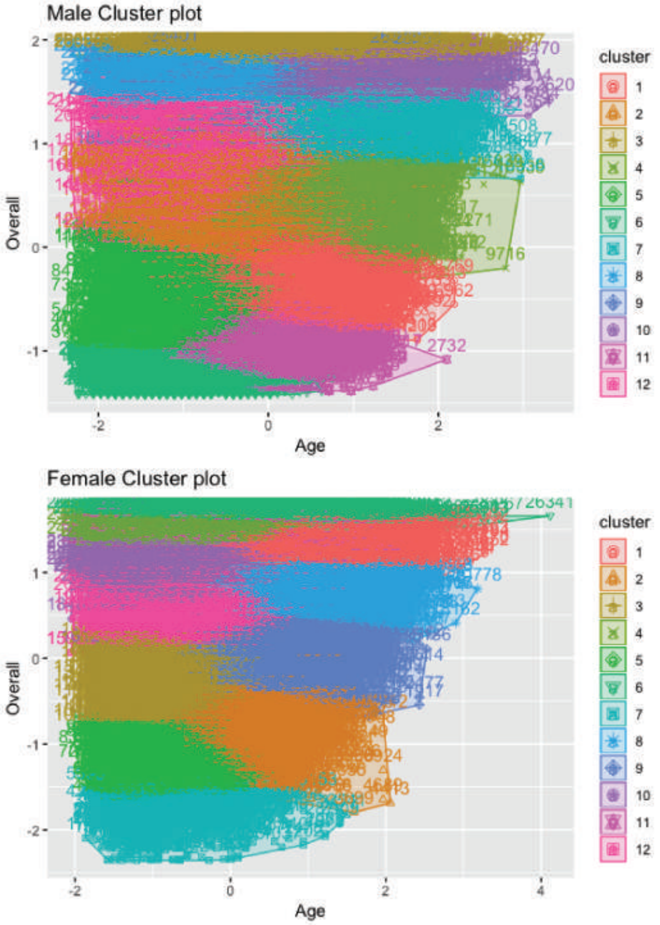

Fig. 8. The Cluster Plot of 2017 Boston Marathon result data. K-means clustering algorithm was applied to the instances containing the following attributes: age, overall place, eight five-kilometer interval times. The plots were projected on two dimensions, age and overall place. Data were scaled and centered: the mean was set at the 0 point in both axes.

models derived from real-world athletic performance data may be viewed as a function of the sum of various aging effects. In a model built by Fair and Kaplan [27], they used 40 and 70 years old as the differentiating points for different mathematical relationships. Another model suggested a single turning point around 30 years old [24]. Currently, the age boundary used to separate open and masters division in all track and field events is 40 years old, regardless of gender. Apparently, there would be a potential problem that males and females may experience different rates of aging, and athletes' performance may peak at different ages for different events. Here a clustering algorithm was used to discover if natural clusters in the performance-age two-dimensional space might be observed. Consider the gender differences of aging effects discovered by previous studies [12], [14]; male and female athletes were investigated separately. This step could provide the foundation for categorizing the populations into reasonable numbers of divisions and the boundaries of separation. Our clustering results suggested that for males and females, slightly different borders were discovered. As shown in Fig. 8, there was a line naturally formed by clusters around the mean age (44 years old for males), whereas for females, the line existed around the mean of 39 years old. Hence, our results suggested a different method of dividing open and masters division i.e., 45 and 40 years old for males and females, respectively.

C. Transfer learning model and Strava data analysis

In addition to the statistical approach, a machine learning model was applied for performance prediction in this section. Performance data from Strava API, a mobile tracking application were used. Strava collects time, speed, distance, calories, heart rate, and other sport activity data. Also, the athletes share comments on Strava. Two methods in studies by Heidari et al [28] and [22] as a natural language processing approach for sentiment classification of Strava comments was utilized in our research. Also, The transfer learning model BERT [29] [30] was used for the sentiment classification of comments. BERT(Bidirectional Encoder representation from transformer) is pre-trained model, which can be fine-tuned for specific task [31] [28]. 50,000 IMDB movie reviews was used for fine-tuning BERT for sentiment classification of Strava comments. A sentiment score assigned to each athlete's comments was considered as a feature for the neural network model's input space. The BERT had a self-attention mechanism, making it a powerful transformer to extract the context from the comments. Also, the multi-head attention of BERT helped to extract different contexts from each comment. A feed-forward neural network model with two hidden layers were chosen in this study. The data for training was labeled as professional or beginner athletes based on performance. The model classified the person as a beginner or professional. The accuracy of the FFNN model was demonstrated to be 89%. One potential problem was that the Strava API imposed a limitation on collecting the history of performance for each user, which could affect the model accuracy.

V. Conclusion and future work

Our analysis of Boston Marathon result data revealed a third-degree polynomial mathematical relationship between performance and age. Our results suggested that the age of 45 and 40, for males and females respectively, may be appropriately used to separate open and masters division in marathon running. Using the transfer learning model and Strava data was a new approach for the classification of professional or beginner athletes. In the future, more data from various events may be used to enrich the model. We also plan to combine statistical and transfer learning models to improve the performance of the algorithm.

***Abstract*—The paper is devoted to the construction of an algorithm for parallelization of temperature field modeling processes based on bicubic spline and the problems that arise in it. It takes a lot of time and memory on a computer to model existing large-scale signals of temperature fields in three-dimensional graphical form. Solving these problems on the basis of the proposed parallel algorithm, the development of parallel algorithms and software tools to qualitatively determine the coordinates of high-temperature hotspots of temperature fields and allow them to be monitored continuously, and to calculate the digital processing of existing large-scale signals of temperature fields. Based on this, the article presents a parallel algorithm for digital processing of signals of temperature fields on the basis of bicubic spline and ways to parallel its computational processes using Open MP technology.**

Keywords— Vectorization, parallelism, bicubic spline, parallel algorithm, Open MP, interpolation, temperature field, coefficient, approximation, parallel processes

I. Introduction

The methods of spline functions are widely used in solving signal analysis and recovery problems. Spline functions are an evolving area of function approximation and numerical analysis theory. An algorithm for parallelization of temperature field modeling processes using the spline method was built. The values of temperature fields x = 1sm, y = 1sm in the grid are known. Based on these values, it is possible to analyze the heating processes. Beta Soft Board (DT) software from Dynamic Soft Analisis Inc. (USA) is used to analyze heating processes. Approaching the measured temperature values on the basis of bicubic splines allows to determine any point of the temperature field in three-dimensional graphical view. Parallel calculation of large-scale values of temperature fields in a short period of time is one of the most difficult issues. Because presenting large volumetric values in a three-dimensional graphical view causes memory and time issues spent on computational processes on the computer. These problems are solved by creating a parallel algorithm for digital processing of signals based on bicubic splines. The main issue discussed in the article is the development of a parallel algorithm and software tool for digital processing of large-scale signals of temperature fields using a bicubic spline. In the studies studied, the temperature fields were modeled using a spline, but its three-dimensional graph and a parallel algorithm of computational processes were not developed.

II. Results of bicubic spline modeling of temperature fields

Creating a parallel algorithm in memory systems requires first of all acquaintance with the processor characteristics and methods and requirements of computer systems. For example, when the process of loading large volumes of temperature field signals from the computer's RAM to the processor, the processor bus idle time and busy time distribution are also limited by the system, which is one of the reasons for slowing down the work to be done. Especially the processor and its aspects related to hardware technology are both important and complex process. The emergence of the concept of multi-core in processors has also led to the concept of “multi-threaded” being more widely used in software. These two concepts are inextricably linked in modern information technology.

There are two different ways to divide computational processes and the operations performed on them into streams. Each method uses OpenMP's streaming directives.

The method of approximation of the values of the temperature of the printing board through bicubic splines allows to eliminate the specified defect (defect) and to parallel their calculation processes.

The grinder leads to the task of minimizing polynomial splines in S(x) form and integral form functions to expressions for F(x) approximate function derivatives or their differentiable analogues for inputs. For example,

$$J(\alpha,S)=\sum_{i=0}^{n}\alpha_i\left(S_m(x_i)-f(x_i)\right)^2+\alpha\int_a^b\left|\frac{d^r}{dx^r}S_m(x)\right|^2dx, \qquad (1)$$

where a is the control parameter: m is the spline level: i is the ordinal number of the spline values (i = 0, 1 ..., n), ai is the weight multiplier (positive numbers), and r is the order of the product from the spline.

Cubic splines S3 (x) with extreme properties are the most common.

It consists of

$$\Psi(f)=\int_a^b\left|\frac{d^2f(x)}{dx^2}\right|^2dx \qquad (2)$$

Consisting of a functional minimum in appearance, C2[a, b], which interpolates a given function, is achieved by a cubic spline S3(x) on the basis of so-called natural boundary conditions in the form S”(a) = 0, S”(b) = 0 between all functions of the space. For such splines, the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

functional expression (1) can be changed to the following form:

$$J(S)=\sum_{i=0}^{n}\alpha_i(S_3(x_i)-f(x_i))^2+\alpha\int_a^b(S_3^{''}(x))^2dx. \qquad (3)$$

The process of minimizing the function leads to the problem of solving a system of non-separate matrix algebraic linear equations in a diagonal-preferred band grid. Level 3 splines typically correspond to five-diagonal symmetrically positively defined matrices [1, 2].

The problem of grinding a variable f (x) function through splines can be summarized as follows. The values of the function at points i.e. f (x), f (x)… .f (x) are given in the table and the following system of ratios can be constructed:

$$-\beta_i\left(\frac{m_{i+1}-m_i}{h_{i+1}}-\frac{m_i-m_{i-1}}{h_i}\right)=S_3(x_i)-f(x_i), \qquad (4)$$

Here it is

$$\beta_i>0, h=x-x_{n+1}(i=1,2,........n), m_1=S''(x_1),$$
$$m_{n+1}=m_1=0, h_0, h_{0+1}\neq 0$$

It is required to find the function S3(x) that minimizes the functions in the following view.

$$F(S)=\int_a^b(S_3^{''}(x))^2dx+\sum_{i=0}^{n}\frac{1}{\beta_i}(S_3^{''}(x_i)-f(x)_i)^2 \qquad (5)$$

a system of linear algebraic n-1 equations is constructed to determine unknown values of mᵢ.

βᵢ (i=0,1,…,n) is a five-diagonal symmetric matrix with coefficients ai,ci,di, depending on the multipliers.

$$Ax=f \qquad (6)$$

System 6 has a unique solution in relation to the mi vector at hi values that differ from each other in a sufficiently wide range. Once the magnitudes are determined after its solution, f (x) has different nodes. The values of the grinding function in these nodes can be found if 4 reciprocal ratios are used [3, 4].

$$S_3(x_i)=f(x_i)-\beta_i\frac{m_{i+1}-m_i}{h_{i+1}}-\frac{m_i-m_{i-1}}{h_i} \qquad (7)$$

It is known that when grinding signals f(xi)=fi there is usualy an error in determining the values, ie as follows:

$$S(x_i)-f_i|\le\varepsilon_i| \qquad (8)$$

Inequality can be given. In particular, ε_1= ε=const can be given

Formula 5 shows an algorithm for finding such multipliers. several iterations must be performed to determine the exact values of βi. The end of the execution of the iterations is determined by the requirement that the magnitude e does not exceed a given value. As an example, we give the problem of calculating the temperature distribution along the surface of the circuit board caused by the heating of the chips for the uneven position of the nodes of the function T (x, y)

TABLE 1 MEASURED VALUES OF TEMPERATURES AT GIVEN POINTS OF THE PRINTING PLATE.

x, мм	T^0C,x	ST^0,x	y, мм	T^0C,y	ST^0,y
48.0	37.60	37.60	90.9	32.88	32.86
110.0	39.17	39.18	94.8	34.45	34.48
141.3	40.75	40.75	99.5	36.03	36.00
158.5	42.32	42.32	104.3	37.60	37.46
181.4	43.90	43.90	111.0	39.18	39.30
204.4	45.47	45.48	118.2	40.75	40.82
246.5	47.05	47.06	123.4	42.33	42.32
262.7	48.63	48.61	128.7	43.90	42.74
298.6	48.63	48.59	135.9	45.48	45.50

328.7	43.90	43.91	191.8	48.63	48.68
356.4	42.32	42.32	206.6	47.05	46.96

As mentioned above, it is difficult to determine the temperature values at a given board point in Beta Soft DT because all calculations are output as temperature gradients in certain intervals i.e. in practice it is convenient to determine the exact values of temperatures only within temperature zone boundaries. Table 1 shows the measured values of the temperatures at the given points on the horizontal and vertical straight lines.

For the values of ST°C(x) and ST°C(y) grinding bicubic splines calculated on the basis of formulas 4 and 7, it is possible to see the dependence of the temperature on the x and y coordinates based on the location of the values given in.

An analysis of the errors that occur when constructing signal grinding splines shows that the characters can be changed depending on the location of the dots on the board in the first place. Second, the values of the interpolation and grinding splines differ significantly in the increase in the values of the βx and βy parameters. It is possible to evaluate the effect of the change of the multipliers βx and βy on the accuracy of the approximation by means of smoothing splines of the temperature field function. The values of both functions are given at the points where the distance between the measured value of the temperature and the spline value is the largest in the modulus [5, 6, 7]. The simplest formula for the approximation of linear combinations to the function of two variables f (x, y) was studied by V.I. Arnold.

According to his testimony

$$F(x,y) = c[f(x) + \Psi(y)] \qquad (9)$$

most of the functions in the view are not dense in the C(D) space. In this case, c is a constant coefficient, D is a two-dimensional field. This means that the approximation in the sum view cannot be performed with infinitesimal error. In practice, when c = 0.5, the maximum error ΔT on the modulus not exceeding 0.02 C for a given temperature area T (x, y) is formed, and the conclusion about the multiplier increase βx and βy is confirmed.

A more universal method of approximation of functions f (x, y) that allows the average square deviation to be minimized was seriously first considered in formula 7 and

$$f(x,y) \cong \varphi_0(x) + \psi_0(y) + \sum_{k=1}^{n} \varphi_k(x)\psi_k(y). \qquad (10)$$

the approximation formula in Figure 10 was used. However, the algorithm for calculating the approximation parameters requires finding the eigenvalues of a particular form and the eigenfunctions of the intergral equations, and this is a rather complex mathematical problem. Approximation of this type of computational field with a bicubic spline is done more efficiently.

III. PARALLEL ALGORITHM FOR MODELING TEMPERATURE FIELDS USING BICUBIC SPLINE.

In the theory of basis splines (B-splines) developed methods for determining the parameters of multidimensional approximation structures that do not require the solution of a system of algebraic equations. For two-dimensional fields, T (x, y) takes the following form:

$$T(x,y) \cong S_{m,m}(x,y) = \sum_{i=-m}^{n_1+m} \sum_{k=-m}^{n_2+m} b_{ik} B_i(x) B_k(y), \qquad (11)$$

In this case, the m-spline level, the number of values on the n1-x axis, the number of values on the n2-u axis, the b$_{ik}$-spline coefficient [8, 9, 10].

Formula 11 is mainly used to create a parallel algorithm for calculating the bicubic spline. The algorithm for calculating it uses a drink cycle. That is, there are 3 cycles. The first loop is used for the columns of the bicubic spline, the second for the rows of the loop, and the third is used to calculate Bi(x) and Bi(y). The parallel flows of the system are used in the programming of parallel computational processes. The organization and management of these parallel flows is done depending on the complexity of the parallel algorithm. That is, in a parallel algorithm, it is necessary to sort the cyclic processes. For example, in a program, it is necessary to create separate streams for drinking cycles. But creating parallel streams in excess of the norm leads to data loss. As a result, the result of the program is incorrect. The same problem is encountered when programming a parallel algorithm for calculating a bicubic spline. To overcome this, the parallel currents must be switched off after the end of the second cycle. They can then be reused again as you move on to the second step of the first cycle.

The stage of implementation of the parallel algorithm of digital processing of temperature field signals is as follows:

1- Identify cyclic processes that can be calculated in parallel in the implementation of the algorithm.

2- Create dynamic arrays in the sequential phase of the algorithm and calculate them.

3- Organization of the procedure for calculating bicubic spline coefficients (bi, j), bases (Bi (x) and Bi (y)).

4- Create and implement a procedure for assembling parallel arrays in computer cores.

5- Create and display an array of results using serial and parallel computational procedures.

The block diagram of the parallel algorithm is shown in Figure 1. The acceleration coefficient of the parallel algorithm is calculated by the following formula (11)

$$S_p(n) = \frac{T(n)}{T_p(n)} \tag{12}$$

Here, T (n) is the time spent running a serial program, and Tp (n) is the time spent running a parallel program. Table 4 shows the acceleration coefficient, the time spent in series and parallel calculations. At 1024, the number of input signals was 0.045 seconds for serial computing, 0.025 seconds for parallel computing, and the acceleration coefficient was 1.8. The acceleration coefficients at different values of the incoming signal using the parallel algorithm of bicubic spline calculation are given in column 4 of the table. As the number of input samples increased, so did the acceleration coefficient of the parallel algorithm. The research results were obtained on an Intel (r) Core (TM) i5-10300H CPU @ 2.50Ghz processor.

FIGURE 1. BLOCK DIAGRAM OF THE BICUBIC SPLINE PARALLEL COMPUTING ALGORITHM.

Table 4 The results of a parallel algorithm on a quad-core processor

Number of input signal samples **N,M**	Sequentially (sec.)	Parallel (sec.)	Acceleration coefficient
1024	0,2 x10^{-4}	0, 1 x10^{-4}	2
4096	1,91 x10^{-4}	0,63 x10^{-4}	3,03
8192	3,48 x10^{-4}	1, 09 x10^{-4}	3,19

The results were obtained on an Intel (r) Core (TM) i5-10300H CPU @ 2.50Ghz processor. As the number of input samples increased, so did the parallel portion of digital processing and the acceleration coefficient. At N = 8192, it took 1.09x10-4 seconds to calculate the temperature field signals in parallel with the digital processing processes, and 3.48x10-4 seconds to calculate the series. The acceleration coefficient was 3.19. Since these results were performed on a quad-core processor, the maximum value of the acceleration coefficient was 3.19.

Parallel algorithm programming used the procedures and functions of OpenMP technology described below. The “#pragma omp parallel” directive to create parallel streams of the operating system, the “omp_get_thread_num()” function to select processor cores, the “omp_get_wtime()” procedure to determine the time taken to compute S1, S2, S3, S4 arrays distributed to cores, and each The directive “#pragma omp parallel for” was used to parallel the cyclic processes in the kernel. In addition, the method of vector calculation of the procedure "sum (S1, S2, S3, S4)" in the block diagram of the parallel algorithm shown in Figure 1 after a single step (clock) of parallel flows was developed [1,4]. This resulted in faster execution of multi-time looping processes and a further increase in the acceleration coefficient of the algorithm [11, 12, 13, 14].

A three-dimensional graphical representation of the available large-scale signals of temperature fields is organized as follows.

Figure 2. A three-dimensional graphical view of the initial state of the temperature field signals

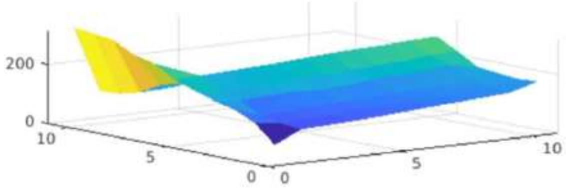

Figure 3. Three-dimensional graphical representation of temperature field signals modeled on the basis of bicubic spline.

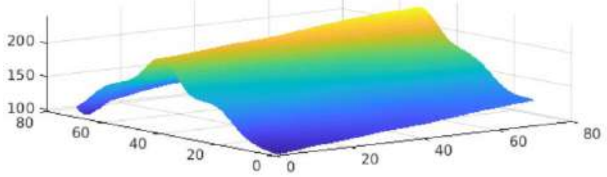

In the graph, yellow is the heated part of the temperature fields. Created on the basis of a parallel algorithm, this graph allows tracking of heated areas in real time. The software allows you to view and analyze the exact coordinates of the heated areas and their values.

IV. Conclusion.

In conclusion, the results of two-dimensional thermal field modeling show that not only geophysical fields, but also seismic, acoustic and thermal and other complex multidimensional signals can be modeled using the proposed spline functions. The advantage of splines in computational problems of many variable functions is that they fully satisfy the conditions of parallelization of computational methods. This means that in the programming of parallel algorithms for memory systems, the correct organization of internal loop processes for parallel flows of the operating system and the adaptation of computational processes to the conditions of vectorization, the program eliminates errors and accelerates computational processes. The use of a one-dimensional array in the calculation of two-dimensional bases increases the program's ability to distribute parallel internal loop processes into parallel streams. This halves the calculation time.

***Abstract*—The use of UAVs or drones for criminal or terrorist enterprises is an increasing problem. Many countermeasures have been proposed to prevent, deter, detect and/or mitigate the dangers posed by such malicious UAVs. One such countermeasure is to track or pursue a malicious UAV back to its point of origin using one or more surveillance UAVs in order to apprehend the UAV and possibly its owner. If the malicious UAV has a higher capability set than the surveillance UAVs, it will be able to outrun any one of them, and therefore the tracking responsibility must be distributed over a swarm of surveillance UAVs that are geographically dispersed across the tracking area of interest. One aspect of particular interest is how the initial formation of the swarm of surveillance UAVs impacts its ability to successfully track a malicious UAV. In this paper, we examine a specific circular initial swarm formation comprising uniformly spaced concentric rings of uniformly spaced UAVs. The total number of surveillance UAVs follows the sequence of centred hexagonal numbers as the number of rings increases. The tracking performance of this circular swarm of surveillance UAVs is compared to a reference swarm of the same size in which the initial locations of the UAVs are randomly chosen. Two tracking strategies are considered: 1) Reactive tracking, in which each surveillance UAV acts independently of the others and only pursues the malicious UAV when it itself detects it, and 2) Reactive tracking with predictive pre-positioning, in which once one surveillance UAV detects the malicious UAV, it communicates the estimated trajectory and speed of the malicious UAV to all swarm members so they can predictively move to a more optimum tracking position before the malicious UAV arrives. The results demonstrate that this particular circular swarm of surveillance UAVs has superior tracking performance relative to the reference randomly positioned swarm of the same size; this is true for both tracking strategies, but particularly when predictive pre-positioning is employed with a relatively small number of surveillance UAVs.**

Keywords — UAV, swarm, formation, communication, tracking

I. Introduction

There have been several high profile episodes of Unmanned Aerial Vehicles (UAVs) being used for nefarious purposes over the past few years. Perhaps the most well known example is the use of a UAV to invade the airspace of London Gatwick airport in 2018, causing massive disruption to civilian airport operations. More generally, such malicious UAVs can be deployed with a variety of motivations, including invasion of privacy (via aerial photography), trade of illegal substances (via delivery of small packages), causing physical damage or injury and causing critical service disruption [1-3].

Many technical techniques have been proposed to deter and/or mitigate the dangers posed by such malicious UAVs. These include physically catching UAVs, using high power laser beams to destroy UAVs, jamming of UAV control signals and GPS spoofing [3]. There are also possible administrative and regulatory countermeasures such as owner registration and licensing, and remote identification of UAVs [1-3].

From an academic perspective, one particularly interesting scenario involves a highly capable malicious UAV that may be able to evade current technical countermeasures. One option with such a UAV is to track or pursue it back to its point of origin using one or more surveillance UAVs in order to apprehend the malicious UAV and possibly its owner. Such a highly capable malicious UAV may be able to outrun individual surveillance UAVs, but this can be overcome by distributing tracking responsibility over a geographically dispersed swarm of such surveillance UAVs [4-6].

This leads to the question of how to design the initial formation of surveillance UAVs across the tracking area of interest so as to maximize tracking performance when a malicious UAV enters the tracking area. We assume that the tracking area of interest is circular with an important object of interest (e.g. an airport) at its centre. We further assume that the swarm of surveillance UAVs are static (i.e. they maintain their position by hovering) until one of the surveillance UAVs detects a malicious UAV in its vicinity, which may, for example, be via computer vision or on-board radar.

In this paper, we examine a specific circular initial swarm formation comprising uniformly spaced concentric rings of uniformly spaced surveillance UAVs. The number of surveillance UAVs in each ring increases linearly with radius so that the distance between an arbitrary surveillance UAV and its immediate neighbours is approximately constant. An example swarm is illustrated in Fig. 1 for $n = 4$ rings (not including the surveillance UAV at the centre) and a total of $N = 61$ surveillance UAVs. The rules for building similar swarms of different sizes are detailed in Section III. As will be seen, the available swarm sizes follow the sequence of centred hexagonal numbers.

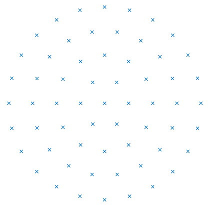

Fig. 1. Example regular circular formation with a total of $N = 61$ surveillance UAVs comprising $n = 4$ uniformly spaced concentric rings of uniformly spaced UAVs

We examine the tracking performance of these regular circular initial swarm formations via simulation in which the high capability malicious UAV moves along a diameter of the designated tracking area i.e. directly over the target object of interest at the centre of the tracking area. As a point of comparison, we also consider the performance of a reference swarm of the same size in which the initial locations of the surveillance UAVs are randomly chosen. Two tracking strategies are considered [5]: 1) Reactive tracking, in which each surveillance UAV acts independently of the others and only pursues the malicious UAV when it itself detects it, and 2) Reactive tracking with predictive pre-positioning, in which once one surveillance UAV detects the malicious UAV, it communicates the estimated trajectory and speed of the malicious UAV to all swarm members so they can predictively move to a more optimum tracking position before the malicious UAV arrives.

The contributions of this paper are as follows:

- A method of constructing a regular circular initial swarm formation of surveillance UAVs comprising uniformly spaced concentric rings of uniformly spaced surveillance UAVs, in order to detect and pursue a highly capable malicious UAV.
- Demonstration by simulation of the improvement in tracking performance afforded by using the regular circular initial swarm formation of surveillance UAVs compared to a randomly formed swarm. The performance improvement is particularly significant when a predictive pre-positioning tracking strategy is employed with a relatively small number of surveillance UAVs.

The paper organisation is as follows. In Section II, we review the literature on the topic of pursuit of malicious UAVs, and in particular discuss an optimal tracking guidance law for the surveillance UAVs to use in their pursuit. Section III discusses the building of regular circular formations of surveillance UAVs of different sizes. The available swarm sizes transpire to be the sequence of centred hexagonal numbers. Section IV discusses the simulation environment and specifies the simulation parameters. We consider a reference swarm in which the initial locations of the UAVs are randomly chosen in order to benchmark the tracking performance of the regular circular formations. The results of the simulation and analysis of the results are provided in Section V. Finally, conclusions and recommendations for future study are discussed in Section VI.

II. Previous Work

This section provides a review of the literature on the topic of pursuit of malicious UAVs. There has been very little research specifically on tracking of high capability malicious UAVs i.e. where the malicious UAV has a higher capability set than individual surveillance UAVs. Rather, most existing research focuses on tracking of a malicious UAV with similar or inferior capability to the individual surveillance UAVs, often by encircling it.

The work discussed in [7] involves the use of a swarm of *defense UAVs* (which is similar to the concept of a swarm of surveillance UAVs) to encircle a malicious UAV so as to restrict its movement. This is only possible because the malicious UAV is considered to have inferior capability compared to the defense UAVs. The paper discusses the various stages of encirclement including clustering, formation, chasing and escorting.

In [8], surveillance UAVs use the radio transmissions of a malicious UAV to pinpoint its location. A technique is described to increase the accuracy of the location fix by moving the surveillance UAVs into various positions relative to the malicious UAV. The paper does not discuss the relative capability of the malicious and surveillance UAVs.

In [9], research into the development of a testbed for a *Counter Unmanned Aerial System (CUAS)* is discussed. The surveillance UAVs in this system utilise computer vision in order to detect and pursue malicious UAVs. This testbed could in principle be used to investigate tracking of a high capability malicious UAV.

The work of [10] focuses on using on-board radar in a swarm of surveillance UAVs to facilitate detection and pursuit of a malicious UAV. This research makes an explicit assumption that the malicious UAV has inferior capabilities relative to the surveillance UAVs.

In [6], a guidance law was proposed to enable a surveillance UAV to set the optimum bearing to maximize tracking time of a highly capable malicious UAV once detected. Since we use this result in the simulation discussed in this paper, we provide an overview of it here. Fig. 2 shows a scenario where a surveillance UAV *S* has just detected a malicious UAV *M* as *M* arrives on the periphery of the detection zone of *S*. We define the following parameters:

- r is the maximum detection distance of *M* from *S*
- u is the maximum pursuit speed of *S*
- v is the speed of the malicious UAV (where $v > u$ since *M* is assumed to have higher capability than *S*)
- φ $(-\pi/2 \le \varphi \le +\pi/2)$ is the angle between the x axis and line joining *S* and *M*
- θ $(-\pi/2 \le \theta \le +\pi/2)$ is the angle relative to the x axis in which *S* moves to follow *M*

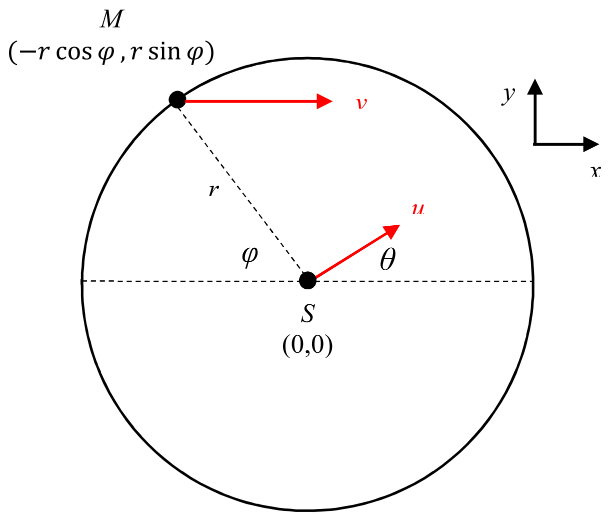

Fig. 2. Definition of parameters for guidance law

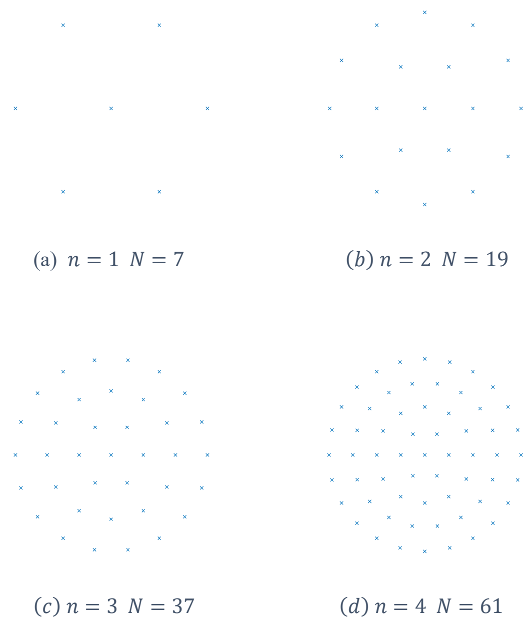
The optimal value of θ which maximizes the tracking time of M by S is given by [6]:

$$\theta_{optimal} = \cos^{-1}\left(\frac{2uv\sin\varphi}{\sqrt{u^4+v^4-2u^2v^2\cos 2\varphi}}\right) - \tan^{-1}\left(\frac{v^2-u^2}{[u^2+v^2]\tan\varphi}\right) \tag{1}$$

III. Regular Circular Swarm Formation

We first make an assumption that, in any regular swarm formation, there is a surveillance UAV at the centre of the circular tracking area i.e. hovering directly over the important object of interest to be guarded, such as an airport. When building a regular circular formation comprising uniformly spaced concentric rings of uniformly spaced surveillance UAVs, a question arises as to how to disperse the surveillance UAVs in the first ring out from the centre of the tracking area. If the distance between adjacent surveillance UAVs in this first ring is to be the same as the distance to the centre of the tracking area, there must be exactly six UAVs in the first ring which form the vertices of a hexagon, as illustrated in Fig. 3(a). In this formation, we have $n = 1$ ring (not including the surveillance UAV at the centre) and a total of $N = 1 + 6 = 7$ UAVs.

As the number of rings increases, the number of surveillance UAVs in each ring should increase linearly with radius so that the distance between an arbitrary surveillance UAV and its immediate neighbours is approximately constant. Therefore, a second ring of surveillance UAVs which has twice the radius of the first ring should have $2 * 6 = 12$ UAVs, as illustrated in Fig. 3(b). This implies for $n = 2$ rings, there will be a total of $N = 1 + 6 + 12 = 19$ UAVs. Similarly, this implies for $n = 3$ rings, there will be a total of $N = 1 + 6 + 12 + 18 = 37$ UAVs, and for $n = 4$ rings, there will be a total of $N = 1 + 6 + 12 + 18 + 24 = 61$ UAVs, as illustrated in Fig. 3(c) and Fig. 3(d) respectively.



(a) $n = 1$ $N = 7$

(b) $n = 2$ $N = 19$

(c) $n = 3$ $N = 37$

(d) $n = 4$ $N = 61$

Fig. 3. Regular circular formation comprising uniformly spaced concentric rings of uniformly spaced UAVs

Using the well known formula for the sum of terms in an arithmetic progression, it is simple to show that the general result is:

$$N = 1 + 3n(n+1) \;\; for\; n \geq 1 \tag{2}$$

This defines the sequence of integers sometimes referred to as centred hexagonal numbers.

IV. Simulation Environment

For the simulation, we compare the tracking performance of the circular swarm of surveillance UAVs discussed in Section III to a swarm of the same size (both in geographic terms and in terms of the number of UAVs in the swarm) in which the UAVs are initially randomly positioned. The meaning of “randomly positioned” in this context is open to interpretation. However, the regular circular swarm is built on the principle that the distance between adjacent UAVs is approximately the same, so for the reference randomly generated swarm, we should ensure that, on average, the same principle holds.

A naïve way to build the reference randomly generated swarm is to choose both the radial and angular coordinates of each swarm UAV from a continuous uniform probability distribution. That is, the radial coordinate ρ is chosen such that $\rho \sim U(0, R)$ where R is the radius of the swarm, and the angular coordinate ψ is chosen such that $\psi \sim (0, 2\pi)$. The problem with this approach is that, on average, the same number of UAVs are placed with radial coordinate ρ_1 as at radial coordinate ρ_2 even when $\rho_1 \neq \rho_2$. This results in a higher density of UAVs positioned close to the centre of the swarm than at the periphery as illustrated in Fig. 4(a).

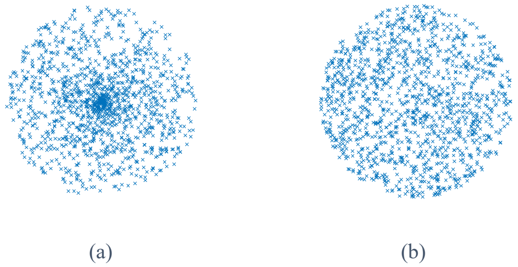


Fig. 4. Spatial distributions of reference randomly generated swarms comprising $N = 1387$ UAVs (a) radial coordinate uniformly distributed, and (b) square of radial coordinate uniformly distributed

Since circumference is a linear function of radius, the radial coordinate ρ should be chosen such that its probability density function $f(\rho)$ increases linearly as illustrated in Fig. 5(a), and therefore its cumulative distribution function $F(\rho)$ is as illustrated in Fig. 5(b). This ensures that, on average, the number of UAVs placed with radial coordinate ρ_1 is greater than the number placed with radial coordinate ρ_2 if $\rho_1 > \rho_2$ and furthermore, the principle that the distance between adjacent UAVs is approximately the same on average is satisfied.

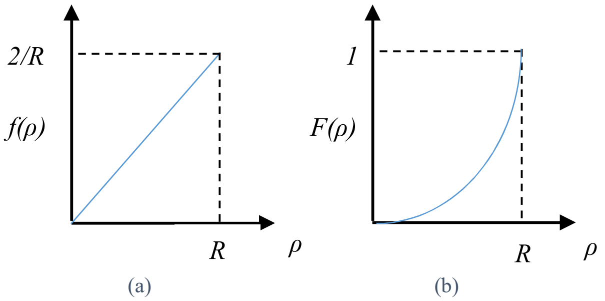

Fig. 5. Required characteristics of the radial coordinate ρ (a) probability density function $f(\rho)$ and, (b) cumulative distribution function $F(\rho)$

The required form of the cumulative distribution function $F(\rho)$ in Fig. 5(b) is as follows:

$$F(\rho) = \frac{\rho^2}{R^2} \qquad 0 \leq \rho \leq R \tag{3}$$

Now if $X = \rho^2/R^2$, X has a continuous uniform probability distribution i.e. $X \sim U(0,1)$ since its cumulative distribution function is linear. Given $\rho = R\sqrt{X}$, this implies that the radial coordinate ρ for each UAV should be chosen so as to be the product of R and the square root of a random variable with a continuous uniform probability distribution in the range (0,1). When this is implemented, the spatial distribution of UAVs is as illustrated in Fig. 4(b). Clearly the density of UAVs appears consistent across the region of interest.

In the simulation, the malicious UAV moves through a diameter of a circular tracking area. It is logical that the malicious UAV should pass through the centre of the tracking area, since this is likely to be the location of the target object of interest (e.g. an airport) that it is attempting to disrupt. The regular circular swarm of surveillance UAVs always has one UAV at its centre, therefore the malicious UAV will always be detected by at least this centred surveillance UAV. This is a key difference with respect to the reference randomly generated surveillance UAV swarm, for which it is possible that the malicious UAV will not be detected by any of the surveillance UAVs as it moves along a diameter.

For the regular circular swarm of surveillance UAVs, different diameters will pass through the detection zones of a different number of UAVs in the swarm. Given the malicious UAV follows a diameter of the tracking area, the angular orientation of the swarm must be randomised relative to the path of the malicious UAV in order to ensure a fair comparison with the reference randomly generated surveillance UAV swarm. This is achieved by rotating the circular swarm through an angle randomly drawn from a continuous probability distribution in the range $(0, 2\pi)$ prior to executing each iteration of the simulation, and then averaging the simulations results over all iterations. Different angular orientations of the same circular swarm are illustrated in Fig. 6.

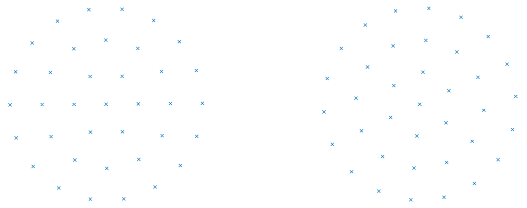

Fig. 6. Different angular orientations of the same regular circular swarm comprising $N = 37$ UAVs

The parameters of the MATLAB simulation are illustrated in Table I. As can be seen, two different tracking strategies are considered:

- reactive tracking only, in which a surveillance UAV only moves once it has itself detected the malicious UAV, and
- reactive tracking with predictive pre-positioning, in which the first surveillance UAV to detect the malicious UAV communicates the estimated speed and bearing of the malicious UAV to all other members of the swarm, allowing the other surveillance UAVs to predictively move into the optimum position to track the malicious UAV if and when it enters their vicinity.

The objective of the tracking is to maximize the time that the malicious UAV is within the detection range of at least one surveillance UAV from the swarm. Therefore, the simulation metric calculated is the proportion of time that the malicious UAV is being actively tracked by one or more surveillance UAVs while in the tracking area.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Simulation step	1m for the malicious UAV
Number of simulation iterations for each set of parameters	500
Tracking area shape	Circular
Tracking area size	15km radius
Number of UAVs in surveillance swarm (*N*)	Fixed for any one simulation run: the following subset of centred hexagonal numbers are considered $1 + 3n(n+1)\ for\ 1 \leq n \leq 21$ (7, 19, 37, 61, …, 1261, 1387)
Initial formation of surveillance UAVs in tracking area	Fixed for any one simulation run as either: Regular circular: see Section III Reference random: see Section IV
Tracking strategy	Fixed for any one simulation run as either: Reactive tracking only Reactive tracking and predictive pre-positioning
Surveillance UAV maximum speed (*u*)	Fixed for any one simulation run at 20m/s, 25m/s or 29m/s
Surveillance UAV direction on detecting malicious UAV (θ)	$\theta_{optimal}$ according to Eq. (1)
Surveillance UAV direction for predictive pre-positioning	Perpendicular to estimated malicious UAV path
Malicious UAV detection range (*r*)	100m
Malicious UAV maximum speed (*v*)	30m/s
Malicious UAV path	Diameter of tracking area
Surveillance UAV communication range (for predictive pre-positioning)	Not limited
Surveillance UAV communication method (for predictive pre-positioning)	Flood/Broadcast

V. RESULTS AND ANALYSIS

Fig. 7, Fig. 8 and Fig. 9 show the metric of interest, the proportion of time that the malicious UAV is directly pursued and tracked by at least one surveillance UAV while in the tracking area, versus the swarm size in terms of the number of surveillance UAVs. The figures represent maximum surveillance UAV speeds of *u*=20m/s, *u*=25m/s and *u*=29m/s respectively. Compared to the fixed malicious UAV speed of *v*=30m/s, they represent a large, medium and small capability mismatch between the surveillance and malicious UAVs respectively. All three figures illustrate plots for each combination of initial swarm formation (regular circular versus reference random) and tracking strategy (reactive tracking only versus reactive tracking with predictive pre-positioning).

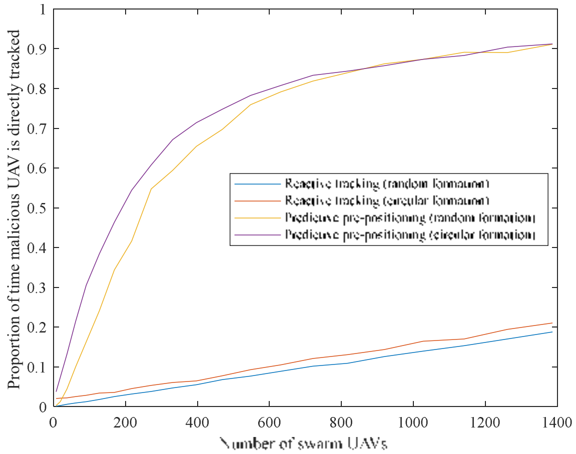

Fig. 7. Proportion of time malicious UAV is actively tracked against number of swarm UAVs for *u*=20m/s, *v*=30m/s and different swarm formations/tracking strategies

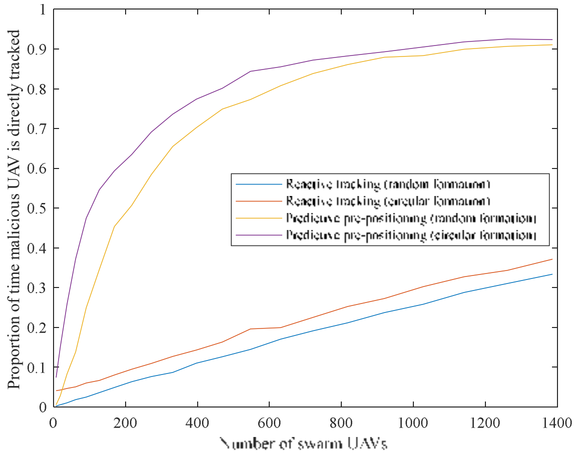

Fig. 8. Proportion of time malicious UAV is actively tracked against number of swarm UAVs for *u*=25m/s, *v*=30m/s and different swarm formations/tracking strategies

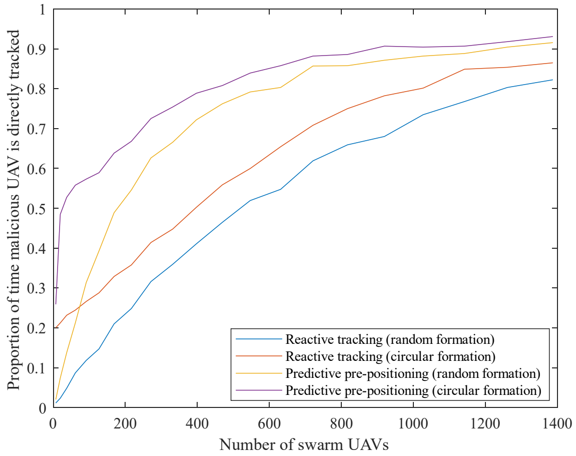

Fig. 9. Proportion of time malicious UAV is actively tracked against number of swarm UAVs for *u*=29m/s, *v*=30m/s and different swarm formations/tracking strategies

It is clear from all three figures that a regular circular swarm formation outperforms a reference random swarm formation for both tracking strategies i.e. the proportion of time that the malicious UAV is directly pursued and tracked by at least one surveillance UAV is higher for a regular circular swarm formation. The fundamental reason for this is that surveillance UAVs may be positioned in close proximity to each other by random chance in the reference random swarm formation, leaving relatively large voids where there are no surveillance UAVs present; hence there is a greater probability that the malicious UAV can fly between surveillance UAVs without being detected.

The difference in performance between the regular circular and reference random swarm formations is particularly notable when examining the plots for reactive tracking with predictive pre-positioning with a relatively small swarm size. For example, examining Fig. 9, for a small swarm size of $N = 37$ UAVs, the proportion of time the malicious UAV is actively tracked when the tracking strategy is predictive pre-positioning is 0.53 for a regular circular swarm formation versus 0.14 for the reference random formation. This large difference is in some respects due to the fact that, with the regular circular initial formation, the malicious UAV will always pass through the detection zone of at least one surveillance UAV (i.e. the surveillance UAV at the centre of the tracking area), whereas this is not guaranteed with the reference random initial formation. This difference is clearly most significant when the surveillance UAV swarm is relatively small – for larger swarms, there is a high probability that the malicious UAV will pass through the detection zone of at least one surveillance UAV even for the reference random initial formation.

As discussed in [5], reactive tracking with predictive pre-positioning outperforms reactive tracking only, particularly when the malicious UAV is significantly more capable in terms of maximum speed than the surveillance UAVs. This is the case even when the reference random initial formation of surveillance UAVs is employed.

VI. Conclusions and Future Work

This paper has demonstrated that a particular regular circular formation of surveillance UAVs has superior tracking performance (when tracking a highly capable malicious UAV) relative to a reference randomly positioned swarm of the same size. This is true for both tracking strategies (reactive tracking only and reactive tracking with predictive pre-positioning), but particularly when predictive pre-positioning is employed with a relatively small number of surveillance UAVs.

The next challenge is to devise regular initial formations of surveillance UAVs that outperform the regular circular formation examined in this paper. One proposal is to offset the angular orientation of adjacent rings of surveillance UAVs relative to each other in order to reduce the size of voids in the tracking area.

***Abstract*—One of the most dynamic network is the Mobile Adhoc (MANET) network. It is a list of numerous mobile nodes. Dynamic topology and lack of centralization are the basic characteristics of MANET. MANETs are prone to many attacks due to these characteristics. One of the attacks carried out on the network layer is the black-hole attack. In a black-hole attack, by sending false routing information, malicious nodes interrupt data transmission. There are two kinds of attacks involving a black-hole, single and co-operative. There is one malicious node in a single black-hole attack that can act as the node with the highest sequence number. The node source would follow the direction of the malicious node by taking the right direction. There is more than one malicious node in the collaborative black-hole attack. One node receives a packet and sends it to another malicious node in this attack. It is very difficult to detect and avoid black-hole attacks.Many researchers have invented black-hole attack detection and prevention systems. In this paper, We find a problem in the existing solution, in which validity bit is used.This paper also provides a comparative study of many scholars. The source node is used to detect and prevent black hole attacks by using a binary partition clustering based algorithm. We compared the performance of the proposed solution with existing solution and shown that our solution outperforms the existing one.**

***Index Terms*—MANET, AODV, Black hole attack, routing protocols, clustering.**

I. Introduction

MANET is a short term for Mobile Ad-hoc Network. It is also called wireless adhoc network, an unbroken network of mobile devices connected without using cables and without any infrastructure setup. Devices can travel in any direction in a MANET architecture independently and thus often change their ties with other devices. Wireless communications, from satellite transmission to home wireless personal area networks, have increased exponentially in recent years [1].

The wireless media communicates between a fixed node and a mobile node within its range. However, a permanent fixed infrastructure is required. The MANET system is a different model, however the broadcasting range of each node is restricted to the closeness of each other, and out-of-scope nodes are routed through intermediate nodes. However, the MANET system is designed to set up a system where necessary [2]. Each mobile node acts in such a network not only as a host, but also as the router, transmitting packets to other mobile nodes in the network that can not be directly wireless [3].

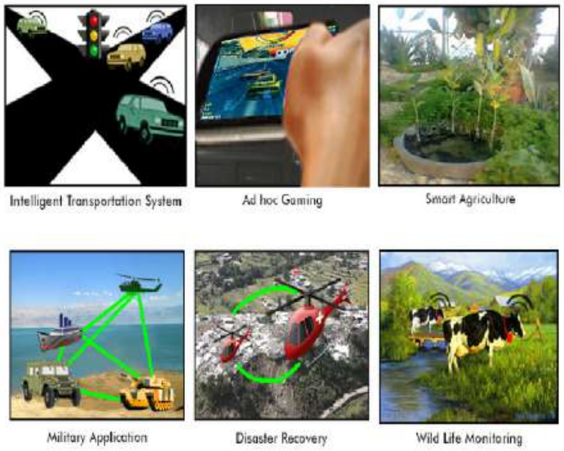

Fig. 1. Application of MANET in different areas.

One of MANET's recent applications is a sensor network consisting of several thousand small, low-powered sensing nodes [4]. Example of MANET implementations are shown in Figure 1. Security in these areas clearly is a critical problem. Secure communication is essential in

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

any wireless network [5] and [6] to make the system more trustworthy to the end users.

In MANET several attacks can be performed by the malicious node that prevents the operation of MANET. Blackhole attack and Grayhole attack are the most important attacks that needs to be investigated.In this paper we investigated the blackhole attack and proposed a solution to solve the issue.The organization of the paper is as follows.

In section-II literature survey is done. Section-III presents the motivation. In section-IV, we present the solution approach.Section-V discusses the performance analysis. Section-VI presents the simulation results. Finally in section-VII, we conclude and discuss the future work.

II. Literature Survey

In paper [7] Ashish Kimar Jain et al. proposed a method to detect black hole attack through first route reply mechanism in AODV protocol of MANET.

In paper [8] J. V. Vadavi et al. try to detect the black hole attack and avoiding them in participating in the network by enhancing the AODV protocol by making it delay aware.

Sushama Singh et al. try to enhance the performance of the AODV protocol by introducing a trusted AODV routing algorithm (tangent hyperbolic function is used to calculate the trust value) to detect the collaborative black hole attack. [9]

In paper [10] Heerendra Mahore et al. focused on agent based AODV protocol which means some sender nodes are assigned a task of the agent to check the RREP coming from the destination nodes to check and avoid the black hole attack.

In paper [11] Vidya Kumari Saurabh et al. proposed a clustering based AODV routing protocol in which each single node of the cluster in ping once to the cluster head to detect the difference between the data packets received and sent by the exact node to detect the black hole attack.

Sathish M. et al. in [12] proposed a method to detect the single as well as collaborative black hole attack by sending fake RREQ and Destination Sequence Number and when receives RREQs from nodes with higher DSN it will collect them in a list and inform all the other nodes that these are the malicious nodes.

III. Motivation

The method for the MANET black hole detection, proposed in [1] says that the validity of the message RREP is attached and stored on each node of the active path in an itinerary table. Whenever a route request is received for a node, the route response message is created by setting a value for a validity bit in RREP, whether that route is the target or if it has a legit route. This RREP will then return to the next hop it got RREQ from. The proposed route reply message varies from the basic AODV route reply message in terms of validity. The RREP message incorporates the validity mechanism. AODV RREP will have an additional header in a validity bit.

This new field is used to validate the route validity. Whenever a Route reply is received from a node, it is processed only if the RREP 's validity bit is specified. Only if the validity bit is set will an entry be made for this path. As an assailant, this mechanism is not known; it reacts without looking into its route table. This implies that the validity bit in the RREP sent by the attacker node would have a null value. A node with a validity value not identified will simply drop the RREP without entering the routing table [13].

The above technique is a great way to detect blackhole attacks [14], and a negligible overhead would be applied to the overhead network when a single bit is used in this strategy to detect attacks. However, if the attacker looks at the attackers' routing table and sets the validity value, and sends RREP to the source, then the source node does not detect a black-hole attack and sends data packets to that route assuming that the destination is reached by this route. The attacker would then drop data to the destination node without forwarding it.

The abbreviations used in this paper is described in TABLE IV.

A. *Flowchart of Existing Solution*

The above Fig.2 is the flowchart of existing solution from which we drew the motivation. The proposed work is the method to overcome the limitations of the above strategy.

IV. Solution Approach

In our proposed approach SOURCE node is used for the detection of black hole attack. After generating a route request, broadcast it and wait for RREPs. Source receive RREPs from k1+k2 no. of nodes. After receiving RREPs from k1+k2 no. of nodes store them in a list [15].

Make two groups of RREPs and store them in the list using a binary partition clustering algorithm such as k-means [16] based on destination sequence number. Then the average destination sequence number(ADS) is calculated for both the cluster that is (ADS1, ADS2). If ADS1 is greater than ADS2 and the difference is greater

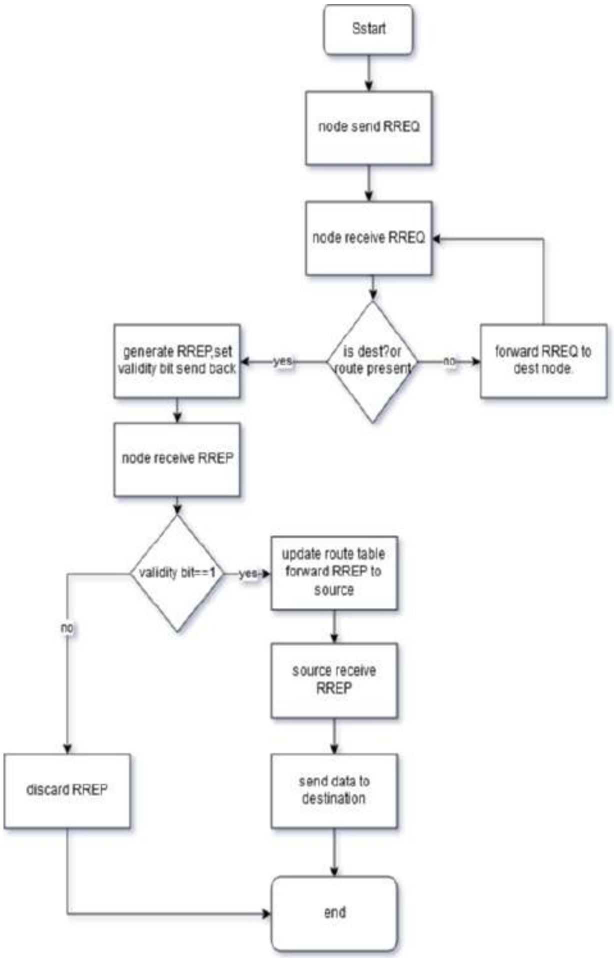

Fig. 2. Flowchart of existing solution

than a threshold value then cluster-1 may contain a set of black-hole nodes otherwise source node selects the best node from cluster-1, check validity bit, if set, send data [17].

If ADS2 is greater than ADS1 and the difference is greater than a threshold value then cluster-2 may contain a set of black-hole nodes otherwise source node select the best node from cluster-2 and check validity bit if set, send data through that node.

A. Proposed Method

The source generates RREQ for the establishment of a path to send data. The explanation of our solution approach is described as follows.

The source node generates RREQ and broadcast it through the network and waiting for the RREPs. Source node after receiving the RREPs from k1+k2 number of nodes stores it in a list.

The source node makes two groups using a binary partition clustering algorithm such as k-means [16] based on destination sequence number. Here cluster-1 and cluster-2 are having n11, n12... , n1k1 nodes and n21, n22, n23..., n2k2 nodes respectively we can see it in TABLE II and TABLE III.

In TABLE II it can be seen that cluster-1 contains the number of nodes n11 to n1k1 having destination sequence number ds11 to ds1k1. Similarly in TABLE III cluster-2 contains the number of nodes n21 to n2k2 having destination sequence number ds22 to ds2k2.

After that average destination sequence number is calculated for cluster-1 (ads1) and cluster-2 (ads2) by the equations given below.

$$ads_1 = \frac{\sum_{i=1}^{k_1} ds_1 k_i}{k_1} \tag{1}$$

$$ads_2 = \frac{\sum_{i=1}^{k_2} ds_2 k_j}{k_2} \tag{2}$$

After calculating the average destination sequence of cluster-1 and cluster-2, we check for cluster-1. If the average destination sequence of cluster-1 (ads1) is greater than the average destination sequence of cluster-2 (ads2) and their difference i.e. (ads1-ads2) is greater than a threshold value then cluster-1 is suspicious and may contain a set of black-hole nodes otherwise source node selects the best node from cluster-1, check the validity bit, if set, then send data through the node to the destination.

Similarly, the average destination sequence of cluster-1 and cluster-2 is calculated and check for cluster-2. If the average destination sequence of cluster-2 (ads2) is greater than the average destination sequence of cluster-1 (ads1) and their difference i.e. (ads2-ads1) is greater than a threshold value then cluster-2 is suspicious and may contain a set of black-hole nodes otherwise source node selects the best node from cluster-2, then check the validity bit is set or not, if set, then send data to destination through the node.

B. Proposed Algorithm

1. Start.
2. Broadcast RREQ (source).
3. Received RREP from k1+k2 nodes.
4. Store it in list.
5. Make 2 clusters using partition clustering algorithm(based on destination sequence number).

TABLE I
CLUSTER-1 CLUSTER-2 TABLE WITH DESTINATION SEQUENCE NUMBER

Cluster 1	Cluster 2
n_{11}	n_{21}
n_{12}	n_{22}
n_{13}	n_{23}
n_{14}	n_{34}

TABLE II
CLUSTER-1 TABLE WITH DESTINATION SEQUENCE NUMBER

number of nodes	destination sequence number
n_{11}	$ds_1 1$
n_{12}	$ds_1 2$
n_{13}	$ds_1 3$
n_{14}	$ds_1 4$
$n_1 k_1$	$ds_1 k_1$

TABLE III
CLUSTER-2 TABLE WITH DESTINATION SEQUENCE NUMBER

number of nodes	destination sequence number
n_{21}	$ds_2 1$
n_{22}	$ds_2 2$
n_{23}	$ds_2 3$
n_{24}	$ds_2 4$
$n_2 k_2$	$ds_2 k_2$

6. Calculate ads1 and ads2 by putting equations-1 and equations-2
7. If ads1 > ads2 and ((ads1-ads2)>ds-threshold) Cluster-1 is suspicious
8. Else source select best node, check validity bit and send data.
9. If ads2>ads1 and ((ads2-ads1)>ds-threshold) Cluster-2 is suspicious
10. Else goto 8
11. End.

where
ads1= average destination sequence number of cluster-1
ads2= average destination sequence number of cluster-2
ds-threshold= threshold difference of average destination sequence number.

TABLE IV
ACRONYMS AND THERE MEANING USED IN THIS PAPER

Acronyms	meaning
AODV	Ad hoc On Demand Distance Vector
MANET	Mobile Ad hoc Network
RREP	Route Reply
RREQ	Route Request
ADS	Average Destination Sequence Number
ADS1	Average Destination Sequence Number of cluster-1
ADS2	Average Destination Sequence Number of cluster-2

In step 1 start the algorithm, source broadcast route request, and in step 3 it received route reply from k1+k2 nodes then store it in a list in step 4.

In step 5 make two clusters using partition clustering algorithm(based on destination sequence number). then calculate ads1 and ad2 in step 6. In step 7 it checks If ads1 > ads2 and ((ads1-ads2)>ds-threshold) then Cluster-1 is suspicious.

In step-8 else source select best node, check validity bit and send data. In step 9 If ads2>ads1 and ((ads2-ads1)>ds-threshold) Cluster-2 is suspicious. In step 10 it goes to step 9 and in 12 it ends.

C. FLOWCHART

The below Fig. 3 is a flowchart that shows how a black-hole attack occurs with respect to time. It is further described with the timing diagram in Fig. 4.

D. TIMING DIAGRAM

The source node wants to send data to the destination node. In T1 time the source node generates RREQ and sends the RREQ in the network. Both the attacker and the destination node received the RREQ.

After receiving RREQ both attacker and destination send RREP to the source node or from where they received RREQ. In T2 time the source received RREP from an attacker and in T3 time receives RREP from the destination node. The RREP from the attacker having destination sequence number is higher than the RREP received from the destination node, source node thinks that this is the fresh enough route to the destination. So the source discards the RREP from the destination.

After discarding the RREP from the destination, the source node sends data to the attacker in T4 time then it drops all the data packet coming from the source without forwarding it to the destination.

V. Discussion And Performance Analysis

In MANET, protection is a major problem. The entire network can be devastated by attacks. One of them is the Black-Hole attack [18]. Due to complex network topology, the location of the malicious node is very difficult to locate.

In this paper, we have proposed a method for detecting the black hole attacker using the proposed algorithm based on binary partition algorithm. In [1], the RREP message incorporates the validity bit mechanism.This new field is used to validate the route validity. Whenever a Route reply is received from a node, it is processed only if the RREPs validity bit is specified. Only if the validity bit is set will an entry be made for this path. As an assailant, this mechanism is not known; it reacts without looking into its route table. This implies that the validity bit in the RREP sent by the attacker node would have a null value. If a node receives a validity value not specified, the RREP can be simply dropped without entering the routing table.

We found that the above-proposed method is a good method that detects a black-hole attack. However, there is a problem, if the attacker will look to its routing table and set the validity value and send RREP to the source, then the source node will fail to detect the black-hole attack and send data packet in that route thinking that this is the destination path. Then attacker will drop data without forwarding it to the destination node. According to our proposed method,the source after generating a route request broadcast it and wait for RREPs. Source receive RREPs from k1+k2 no. of nodes. After receiving RREPs from k1+k2 no. of nodes store them in a list.

Make two groups of RREPs store in the list using binary partition clustering algorithm based on destination sequence number. Then we calculate the average destination sequence number (ADS) of both the clusters i.e ADS1 and ADS2. If ADS1 is greater than ADS2 and the difference is greater than a threshold value then cluster-1 may contain set of black hole nodes otherwise source node select the best node from cluster-1, check validity bit, if set, send data.

If ADS2 is greater than ADS1 and the difference is greater than a threshold value then cluster-2 may contain a set of black-hole nodes otherwise source node select the best node from cluster-2 and check validity bit if set, send data through that node.

An example is taken to discuss the proposed solution. The example is discussed in the following lines.

We take 11 RREPs nodes. Source receiving these 11 RREPs store it in a list. Then source makes two clusters namely cluster-1 and cluster-2. The cluster table is given in TABLE V and TABLE VI.

TABLE V
CLUSTER-1 TABLE WITH DESTINATION SEQUENCE NUMBER

Number of nodes	Destination sequence number
1	50
5	40
2	45
8	48
3	46

TABLE VI
CLUSTER-2 TABLE WITH DESTINATION SEQUENCE NUMBER

Number of nodes	Destination sequence number
4	10
6	15
7	14
9	11
10	12
11	13

The method is used to calculate the following
$ads1 = 50 + 40 + 45 + 48 + 46/5 = 45.8$
$ads2 = 10 + 15 + 14 + 11 + 12 + 13/6 = 12.5$
$ads1 - ads2 = 45.8 - 12.5 = 33.3$

let $ds - threshold$ value is 10.

From the proposed method, it is found that cluster-1 having the highest ads1 values as well as the difference between ads1 and ads2 is greater than the ds-threshold. From this, we can know that cluster-1 may contain a set of black-hole attacker nodes.

So source select the highest sequence number node from cluster-2 that is node-6 which have destination sequence number 15. The source node checks the validity bit, if it is set then send data through that node. In [1] the attacker can easily perform a black-hole attack by modifying the validity bit. But the proposed method solves the problem by segregating the attacker nodes from the normal nodes by using our proposed algorithm. Hence the sender can detect the attacker nodes easily and prevent the black-hole attack.

TABLE VII
SIMULATION PARAMETERS

Parameters	Values
Simulator	ns-2.35
Simulation Time	200 seconds
No of Nodes	100
No of attacker	1, 2, 3, 4, 5
Maximum Speed	30 m/s
Protocol	AODV
Packet Size	1024 Bytes
Traffic Model	TCP

VI. SIMULATION RESULTS

The Proposed solution is simulated using ns-2.35 and compared with Validity bit based approach [1].The simulation parameters are listed in table-VII. In figure-5, we plotted the graph of packet delivery ratio and in figure-6, we plotted the graph of routing overhead with the increasing no of attacker nodes from 1 to 5. From the figure-5, It is observed that packet delivery ratio is close to 1 and then decreases with the increasing no of attacker nodes but at all the points it is better than the validity based approach. Similarly in figure-6, it is observed that the proposed solution gives better result in terms of routing overhead with increasing no of attackers.

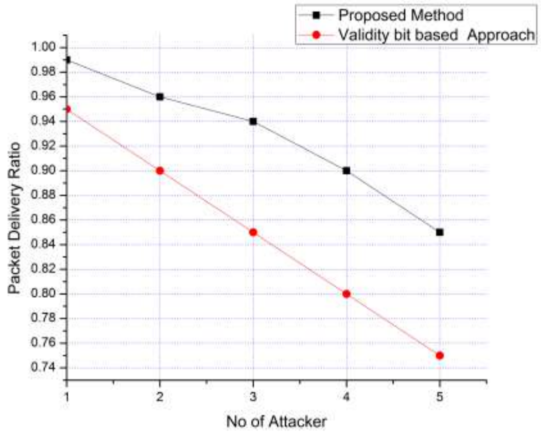

Fig. 5. Packet Delivery ratio Vs No of Attacker Nodes

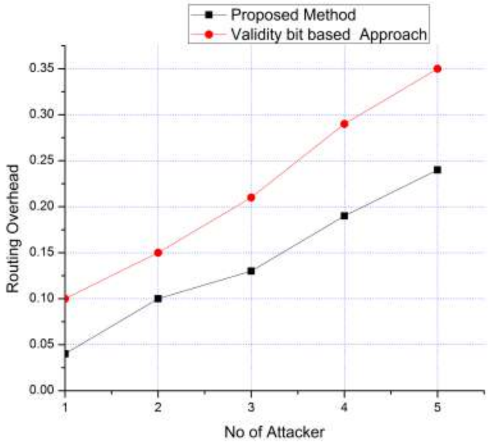

Fig. 6. Routing Overhead Vs No of Attacker Nodes

VII. Conclusion Future Direction

In this paper, we shown that, how the blackhole attack can be performed in the validity based approach [1] and proposed a solution for solving the issues. We compared our proposed method with the validity based approach and shown a better result using simulation result and analysis using example. In future we aim to extend this work for VANET in different scenario and more simulation and analysis results

Abstract*—For many years, there was a challenge of using detecting drivers who operated vehicles under the influence of alcohol. Getting tools that were accurate for measuring results was a major challenge. However, the innovation of Vehicle Breathalyzers assisted in boosting the reduction of Driving Under the influence [DUI] of alcohol or drug deaths. The existent errors in examining the DUI for drivers were resolved through the invention of the Breathalyzer whose capability to measure alcohol amounts has always helped to determine consuming alcohol amongst individuals. The Breathalyzer is one of the essential devices that identify whether a person being examined is drunk legal. This is *because* it provides the proportion of alcohol vapors that are exhaled into the air with a proportion that illustrates the alcohol content in the blood. The current Breathalyzer ignition systems usually require a driver to breathe into the device before starting the vehicle. If the driver alcohol content is above 0.08 percent blood concentration of alcohol, the driver can receive penalties according to the law. Studies have shown that the use of Breathalyzer has grown by a rate of 15 percent per year since their development. The Breathalyzer technology includes data systems which provide a recording of both driver and vehicle responses and rapid systems for monitoring the alcohol state in the driver. This paper provides a description of how these technologies can be applied by drivers to enhance safety in driving. This research will bring insight into how accidents are associated with drunk-driving crimes. It contributes also to the researchers who are looking for a way to reduce road accidents. Through the data collection, analysis, results, and findings, we will get the realization that using a breathalyzer to test drivers, especially at night will help police to identify drivers who have committed the crime easily.

Keywords— Breathalyzer, Monitoring devices Drinking Under Influence (DUI), Blood concentration of alcohol, Interlock programs.

Introduction

Driving under influence (DUI) was identified as the major cause of fatal traffic accidents by the Texas state government. However, a solution to detect drunk drivers was always a major challenge facing drunk drivers. Every hour, a person around the world dies because of alcohol-related driving. For many years, technology has played a major role in enhancing traffic safety. In many years' alcohol tests for drunk drivers had depended on the testing of urine and blood among the drivers. However, many state laws found these laws to be ineffective in providing sufficient outcomes, especially for drunk drivers. Current evolutions have led to the development of chemical testing methods that are ineffective among the drivers. However, the recent growth of these laws has led to the advancement of systems that can control drunk driving while at the same time providing sufficient measures that can control impaired drivers [1]. The present research examines the need for using alcohol Breathalyzers in curbing driving under the influence (DUI). Past studies have shown that drinking under the influence is the major cause of death on the roads. However, the installation of Breathalyzers of curbing DUI offenders has reduced accidents by 15 percent. This shows that the reduction of alcohol-related deaths can be achieved using these Breathalyzers whose focus is to stop the vehicle once it has detected that the driver has been under alcohol impairment. Most of the current vehicles have shown the existence of mandatory ignition interlock systems with the capacity to control alcohol-related crashes. The reduction of mandatory air bag laws and the 21-year minimum drinking age has been a major factor that has been identified for the reduction of alcohol consumption. [2]. The advancement in technology has a significant impact on the consolidation of rules versus DUI of alcohol and drugs. The evolution of Breathalyzer by Birkenstein is one of the most distinguished progression that have assisted to suppress DUI. This is because the Breathalyzer technology comprises a GPS that manages the driving and the position of the driver. Breathalyzers provide a real test of an intoxicated individual. The vehicles also connect to the GPS that would allow law enforcement officials to detect any suspected driver [3].

The major goal of this research work was to inspect Breathalyzer ignition devices and their efficiency to minimize alcohol intoxication between drivers. The selected studies in this paper investigated the performance of the Breathalyzer interlock programs on discontinuing drunk driving. The research studies utilized assistance to offer adequate results of the program through the selected individuals. The outcomes of the studies demonstrated that the use of Breathalyzer programs in stopping alcohol-linked deaths were considerable. However, the former testing of these technologies presented their efficiency in ensuring that alcohol-linked deaths have been reduced, it's evident that the quick advancement of these programs would help to improve

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

road safety in the future. This paper helps to outline that the developments in the interlock programs would play a main role in the special DUI courts in the monitoring of the vehicles with drunk drivers [4]. The remainder of the paper includes research significance, followed by a literature review which analyzed the approaches to the advancement of the road safety linked with drunk driving. It has been inclusively elucidated that the use of interlock systems, remarkably reduced the numbers of accidents. The methodology section concerned the estimation of data since the installation of Breathalyzer technologies as well as the sufficient analysis of the data to ensure that the control of death was efficient. The data and results section demonstrated that the use of Breathalyzers was effective in managing deaths related to DUI. The discussion section covered in-depth analysis of the gathered data associated with the research. The conclusions comprised a summary of the findings and recommendations.

I. RESEARCH SIGNIFICANCE

The significance of this research is that the results of data analysis of this research will be helpful to identify ways that drunk-driving crime can be controlled. This research also helps to bring an insight cover of the previous method that had been implemented but not effected. It also outlines the weakness of the previous methods, to create an idea of how engineers and medical practitioners could come up with a device that will assist the policemen in the day-to-day management of drunk trafficking. This research also will create a good foundation for future researchers who would like to make an invention on automatic machines or vehicles that raise a siren when the driver is drunk.

II. LITERATURE REVIEW

According to the United States Government Accountability officer in 2015, only 20 percent of drivers chose to use Breathalyzer. While the installation of the Breathalyzer is relatively cheap, it is evident that most individuals do not install it due to the interlock system that prevents individuals from using their vehicles, especially when drunk. Sufficient evidence conducted by the Boston State University in 2017 has shown that there is an increasing number of individuals who have installed the Breathalyzer in their vehicles. The focus is to comply with the laws [5]. Close monitoring of the effectiveness of the Breathalyzer interlock programs has shown that there is an increase of 65% in recidivism benefit during the period. This shows that monitoring of vehicles can be a major way that would help to control drunk driving in the United States and all over the world. While the installation of these devices has not been enforced by all states, it is evident that the increased installation of these devices has helped to curb the issue of drunk related driving in the country.

There is a need to identify measures that can be adopted to ensure that these systems are not used as punitive measures among individuals to control drunk related driving in the country. There is a need for the implementation of programs that would ensure that impaired driving has been reduced in the country. The installation of alcohol detection systems would pave way for improved management of road safety. Innovative ways to support the expansion of these programs would also help to control any alcohol-impaired driving in the country [6]. Figure 1 is a graphical representation of how Breathalyzers can be used in the detection of alcohol concentration in the blood. The importance of this graph is to show that the use of breathalyzers has helped to prevent any existence of alcohol-related crashes. This relationship also shows that the detection of alcohol consumption is greatly reduced beyond the 6 second blow time [7].

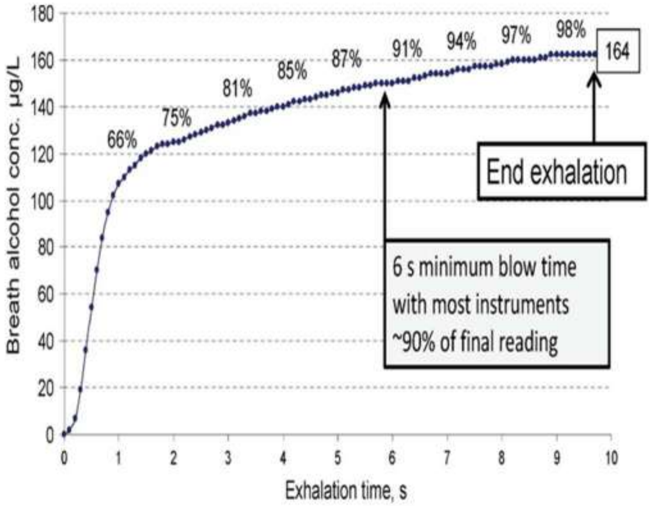

Figure. 1. Breath alcohol concentration as a function of exhalation time

The present study describes how these new electronic technologies can enhance safety on our roads. The first application of Breathalyzer technology by the Department of Transportation provided a solution to the prevalent concerns associated with license suspension, while at the same time protecting the public against the DUI offenders as representative to other drivers. The suspension and revocation of licenses through individuals who had repeated offenses help to curb the deaths associated with DUI [8]. According to Lebow, the main elements of the Breathalyzer technology are the interlock system, alcohol sensors, and an ignition sequence. The other functions of the program entail rolling retests, circumvention prevention, and the interlock categories. These systems help in the control of how this technology is used on the roads. The use of these technologies helps to monitor driving and controls the use of programs that control driving. The system contains technologies that ensure an adequate monitoring of the driver’s breath on a 24.7 basis [9].

The use of the GPS systems is to provide sensor advancements that would control the use of these technologies, hence preventing offenders from increased consumption of alcohol. Providing improved abstinence from alcohol is one of the major objectives associated with Breathalyzer technologies. The current use of continuous monitoring of vehicles using these systems has provided an alternative that would help to ensure that drunk driving has not been implemented in the country. The utilizations of these systems have provided a better alternative that would ensure that these systems have helped detect drinking habits in the population. Currently, there are more than 36 states that require the use of devices to help control DUI. Most of these laws are worse, especially for the offenders who have been found to have been culpable for any DUI offense. Repeat offenders are also found to have major cases related to drunk driving. Installation of ignition interlock has not been a mandatory practice in the country [10]. Numerous Studies have exhibited that the assessment of interlocking technologies such as Breathalyzers has become difficult over the years. Programs for assessing these technologies have not been established. However, data logger technology offers an effective program for managing the systems to guarantee that their performance has been identified. The effectiveness of these systems requires to be identified. Lockouts require to be specified for providing screening devices for the identification of drivers at high risk due to impaired driving [11]. State legislatures should identify means for managing any driving behaviors to determine a basis for the accomplishment of technologies that have been modified for the improvement of interlock experiences [12]. Statistics performed by the Federal Transport Department have demonstrated that car crashes that include the use of alcohol usually approaches 35% of all vehicle fatalities on the roads. This results in more than 10,000 individuals who die on the roads every year. Based on research carried out by the National Highway Traffic and Safety administration, more than one million driving convictions have taken place each year due to alcohol-related consumption. There is a need to undertake measures to ensure that these levels of alcohol consumption have been reduced on the roads. The present laws do not provide adequate prevention measures. However, the contrivance of alcohol breathalyzer offers a satisfactory measure as an interlock law that assists to guarantee that individual fatalities on the roads have been reduced [13].

In 2017, a study conducted by the National Safety Council indicated that the use of interlock systems was one of the most innovative ways to the reduction of road accidents. This was one of the measures that could be adopted to ensure that there were no road crashes that could affect individuals on the roads. The study indicated that the sufficient use of the roads with adequate ignition systems could play a major role that would ensure that road accident never occurred on the roads [14]. While the existing policies and interlock laws have helped to reduce drunk driving, few measures have been established to ensure that drunk driving has been controlled. There is a need for the establishment of policies that provide control for drunk driving to enhance road safety. These measures would be effective in ensuring that public health conversations can be enhanced without any fear of road crashes [15]. There is also a need for policy measures to ensure that public health engagements have involved the use of roads. Reforms of the interlock laws in all states should be carried out to ensure that public health conversations have been established. These policies would help to provide a comprehensive approach to driving. The alcohol culture in many states needs to be identified and reduced to ensure that the establishment of safety in driving has been enhanced. The establishment of these laws that help to curb drunk driving is one of the measures that can be established to improve road safety among the users [16].

There is a shred of strong evidence that shows the consistent use of alcohol breathalyzers for road users can enhance road safety. The drivers who have been advised to use interlocks are individuals who have been previously convicted of engaging in alcohol usage. There is a need to establish sufficient measures among road users that would help to curb and control the use of vehicles while under the influence of alcohol [17]. The adoption of these measures would provide a piece of strong evidence that indicates the need for road users to ensure that they have used sufficient interlock systems that would help them to control their alcohol use. These measures would provide adequate safety that would guide road users and ensure that there is immediate feedback when it comes to the consumption of alcohol among the road users. This would also help to advance road safety while at the same time improving appropriate alcohol consumption. The implementation of the ignition interlock system is one of the ways that can be used to ensure that the circumvention and data collection among road users has been enhanced. The durability and compliance among road users are one of the most important measures that can be used among road users to enhance road safety while at the same time increasing the ability to control alcohol usage among users on the roads [18].

The present research paper incorporates the approaches to the enhancements of the road safety associated with the drunk driving. There are many commitments that have been achieved in this work. It has been comprehensively demonstrated that the use of the interlock system significantly reduced the figures of road accidents. The rationale behind such an advancement on the road safety is the road transport department implementing the policy on the utilization of the Breathalyzer technologies. The legislation of the penalties for any driver who violate any of the road safety provisions improved the road safety across various states. Eventually, the results of the data analysis show a positive relation between the adoption of the breathalyzer interlock systems and the reduction in the number of road accidents across various states.

III. METHODS

This study identified both fatal and non-fatal injuries related to the DUI vehicle crashes from the National Automotive Sampling Systems General estimates data sets from 2015 to 2019. Similar reports were also obtained from the Fatality Analysis, Reporting systems in the same period. The estimation of data from the installation of the Breathalyzer technology was also identified. This estimate was also compared with the proportion of alcohol-related crashes. [19]. The number of deaths that were preventable because of the implementation of the system was also identified. The focus was to ensure that in the years during the installation the Breathalyzers helped to control the number of crashes that occurred as a result. The analysis also assumed that the economic savings and the lives that were saved during a similar period. The data were sufficiently analyzed to ensure that control of deaths was efficient. The device's effectiveness in the control of accidents was also identified to ensure that no deaths occurred as a result.

Probability sampling of 100 vehicles in which installed a Breathalyzer was used were compared with normal vehicles that did not employ the gadgets. The participants came from different states. Descriptive correlations were used to test and retest of all breathalyzes with 0.000 readings. The aim was to ensure that the correct readings were identified to measure the accuracy of the systems in measuring alcohol consumption. The participants in this research were approached to ensure that they had carried out a Breathalyzer test. Every participant had been requested to provide accuracy in their reading to ensure that correct feedback had been provided for the research purposes [20].

IV. RESULTS

From the results and findings, breathalyzer program is effective on installation on vehicles. Having done some analysis, the risk occur was 0.36 having 95% intervals of 0.2

and 0.63. Additionally, the program had been supported by controlled trials having the same test proofed that the installation of the breathalyzer on vehicles have helped to reduce the number of accidents caused by drunk drivers. The results also indicated that the use of Breathalyzers was effective in controlling deaths because of DUI. Having implemented this, with an alcohol limit of 0.08, it has significantly reduced the number of road accidents. [21]. From the results, a significant difference was identified. This was avoided by using correlations. Additionally, the large samples from different states were examined to give support to the results. Physical behavior of the alcoholic persons was also recorded to help me identify the real drunk driver. The participant reading using the One-way analysis of Variance (ANOVA) would be employed through this study to give samples. This contributed in coming up with a different in the collected samples. A 95% RCI difference would also be used as an efficient measure for the analysis of the research to accurately identify the samples. The identified absolute mean for the Breathalyzers was F (3, 115) = 0.35, p = 0.79.

The results of testing the Breathalyzer on its reduction of accidents related to DUI as follows. Figure II shows that the installations of Breathalyzer have a significant impact on the reduction of DUI offenders in the United States. The circled part shows the 5-month period on which the Breathalyzers interlock systems have been relicensed. The devices did not show any errors in the recording as there was more than a 15 percent indicated that drivers have been tested before they had driven their vehicles [22]. Table 1 showed the cumulative results of deaths associated with a DUI. Additionally, the number of records of captured drivers has been recorded which typically shows the trends on how the number of culprits is significantly reduced. Table 2 represented the record just from the last 12 months of the year 2020.

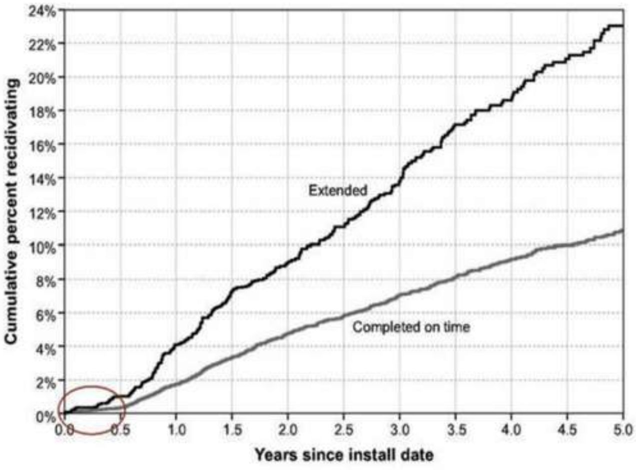

Figure 2. Cumulative percent recidivating as a function of years since install date.

December	91%	9%

V. DISCUSSION

The Breathalyzers have been designed to utilize the three technologies. These three technologies include semiconductor oxide sensor, an infrared spectrometer, and a fuel cell sensor. By using this technology, it facilitates the identification of alcohol in the blood. Normally called Blood Alcohol Content (BAC). The in-car Breathalyzer device can be described as ignition interlock systems whose focus is to measure the alcohol level in the breath hence preventing people from starting their vehicles. The alcohol content is measured from the breath through the breath alcohol concentration. The installation of the Breathalyzer is required to be used in law, especially by people who have been convicted of engaging in drunk driving. In many cases, the installation of these devices helps to ensure that driving privileges have been gained by individuals. The interlocks care of these devices helps to ensure that the driver has been efficiently controlled. This is due to the focus on the implementation of the systems on vehicles. It's clear that the interlock system data provide storage for the data and driving experience and locks the vehicle when the driver has been detected to have been drunk. The restriction on the driving experience of an individual is controlled through the reduced driving because of the use of the system for a long.

Table I indicated that the data collected show that in 2010, there was a greater number of a road accident caused by drunk drivers. We see the percentage generally is above 80%. As compared to 2015 where the number of accidents caused by DUI reduced. Comparing with 2020, the percentage rate had drastically reduced. This is because the introduction of Breathalyzers helps to control the number of drunk drivers on the road. For that year only we can see that the percentage rate is reduced from January to December where we had a slight high. This is for the fact that December has got holidays which, well, most of the people go out for fun. The gathered data presented in Table II clarify the percentage number of drunk drivers who linked to a low or high number of alcohols in their blood. Classified records were used for the year 2020. The registered data demonstrated that the driver's numbers with a high percentage of alcohol was high at the beginning. Subsequently, the numbers start to decrease with time. This happened because the drastic rules and regulations of the government may be established. Furthermore, moving towards the end of the year, the number of drunk drivers with a high amount of alcohol became lower. This is associated with the fact that most of the drivers had known that the Breathalyzer tool can give a clear evidence of the level of alcohol that the driver has taken. Any driving behavior that has been detected to have been unreasonable is always detected by the law enforcement agency. This is because the system also contains a GPS installed on it that can provide accurate location of the vehicle on a real-time basis. The improvements in safety behavior, especially in driving are also enhanced hence improving the driving experience for the drivers. DUI offenders have been forced by the government to use this system to control the driving experience on the roads. This helps to ensure that the driving among the road users has been controlled [23].

Over the years, the high cost of incarceration has contributed to the replacement of jail with monitoring programs. Breathalyzers have been identified as one of the most efficient systems that can be used to control the driving behaviors of major road users. This is because the technology contains an emphasis on the management of controlling electronic devices that are used by the drivers on the roads. There is a need for using interlocks that help to control any consumption habits among users on the roads. The interlocks provide efficient ways of managing these road users while at the same time providing consumption adjustments on the roads. These systems are efficient in providing control of the usage of the programs while at the same time providing sufficient measures for an advisory to the road users. To operate a car that has been installed with the Breathalyzer interlock system, the driver is required to provide a breath specimen. The alcohol concentration level is then monitored, which makes it easy to detect, especially if the road user has engaged in intoxicated levels of consumption. The use of random retests is also a requirement that should be identified and monitored early enough to ensure that road users have effectively been tested on their alcohol consumption levels. Studies have shown that the Breathalyzer often reacts to the potassium solution which turns green with the slightest detection of alcohol that is expelled in the air. The ability of this device to detect alcohol through chemical reaction is one that makes it an efficient system. Most of the available breathalyzes have a fuel cell sensor, semi conduct oxide sensor, and an infrared spectrometer. Most of the available fuel testers have a high degree of sensitivity and high accuracy for handheld and portable systems. Initially, drivers had tested for alcohol impairment through the roadside screening device. However, the development of the Breathalyzer has helped to provide real-time positive testing that helps to provide the identification of the motorists who have engaged in alcohol consumption over time. [24]

Breathalyzer devices are used for evidential breath testing to increase ethanol consumption. The accuracy of the device often depends on the breath being taken deep from the lungs. This means that the use of this device is not 100% guaranteed to identify a low concentration of ethanol consumption. However, increased testing using the device has proven that it is easy to identify alcohol consumption when an individual has taken too much to become impaired to drive. Figure 3 demonstrates that the breath alcohol concentration and how it is identified by a person who has consumed too much alcohol. According to the graph, individuals who have consumed large quantities of alcohol end up being detected earlier. However, less consumption is not identified using the Breathalyzer [25].

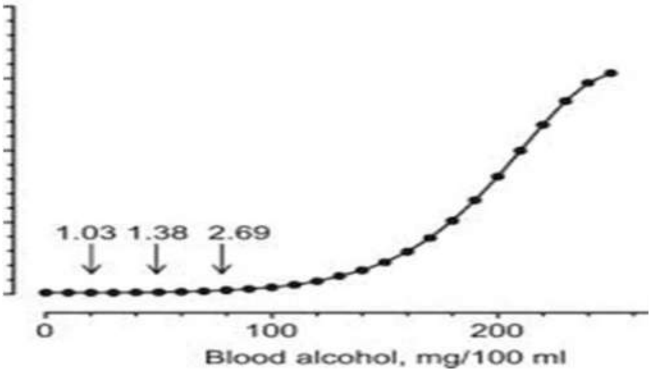

Figure 3. The breath alcohol concentration as a function of blood alcohol

The studies have indicated that road users are not fully informed about their transportation behaviors, especially how they should drive their vehicles. There is a need for educating the driver's on-road behavior to control any existing road accidents. Also, there is a need for established inspections that would be conducted periodically to ensure that vehicles do not endanger road users. There is also a need to have collision information to control the behavior of road users and ensure that transport information has been kept. This would increase the behavior of the road users and ensure that no accidents occur on the roads. Penalties for individuals who do not install the vehicle ignition systems should be established to ensure that road users have adequate systems that can be used to improve road safety. This would improve the transportation of vehicles while at the same time enhancing road control measures.

There is a need to have zero tolerance on drugs and alcohol especially when driving. The absolute adherence to road safety rules will ensure that a better driving experience has been established on the roads. This would also reduce the level of deaths and crashes that occur on the roads. The adoption of the present policies and laws on the roads will improve the statistics of road users. Since the statistics show that Breathalyzers can help, enforcement officials need to ensure that safety measures have been adopted hence improve road safety. This would be one of the measures that would help to ensure that road safety has been improved while that the same time ensuring that the culture of road measures and accident reduction strategies have been improved on the roads [26]. The advancement of the Breathalyzer needs some software code design with the communication. The software codes should be capable of giving a judge without human interference. The associated coded software should be integrated with the device. The software codes have a logic provided that, if the out-breath or the bloodstream of a drunk person comprises some alcohol, the software code can be designed to highlight a red alarm and indicate on the screen that the driver is drunk. Such software can make the Breathalyzer authoritative to be adopted as a control and judge tool for this purpose. Moreover, this software can be designed to give an alarm signal to the police department indicating that there is a drunk driver. Figure 4 is a diagrammatic representation of the Breathalyzer.

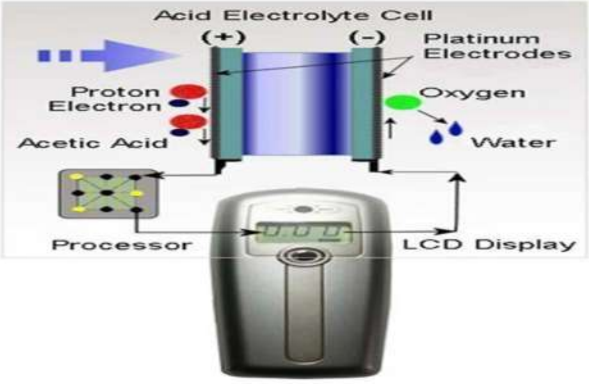

Figure 4. Diagrammatic representation of the Breathalyzer.

VI. CONCLUSIONS

To sum it up, while alcohol Breathalyzer work to reduce deaths associated with drunk driving, abstinence from drugs before driving is the only key to safe driving. The high costs of incarceration in the country have led to the implementation of DUI courts whose focus is to control drunk related offenses. The courts have established models and programs whose benefit is to enhance monitoring and treatment of drunk related offenses. When successful, these systems can help provide low cost to the government for the incarceration of offenders. The development of vehicle interlock programs can also provide sufficient management of alcohol consumption among drivers. The use of Breathalyzer technique will assist to minimize detention times, license suspension, and even reduction of fines among the users. The reduction of correction programs among the users is also another advancement that would be adopted, especially when the new systems have been implemented. Courts will also have more options for enhancing interlock programs while at the same time enhancing the confinement efforts for users. Since studies have shown that the Breathalyzer system has been effective in the control of drunk driving, measures should be established to ensure that there is improved durability, compliance, and also participation rates that improve the use of these systems to avoid the punishment of offenders.

VII. LIMITATIONS OF THE STUDY

This study has been limited due to the reduced nature of the samples selected. There was a need to conduct more data that could have helped to provide sufficient analysis of the study. This could have led to an increased examination of the study while at the same time enhancing the credibility of the findings. The selected sample size also contained limited data access, hence leading to insufficient sizes that could be used for efficient statistical measures. The use of a small sample size increased the margin of error in the research. For this reason, there was a need to increase the sample size to provide accurate representation of the statistical measures that were used in this research. This would have enhanced the outcomes of the research while at the same time providing more reliable information that could be used in the analysis. Moreover, this could have presented the researchers with better research outcomes that would have helped to provide sufficient data analysis [27].

Time constraints in also conducting this research were also minimized because of the existing data examination. The increased conflicts in personal bias and cultural issues were also major factors that limited the undertaking of the study, hence having negative outcomes on the consistency of the findings. Certain perspectives and phenomena in this research were required to provide a sufficient examination of the results, thus providing reliable information that would be used in the research process. One of the main limiting factors in this study was the lack of sufficient resources from the ministry of transportation to provide accurate and reliable results. The study could have increased its sample size and even used a more accurate methodology if the existing resources were sufficient. There was a need to provide transparency and honesty as a statistical measure to provide sufficient findings that could have been used by the ministry in the process [28].

VIII. RECOMMENDATIONS

The US Department of Transportation should adopt the Breathalyzer project and offer the required resources for its development to secure and enhance the road safety. The outcomes of the current research study have demonstrated that prohibiting every drunken driver from igniting his vehicle based on the interlock laws can considerably prevent car accidents and subsequent rescue peoples' lives. The establishment of the ignition policies on vehicles, can save greater than 15% of the lives, hence enhancing the road safety. Constructing of interlock programs and innovative measures to stop these vehicles can act as an adequate measure that can assist in managing road accidents while simultaneously providing innovative technologies for stopping road accidents [29]. State governments need to adopt sufficient measures for reducing car crashes on the roads through the adoption of policies that can help to curb road accidents. This can be achieved by providing a sensitivity and awareness of the breathalyzers and how they have helped to curb road accidents. This would be an efficient measure that can guide road users and give them an accurate understanding. One of the challenges that are faced on the roads. The adoption of sensible measures could provide an accurate understanding of the roads and how they pose danger to many users. Only interlock systems, vehicles should be allowed on the roads. This would make the vehicles more efficient for road users, as a result stop the road accidents that occur on a routine basis. Also, the limitation of driving while using cell phones should be identified as one of the measures that can be used to eliminate car crashes and enhance road safety [30].

The need for road safety needs to be established efficiently through the creation of a road safety culture. The focus is to ensure that organizations have adopted measures for road accident reduction. These measures would be efficient in providing employees with realistic measures and schedules that can help to provide road safety. A culture of road safety is one of the measures that need to be adopted to ensure that road users do not engage in activities that can threaten their safety controls. Apart from alcohol drinking, there is also a need for assessing driver's skills regularly with a need for checking and examining their driving behavior. This is an efficient measure that can help to improve the experience of a driver on the road, thus preventing them from engaging in behaviors that can contribute to road accidents [30].

***Abstract*— Nowadays, fossil fuel exhaustion is one of the significant environmental issues. Hence, the existing power system of Renewable Distributed Generations (RDG) is used to overcome this issue. The proper planning must be implemented to allocate the separate sources in the network of distribution areas. This paper proposed an optimal placement and sizing of Distributed Generation (DG) with an improved flower pollination algorithm (IFPA). This paper aims to find the optimal location and sizing of the Distributed Generations (DG). The objective of power loss minimization is considered with some constraints like power balance equations, voltage limits, DG sizing limits, and thermal limits are being done in this research. This proposed technique is evaluated on the practical Indian 52 bus system. The results of the optimal Distributed Generation location and sizing are obtained with the help of IFPA. Therefore, the percentage of loss reduction through IFPA is comparatively higher than the FPA and the chaotic FPA.**

***Keywords*— Distributed Generation (DG), Optimal placement and sizing, Improved Flower Pollination Algorithm, Power loss reduction, Practical Indian-52 bus system**

I. Introduction

Due to the fast growth of industries and population, there is a demand for electricity for the customers. Hence, 13% of the total generated power is wasted in distribution as line losses. The inductive loads are sustained mainly by the distribution network (DN). It sometimes gave poor power factor, voltage sag, and high system loss. Distributed Generation (DG) is installed to solve and overcome these problems, a possible solution [1]. The DN is the one portion of the entire system. It would join the transmission system of high voltage to consumers of low voltage. When the level of the target is at 7.5%, then the distribution loss is 15.5%.

Therefore, proper planning must be done for the DN of the primary and the second part. In the primary and the secondary distribution sectors, the total losses obtained were 70%, and the remaining 30% losses are obtained in the transmission and the sub-transmission lines. The Distribution Networks of the conventional arrangements are modified by the different sizes and formations established by the rapidly developed DG [2]. Its integrity result from the challenges provided from the technical and the economic perspectives. For ensuring the DN performance, optimal planning is pointing out the supreme importance. This DG encountered the stability of voltage, reliability, reduction of power loss, profitability, and the quality of power [3]. The losses can be minimized by installing the DG units at the proper positions. In remote areas, distributed generation plants such as wind turbines and photovoltaic (PV) energy are placed. The operating system required thorough integration into the distribution network and transmission network. This DG's motive is to reduce the cost, greenhouse gas emission, and losses by integrating all types of generation plants. To improve the stability, voltage, and power factor, DG is used. Thus, in DN, the DG sizing and its locations are playing a significant role. The DG means the electricity generation from the small-scale region to load centers. When the network had an expansion like the Distributed Generation, it took care of the areas of the new loads. Solar and wind are the most predominant renewable DG, which is eco-friendly in nature.

Depending upon the generation of the power, the DG is classified as,

- Type 1: the system injected only the actual power
- Type 2: the system had both the reactive and the real power
- Type 3: the system injected only the reactive power.
- Type 4: the system injected the real power but also absorbed the power, which is reactive.

The allocation of the optimal DG is an essential job in the whole system. If the DG is installed in a non-optimal location, it provides high system loss and voltage instability [4]. Finally, the results were provided the high operating cost. To increase efficiency and therefore get higher benefits, there would be an optimal allocation of DG to be obtained. Many research works are entitled to finding the optimal location and sizing the DGs. The Resistance/Reactance ratio (R/X) must be high in the Radial Distribution Network (RDN). Most published articles are found to work based on reduction in power loss during the location and sizing of Distributed Generations [5] for standard test systems of IEEE. This article proposed a new, improved Flower Pollination Algorithm for the allocation and sizing of DG. This research is evaluated with a real-time system such as the practical Indian 52 bus system.

II. LITERATURE REVIEW

The optimal operations of the Distributed Generations have been rendered by Ant Colony Search Algorithm (ACSA) method. The problem of placement of the optimal capacitor and the optimal feeder's reconfiguration is solved using the ACSA method [6]. The Cloud Mutation Flower Pollination algorithm is proposed for the problem of continuous optimization. In the optimization of the global zone, it added information in all the dimensions [7]. For the multi-objective findings like improvement in voltage profile, minimization in power loss, and operating cost, the Whale Optimization Algorithm (WOA) is proposed. It is evaluated in the 32-bus and 69-bus systems [8] [9] [10]. The Distributed Power Generation is used for the conversion of the power and the technology control. Here, the impacts are examined, and the connection strategies are enhanced [11]. The various DG performances are analyzed, and the advantages of those DG are increased [12]. The Combined Loss Sensitivity is proposed to find the location and size [13]—the Fuzzy-FPA (FFPA), a hybrid phase swapping algorithm. The deviation of the phase current is minimized here. Optimization of the fitness value is calculated [14]. The particle swarm optimization strategy is proposed with the hybrid genetic algorithm. For DG allocation, this algorithm is presented. It includes position, capacity, and number. Also, it identifies the required total power [15]. The main objective is to minimize the losses. To reduce the power losses, the DG addition is very effective [16]. To achieve less oscillation and maximum power, the conventional method is used [17]. The Flower Pollination Algorithm is proposed for the modeling and simulation of the MPPT SEPIC-BUCK converter series. For quickly finding the maximum power

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

point, this technique is proposed [18]. For the DG allocation, the Flower Pollination Algorithm is proposed, and the minimization of the total power loss was done. Hence the voltage of the system bus is improved. It is done with the help of MATLAB software [19]. The modified Flower Pollination Algorithm is used for the allocation and minimization of losses. By the DER unit allocation, the MFPA validation has been done [20]. The Chaos-FPA (CFPA) has been entitled to the DG placement problem. The equations of the Gauss map chaotic variable have been altered. The main aim is to increase the aggregator profit [21]. A non-linear nature of generation has been handled with the secured operation. The adaptability could be gained through chaotic variables [22]. The DG capacity is used for solving the problem of congestion management. The normalized weights have been used for converting the function of multi-objective into a single objective problem [23]. To control the speed of the BLDC motor, the FPA is proposed. The comparison has been made with the Ziegler-Nicholas method's help, which is conventional [24]. To reduce power loss and capacity of optimal DG, the method of FPA is being used. The photovoltaic DG is implemented [25]. For the dispatching of emission and the optimal load, the FPA and the hybrid Fuzzy were proposed. For optimum levels with the emission and economical combination, the FFPA method has been utilized [26]. In RDNs, the allocation of DG is solved with a chaotic symbiotic organism search algorithm. Also, Moth Flame Optimization is used for the allocation of PV-DG [27] [28].

The Improved single and Multi Harris Hawks Optimization Algorithms have been proposed to allocate and size DG. The main aim is to reduce the voltage deviation, total power loss and increase the voltage stability index [29] [30]. The comparison of Perturb & Observe, Modified Particle Swam Optimization, and FPA is made. For the reduction of the ripple current, the SEPIC converter is presented [31]. The allocation of the optimal capacitor is brought out with the help of FPA. The load flow analysis gives the power loss and flows with data structures' help [32]. Artificial Intelligence techniques have dominated the Distributed Energy Generation. To maximize the optimum operation schedule and reliability is the main objective, and to improve the operational efficiency, developments are being done [33].

III. PROBLEM FORMULATION

To allocate the proper Distributed Generations, more concern needs to be taken in the DN. The power loss minimization with optimal solar and wind DG allocation in RDN is the main objective in this paper. The various constraints in the distributed network need to satisfy the objective functions.

A. Objective Function

a) Minimization of Power Loss: When solar and wind DGs of the RDN are considered, the primary objective is its optimal location through power loss minimization. It is given in Eqn 1.

$$f_{obj}(X) = \sum_{k=1}^{nb} |I_K|^2 R_K \qquad (1)$$

Where, R_k, I_k are the resistance, k^{th} branch of the current magnitude, and the number of branches is denoted by *nb*.

b) Constraints: The various constraints in the DN need to satisfy the objective function given in Eqn 2– 5.

Power Balance

$$P_{slack} + \sum_{k=1}^{N_{SDG}} P_{SDG,k} = \sum_{k=1}^{N_L} P_{D,k} + \sum_{k=1}^{nb} P_{loss}(k) \qquad (2)$$

Voltage Limits

$$|V_{min}| \leq |V_k| \leq |V_{max}| \qquad (3)$$

DG sizing Limits

$$P_{SDG,min} \leq P_{SDG,k} \leq P_{SDG,max} \qquad (4)$$

Thermal Limits

$$I_{jk} \leq I_{jk}^{max} \qquad (5)$$

Where,

P_{slack} is used to indicate slack bus power
P_{SDG} is used to indicate DG power
P_D *is* used to indicate power demand
P_{loss} is used to indicate actual power loss
V_{min} and V_{max} Are used to indicate the minimum and maximum voltages, respectively.
$P_{SDG,min}$ and $P_{SDG,max}$ are used to indicate the minimum and maximum DG power
I_{jk}^{max} is used to indicate maximum current
j and *k* are used to denote branches
N_{SDG} *is* used to denote the number of DGs
N_L *is* used to denote the number of lines

IV. IMPROVED FLOWER POLLINATION ALGORITHM

Flower Pollination Algorithm is the concept from the flowering process of pollination [18]. The reproduction process of flowers does pollination. The pollinators are transferred from the pollens. This is classified as the abiotic and the biotic process. Based on the process of the execution, it is divided into cross-pollination and self-pollination. Some of the steps are involving in the Flower Pollination Algorithm. They are,

Step 1: Global pollination is called biotic or cross-pollination due to the pollinator's movement. It carries the pollen which following the Levy flight.

Step 2: The local pollination of the self or abiotic pollination is called an absence of pollination.

Step 3: There is a similarity in the reproduction probability of the associated two flowers.

Step 4: The switching probability's critical factor is p [0,1], which is an interaction between the local and global pollination.

In terms of an equation, steps 1 to 4 are updated. The pollinators are transferred from the gametes of flower pollen when the global pollination. Thus the pollen covers longer distances [32]. Hence the global pollination and the representation of constancy of the flower are given in Eqn 6.

$$x_i^{t+1} = x_i^t + L(x_i^t - g_*) \qquad (6)$$

Where the solution vector is denoted as x_i^t and the best current solution is denoted as g_* . L from Levy distribution represents step size, and the random number is denoted as GS.

$$\text{L}=\frac{\lambda\, \Gamma(\lambda) \sin(\frac{\pi\lambda}{2})}{\pi} \frac{1}{s^{\lambda+1}}\ , \quad (\text{s} > s_0 > 0) \qquad (7)$$

Hence, the standard gamma function is denoted as $\Gamma(\lambda)$ Where s>0.

From rule 2, the flower's constancy is expressed using the golden section ratio [34] in Eqn 8.

$$x_i^{t+1} = x_i^t + GS(x_j^t - x_k^t) \qquad (8)$$

Where the species of plants from the different flower pollens are denoted as x_j^t, x_j^t

Here, The Local pollination is rendered by golden section ratio. The technique of the IFPA has solved the problem of the power system [25]. In the identified allocation, the IFPA helps identify the placed solar and wind DGs. IFPA is easy for balancing because the parameters are significantly less controllable between the exploitation and exploration ability while optimization occurs.

A. Steps for solving the optimal location of solar and wind DGs with the help of Improved Flower Pollination Algorithm

1. To read the test system data
2. To initialize the IFPA parameters such as switch probability *p*=0.8, Iterations=150.
3. To identify the correct allocation of the DG placement.

4. To identify the best allocations, which is a Flower Pollination Algorithm input.
5. No DGs should be placed if rand>p in the installed locations
6. The concept of local pollination through golden search is adopted to identify the placed DGs.
7. To update the current best global solution.
8. To display the solution results. Stop the process if the values are correct; otherwise, repeat the process from step 4.

V. SOLUTION METHODOLOGY

The proposed system is evaluated in the practical Indian 52-bus system [35]. It is portrayed as RDN. There are three types of feeders used in the test system. This research aims to minimize the deviation of the total network loss [5]. There is a possibility of allocating two DG, which are considered here. In the simulation process, it is considered that Type-2 DGs are analyzed that would have both the reactive and the real power. The Indian practical 52-bus radial distribution system portrayed is considered for evaluation of IFPA. This test system consists of 3 main feeders, 51 branches, and 52 bus. It feeds a total network load of the absolute power of 4184 kW and reactive power of 2025 kVAr. The power factor of the connected load of this test system is 0.9 lagging. The base kV and MVA for this considered test system are considered as 11 and 1, respectively. The maximum and minimum bus voltage magnitude limits for the given test system are 1.05 p.u and 0.9 p.u., respectively. The vital objective of this work is the minimization of network loss and total load voltage deviation. The maximum number of DG units installed for this system is considered equal to the number of feeders.

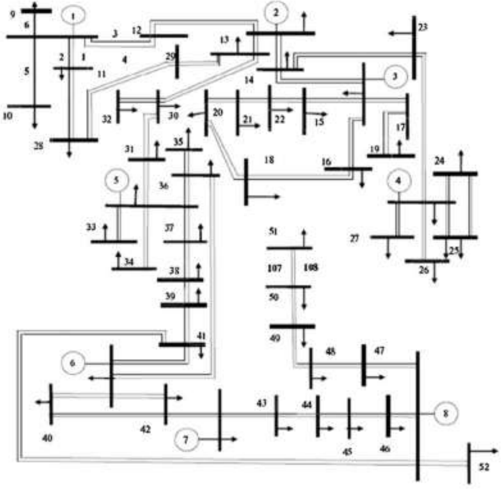

Fig. 1: Indian-52 Bus System

VI. SIMULATION RESULTS

There is a comparison obtained between the Flower Pollination Algorithm (FPA), Chaotic Flower Pollination Algorithm (CFPA), and the Improved Flower Pollination Algorithm (IFPA) are shown in Table 1. The Distributed Generation location and sizing are calculated for each algorithm [13]. The overall power factor and the loss reduction percentage are also calculated for each algorithm [14]. From Table 1, we can observe that the percentage of the loss reduction is higher in the Improved Flower Pollination Algorithm. But the power loss is very high while using the Flower Pollination Algorithm compared to the other two algorithms.

The Improved Flower Pollination Algorithm (IFPA) convergence characteristics are shown in Figure 2. This figure shows the best cost at various iterations. In this graph, we can clearly understand that while increasing the number of iterations, the best cost is attained. Here, the cost tends to our objective (i.e.,) Power loss.

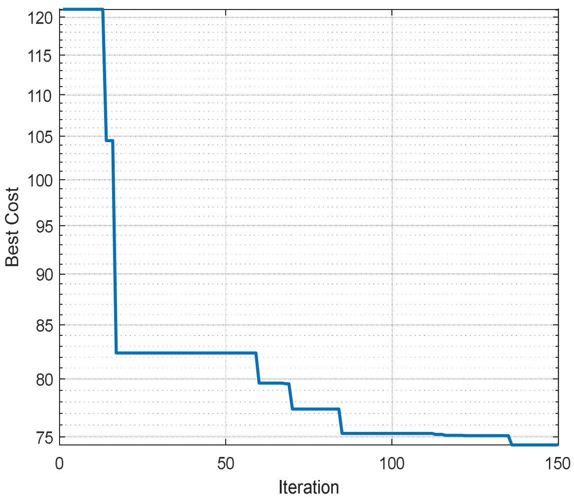

Fig. 2: IFPA Convergence Characteristics

In figure 3, the Power loss profile is obtained. This graph shows the power loss that occurred at various buses due to DG sizing and location. And it is calculated for 52 bus systems. At the point of 52 buses, the power loss is found to be decreased.

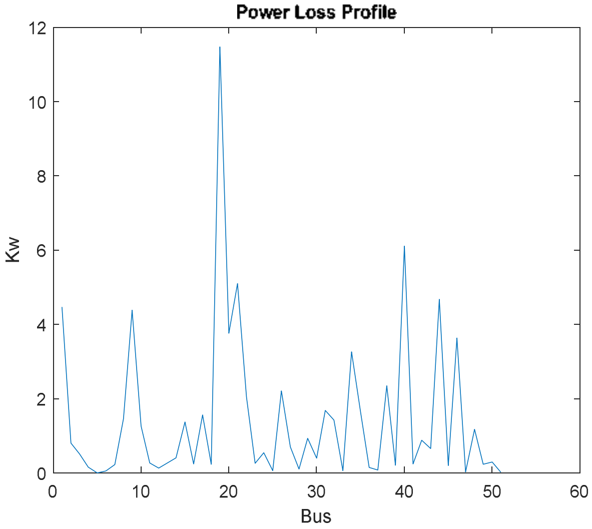

Fig. 3: Power Loss Profile at each bus in Indian-52 bus system

From figure 4, we can observe the voltage profile characteristics for the 52 bus system. And there, we can observe that a little much improvement in the voltage profile is obtained in the Indian - 52 bus system.

TABLE I. Analysis of Practical Indian 52 bus system

	Ploss (kW)	DG location	DG size (kW)	DG size (kVAr)	Loss reduction%
FPA[30]	89	10,47	922, 1102	478,647	79
CFPA[21]	84	11, 41	686, 1258	509 651	81
IFPA	79	41, 16	1261 ,968	683 362	82

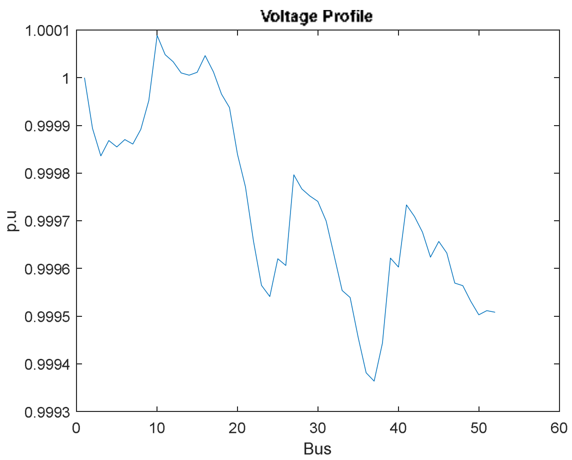

Fig. 4: Voltage Profile of Indian-52 bus system

VII. CONCLUSION

In this research, the practical Indian 52 bus, which belongs to the RDN problem, has been solved to allocate the optimal DG. Its location and sizing are determined using the Flower Pollination Algorithm (FPA) and chaotic FPA. Different type of heuristic algorithm like Improved Flower Pollination Algorithm (IFPA) is proposed in this work. From the above results, it is concluded that the power loss is minimized, and there is an improvement in the voltage profile factor. Hence, the efficient outcome is showcased with the practical Indian 52 bus system.

ACKNOWLEDGMENT

The authors are very grateful to the VIT University-Chennai campus authorities for carrying out this research work with extensive facilities.

***Abstract*— Data storage in IoT systems describe how data is pushed from the sensor and where it will be stored. In Bitcoin, there is a limit to the number of transactions that can be stored in the block, similarly in Ethereum it is limited by the gas limit in block. An IoT infrastructure have several applications that includes a sensor collecting data from physical environment. Storing a large amount data in a blockchain faces several challenges due to the distributed nature of the blockchain, high transaction processing time, and reduced scalability. Hence it is crucial to identify what data should be stored and how to store it in a secure way. In this paper, we provide how data is being stored in various blockchain based IoT applications and provides data storage compliance in treating IoT data in a blockchain environment.**

Keywords—blockchain, Internet of things, data storage, sensors, data compliance, cloud.

I. Introduction

Blockchain is a recent technology that can provide data security and privacy in IoT Systems. It uses a distributed ledger design that stores data in multiple nodes within the network. In a decentralized system, computing and storage tasks are redundant, which means every node in the decentralized network must store a complete copy of all data and perform the same operations of data. This is how blockchain maintains trust among nodes and provide security to the data. However, when the number of participating nodes increases or the amount of data to be stored is high, it will not be practical to replicate the entire data into all participating nodes and to perform concurrent computations on it.

The existing internet of things systems uses either offline or cloud-based information-sharing technology. It has several shortcomings including the high maintenance cost, low efficiency, and lack of an effective mechanism to ensure IoT equipment Identity, information validity, authenticity, consistency, and integrity of information in different systems [1].

Blockchain systems do not rely on trusted third parties. All nodes make decisions together to verify the legitimacy of the transaction. Even if some nodes are attacked or destroyed, it will not cause damage to the entire blockchain system.

II. Background

A. Blockchain

Blockchain is a distributed ledger where blocks are connected with cryptographic hashes and are distributed over all the nodes in the system. Generally, there are two types of blockchain: public and permissioned. In a public blockchain, anyone can join the network or participate in the consensus mechanism. An example of a public blockchain is Bitcoin. In a permissioned or private blockchain, only certain entities will have access to participate in the blockchain process. This is typically used in applications that involve multiple entities in a restricted way. It will have a certain control on who can access the data and who can participate in the consensus. The consensus is an agreement on how and what data are added to the blockchain.

B. Internet of Things

As defined in [2] Internet Of Things (IoT) is an emerging global Internet-based information architecture facilitating the exchange of goods and services in the global supply-chain network. The IoT data comes from a large number of devices generating billions of data objects. The IoT network has to collaborate with different devices to sample, process, and make this data useful for analytical and decision making. Realizing the full potential of IoT has not yet been achieved. This is due to the lack of standards, heterogeneous nature of devices, diversified communication protocol, and security [3].

III. Data Storage in Blockchain Based IoT Usecases

A majority of blockchain-based IoT Application is in the field of healthcare, Smart home, smart city, Industrial IoT and agricultural applications.

A. IoT Devices employing blockchain

The blockchain-based design for IoT data storage takes a distributed access control and data management approach. In this scenario, data ownership is transferred to users instead of following the traditional centralized access control system based on trust modeling. With the use of blockchain-based functions, secure and fail-safe data management with a verifiable and distributed access control layer on the storage layer is practiced. The storage of time-critical IoT data is facilitated at the edge of the network via a location-based decentralized storage system, which in turn is managed with blockchain technology [4]. The parallelism of large storage systems is suggested by Quanqing Xu[5] in order to shorten the execution time of many basic data analysis tasks, whereby blockchain can be used as intelligent contracts to facilitate the negotiation of a contract in the IoT and also to enforce it. OSD-based smart contract (OSC) approach is used in which IoT devices interact with such blockchains. For data analysis applications, the IoT device processors perform application-specific operations. That way, only the results are returned to the clients, rather than the data files they read [5].

B. Healthcare

Since the advent of smart IoT devices in the Healthcare industry, promising technologies such as cloud computing, ambient assisted living, big data, and wearables are being applied in various platforms within Healthcare [6]. E-health regulations related to data and policies worldwide to determine how they assist the sustainable development of IoT and cloud computing in the healthcare industry evolved as well with the thriving data in all these platforms [6]. The Medical data of a patient is treated with utmost care and secrecy. Hence the IoT devices in healthcare systems are devised to ensure the security of patients' healthcare data, realize access control for normal and emergency scenarios, and support smart deduplication to save the storage space in big data storage system. The medical files generated by the healthcare IoT network are usually encrypted and transferred to the storage system, which can be securely shared among the healthcare staff from different medical domains leveraging a cross-domain access control policy. A smart secure deduplication method could be followed as proposed by Tang et al. [7] to ensure the medical files or data can be accessed by all the data users after deduplication and authorized by the different original access policies.

C. Industrial IoT(IIoT)

The main goal of industrial IoT is to improve operational efficiency, increase the scale of production and better management of industrial components and processes through product customization, condition of machines getting monitored in an intelligent way, smart monitoring applications for production workshops as well as predictive and preventive maintenance of industrial equipment [8].

In industrial usage of IoT devices, storage and retrieval are done by integrating fog computing and cloud computing [9] and a flexible and economic framework for data processing was made by the authors. The data in these devices are preprocessed in the edge server with the addition of timestamps and stored locally. The remaining data gets sent to the external storage medium and away from the local storage for information retrieval and data mining [9]. This set of data is not time-sensitive.

D. Smartcity/Smart Home

Smartphone applications are used to control and monitor home functions using wireless communication technologies. Domb in [10] examines the concept of the smart home and the data associated with it, incorporating IoT services and cloud computing It also discusses embedding intelligence in sensors and actuators, networking intelligent devices using the appropriate technology, saving storage space and improving data exchange efficiency, and facilitating data interaction with intelligent things using cloud computing and storage for easy access to various locations. A precise, fast, open and shared information system is the basis for Smart City applications. In view of this massive, distributed, heterogeneous and complex state data, the storage and management of traditional data will encounter great difficulties. The traditional infrastructure uses a centralized approach, an expensive large server, hard disk storage hardware, and a relational database management system. This leads to poor scalability of the system, higher costs and, for the most part, difficult adaptation to the demand for higher reliability of real-time status data from smart city applications [11].

E. Agricultural Applications

Some IoT-based smart farming surveillance systems use a two-tier approach to data storage to store and secure large amounts of data from any IoT device. Tier-1 focuses on collecting data from various sensors and storing them locally using the SD card. Tier-2 uses a cloud server to store the large volume of IoT sensor data [12]. Gill et al. [13] explains the benefits of a cloud-based autonomous information system for the delivery of Agriculture-as-a-Service (AaaS) using cloud and big data technologies. Accordingly, the Aaas system collects information from various users via pre-configured devices and IoT sensors and processes it in the cloud with the help of big data analysis and provides the users with the necessary information automatically.

IV. DATA STORAGE ARCHITECTURES IN IOT BLOCKCHAIN

A. Storage in cloud

Permissioned blockchains use cloud servers to store encrypted data blocks. All transactions in a different block and create a combined hash of each block using Merkle Tree and transfer it to the distributed network. This way, any changes in cloud data can be easily detectable. Doing the storage in this manner also preserves decentralization to some extent [14]. Fig.1 shows blockchain based IoT architecture where a cloud storage is being used to store the IoT Data. Cloud storage uses users' data in an identical group. The Hash of the data stored in the cloud is sent to the overlay network. The hierarchical storage structure in storing the majority of the blockchain in the clouds helps faster upload of one day’s blockchain to the cloud, it maintains the most recently created blocks in a blockchain overlay network. The blockchain connector and the cloud connector are the two software interfaces that are defined to create the blocks and coordinate to the clouds but one disadvantage of this method is a need to be implemented in a more real IoT application to find out if this technology is reliable [15].

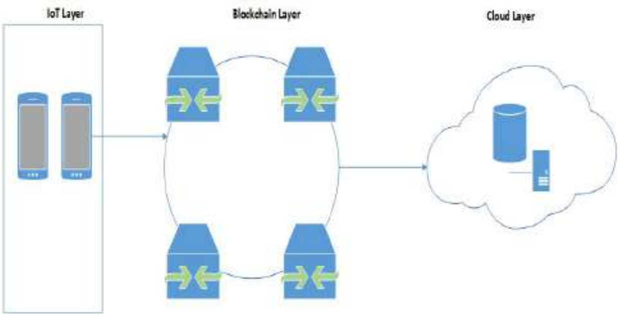

Fig:1 Storage in cloud

B. Storage in Decentralized way

This is a fully decentralized way of storing data. Liu et al. [16] integrates decentralized blockchain network and distributed storage network. Data produced by the IoT device is stored in the distributed storage nodes in the peer-to-peer network, whereas the reference to data that serve as the identifier is stored in the Blockchain. Blockchain only stores the digest of data but not data itself. Hence the amount of data on the blockchain is greatly reduced. The use of blockchain technology in storing data and with the use of management hub including the integration of IoT and decentralized access control to the blockchain solves the issues in managing several controlled IoT devices, it was able to cope up with different IoT scenarios but there are possibilities of threat and vulnerabilities in the IoT since it is no longer part of the blockchain technology [17]. Fig.2 shows a blockchain architecture that uses decentralized storage for storing IoT data. Decentralized cloud architecture was used in which small-scale data centers meet low latency and high bandwidth because these data centers are located closer to the users. The locality-aware data storage and the processing development provide its full potential with the decentralized access control layer. Data streams that are chucked at pre-defined lengths show reasonable results but this one is still in the initial stage and needs improvement[4]. Sapphire system which is a large-scale blockchain storage system used for data analytics in the IoT it uses an object-based storage interface that provides richer semantic information for the stored object to optimize its performance more effectively than other storage systems[5]. A secure structure for IoT data storage and protection which is based on blockchain technology incorporating edge computing helps manage data storage and assist small IoT devices to accomplish computations. The authentication system adapted the certificate-less cryptography, but it needs to improve the authentication scheme for the blockchain-based systems[18]. The integration of IoT, blockchain, and cloud technologies allows observation of vital signs of the patient in a protected approach. The storage and access of data used in the blockchain technology data sharing significantly increase overall throughput but need to be tested using various IoT frameworks[19]. Blockchain technology solves the problem of IoT information sharing security but performance needs to be enhanced when applied to a specific industry [1].

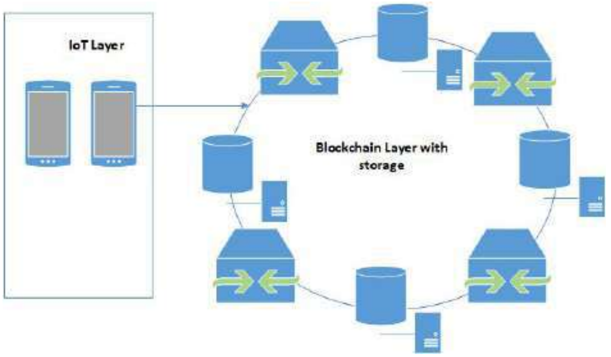

Fig:2 Storage in Decentralized way

C. Storage in Hybrid way

In this method data will be stored in a hybrid way, where processed/ or raw data from the sensor is stored in a cloud server and a reference to the data will be stored in the blockchain. Si et al. [1] propose a double-chain model combining data blockchain and transaction blockchain. IoT data is divided into lightweight data and multimedia data, where multimedia data is compressed and integrated to reduce data capacity and to improve data quality. The processed data is divided into account book data and outsourced storage data (multimedia data) stored in a fog node that can be easily downloadable. Fig.3 shows blockchain architecture that uses hybrid storage. A comparison of various storage options in IoT based blockchain architectures is provided in Table1.

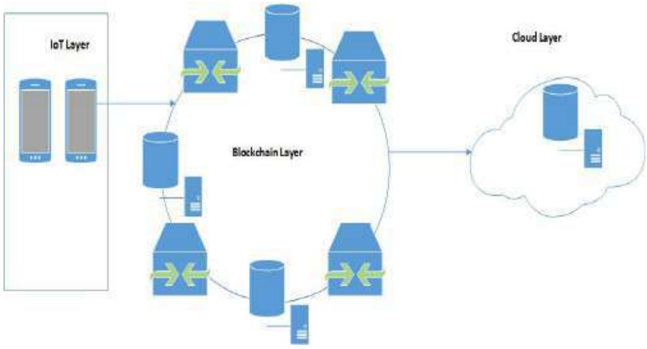

Fig:3 Storage in a Hybrid Way

Table 1: Comparison of various data storage options in IoT Blockchain

Type	Storage Design	Advantages	Disadvantages	Reference paper
Cloud	Hierarchical storage structure	• Faster upload of one-day's blockchain to the cloud	• Not yet implemented in a more real IoT application	[15]
Decentralized	Blockchain system with Management Hub	• It performs best with the use of management hub node	• It might face different threat and vulnerabilities since IoT is no longer part of the blockchain technology	[20]
Decentralized	Data streams are chucked at pre-defined lengths	• Initial results show reasonable overhead	• Still at the initial stage and needs for improvement	[4]
Decentralized	Object-based Storage interface	• Has richer semantic information for the stored object to optimize its performance more effectively than other		[5]

		storage systems		
Decentralized	Blockchain system combined with Edge Computing	• Secure scheme for IoT data storage and protection	• Need to improve authentication scheme for blockchain-based system	[18]
Decentralized	Data Sharing using Blockchain technology	• The overall throughput increased significantly	• Need to be tested using various IoT frameworks	[19]
Decentralized	Blockchain technology	• Solve the problem of IoT information sharing security	• Performance needs to be enhanced when applied to a specific industry.	[1]

V. Compliance on Data Storage

To start with knowing the objectives of the organization. This interprets to knowing which regulations will apply to the organization directly related to the regional legal and regulatory requirement and which types of data are expected to manage or not, how long to retain it and how to protect it. In the organization the compliance officers can be the ones to provide information.

Organizations need to focus on data classification and data mapping. Data classification and data mapping are crucial in discovering the types of information that are being held in storage systems and how they are being moved across the network. Not only are they essential factors in determining how regulated information is stored, but also a solid step in establishing compliant policies.

Continual monitoring: Storage compliance is not a set-and-forget affair. Continual monitoring is key in ensuring that regulated data is properly cared for during its lifecycle. Procedures must be in place to make sure this monitoring happens regularly.

More than security: Security and storage often go hand-in-hand, but storage compliance takes it to another level. Encryption will help, and many storage solutions feature support for the security-enhancing technology, giving both storage and security professionals one less thing to worry about.

Critical: Testing and audits will ensure compliance with policies and IT mechanisms are up to the task. It's best to work out the kinks now before having to explain to investigators why sought-after emails or transaction records have gone missing. There are many requirements based on the type of information and data the organization has. Some might involve using what is called DAR (Data Encryption at Rest), which encrypts the storage device so that if removed from the system, the data is nearly or totally impossible to access (the degree of difficulty depends on the encryption algorithm and the size, complexity and entropy of the key or keys for the device).

Understanding what is required from a governance point of view for the organizational data or the resulting information is based on things like best practices for the industry or regulations and agencies like the U.S. National Bureau of Standards (NIST), ISO, HIPAA, SEC, GDPR in Europe. And the resulting architectural or procedural changes are the types of things that will be needed to address as part of the architecture. Compliance is not easy, nor is it free. The cost depends on lots of factors but trying to force compliance after the architecture is planned and built is always far most costly than doing it beforehand.

Decentralization: The main benefit of using blockchain would be that no single authority would have control over the data generated by the IoT devices. That way, a distributed peer-to-peer network is born that permits the parties that don't know or trust each other to collaborate more smoothly. This type of network will also make it possible to unify IoT devices and streamline the distribution of updates throughout the network.

Security: The current security architecture of IoT has its shortcomings. When the data is managed by a central authority, the system is more susceptible to a single point of failure. Blockchain's unique security protocol normally described as transparent and immutable is a good solution to the largest issue of IoT development. Blockchains will store unalterable data history that can be consulted for each unique address. This lays the foundations of a platform that provides improved identification and authentication in IoT. The robust level of encryption that blockchain guarantees won't let the hackers overwrite data records.

Transparency: Anyone with authorization could track the transactions made on the network to follow up on what has happened in the past. This feature is useful to identify any leakage and take action.

Autonomy: Blockchain will reinforce the machine-to-machine economy that IoT is based on by offering a safe way to store information on different transactions. That way micropayments for services and data can be processed in a straightforward way. IoT devices that rely on blockchain can execute digital agreements automatically when the terms are met. Automating transactions between devices improves machine-to-machine communication.

Reduced costs: Integrating blockchain to the organizational processes would allow IoT companies to reduce costs. Eliminating the massive overhead costs related to IoT gateways will help them to reduce the strain on the company budget.

When defining compliance requirements, one should be looking to the future rather than the present because of the cost and challenge of shoehorning things in after the fact. That means that someone needs to be continuously studying compliance requirements in the given industry to which the organization belongs, along with best practices. Data will only become more important in the future, and we need to be up to the challenge.

VI. Conclusion

Due to the heterogeneity of applications, the amount of data generated by IoTs differs. Identifying what data to be added to blockchain is a primal task. Healthcare data should be treated in a confidential way and hence utmost care should be taken in sharing and storing of data. The IIoT data use external storage medium away from the local storage for information retrieval and data mining. This is achieved through Edge/Fog computing. Agricultural applications either store data locally or to cloud if the data generated is large. The decentralized nature of the blockchain requires the data to be stored in multiple locations. The most common method of storing data is in still in the cloud. However, decentralized ways integrates blockchain with distributed storage network. Hybrid storage is gaining more popular which divides the data into two, the one to be added to the blockchain network and the other to the cloud data storage. This is a more economical way that implements the concepts of blockchain while maintaining the network latency. The IoT will enable electronic objects to exchange huge amounts of data; storing it in a reliable way will be challenging. Organizational compliance group will know best how long data or information is required, but there are many other requirements that will have to address to ensure that the business objectives in the areas of performance, availability and data integrity, all of which need to be address for the life of the data and information.

In this paper, we follow the interpersonal comm nication process principles with its comm nication components for defining a whole comm nication chain that combines the sensor act ator and data transfer items in one concept, pointing to the person to person and de ice to de ice comm nication similarities. e come with an approach of a methodology for the Internet of Things abstracted by the Spread o t Electronic e ice concept. e consider the whole IoT as a single electronic de ice with c t o t and bro en wires and replaced with comm nication chains.

—

I. Introduction

Nowadays, the new trend in technology, the Internet of Things (IoT), connects a massive number of smart objects, products, smart devices, and humans. In this trend, all mentioned things could be organized in groups or systems and cooperate in solving some specific tasks providing information and services to each other involving a typical communication process. Communication is the act of data exchange between things as an extensive system entity and plays an essential role in the system operation. There are a lot of technologies that implement the communication process for information transfer between entities. Curiously, almost all communication technologies are inspired by interpersonal communication, meaning communication between people.

One such example of communication is the online social networking tool Twitter, where users send and receive short posts called tweets. People who want to share information publish and those interested in someone s posts are subscribing to his tweets [1]. This social network platform s system is complex, but its communication relies mainly on the publish-subscribe message architecture.

There are many similarities between Twitter and one of the most popular protocols used for IoT applications - Message Queuing Telemetry Transport (MQTT). MQTT is a protocol specifically designed for machine to machine communication. MQTT protocol runs over TCP / IP stack and has a data packet size with a low overhead minimum (> 2 bytes) so that consumption of the power supply is also reduced [2]. MQTT is the perfect solution for Internet of Things applications. It is designed for devices with low bandwidth. Additionally, it is a simple messaging protocol that allows sending, reading, and publishing data from sensor nodes and much more. Comparing with Twitter, it is the same thing but for devices. MQTT protocol uses a publish/subscribe architecture. Its event-driven approach enables messages to be pushed to the client [3]. Devices are like users. Like Twitter, where users tweet a message to all the followers, a device publishes a message to all subscribers. And just like a Twitter user receives tweets from all people he follows, a device receives messages from all the devices it is subscribed to [4].

Robot Operating System (ROS) proposes another publish/subscribe architecture consisting of a collection of programs. That allows a user to control a mobile robot s operations efficiently. At its core, ROS is an anonymous publish/subscribe message-passing middleware with asynchronous communications. Some modules will issue a set of topics, while others subscribe to that topic. When new data is published, the subscribers can learn about the updates and can act on them. ROS provides the communication using a message-passing approach that forces developers to focus on pure interface logic. [5] The ROScore is a service that provides connection information to nodes so that they can transmit messages to one another. Every node connects to ROScore at startup to register details of the message streams it publishes and the streams it wants to subscribe to. When a new node appears, ROScore provides it with the information needed to form a direct peer-to-peer connection with other nodes publishing and subscribing to the same message topics. Every ROS system needs a running ROScore service so nodes can find other nodes [6].

Automotive is one of the most safety-critical domains. A typical automotive system consists of several Electronic Component Units (ECU) communicating on Controller Area Net (CAN) buses. Software stacks provide support for the computations and communication, including application tasks, the middleware, drivers, and bus peripherals. For communication purposes, tasks read input signals at their activation and write their outputs in shared variables at the end. Some application task reads the input data from a sensor, computes intermediate results sent over the network to other tasks, and, finally, another task, executing on a remote node, generates the outputs as the result of the computation [6]. The read/write operations with shared variables are similar to the publish/subscribe architecture for communication in the vehicle network.

All the aforementioned architectural approaches implement the communication processes that are most convenient in the domain those are operating, a worldwide social network for Twitter, a collection of devices for IoT with MQTT, a complex ECU with ROS, or an ECU interconnection for Automotive with CAN. Even those who

978-1-6654-4067-7/21/ 31.00 2021 IEEE

are targeting different technologies are using the same principles for data transfer – the subscribe-publish. This paper proposes a communication chain concept for the IoT systems abstracted to a spread-out electronic device, providing a methodology and an application example for validation.

II. Materials and Methods

A C C

For an Internet of Things system such as a spread-out electronic device, we will classify the communication process that is conducting the information through the entire system connecting its components. Here we present two primary classifiers – interaction and domain, describing a perspective and defining the classifier s aspects.

1

It refers to interactions in the entire system and will consist of the two types of interactions with devices and the environment.

Those interactions represent all the networking infrastructure that interconnect the parts of the spread-out electronic device together. In the classical references, it is referring to inter-device communication. Fig.1 present an abstraction for this classifier. This group includes all the connectivity techniques and methods, starting from the short-range wired link by an SPI or I2C protocol to the more complex like wireless via 4G or LoRa [7] as a physical link and TCP/IP stack for software abstraction. For the spread-out electronic device concept, the device-to-device communication mechanism abstracts the electrical interconnection between parts of the spread-out device, providing the application s higher abstraction layers to interact with the system as a whole.

E

Those interactions state for an abstraction to the whole system s interface to the physical environment, conceptually presented in Fig. 2. The spread-out device system concept assumes that all the network s sensor-actuator components are accessible to the application as being located on the same physical device [8]. The human-machine interface (HMI) is considered a particular case of sensor-actuator components designed for user interaction scope. Subsequently, those are also classified as device-environment interaction.

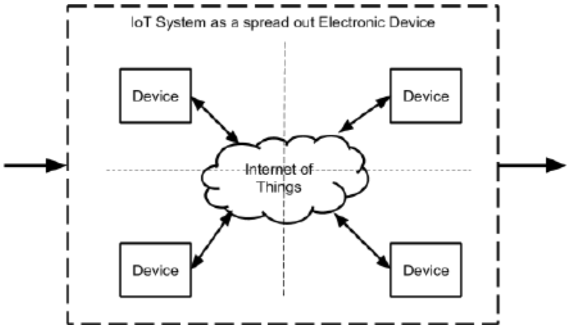

Fig.1. Spread-out electronic device with IoT interconnections [8].

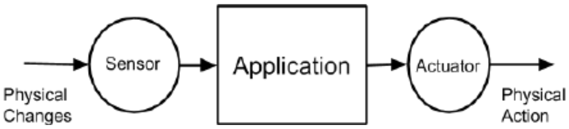

Fig. 2. Device to Environment interaction.

It classifies the communication interconnection by domain affiliation. This classifier ranks the communication interaction to the Hardware (HW) or Software (SW) domain.

The HW domain consists of interconnected electronic components like mechanical parts involved in the signal flow between the physical environment interaction, such as sensing or physical environment of the communication process, and the software domain. The sensor actuator stack will consist of all hardware domain features, such as transducing, power conversion, and hardware conditioning. The communication stacks will consist of the communication chips and the hardware protocol handling components. The physical communication channel itself, e.g., copper twisted pair or pulled-up I2C bus, refers to the hardware domain.

The SW domain represents the software resources that comprise all SW methods applied to the information channels that interconnect all the application components and conduct the signal through the application. The sensor, actuator, user interaction, and communication SW stacks, in this paper, are treated similarly, as information flow with transfer function chains for information transfer. In this domain, the inter-process communication mechanisms [9] and component interfaces [10] are involved in the information transfer between application components. Conceptually the interactions and domains are presented in Fig. 3.

C

1 C

Communication refers to the process of transferring information from source to destination via a communication channel. This statement is not limited to any specific domains.

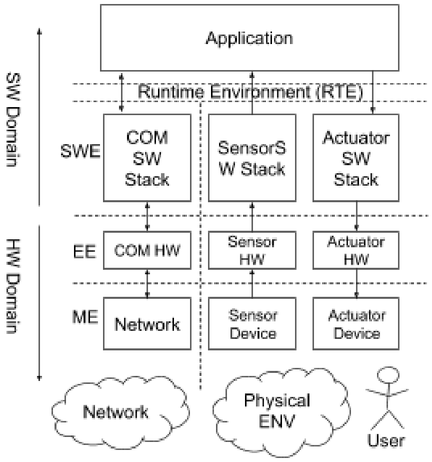

Fig. 3. Interactions and domains in the spread-out device concept.

There are a lot of similarities between interpersonal communication and IT communication. In both, there are similar components of communication, such as source and sender, channel, receiver and destination, message, feedback, encoding, decoding, and noise or barriers, as in Fig. 4.

Following the device to environment interaction concept from Fig. 2, the physical environment is the initial information source. The device collects the information by its sensing component and transfers it to the application components. The application evaluates the data and generates a reaction. Finally, the device sends the response back to the environment via its actuator stack. A wireless network is following the same concept of gathering information from the air. The device first senses the radio signal, conditioning it, and converts it into the information flow. A particular example that justifies the concept is the audio or lighting morse communication. Here, on receiving, the device detects the dot and dash first in the sound or light signal following the classic sensor conditioning signal flow before building a chars frame,

Considering theses from above, the communication chain for an IoT device will consist of the components included in the sensing-actuating chain merged with the components for information transfer or transportation. By this assumption, the entire component collection for the communication process will consist of the component chain presented in Fig. 5. Depending on the application needs, we could define various communication chains where some of the communication phases we could omit. For example, there is no need for conditioning when using a digital sensor and, similarly, no need for frame detection and decoding for an analog sensor. Still, for digital communication through an optical channel, we will need the whole communication chain.

The signal goes through several similar phases in the communication chain component set but complementary for receiving and transmitting processes. Those are following the diagram from Fig. 5, and detailed as follows:

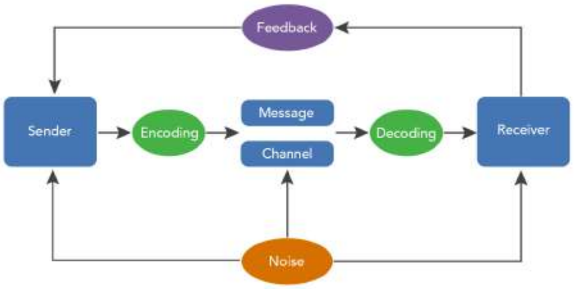

Fig. 4. Key components of communication [4]

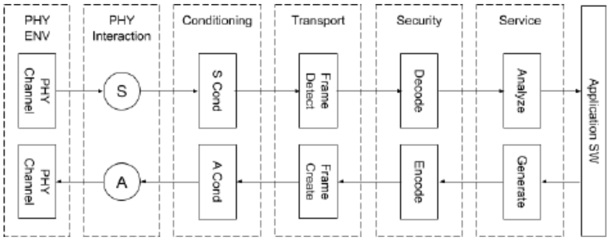

Fig. 5. Communication chain component set.

- PHY ENV phase stands for the physical communication channel that interconnects source and destination. The channel properties involve various chain components, such as conditioning or security, but not limited.
- PHY Interaction phase stands for converting the physical parameter values to the system internal information and vice versa. It consists of sensor and actuator components.
- The conditioning phase stands for information adaption and noise filtering gathered to form the channel or internal processes. We can omit this phase in cases like the wired digital communication on the same voltage level.
- The transport phase consists of detecting and creating frames according to a specific pattern or protocol. This phase is responsible for the safe transfer of the information through the channel.
- The security phase stands for securing the information and protect it from unauthorized access. The system encodes information on sending and decode on receiving.
- The service phase analyzes the received information, prepares it for the application, and generates information according to the application request.
- Application stands for the sender and receiver in the information flow.

C

Structurally, the system forms a collection of interconnected components that cooperate to produce a result [11]. According to the IoT concept as a spread-out electronic device mentioned above, physically, the system s components could be located on any of the IoT devices that are members of the system. Here an IoT system is considered a wholly electronic device that imaginary we cut in parts, and communication channels replace the broken connectivity lines. In this way, we will have two primary types of interconnections between components, as presented in Fig. 6.

The *C* *A* from Fig. 6. is an internal channel that connects *C* *A* and *C* from the application running on *A* . Internal channels are following the software interfaces and inter-process communication techniques [9].

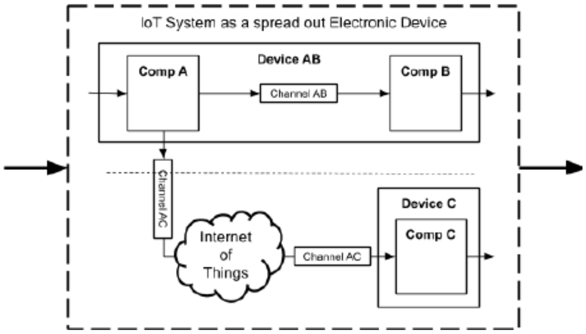

Fig.6. Communication channel types in a spread-out electronic device system.

The *C* *AC* connects *C* *A* and *C* *C* components that are part of applications running on different devices, *A* and *C*. Such connections are the target of the communication chain component set presented in the current work. The component interface is similar to the internal channel access to a component located on the same device.

Assuming that communication channels are abstracting the component s physical localization, at the flatten level, we could represent the whole system as components with internal transfer functions interconnected with channels, as illustrated in Fig. 7. Several similar signal channels that provide values for the same domain or parameter logically could be combined in a group and operated together. Following the subscriber-publisher concept, the publishing phase will update the component signal by a transfer function. The subscribing phase will connect to a specific component interface via a communication channel. In this work, we use the term to create a link or a channel between components for subscribing. Depending on which end of the communication channel has an active role, two types of channel linkages are possible – push and pull, as in Fig 8. Such connection involves a push or a pull method to operate the channel to apply or extract information. The same procedure we use for all channels included in the same group. Push means that the channels accept the change of its value by a specific method; Pull means that it is evaluated internally and accessible by an on-demand method. Reference [12] proposes a method for embedded systems development by configurations and code generation based on JavaScript Object Notation metamodels using the channel s concept defined in this paper and a tool proposal for operating the methodology.

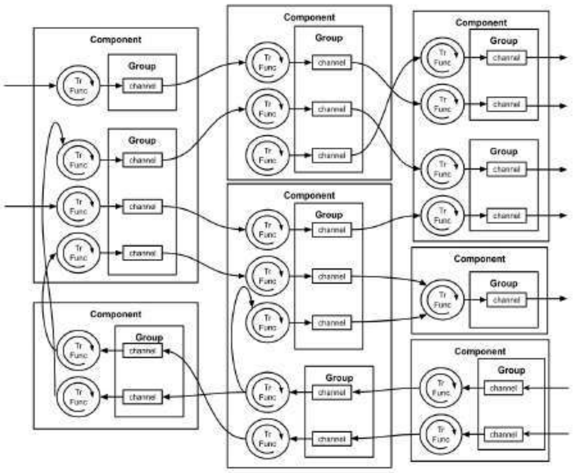

Fig.7. Interconnected compoenents of the system with channels at the flatten level [12]

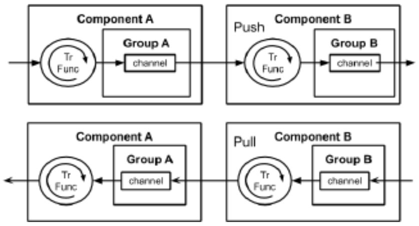

Fig. 8. Types of channel linkage [12]

III. Results

Following the concept of the spread-out electronic devices discussed in this paper, a remote mechatronic manipulator application is under test. The entire system consists of two robotic manipulators connected via a wireless network, here Wi-Fi. First is actuator-free used as a remote manipulator. It collects the arm joint s angles by sensors and transmits them via the network. The second, underactuated 3-DOF arm receives setpoints and uses them in its joints and head position. Fig. 9 presents the conceptual system architecture diagram. First tests are performed on a 3-DOF robotic arm, extending to a more complex mechatronic system with many DOF. Such an example could be an exoskeleton for helping people with locomotor diseases.

According to the layered architectural approach and the communication chain discussed here, the signal from the remote setpoint arm, which joints sensor data we use as the second arm s setpoint, passes through the whole communication chain and reaches the underactuated arm sensor service components. It can abstract the network and use it as the sensor is connected directly to the device. Fig. 10 presents the layered architecture of the system and the flows for the sensing and actuating signals. The resulting application allows handling a 3-DOF robotic arm via a copy of it, shadow, or an arm s software model. The control consists of sending joint setpoint angles to the underactuated arm through the wireless network. Cartesian coordinates of the arm head are sent instead of angle setpoints when inverse cinematics is involved.

IV. Discussions

The communication chain presented in this paper has a significant role in the spread-out electronic device concept. We follow it to interconnect the devices and threaten the entire IoT system as a single electronic device. By this abstraction, applications are developed considering that all resources are available through the platform s simple service via RTE. The paper [12] presents a method that allows the platform s configuration to define the communication chain through a metamodel. This way allows to specify only the chains from a single device, but the next steps are to extend the technique to define multidevice platforms within the same metamodel.

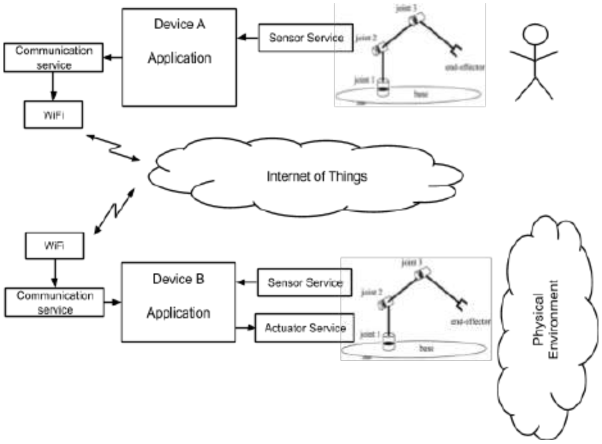

Fig. 9. Conceptual system architecture for remote manipulator control

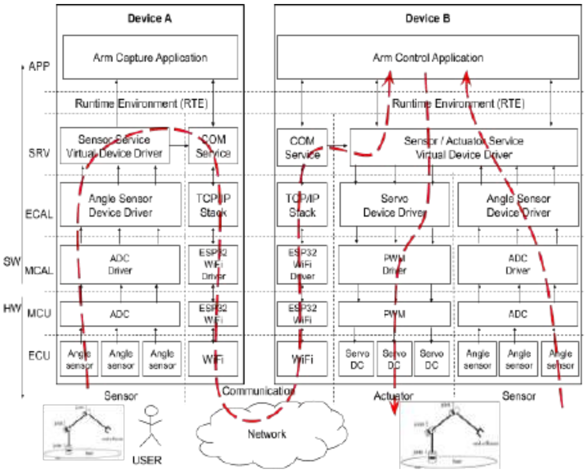

Fig.10. Layered architecture of the system and signal flow through communication chain.

The target of the research is to have a concept of systems with autonomous evolution of configurations. It will solve complex business chains considering that all the equipment and services in the world are available as services. This way, we can build complex systems, configurable templates, adaptable to the current needs or continuously changing environment. The bricks for such systems are component databases and configurable channels.

V. Conclusions

Communication is one of the most critical issues in the system component interconnection. Various projects implement many communication concepts. Still, almost all follow the general idea of the communication laws, which is far to be limited to the engineering domain. The method is inspired by interpersonal communication, containing all the communication components such as source and sender, channel, receiver and destination, message, feedback, encoding, decoding, and noise or barriers.

The primary information source is the physical environment. Considering that all the world devices are part of an enormous spread-out electronic device, the information should pass the whole communication chain to reach the application running on one huge device. A typical chain will involve interaction with the environment, signal conditioning, transport, and coding/encoding, providing the application s required service.

An application running on the spread-out electronic device system has been presented, consisting of a collection of components represented by its transfer functions, interconnected with communication channels. When interconnected components are not physically on the same device of the spread-out system, we insert a communication channel following the communication chain concept, including all required phases for information transfer.

The spread-out electronic device concept allows the IoT s abstract to a single device with access to Everything from Everywhere.

***Abstract*—COVID-19 pandemic has a significant effect on the unemployment rate in the United States. However, the economic effect in different states is not the same for each household. In this work, Our goal is to capture and outline the relationships between pandemic incidence, economic inclusion, unemployment, and bank branch closures in order to understand the emerging relationship between the coronavirus pandemic, rates of economic inclusion, and economic well-being of localities. Furthermore, we machine learning algorithms to evaluate the predictive power of coronavirus incidence and fatality rates, county-level unemployment, and bank branch closure rates on rates of economic inclusion. Also, a natural language processing approach is used to analyze the unemployment COVID-19 textual data. We use BERT as a powerful transformer for sentiment classification on COVID-19 unemployment data.**

***Index Terms*—Machine learning, Natural Language processing, COVID-19, Transformer**

I. Introduction

The 2019 Novel Coronavirus (COVID-19) pandemic has presented fundamentally new disruptions and challenges in many areas. However, it continues to exacerbate existing long-term issues and underlying disparities in the United States with a significant impact on public health and the general economy [1] [2].

The economic and financial impact of the COVID-19 pandemic is also extensively monitored throughout the beginning of the pandemic through U.S. Census Bureau research, including the Household Pulse Survey launched in April 2020, as well as relevant data from the Current Population Survey and the Department of Labor [3] [4]. The coronavirus has a considerable influence on the employment sector in the United States, and researchers have noted an increase in unemployment rates, which have been increased to 14.7%, which is the highest ever since 1948. The link between the COVID-19 pandemic and unemployment rates has been demonstrated in recent research, with 46% of the adults whose salary is low having faced inconvenience paying their bills. There has been a loss of employment and reduced pay for most of the employees, eventually leading them to struggle to pay their house rent. Young workers aged 18 to 29, in comparison with those 50 to 64, are now employed at a different job because of pandemic [5] [6].

Emerging arguments in financial and public policy have focused on the potential of the COVID-19 pandemic to exacerbate existing issues in access to credit in the U.S. banking system, with a specific focus on the public benefits of enabling unbanked populations to quickly access federal relief funds in a low-cost and digital manner [7]. Furthermore, the physical banking branch network, or more specifically the presence of bank branches, in areas especially designated as Low and Moderate Income has been linked to greater credit and lending activity in a community, especially for mortgage originations and small-business lending [8] [9]. Retail bank branches also help collect hyper-localized soft information on bank customers that are not easily captured in automated or algorithmic underwriting, which can help identify more creditworthy personal and small-business borrowers [10] [11] [12] [13].

The Federal Deposit Insurance Corporation (FDIC), an independent agency tasked by Congress in maintaining stability and public confidence in the U.S. financial systems, as of 2009 actively seeks to expand financial inclusion as a means of expanding overall public confidence in the U.S. banking system and works both with the private and public sector in achieving that goal. Furthermore, the Federal Reserve Board of Governors and the twelve member Federal Reserve Banks actively promote financial inclusion as part of its dual mandate of ensuring maximum employment and stable-prices and moderate long-term interest rates. As such, both entities contribute to the body of research dealing with financial inclusion in the United States, and economists within the Federal Reserve System and FDIC have produced literature on removing the barriers to increasing financial inclusion [14] [15].

As far as industry, the American Bankers Association, a trade group representing U.S. banks, has partnered with the Cities for Financial Empowerment (CFE) Fund to promote the Bank On initiative, a national program for banks coordinating efforts in increasing access to bank accounts in the United States [16] [17] [18] furthermore, while themselves not significant contributors to existing research in financial

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

inclusion, Fintech startups that focus on deploying innovations in financial technology to compete with banks and traditional providers of financial services actively positioned themselves as potential solutions in increasing financial inclusion and contribute to trade groups and associations that produce industry-related research.

II. Methodology

A. Data Preprocessing

Data collected for this paper came from several sources. COVID-19 news and data comes from different online sources however Heidari et al [19] advanced bot detection tools helps us to avoid collecting data that contain misinformation and creates reliable data for our experiments. Also, we use official sources, such as The National Survey of Unbanked and Underbanked Households; a survey conducted every two years by the Federal Deposit Insurance Corporation to collected data on household participation in the banking system [20]. County-level coronavirus pandemic data was obtained from the COVID-19 Data Repository by the Center for Systems Science and Engineering (CSSE) at Johns Hopkins University [21]. The Local Area Unemployment Statistics (LAUS) program produces monthly and annual employment, unemployment, and labor force data and was used for county-level unemployment rates [22]. The Office of the Comptroller of the Currency's Corporate Applications Search was used to gather and aggregate the number of bank branch closures and openings in the United States, which was used to derive the number of banks closed or opened per population [23]. Furthermore, the United States Census Bureau's 2010-2019 county population totals dataset was used for 2019 U.S. county population estimates [24]. Lastly, Federal Information Processing Standards (FIPS) codes were used to map county names to unique codes for all datasets for consolidation, consisting of a unique two-digit code for state, including Washington, D.C., and Puerto Rico, and three-digit county or county-equivalent code unique to the state code.

A universal index was created, which mapped standardized county and county-equivalent labels to a unique FIPS code, a five-digit code consisting of two digits representing a particular county's state, and a three-digit representing the specific county or county-equivalent in that state. This representation enabled easy identification of individual counties across all datasets used, enabling more data aggregate on the economic inclusion dataset.

The initial FDIC supplemental dataset consists of hundreds of variables collected for over 70,000 U.S. households, requiring pruning of survey features not needed for this analysis. Since banked status was collected for only 47.9% of respondents, more than half of all respondents were removed from the dataset, resulting in approximately 32,904 observations of U.S. households where banked status was definitively known. At the geographical level, while the state and state-equivalent levels could be identified for every household response in the survey, accuracy to the county and the county-equivalent level was only possible for 12,990 households. These 12,990 households represented data from 280 uniquely identified counties across 41 states, in which the respondent household banked status was known.

We extract unemployment rates from U.S. Census Bureau contains unemployment rates and population estimates for more than 3,000 U.S. counties and county-equivalents. The unemployment dataset provided by the U.S. Census Bureau consisted of employment variables by month and by county for 13 months between August 2019 and September 2020.

The resulting data preprocessing yielded two datasets used for analysis. The first, more compact dataset consists of data specific to county and county-equivalents, including the rate of unbanked households based on 12,990 household survey responses, COVID-19 incidence and case fatality ratios, bank rate branch closures and establishments as reported to the OCC, and county-level unemployment rates. This dataset was used for predictive analysis using the Random Forest ensemble, Support Vector Regression, and Linear Regression algorithms to predict county-level unbanked rates using county-level data. The second, larger dataset excluded unbanked rates, allowing data inclusion for 3,219 U.S. county and county-level equivalent areas to visualize and understand overall county trends in unemployment, the COVID-19 pandemic, and many bank branch closures.

B. Data Merging

Firstly, the financial inclusion dataset is merged with the COVID dataset by merging the county code and unbanked rate from the financial inclusion dataset with the FIPS, Incidence rate, case fatality ratio, latitude, and longitude from the dataset. Then we merge the dataset of the financial inclusion and COVID with the unemployment dataset. Here the Civilian labor force, unemployed rate, and county code are merged into the dataset. To understand how the population has been changed in the year 2020 due to the pandemic, we merged the 2019 population estimate dataset using the county code followed by the bank closure data. As a result, the final dataset consists of the COVID-19 unemployment data, population, bank branch rate, geographical index data, bank closure, and opening rates for each county.

III. Exploratory data analysis

The 280 counties in which unbanked status was attributed to 12,290 nationally representative household respondents combined represent 149 million people or approximately 45% of the entire 2019 U.S. population estimate. Notably, the counties and county-equivalents with attributed economic inclusion status are more populated than a typical U.S. county and county-equivalent. Table I shows the unbanked rate in different states based on specific counties.

Relative to the overall weighted household, the national rate for unbanked rate is 5.3%. However, the unbanked rate mean for these counties is 4.5% while the median is only 2.2%, and a large share of counties do not have significant unbanked households. Figure 1 shows that the distribution of unbanked rates. The distribution skewed to the right which

means that if one states has more counties, it does not mean it has higher unbanked household rate. Population-wise, counties with higher populations have higher unbanked rates compared with a typical county with less population. The small county with attributable banked rates has a 102,855 population, exceeding the average U.S. county population. So the cohort of 280 counties with attributable unbanked rates is more urbanized than a typical county due to higher population, and that the cohort consists of counties centered around either around 5% or 20% for the rate of unbanked households.

We use k-means clustering as an unsupervised machine learning algorithm and principal components analysis in 280 counties with known unbanked rates. We include county-level observations for COVID-19 incidence and case-fatality rates, unemployment level, rate of bank closures and openings, and unbanked rates. Figure 2 shows the results based on PCA and k-means clustering. Five clusters will yield the optimal results. Figure 3 shows a positive correlation between unemployment and unbanked households.

Figure 4 shows a positive correlation between branch rates in a county and the incidence rate of COVID-19. Also, The relationship between the unemployment rate and unbanked

Linear Regression, feed-forward neural network. Algorithms were used to accurately predict county-level unbanked rates based on COVID-19 pandemic rates, rate of bank closures, and unemployment rate. Table II shows the results. The best performing algorithm was Random Forest with an f1 score of 0.93, and the Neural network model ranked second with an f1 score of 0.90.

IV. USING TRANSFER LEARNING MODEL

In addition to applying machine learning models, we apply sentiment analysis on the COVID-19 unemployment data by using the natural language processing model in this section. For this task, We collect COVID-19 unemployment data by using api [25] of spatial AI and we remove bot comments by using method by Heidari et al. [26]. We compare three approaches for sentiment classification of COVID-19, which are TextBlob [27], VADER [28], and BERT [29] [30].

The TextBlob is based on the supervised learning method, the Naive Bayes classifier. TextBlob assigns a score of 1 for positive and -1 for negative, and 0 for neutral sentences.

VADER(Valence Aware sEntiment Reasoner) is a model used for sentiment analysis, which is sensitive to both polarity(positive and negative)and intensity of emotion.

Figure 9 shows a BERT model [29]. We use BERT [31]or the Sentiment classification task. BERT is a strong transformer model, and studies by [32] show how We can fine-tuning the BERT for sentiment classification in this work. Table III shows the result for sentiment classification model for COVID-19 data. Although the three models provide very similar accuracy for sentiment classification, we choose BERT as the best model since it is a transfer learning model, and we can fine-tune the model based on a specific task that we need on COVID-19 data.

TEST CAPTION2

Model	Accuracy
TextBlob	0.78
VADER	0.80
BERT	0.83

V. CONCLUSION AND RESULTS

In this work, several factors could be contributing to the lack of predictive power. Primarily, features selected to predict economic inclusion rates could have limited relevance and usefulness to the models used in banked households. The relationships between economic inclusion, the impacts of the pandemic, unemployment rates, and bank branch closure rates are complex and not clearly delineated, and thus may share the same underlying dependencies that can contribute to model confusion, such as racial makeup, level of income, other demographic compositions of counties, and even the overall unbanked household rates at the state level.

As race and ethnicity have been linked to both the economic and public health impacts of the pandemic and access to the financial system, training the model on race and the selected features might yield a more informative model in terms of predictive power in future studies. One issue of this approach is that there is already a link between race and access to the financial system, and alleviating economic inclusion barriers caused by race is complex in policy implementation.

One novel point is that the rate of bank closings and establishments, used as a proxy to measure not only a community's access to credit but the general health of the economy, was not a significant feature for predicting unbanked household rates at the county-level. However, since the bank rate consisted of subtracting a specific county's bank closings from bank establishments and normalizing to a rate per 100,000 in population, it is possible that looking instead at the total number of banks present in a locale might be more beneficial for predicting rates of unbanked households, although this approach presents its challenges in terms of data availability. This paper represents a starting attempt to predict unbanked household rates with an appropriate degree of accuracy for use in informing broader policy decisions, especially in attempts at increasing economic inclusion through the adoption of novel and impactful methods. In this work, we apply transfer learning model BERT on the COVID-19 unemployment data to get more insight and context about people's ideas about the effect of a pandemic on unemployment. It is essential to consider textual information of different groups in society as semantic input for the machine learning models to provide more accurate results in future work.

***Abstract*—According to the World Health Organization (WHO), tuberculosis continues to be a global problem of great importance. In Peru, around 31 120 cases of TB were registered annually, with an incidence of 116 new cases per 100 000 inhabitants. Peru still occupies first place in Latin America in the number of resistant tuberculosis cases. Overcrowding coupled with the lack of rapid diagnostic equipment accessible to the neediest populations has resulted in the disease remaining a problem. The diagnostic process is manual, leading to great variability in the results because it depends on the laboratory staff's experience and concentration. Although not the most sensitive, conventional baciloscopy techniques are the most widely used due to their speed and cost. These techniques involve a staining stage and a microscopy stage. Ziehl Neelsen (ZN) staining method is used in smear microscopy because it is effective and simple. This article shows a prototype that performs tuberculosis diagnosis for 4 samples, consisting of two automatical modules: the staining module and the microscope module. The staining module consists of a sample positioning sub-system, a reagent dispensing sub-system, and a heating sub-system. The microscope module captures fields' images of up to 4 samples stained using the Ziehl-Neelsen method and determines the diagnosis of Tuberculosis (TB) through image processing algorithms. The mechanical system of this module is made up of three subsystems: the main support that houses the electronic circuits, a mobile platform that moves the samples, and the microscope holding structure. Tests have been performed on 206 samples at the Dos de Mayo National Hospital in Peru. These tests involved several adjustments that allowed reducing the staining times and the quantities of reagents used.**

***Index Terms*—Tuberculosis diagnosis, microbiological diagnosis, staining methods, smear microscopy, microscopy, Ziehl Neelsen staining.**

I. Introduction

According to the World Health Organization (WHO), tuberculosis continues to be a global problem. Thus, according to the WHO World TB Report 2016, Peru still ranks first in Latin America in the number of cases of multidrug-resistant (MDR) and extensively drug-resistant (XDR) tuberculosis [1]. In 2017, only in Peru, there were about 31 120 new tuberculosis cases with an incidence of 116 new cases per 100 thousand inhabitants [2]. In 2019, there were 10 million cases worldwide, of which 1.4 million people were fatally affected [3].

TB diagnostic methods can be classified into smear microscopy, culture, and direct genetic detection in samples. The smear microscopy techniques are the most commonly used, involving a staining stage and a microscopy stage. Ziehl Neelsen (ZN) staining is the most-widely-used staining method in smear microscopy because it is effective, simple, economical, and fast; besides being the staining method recommended by the WHO for developing countries. This baciloscopy process consists of the next sub-processes: first, the sample is spread on a slide (smear), then the staining method to highlight Acid-Alcoholic Resistant Bacilli (AARB) is performed by the ZN method based on phenylated fuchsin, methylene blue, acid alcohol, and water. Finally, for diagnosis, the stained sample is examined under a microscope, where the tubercle bacilli present in the sample are counted. The diagnostic process involves the time and exposure of the personnel in charge, who perform an average of 70 diagnostic samples per day.

The Ziehl Neelsen method is performed manually by expert laboratory technicians who inevitably perform the process with wide variability, affecting post-diagnostic activities. Errors in AARB concentration can lead to the non-detection of TB patients (false negatives) who will continue the chain of transmission in the community or the futile treatment of non-tuberculous (false positives). [4]. This is why the guarantee or assurance of a standardized, rapid and reliable diagnosis is essential.

II. State of art

Currently, several scientific research centers have developed equipment for the automatic diagnosis of tuberculosis [5] [6] [7]. These medical kits correct the imperfections made by highly experienced laboratory technicians; therefore, a faster and more reliable medical diagnosis is obtained in comparison to the conventional method. The equipments developed in most

We are grateful to the National Innovation Program for Competitiveness and Productivity of the Peruvian Ministry of Production for financing this project, and the Dos de Mayo Hospital for their collaboration in the validation of the system.

cases are focused on genetic detection techniques. The present section is a review of existing diagnostic equipment initiatives.

The MODS method (microscopic observation drug susceptibility assay) is a technique based on culture methodology. It is based on a Middlebrook 7H9 liquid medium culture monitored through the observation of an inverted microscope. The formation of ropes, which are visible before colonies, is observed in an average of 8 days. Technologically, this is an inexpensive option and applicable to high incidence and low resource countries [8]. In Peru, the Universidad Peruana Cayetano Heredia (UPCH) and the Universidad Nacional de Ingeniería (UNI) have developed a MODS Plate Reader system that can diagnose multidrug-resistant tuberculosis (MDR-TB) in less than fifteen seconds, after the appearance of ropes. The system includes an automated plate reader for microscopic observation of MODS cultures. The reader automatically handles the MODS plates, and after running the autofocus algorithm, digital images of microscopic structures characteristic of Mycobacterium tuberculosis are obtained. Once the image is obtained, the diagnosis is made through MODS pattern recognition software. In this way, the automated reader reduces labor time and handling Mycobacterium tuberculosis (MT) cultures by laboratory personnel [6].

On the other hand, Cepheid, Inc. developed the Xpert MTB/RIF technique, an automated test for the diagnosis of tuberculosis based on the detection of specific Koch's bacillus nucleic acids with cartridges in an organic sample. Unlike conventional nucleic acid amplification tests (NAAT), the Xpert MTB/RIF simplifies the identification of mycobacterial DNA by automating the 3 processes required for PCR-based molecular testing: extraction, amplification, and detection [1]. The Xpert MTB/RIF technique can detect MT complex and rifampicin resistance within 2 hours of test initiation, with minimal technical intervention. This method has very high sensitivity and specificity. Additionally, the sample reagent, used to liquefy the sputum, has potent disinfectant properties (with the ability to kill TB bacteria) and largely eliminates biosafety issues during the testing procedure. These features allow the technology to be taken from a reference laboratory and used closer to the patient. The Xpert MTB/RIF equipment requires an uninterrupted and stable electrical power supply, temperature control, and the cartridge modules' annual calibration [9]. The Xpert has a high specificity for diagnosing tuberculosis, which in the series evaluated by the National Chest Institute of Chile was 95% in respiratory samples and 94% in non-respiratory samples (the standard for positivity is culture). Considering the cost of this test, it should not be indicated to all patients who are requested smear microscopy, but only in those cases with a well-founded suspicion of tuberculosis in which the smear microscopy is negative. As it is a susceptible method, it is not indicated for patients who have had tuberculosis because it is a PCR technique. Any mycobacterial DNA residue left over from the past will be amplified many times and may give a false positive result [1]. The most commonly used device is the GX4, which has 4 modules (allowing 16-20 tests per 8-hour shift) and its discounted cost for developing countries is approximately $ 17 000 [10].

An alternative to ZN-stained baciloscopy is fluorescence microscopy with Auramine-Rhodamine staining, which achieves better sensitivity and specificity results than the ZN-stained method. However, due to the high cost required to acquire a fluorescence microscope (a microscope with a mercury vapor lamp), ZN staining continues to be chosen in developing countries [7].

Finally, the Pontificia Universidad Católica del Perú has been developing automatic Ziehl Neelsen staining systems for the standardized diagnosis of TB. In a previous version [11] [12] [13] [14], the systems considered staining but not microscopy and also did not have a closed loop temperature control.

III. Description of Hardware and Software

The tuberculosis diagnosis prototype has a staining module and a microscopy module for 4 samples simultaneously. Each module is described in the following lines.

A. *Staining module*

The module for simultaneous staining of four samples is shown in Figure 1, and the Figure 2 shows the block diagram of the complete system.

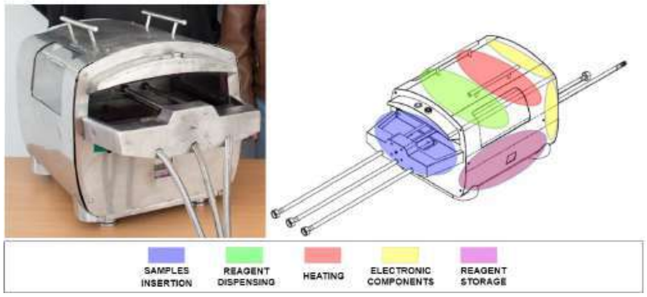

Fig. 1: Staining Module.

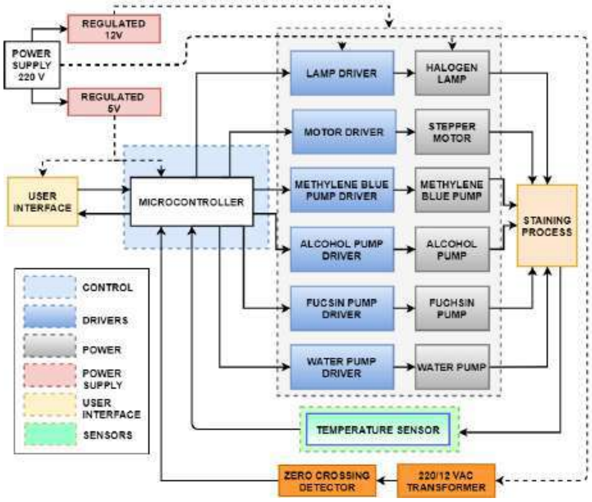

Fig. 2: Staining Module Block Diagram.

This staining module consists of a sample positioning sub-system, a reagent dispensing sub-system, and a heating sub-system. The stepper motor is part of the sample positioning sub-system. The pumps are part of the reagent dispensing sub-system. Finally, the halogen lamp and temperature sensor belong to the heating system. The microcontroller controls all sub-systems and the interaction between them.

The sample positioning sub-system receives the samples and moves them throughout staining process. The heating sub-system has a temperature control that maintains the temperature around 75 °C. The dispensing sub-system distributes the reagents to cover the samples and keep the surface tension on each sample.

*1) **Position sensor**:* The system has a limit switch sensor to define the zero position of the displacement. Figure 3a shows the schematic diagram of the conditioning circuit.

*2) **Temperature sensor, heating actuator, and actuator driver**:* The temperature sensor used is the LM35, working between room temperature and 100 °C. The sensor is located below the samples. Figure 3c shows the 10 mm distance between the reference sensor slide and the analysis slides. The sensor is in contact with the slide through the thermal paste.

The heating system has two OPALUX 220V-350V halogen lamps. Each lamp is inside a ceramic container and radiating heat on 2 samples. The system has an on-off control of the temperature with a margin of 5 °C error downwards to avoid exceeding the reference since the heating process is slow. In other words, when the reference is set at 80 °C, the lamps work at full power until the sensor reaches a temperature of 75 °C, where on-off control begins functioning. The control algorithm considers the error as the difference between the desired temperature and the measured temperature by LM35 sensor; the algorithm use a trigger angle of 1 ms (on) in case the error is greater than 5 °C; otherwise, there is no trigger angle (off).

The zero-crossing identification circuits is shown in Figure 3b and the firing angle control circuit for each lamp is as shown in Figure 4c. These circuits allow future implementations of more complex control algorithms.

*3) **Pumps and pump driver**:* The four pumps used to dispense the three reagents and water are the RS-385, which are power by 12 V with a maximum current consumption of 0.5 A. The driver selected is a mosfet IRF530 with a 1N4004 diode and a pull-down resistor R1 of 100 KΩ. Figure 4a shows the driver circuit for each pump.

*4) **Stepper motor and stepper motor driver**:* A bipolar stepper motor, which is used in the sample displacement, can be controlled through micro-stepping and varying the rotation direction using the exciter A4988. Figure 4b shows the schematic diagram of the stepper motor driver for the movement on one axis. The stepper motors are energized with 12V.

The pulley that generates the linear displacement has 16 teeth separated by 2mm between teeth. One complete revolution of the motor shaft, 360° rotation, would be equivalent to 32mm. The motor is a NEMA 17 with 200 steps per revolution, equal to 1.8° each step, and as it is working at 1/8 step, this generates a linear movement of 0.02mm.

*5) **Power supply**:* The system is energized by a switching power supply RD65 of 5V at 6A and 12V at 3A.

*6) **Microcontroller and its software**:* The arduino platform was used but a custom board has been designed using the ATmega328P microcontroller [15]. The flow chart shown in the Figure 5 describes the whole staining process: inserting samples, fuchsin staining, heating samples, rinsing, dispensing acid alcohol, rinsing, methylene blue staining and the final rinse.

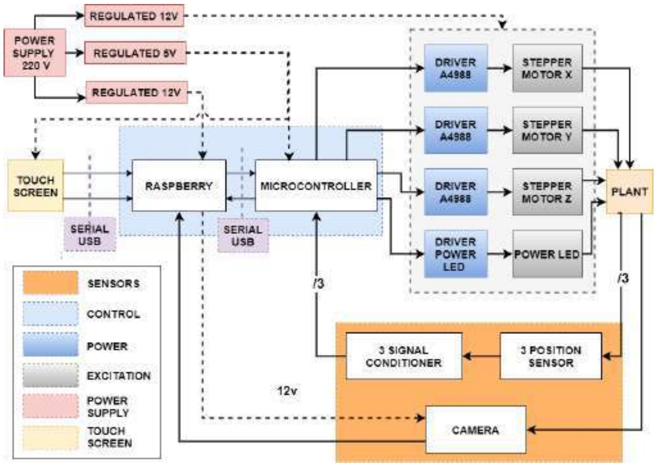

Fig. 7: Microscope Module Block Diagram.

B. Microscope module

This module's mechanical system is made up of three fundamental structures: the main support (housing); a mobile structure that contains and moves the samples, and the microscope optical structure. The touch screen, the electronic card and power supply, and other electronic components are in the main structure. The mobile structure carries out the movement of the platform through the X-Y–Z axes. The microscope structure is fixed, with the platform being the only one that moves on the Z-axis to perform the sample's focus.

Once illumination from the LED to the sample is activated, the camera and processing unit perform automatic focus while the platform changes its position relative to the microscope location. The module then acquires the focused image, processes it, and counts the bacilli.

Finally, the results are presented to the user through a graphical interface. Figure 6 shows the prototype's mechanical system and Figure 7 shows the block diagram.

*1) **Position sensor:*** The system has three limit switch sensors to identify the initial position in each axis, each of the sensors has a similar configuration and function as the sensor of the staining module.

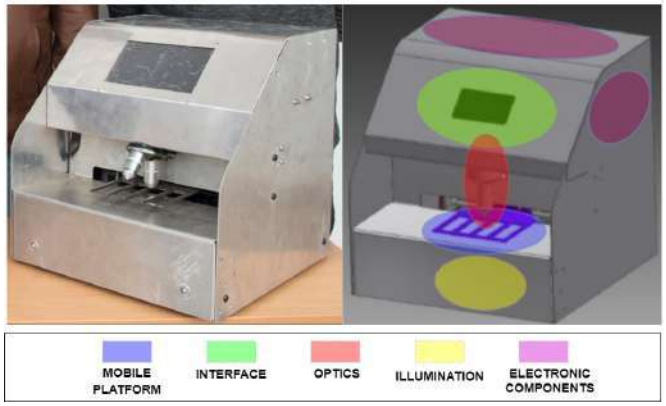

Fig. 6: Microscope Module.

*2) **Power LED and its driver:*** The system uses a power LED as the light source (12V, 0.9A, 6000-6500K). The driver considered is a mosfet IRF530 with a 1N4004 diode and a 100KΩ pull-down resistor R1. The ligth intensity of the LED is controlled by pulse width modulation (PWM).

*3) **Motors and their drivers:*** The microscope module uses three motors, each with the same hardware features as the staining module in order to generate movement in three axes. The X-Y plane's displacements do not need to be readjusted every time, so the microstep setting is fixed. In the case of Z axis motion, the micro-steps need to be readjusted according to the autofocusing algorithm's requirements.

The motor can rotate up to 1/16 of a 1.8° step. Ergo, it can rotate 0.1125°. Considering that the step between threads of a worm-screw is 2mm for the X and Y axes, 0.1125° corresponds to a linear displacement of 0.000625 mm. To move to the next field of 0.2 mm, the motor must rotate 36° or 20 steps. In the Z axis, there is a 1 mm between threads; therefore, a rotation of 0.1125° corresponds to 0.0003125mm.

*4) **User Interface-Touch Screen:*** The touch screen is a 7-inch Waveshare and it is controlled by the Raspberry platform. The development of the interface has been done with the Kivy Python framework. The Pony ORM object-relational mapper and the SQLite database manager have been used to store and search the records. The searches of the records can be carried out with information from any of the fields (Code, Diagnosis, Fields, Bacilli and Date). The user can easily initiate and terminate the process through this interface. Figure 8 shows the connections of the Raspberry to the Waveshare display. Figure 9 shows the main menu displayed on the screen.

*5) **Digital Camera:*** The system uses the C920E WEBCAM digital camera attached to the microscope tube through a structure created digitally in 3D printing. The camera sends the images to the Raspberry Pi 3 through the USB port. See Figure 8.

*6) **Processing Unit:*** It is composed of the Arduino Nano board based on an ATmega328 microcontroller and the Raspberry 3 board, a 64-bit ARM Cortex-A53 processor at 1.2

GHz. The first one is in charge of exciting the X, Y, and Z-axis motors and LEDs through its drivers. The second one is in charge of processing the acquired images; finding the best-focused image and making the samples' diagnosis, and controlling the user interface while communicating via USB so that the user can initiate, monitor, interrupt and terminate the session. Figure 8 shows the connections between them.

IV. RESULTS AND DISCUSSION

The following lines present the factors that influence the performance of both modules.

A. *Sample inclination:*

The samples are clamped by tweezers, which break the reagents' surface tension when heated. The heating of the tweezers causes the fuchsin to flow and fall off the samples. A proper tilt allows the greatest amount of fuchsin to concentrate away from the clamp during heating. Hovever, this tilt pools the reagents to one side of their container. This improper storage prevents the actuator from pumping the reagents as the pumps are located on the opposite side, causing the reagents to remain in the containers.

B. *Fuchsin dispensing tubing:*

The pneumatic tubing used for fuchsin dispensing swells, clogs, and even releases particles. It is important to mention that the dispenser (not the tubing) of channel 1 became clogged after 40 sequences. Figure 11a shows the tubing after more than 15 sequences.

Figure 11b shows that the fuchsin coloration of the sample on the left is different from the sample's normal coloration on the right. This coloration is evidence of fuchsin contamination.

C. *Heating temperature*

The heating temperature can cause the samples to be dry and/or dark in color. By changing the equipment's inclination, the halogen lamps get closer to the samples, making it necessary to reduce the temperature. In the horizontal position, the reference temperature, based on the medical technologist's recommendation, was set at 100°C. In contrast, when tilted forward (due to the equipment structure's misalignment), the appropriate reference temperature was set at 93°C. Figure 11c (left) shows samples with an excess temperature, while in Figure 11c (right), the temperature is adequate.

With the temperature control active and the slides covered with water, the evolution of the reference sensor's temperatures on each of the 4 samples was validated considering several reference temperatures. The thermocouples of 4 Fluke 179 devices with a temperature sensor were used to measure each sample's temperature. The values displayed by the multimeters have been extracted in a synchronized way using image processing. The software used is a modification of the code presented in [16]. The figure 12a and 12b show the results for reference temperatures of 60 °C and 70 °C.

Subsequently, the ON / OFF control was validated with a sample covered with fuchsin; the result obtained is shown in Figure 13a. The Fluke 179 thermocouple multimeter was used to measure the temperature on the fuchsin-coated slide and the Fluke 175 multimeter was used to indirectly measure the temperature of the LM35 (via the sensor output voltage). It can be seen that the temperature difference is 10 ° C and the control is carried out properly. It was observed that the initial temperature of the LM35 does not significantly affect the final value of the sample's temperature; however, a preheating is

(b) Reference sensor temperature during heating and preheating.

Fig. 13: Temperature control analysis.

established prior to the entry of samples to define the initial temperature condition of the reference sensor, this preheating does not change the traditional staining process.

Figure 13b shows the reference sensor values during heating and preheating for two samples in a single graph. The temperature control result is for the sample 13063 (set point of 93 °C) and for the sample 16921 (set point of 100 °C); the ambient temperatures were 21 °C and 21.6 °C respectively. For the 93 °C references, the heating position is given by setting #4 of Table I, while for the 100 °C references, it is given for setting #3. The heating time was seventy-five seconds. For the case of sequence 13063, there was a calibration preheating of the equipment, which had a reference of 60 °C.

D. Sample positions

Several adjustments have been made regarding the position of the limit switch sensor. The most relevant ones during calibration are shown in Tables I and II.

Regarding the changes between setting 1 and 2, it was observed that the dispensing was excessive and there was a waste of fuchsin; therefore, to avoid misuse of fuchsin, the sweep displacement is reduced from 3 cm to 2.6 cm. Besides, a small offset of 1 mm is added to the initial dispensing position to move it away from the clamps. The change between setting 3 and 4 is due to the fact that a two-millimeter adjustment was required for the halogen spotlight to align with the samples.

Table II shows the amount of fuchsin dispensed in ml for settings #1 and #4. Setting #5 is not included because fuchsin is lost during heating, causing the samples not to be completely coated. Figure 14 shows the coating of the slides after heating with setting #4.

TABLE I: Spindle positions in millimeters with respect to the location of the limit switch sensor.

Adj.	Heating position (mm)	Fuchsin dispensing end position (mm)	Initial fuchsin dispensing position (mm)	Initial position for sample entry (mm)
1	6	110	140	214
2	6	114	140	214
3	6	113	139	214
4	4	113	139	214

TABLE II: Variation of ml of fuchsin with respect to the dispensing interval.

Adj.	Dispensing interval (steps)	Dispensing interval (mm)	Sample 1 (ml)	Sample 2 (ml)	Sample 3 (ml)	Sample 4 (ml)	Total (ml)
1	1500	30	3.6	5	3.8	4.6	17
4	1250	25	3	3.55	3	4.5	14.1
5	950	19	2.1	2.75	2.25	3.1	10.2

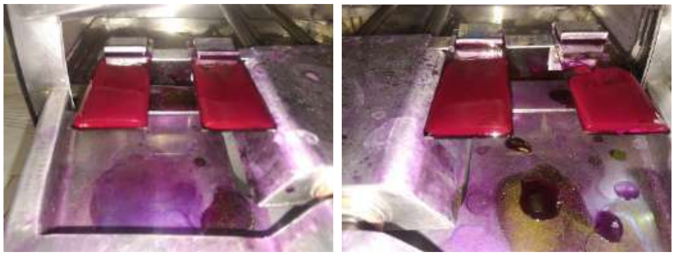

Fig. 14: Fuchsin coating of samples after heating.

E. Microscope module

The microscope module performs a proper displacement for the 4 samples; the X and Y axis have a minimum step displacement equivalent to 0.01 mm. The Z axis enables autofocus with a minimum displacement of 0.0003125mm or 16 microsteps. To implement the microscope module, a commercial one was purchased, and the part corresponding to the optics was cut. This reduced the robustness of the module. Therefore, the observed images have a small vibration that is corrected by the autofocus and the image capture software.

V. CONCLUSIONS AND FUTURE WORK

The staining module can stain 4 samples simultaneously in an automatic way. Regarding the reagent dispensing, it is concluded that the dispensing for all channels as a set can be controlled by varying the interval of dispensing positions. However, the amount dispensed is not uniform in all dispensers. Regarding temperature control, it is found that the temperature in the sample can be controlled from a reference temperature sensor. The mechanic is essential so that a proper clamping of the samples is crucial for the prototype's proper functioning; the inclination must be uniform so that it is the same for the four samples. Finally, the structures' material is also important; it has been proven that metal containers and pneumatic pipes are not appropriate.

The microscope module performs the desired displacements in all its axes, having a higher sensitivity in the Z-axis. However, this module can be improved; two of the most important things to improve are the cancellation of the vibrations that are observed in the samples caused by shocks in the base that supports the module, or when driving its motors; and the improvement of the coupling mechanism between the camera and the microscope.

For future work, it is proposed to evaluate the use of a temperature sensor that does not require contact and moves with the samples, in addition to considering additional temperature and humidity sensors for both the environment and the equipment. This information could be stored automatically in a local or remote database. To establish the initial temperature conditions in each sequence, we propose to evaluate the possibility of including a preheating of the samples before dispensing fuchsin or placing a fan.

Finally, it is possible to perform more detailed studies. That is to say, to carry out a study that allows determining the effectiveness of the equipment for certain types of samples: urine, feces, cerebrospinal fluid, among others.

Abstract–The recent dramatic growth in electric vehicles has brought renewed attention to their motors and power electronics. Of the motors used for electric vehicles, the DC motor and the three phase induction motor are well-studied. Developing countries have created their own solutions for electric vehicles, especially with the Brushless DC Motor (BLDC). The less investigated three phase BLDC motor presents challenges for control of the transient and steady-state response, overshoot, rise time, settling time, etc. A lapse in the control can cause the system to become unstable and reduce the life of components. In this paper, a BLDC motor for electric vehicles is studied with the Modified Proportional-Integral (MPI) controller and logic gates for the drives. The design allows reduction of overshoot to an estimated 5 % and the settling time to 2 seconds This study is expected to contribute to the applications of the BLDC, especially for electric vehicles.

Keywords–Electric vehicles, BLDC, Motor, Proportional Integral, PI controller, Logic controller, Electronics, Power electronics, Motor control, Overshoot, Transient.

I. Introduction

In the growing market of electric vehicles, the motors used include the DC motor, the synchronous motor, the induction motor, and the Brushless DC motor (BLDC). Of these, the DC motor, the synchronous motor and the induction motor are well-developed technologies. In comparison, the BLDC is a relatively new type of motor, made popular largely by advances in power electronics. To meet the growing market for electric vehicles, especially in developing countries, the recent trend has been to use the Brushless DC Motor. BLDC motors use an inverter to convert DC to AC which runs an AC motor. Compared to DC motors of the same power, the three phase BLDC motor is lighter with high torque to weight, requires less maintenance and can be better controlled [1-6].Unlike the DC motor, the BLDC motor does not produce any spark and noise [7] and is convenient to use in critical environments. BLDC motors are becoming popular in Electric vehicles, drones, residential and industrial applications [8, 9].

In electric vehicles, it is desirable to operate the BLDC motor with less overshoot and less settling time. For this purpose, Anti Wind PI (Proportional Integral) control, Artificial Neural Network and Fuzzy logic-based controllers have been proposed. All are mostly complex to implement, have large overshoots, and are otherwise costly [10,11].

This paper presents an inexpensive, robust, and easy-to-implement BLDC motor controller for Electric Vehicles using Modified Proportional Integral (MPI) and digital logic control.

II. Literature Review

Problems with PI control include high overshoot, and settling time. Kiron avoided the PI controller and proposed Auto tuned PID controller, with which he achieved 50% overshoot (at 1000rpm and 0.18N-m torque) [12]. Arulmozhiyal proposed Fuzzy PID controller and achieved 3.6% overshoot at 1500rpm with 5N-m load [13]. Neethu proposed a fuzzy controller and achieved 38% overshoot at 1000rpm [14]. As the overshoot is high, the BLDC motor takes high inrush current to initialize, which may reduce the life of the motor.

III. Theory of Operation

The proposed block diagram of the BLDC motor controller using Modified Proportional Integral (MPI) method is shown in Fig.1. The MPI block continuously checks the speed sensor, current/voltage sensor, and the desired speed and it tries to find the error using the MPI method. The logic operation selects the three-phase inverter gating sequence with the help of the hall sensor and the MPI output. Then the three-phase inverter controls the BLDC motor.

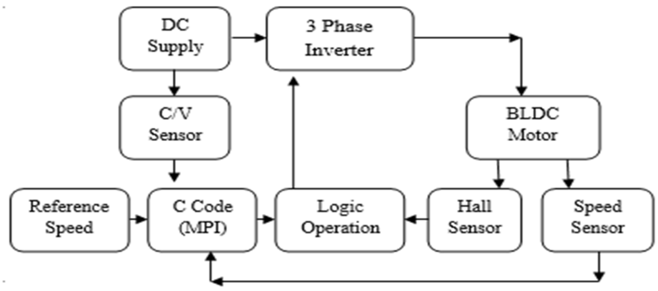

Fig.1: Block diagram of proposed system

IV. Controller Design

A. *MPI Controller*

The Modified Proportional Integral (MPI) controller is shown in Fig.2. To find the error between desired speed and actual speed, the MPI is required. The desired speed is sampled and further processed according to predefined tuned value. The desired speed which is instantaneous and coming from user is defined as

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$$R'(t) = xu(t) \tag{1}$$

In sample and process block, the instantaneous desired speed is modified on the basis of equation 2.

$$R(t) = x\,r(t + 0) - x\,r(t - m) \tag{2}$$

Where x is the given desired speed and m is the desired settling time. The desired speed is then compared with actual speed and fed to PI block. The transfer function of a PI controller can be defined as.

$$\text{Output, } y(s) = e(s) \times (k_P + \frac{Ki}{S}) \tag{3}$$

The gain can be calculated as.

$$y(s)/e(s) = (k_P + \frac{Ki}{S}) \tag{4}$$

In time domain the transfer function of PI is.

$$y(t) = k_P\, e(t) + k_i \int e(t)dt \tag{5}$$

After solving trapezoidal rule, the overall expression becomes.

$$y(t) = K_P\, e(t) + K_i[\frac{Ts}{2}[e(t) + 2e(t-1)] + Past_{int}] \tag{6}$$

where $e(t)$ is the current error and Ts is sampling time. This equation was implemented in a proposed MPI controller in software using C code.

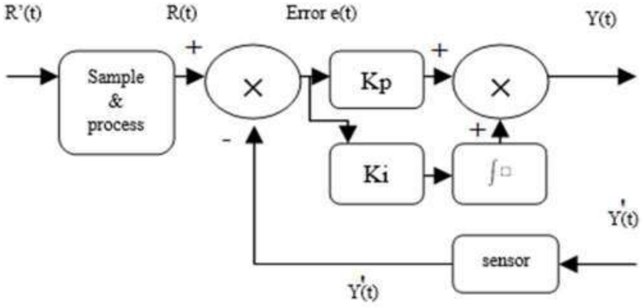

Fig.2: The algorithm of Proposed MPI block used in Software using C code.

B. *Logic Operation Controller*

For this project, three phase six switch inverters have been assigned. To control the switch gating sequence, the logic operation is required. Typically, the BLDC motor consists of three Hall effect sensors which give the information of rotor position. When a rotor magnet passes the Hall sensor, it provides a high signal for the North pole and low signal for South pole. The communication sequence would be $2^3 = 8$, which are 000, 100, 011, 110, 010, 101, 001 and 111. But as 000 and 111 are odd combinations, the logic operation will ignore them. Based on these values the emf can be calculated as.

$$EMF\ sa = Hall\ A\text{-}\ Hall\ B \tag{7}$$

$$EMF\ sb = Hall\ B\text{-}\ Hall\ C \tag{8}$$

$$EMF\ sc = Hall\ C\text{-}\ Hall\ A \tag{9}$$

Where $Hall\ A = 1$, $Hall\ B = 0$, $Hall\ C = 0$ for first sequence 100 and the EMF will be +1, 0 and -1 for sa, sb, and sc respectively. The software built in BLDC motor block gives the rotor position as bipolar communication (-1,0,+1) for each phase. Based on this, the inverter switch gating pulse must be decided to achieve the required terminal voltage which is similar to emf.

To achieve the three-phase terminal voltage, two switches must be on at a time for one phase, according to the emf sequence. When any upper switch conducts, the following phase becomes positive. When the lower switch conducts, the following phase becomes negative. When both switches open the following phase becomes zero. To avoid short circuit, no two switches in a line should conduct at a time. For instance, the first sequence (100) phase Y, B and G must receive positive voltage, zero voltage and negative voltage. To achieve this, switch 1 and switch 4 must be triggered. Based on this, table I and II are drawn below.

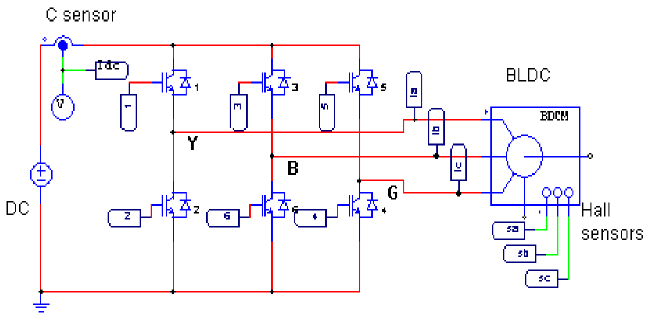

Fig.3: Three phase inverter with BLDC motor.

TABLE I. LOGIC LEVEL GENERATION FOR FORWARD ROTATION CALCULATED FROM ABOVE EQUATIONS

EMF			Forward Rotation					
sa	sb	sc	Switch					
Y	B	G	1	2	3	4	5	6
+1	0	-1	1	0	0	1	0	0
-1	0	+1	0	1	0	0	1	0
0	+1	-1	0	0	1	1	0	0
-1	+1	0	0	1	1	0	0	0
+1	-1	0	1	0	0	0	0	1
0	-1	+1	0	0	0	0	1	1

To run the motor in reverse direction the inverter switching pattern changes and Table II must follow in logic operation.

TABLE II. LOGIC LEVEL GENERATION FOR REVERSE ROTATION CALCULATED FROM ABOVE EQUATIONS.

EMF			Reverse Rotation					
sa	sb	sc	Switch					
Y	B	G	1	2	3	4	5	6
-1	0	+1	0	1	0	0	1	0
+1	0	-1	1	0	0	1	0	0
0	-1	+1	0	0	0	0	1	1
+1	-1	0	1	0	0	0	0	1
-1	+1	0	0	1	1	0	0	0
0	+1	-1	0	0	1	1	0	0

Based on these two tables, the logic operation block drives the BLDC motor using inverter.

V. SIMULATION RESULT AND DISCUSSION

After completing the logic operation table and the MPI tune value, a complete circuit was developed in the software to analyze the proposed system. Fig. 4. shows the complete circuit diagram of the BLDC motor controller with mechanical load of 3 N-m. The inverter block consists of six switches as shown in fig. 3. The logic operation maintains Table I and Table II, based on the reference input. The logic operation and MPI block consist of several C blocks written in C code. The MPI block consist of MPI equations explained in section IV.A and its monitor's instantaneous change in any current or voltage sensors involve speed, torque, direction bit and reference speed. The MPI block tunes the speed error, and PWM is generated at 10 kHz switching frequency, which is then fed to logic operation and generates the gating sequence. Fig.5 summarizes the overall operation of the proposed system.

A. *Forward Operation*

Fig. 6 shows the forward rotation emf generated from BLDC motor. The emf is bipolar communication (-1,0,1) which contains the rotor position, based on which the logic operation follows Table I and generates six-switching pulse (Fig. 7).

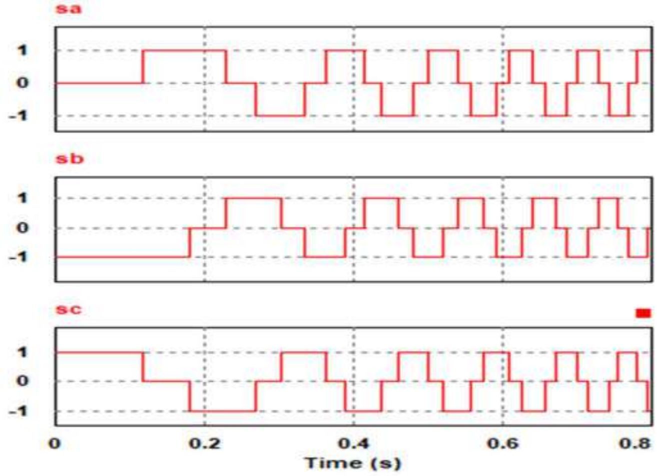

Fig.6: Simulated Forward rotation emf generation from BLDC motor which perfectly matches with calculated table I.

Fig. 6 and Fig.7 show that with the increase in rotor speed, the emf generated from the BLDC motor increases faster and the logic operation also generates six pulses faster which matches with calculated Table I.

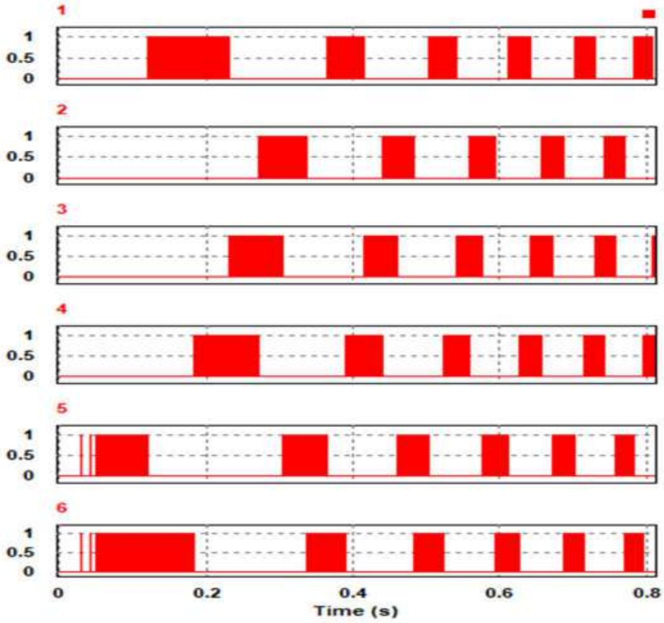

Fig.7: Simulated Gate signal generation from Logic Operation for forward rotation which perfectly matches with calculated Table I.

B. *Reverse Operation*

Fig. 8 shows the reverse rotation emf generated form the BLDC motor. This contains the rotor position and based on the logic operation, follows Table II, creating the six-switching pulse (Fig. 9). The switching sequence is visibly different from the forward rotation sequence.

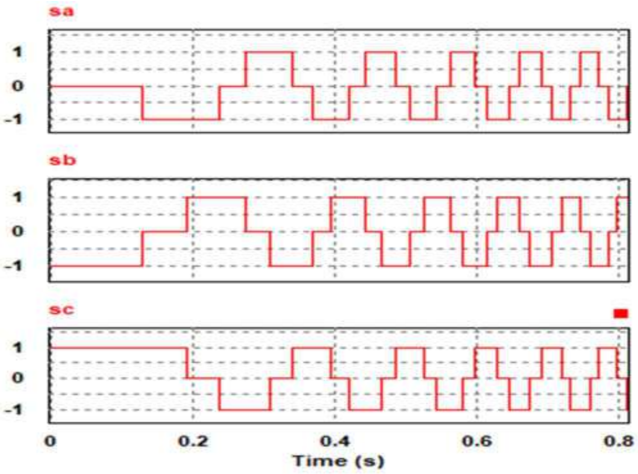

Fig.8: Simulated reverse rotation emf generation from BLDC motor which perfectly matches with calculated table II.

Fig.8 and Fig.9 show that the emf and the six pulses are generated faster as the rotor speed increases. This matches with the calculations in Table II.

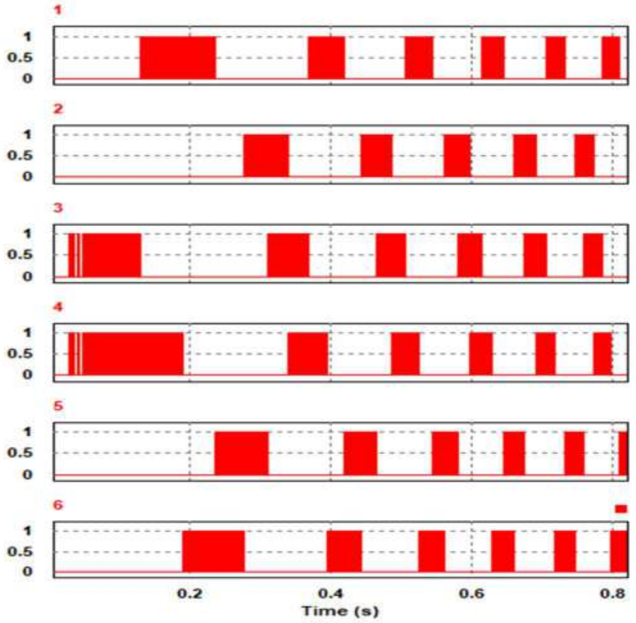

Fig.9:Simulated Gate signal generation from Logic Operation for reverse rotation which perfectly matches with calculated table II.

After successfully switching the three-phase inverter, the output current appears as shown in Fig. 10. The graph shows that there is no inrush current. The output current of the three phase inverter changes according to speed and torque.

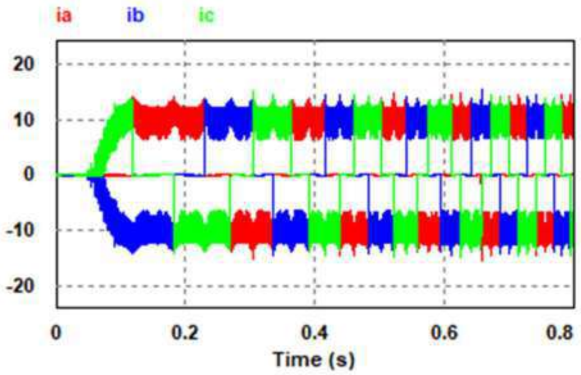

Fig.10: Simulated Inverter output Three phase current.

For forward rotation of 500 rpm and 1000 rpm with 3N-m load, the overshoot was 9.38% and 4.81% respectively, and the settling time was 1.01s and 2s respectively (Fig. 11 and Fig. 12).

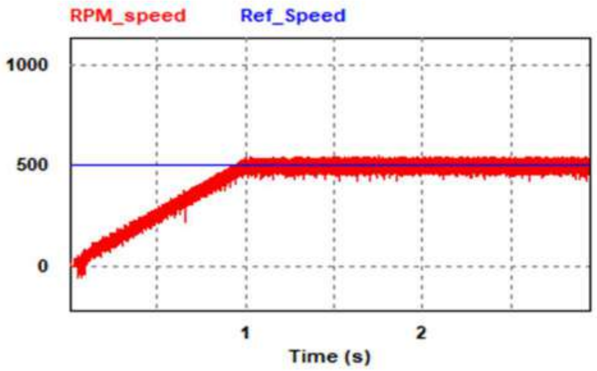

Fig.11: BLDC motor forward rotation at 500 RPM .

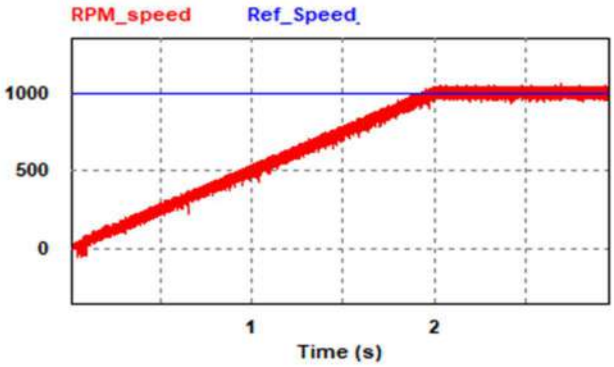

Fig.12: BLDC motor forward rotation at 1000 RPM .

For Reverse rotation of 500rpm and 1000rpm with 3N-m load, the overshoot was 8.12% and 5.18% respectively and the settling time was 1.18 s and 2.09 s respectively (Fig. 13 and Fig. 14).

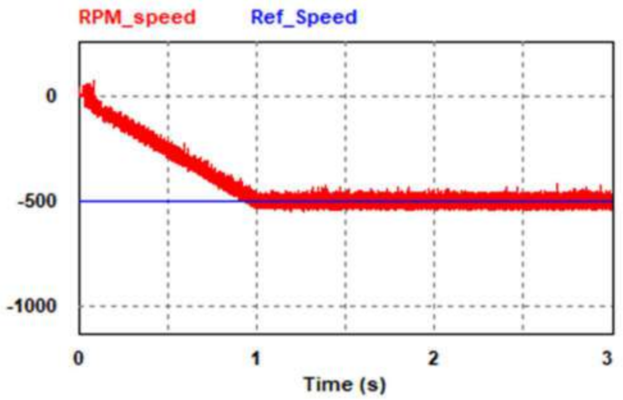

Fig.13: BLDC motor reverse rotation at 500 RPM .

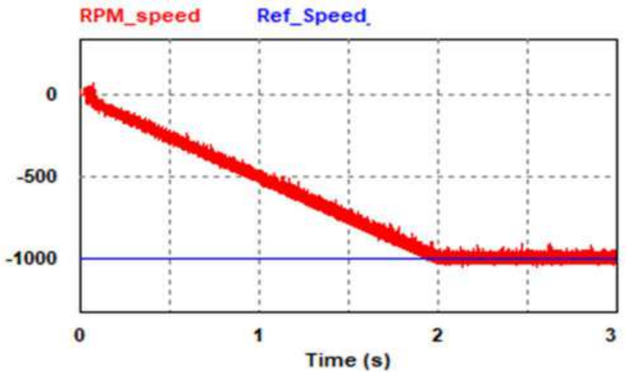

Fig.14: BLDC motor reverse rotation at 1000 RPM .

VI. Conclusion

This paper attempted to use the modified PI control for the electric vehicle's Brushless DC motor's speed and direction. The desired speed is further processed based on predefined tuned value. The PI controller calculates the error between the desired and actual speed and feeds to the logic operation. Accordingly, the proposed system is able to solve the high overshoot in transient response (1000rpm with 3N-m), which will be convenient for electric vehicles.

It is hoped that this study will contribute to applications of the BLDC motor in the electric vehicle industry.

***Abstract*—In recent years, smartphones and other mobile computers have become even smaller. Simultaneously, the number of buttons for user input has decreased, and their size has shrunk, which lowers the operability of user input. In this situation, gesture-based input is expected to be the new input method. gesture-based inputs have advantage in that it can work irrespective of device size Furthermore, there is no need to even look at the screen. Accelerometers equipped in smartphones are the primary tool for recognizing gesture-based inputs. However, such techniques are prone to misrecognitions. One factor contributing to this problem is the high number of gesture candidates. In response, we propose an input recognition method that uses a combination of two far simpler gestures types: trigger gesture (TG) and main gesture (MG). TG determine the start or content of the operation. MG provide the operational detail. In this paper, we test this concept on a music player app installed on a smartphone, which can be used while walking. The proposed method is found to improve recognition accuracy by 50%, assuming five types of input requests.**

***Index Terms*—Sensors and Systems, Signal Detection and Processing, Mobile Computing,**

I. Introduction

In recent years, smartphones and other mobile computers have become smaller, and the convenience of carrying them has been improved. However, the operability of user input has decreased with the number of buttons and screen size. Commonly, while walking or jogging, sound data are used for enjoying music, maintaining a pace, keeping rhythm, and absorbing news information or stories. So, when we want to operate something then, it has become necessary to touch the small screen while staring it, which can dangerously distract uses from their surroundings [1]. This has become a pertinent social problem. In Japan, according to the Tokyo Fire Department, from 2015 to 2019, 211 people have been transported by emergency because of related accidents [2]. This is expected to increase.

Therefore, owing to the ubiquity of smartphones, it has become necessary to operate the interface without looking at the screen. **Gesture-based Inputs** relies on accelerometers equipped in most smartphones. Accelerometers can detect hand motion and classify the types of movement. Gesture-based input is already well-implemented on game consoles, and the intuitive operation using mobile devices has been well-demonstrated. Gesture-based input is basically recognized by comparing acceleration values of input data with training data which are measured in advance [3] [4]. Gesture recognition consists of the following two steps:

1) Gesture detection: detects when a gesture is performed
2) Gesture classification: classifies which one in gesture candidates is performed

Fig. 1 shows the overview of gesture recognition.

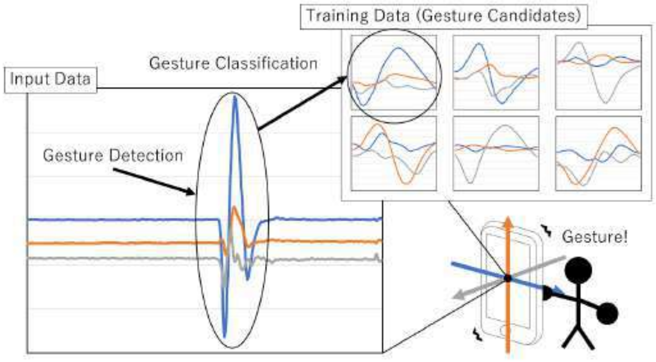

Fig. 1. Overview of gesture recognition

The problem with gesture-based input is that many misrecognitions occur. Noisy acceleration values are typically the problem, and a large number of gesture candidates thwart disambiguation. Misrecognition can be divided into the following three categories:

- False positive: outputs a detected gesture when no gesture is performed
- False negative: does not output results when a gesture is performed
- False classification: outputs the incorrect gesture

False positive and false negative occur with gesture detection. False classification occurs with gesture classification. Notably, there is a tradeoff between false positive and false negative accuracies. In this paper, we focus on improving false classification avoidance. Normally, the number of gestures candidates is the same as the number of input operations. If this number is large, it becomes necessary to prepare a huge number of training data in advance. This is seemed to lead

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

to the difficulty in classifying among them. We confirmed in preliminary experiments that increasing the number of gesture candidates leads to a lower recognition accuracy. Therefore, we propose a method to detect and classify gesture-based input with high accuracy by using two consecutive simple gestures and limiting the number of gesture candidates. The first gestures are trigger gesture (TG) which determine the start or content of the operation. The second are main gesture (MG) which is the actual input operation detail. Recognition accuracy is improved by limiting the number of MG candidates when TG is recognized. Applying a music-player app, we assume five types of input requests. We test these using an input pattern that does not limit MG candidates (baseline method) and an input pattern that limits MG candidates (proposed method). As a result of experimentation, we confirmed that the number of misrecognitions can be reduced by approximately 50% using proposed method.

II. Related work

The acceleration values acquired by accelerometers contain a lot of noise, even when applying a high sampling rate. When classifying gestures, both training data and input data must be matched in real time. Unfortunately, they both contain a lot of noise. Thus, misrecognitions commonly occur. Regarding the problem of noisy acceleration values, Murao et al. used nine accelerometers to acquire more accurate values [5]. It was shown that the recognition accuracy, when recognizing 27 types of gestures, was 62.7% on average. In their research, to reduce misrecognition caused by noise, they used a method of continuously calculating the average value of the acquired acceleration values.

Machine learning is often used in study to calculate the similarity of gestures and assign correct labels [6] [7] [8]. In this paper, however, we do not use feature-based machine learning, but instead classify gestures by calculating the similarity between time series data.

Even with the same gesture, the speed of hand motion changes depending on the time and the situation. In this case, the number of samples and the acceleration values of input data will be different, and it becomes difficult to calculate the similarity to training data. Dynamic Time Warping (DTW) method is an algorithm used for calculating the similarity between such data with respect to the problem that the gesture speed is not the same each time [9] [10] [11]. With DTW, by expanding and contracting the time in two time-continuous data, the difference in the number of samples and the acceleration values can be eliminated, and the similarity can be calculated with less overhead.

In this paper, we use a method of continuously calculating the average value of the acquired acceleration values for information extraction from training data. We apply DTW to calculate the similarity between training data and input data. Izuta et al. used a similarity calculation method via DTW to detect the start of a gesture [12]. It was shown that a gesture could be detected without waiting for its finish by continuously comparing its similarity with all training data.

Izuta et al. also mentioned that recognition accuracy would be degraded in case gesture candidates include similar ones [12]. So, it remains difficult to accurately classify gestures when the number of candidates increases. Therefore, in this study, using two consecutive simple gestures is applied to improve recognition accuracy.

III. Formal description of the problem

The purpose of this paper is to provide a method of recognizing gestures from the acceleration values acquired by accelerometers equipped in smartphones and use them as the input operation of a music player. In this section, we describe the assumptions, conditions, and target problem for gesture recognition.

We assumed that we acquire the acceleration values of gestures while holding a smartphone in one hand. The n gestures are prepared as gesture candidates, and are denoted by G_i $(i = 1, 2, 3, \cdots, n)$.

The variables of this gesture recognition problem include training data and input data. Training data are labeled with ones of the gesture candidates. The output, in turn, is the label with training data. The sequential acceleration values of G_i are training data represented by $B_i = (b_0, \cdots, b_{Ti})$. T_i represents the number of samples of training data B_i. Similarly, input data from the gesture start time t_0 to the finish time t_e, include the sequential acceleration values represented by $A = (a_{t_0}, \cdots, a_{t_e})$.

Almost all types of smartphones equip 3-axis accelerometers. These accelerometers can sample acceleration values for each of the x, y, and z axis. The acquired values include values of acceleration caused by the gestures and of gravitational acceleration. Thus, acceleration values b and a are acquired for the three axes of x, y, and z. Thus, they become vectors of three parameters. For example, in one sample, the parameters of training data, b, and input data, a, are (b_x, b_y, b_z) and (a_x, a_y, a_z), respectively.

With gesture recognition, the similarity between input data A and training data B_i is calculated. In this paper, the similarity is calculated using DTW and evaluated as a distance, $D(A, B_i)$. The smaller the distance of D, the more similar the two data become. Therefore, G_* which is $\min\{D(A, B_i), i = 1, 2, 3, \cdots, n\}$ is output.

IV. Baseline method

A. Gesture detection

It is necessary to detect the start and finish of gesture-based input because input data A is acquired continuously. We used the average of total acceleration as the condition for recognizing the start and finish of gesture-based input. The total acceleration $|a|$ at a certain time was set as following equation (1).

$$|a| = \sqrt{a_x^2 + a_y^2 + a_z^2} \tag{1}$$

From the start acquiring of input data, we continue to take the average value of the total acceleration. When the total acceleration, $|a|$, exceeds α by an amount greater than the average value before it for the first time, t_s, when the gesture starts is as following equation (2). α is a threshold for recognizing whether a gesture is performed.

$$t_s = \min\{\, t' \mid |a_{t'}| > \frac{1}{F} \sum_{t=t'-F}^{t'-1} |a_t| + \alpha \,\} \tag{2}$$

Next, it is recognized that the gesture finishes at the last time the total acceleration, $|a|$, exceeds the above threshold. The reason for doing this is that the total acceleration, $|a|$, may temporarily fall below the threshold during the gesture. Therefore, the time, t_f, when the gesture finishes, is as following equation (3).

$$t_f = \max\{\, t' \mid |a_{t'}| > \frac{1}{F} \sum_{t=t_s-F}^{t_s-1} |a_t| + \alpha \,\} \tag{3}$$

B. Gesture classification

After gesture detection, DTW was used to classify the type of gestures. We extract $A_t^* = (a_{t-F}, \cdots, a_t)$ and calculate the similarity between A_t^* and training data, B_i. calculate the similarity between A_t^* and training data, B_i. The similarity is evaluated based on the distance of DTW. In this paper, we use the Euclidean distance as the seed of DTW. The Euclidean distance, d, is defined as the distance between input data, a, and training data, b, at a certain time, as following equation (4).

$$d(a,b) = \sqrt{(b_x - a_x)^2 + (b_y - a_y)^2 + (b_z - a_z)^2} \tag{4}$$

Next, the algorithm of calculating the distance using DTW is shown. Considering the matrix, dtw, each element, $dtw[j][k]$, stores DTW distance defined as follows. We sequentially calculate the cost from $dtw[0][0]$ to $dtw[F][f_i - s_i]$ by dynamic programming to find a route that minimizes the cost of $dtw[F][f_i - s_i]$. The cost is the Euclidean distance, d, and the value of $dtw[F][f_i - s_i]$ is the distance, $D(A_t^*, B_i)$, which is used as the similarity. Fig. 2 shows the algorithm of calculating the distance using DTW.

We calculate the distance, $D(A_t^*, B_i)$, from extracted input data, A_t^*, for each training data, B_i $(i = 1, 2, 3, \cdots, n)$, by using DTW. Then output the gesture G_I having the smallest distances, $D(A_t^*, B_I)$, is performed.

$$D(A_t^*, B_I) = \min_{i=1,2,3,\cdots,n} D(A_t^*, B_i) \tag{5}$$

C. Preliminary experiment

Basically, it is easy to find the correct answer with high accuracy to the alternative question. However, it is not easy to find just one correct answer from many choices. When this is applied to gesture recognition, it is expected that the recognition accuracy will decrease as the number of gesture candidates increases. To confirm the relationship between recognition accuracy and the number of gesture candidates, we conducted preliminary experiments.

```
Require: $A = (a_1, \cdots, a_F), B = (b_1, \cdots, b_{f_i - s_i})$
Ensure: $D(A, B)$
$dtw[0][0] \leftarrow 0$
for $j = 1, 2, 3, \cdots, F$ do
    $dtw[j][0] \leftarrow \infty$
end for
for $k = 1, 2, 3, \cdots, f_i - s_i$ do
    $dtw[0][k] \leftarrow \infty$
end for
for $j = 1, 2, 3, \cdots, F$ do
    for $k = 1, 2, 3, \cdots, f_i - s_i$ do
        $dtw[j][k] \leftarrow d(a_j, b_k) + \min \begin{cases} dtw[j-1][k] \\ dtw[j-1][k] \\ dtw[j-1][k-1] \end{cases}$
    end for
end for
return $dtw[F][f_i - s_i]$
```

Fig. 2. the algorithm of calculating the distance using DTW

Because we assumed that gestures are input consecutively, we adopted 13 gestures which can be performed while holding a smartphone in one hand, and return to the original positions after a performance(TABLE I, Fig. 3).

TABLE I
BASIC GESTURES

	Shake to the right
	Shake to the left
	Shake up
	Shake down
	Shake to the front
	Shake to the back
	Tilt to the right
	Tilt to the left
	Tilt to the front

	Draw a triangle
	Knock the back twice

The content of the preliminary experiment was measuring the recognition accuracy by changing the number of gesture candidates. The recognition accuracy was defined as the per-

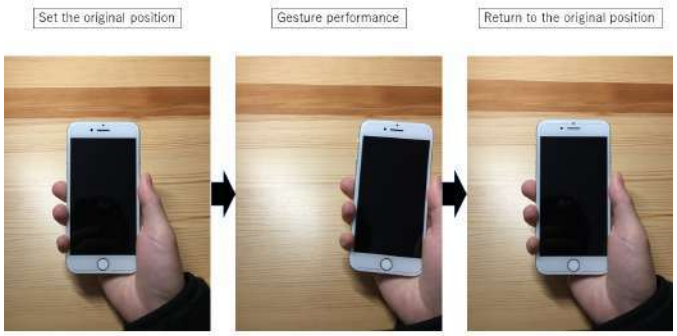

Fig. 3. Performing a gesture while holding a smartphone in one hand

centage that correct gesture labels were output, and the number of gesture candidates was changed from 2 to 13.

Gesture candidate lists were set to maximum of 78 combinations from TABLE I, and the recognition accuracy was calculated as the average value of trials. For the number of gesture candidates was 1, 2, 11, 12, and 13, we were able to examine all the combinations of gesture candidates. For the number of gesture candidates was 3 to 10, the number of possible combinations was too large, so we limited the number of gesture candidate lists to 78 patterns.

Fig. 4 shows the result of this. The accuracy for two choices was more than 99%, while it was 96% for correcting the gestures from 7 candidates, and 92% from 13 candidates. From the above result, the accuracy tends to decrease as the number of gesture candidates increases.

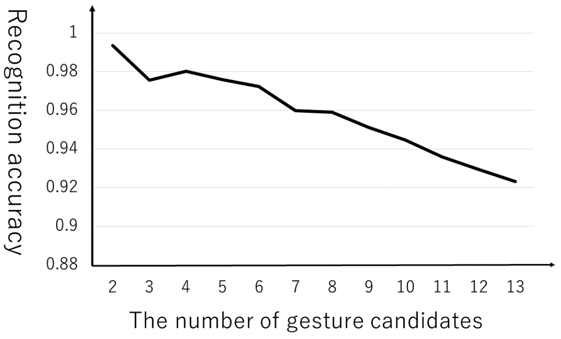

Fig. 4. Graph of recognition accuracy of changing the number of gesture candidates

V. Proposed method

A. System structure

In this paper, we implement the following system structure to recognize two consecutive simple gestures that are input operations. First, to remove the portion of the data that may cause an error in similarity calculation, training data preprocessing is performed. One gesture is recognized by continuously calculating the similarity between input data and training data. Then, two consecutive simple gestures are recognized from the set of candidates determined by which type of TG.

1) Training data preprocessing
2) One gesture recognition
3) Two consecutive simple gestures recognition

B. Training data preprocessing

When calculating the similarity via DTW, all data from the acquisition start time to the finish time are used as training data. Because they include the data acquired when gestures are not actually performed, which may cause an error in similarity calculation. Therefore, we extract the necessary information from training data. For that purpose, it becomes necessary to recognize when the gesture started and finished. We used the method same as baseline method to recognize them. As a numerical value required for recognition, the total acceleration, $|b|$, at a certain time is set as following equation (6).

$$|b| = \sqrt{b_x^2 + b_y^2 + b_z^2} \tag{6}$$

When the total acceleration, $|b|$, exceeded α greater than the average value before it for the first time, it recognized that the gesture started. Then, it was recognized that the gesture finished at the last time the total acceleration, $|b|$, exceeded the threshold. Therefore, the times, s and f, when the gesture started and finished were as following equations (7) and (8).

$$s = \min\{\, s' \mid |b_{s'}| > \frac{1}{s'-1}\sum_{t=0}^{s'-1} |b_t| + \alpha \,\} \tag{7}$$

$$f = \max\{\, f' \mid |b_{f'}| > \frac{1}{s-1}\sum_{t=0}^{s-1} |b_t| + \alpha \,\} \tag{8}$$

s_i and f_i are calculated for training data, B_i. In the following, training data, B, is $B = (b_s, \cdots, b_f)$. Next, the time required for one gesture, F, is determined. The time taken for each gesture, G_i, can be calculated by $f_i - s_i$. When recognizing a gesture of input data, it falls into a state in which the gesture is not known. Thus, the maximum time required for each gesture is F as following equation (9).

$$F = \max\{f_i - s_i, i = 1, 2, 3, \cdots, n\} \tag{9}$$

Fig. 5 shows the result of information extraction of training data when shaking a smartphone to the right.

C. One gesture recognition

Assuming that the current time is t and one gesture was performed in the past F samples, we extract $A_t^* = (a_{t-F}, \cdots, a_t)$ and calculate the similarity between A_t^* and training data, B_i. In the range of past F samples, $A_t^* = (a_{t-F}, \cdots, a_t)$, we continued to take the average value of total acceleration. At a certain time t, the smallest of the distances, $D(A_t^*, B_i)$, from each training data, B_I, is the output candidate. However, a gesture may not have been performed in the extracted input

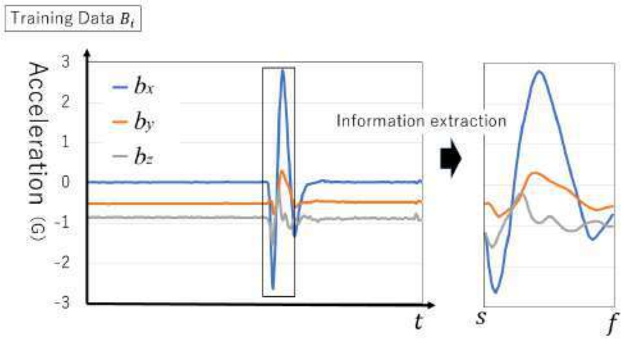

Fig. 5. Example of information extraction of training data (shake to the right)

data. If no gesture is performed, all distances will have similar values. Therefore, when the distance with training data, B_I, is clearly smaller than the distance with training data B_{II} having the second smallest distance, it will be recognized that the gesture, G_I, is performed. The condition at that time is as follows. $\beta(> 1)$ is the threshold for recognizing gestures.

$$\beta D(A_t^*, B_I) < D(A_t^*, B_{II}) \tag{10}$$

All distances have similar values when the gesture is not performed. This helps us recognize that the gesture starts when the above condition is first met and finishes when the condition is finally met. Therefore, the start time, t_s, and the finish time, t_f, of the gesture are set as following equations (11) and (12), respectively.

$$t_s = \min\{\, t' \mid \beta D(A_{t'}^*, B_I) < D(A_{t'}^*, B_{II}) \,\} \tag{11}$$

$$t_f = \max\{\, t' \mid \beta D(A_{t'}^*, B_I) < D(A_{t'}^*, B_{II}) \,\} \tag{12}$$

D. Two consecutive simple gestures recognition

In this paper, we focus on the operation of a music player. Table II shows the minimum 5 inputs required for operation.

TABLE II
INPUT REQUIRED TO OPERATE THE MUSIC PLAYER

Play/Pause
Play the next music
Play the previous music
Turn up the volume
Turn down the volume

Each gesture should be simpler because a complicated gesture puts a load on users. Therefore, we consider a simple gesture that is used for combination. We selected the gestures that require shaking smartphone once along each axis direction from the basic gestures. Table III lists gestures along each axis.

There are 6 types of simple gestures to be assumed, so we can select 6×6 of 36 combinations of two gestures. Of these, we assign them to the five inputs required to operate a music player. There are two possible methods for the role of TG.

TABLE III
GESTURES OF SHAKING THE SMARTPHONE ALONG EACH AXIS DIRECTION

axis	Positive (+) direction	Negative (-) direction
x	Shake to the right	Shake to the left
y	Shake up	Shake down
z	Shake to the front	Shake to the back

The first pattern is input-pattern A, which is an assignment method that selects only combinations that use the same TG for all MG. The second pattern is input-pattern B, which is an assignment method that selects combinations that use multiple TG. In input-pattern A, TG has the meaning of a signal to start input, and MG indicates the actual input contents. In input-pattern B, the input content is already determined when TG is input, and MG determines the degree. TABLE IV and TABLE V show the combinations of gestures for each input pattern. The combinations were decided so that the input content and the gesture could be connected intuitively. The parentheses in the table indicate the direction of the axis that primarily reacts.

TABLE IV
INPUT PATTERN A

Input operation	TG	MG
Play/Pause	Front(z+)	Back(z-)
Play the next music	Front(z+)	Right(x+)
Play the previous music	Front(z+)	Left(x-)
Turn up the volume	Front(z+)	Up(y+)
Turn down the volume	Front(z+)	Down(y-)

TABLE V
INPUT PATTERN B

Input operation	TG	MG
Play/Pause	Up(y+)	Back(z-)
Play the next music	Front(z+)	Right(x+)
Play the previous music	Front(z+)	Left(x-)
Turn up the volume	Right(x+)	Up(y+)
Turn down the volume	Right(x+)	Down(y-)

Both TG and MG are recognized by the same method, as shown in Section 4.3. In this paper, the interval between TG and MG is within 1 s. If MG is recognized within 1 s after the recognition of TG, the operation by the combination of TG and MG is output. If it exceeds 1 s after the recognition of TG, it means that no input has been made. Additionally, because the type of TG is classified at the time of MG recognition, MG is not output and is set as a new TG if MG does not match TG (Fig. 6). Therefore, in input-pattern A, it is easy to classify with only one type of TG. However, because the type of MG is not limited after TG is recognized, MG must be selected from five types. On the other hand, in input-pattern B, TG must be selected from three types. However, after TG recognition, the MG type is limited, and MG is selected from a maximum of two types.

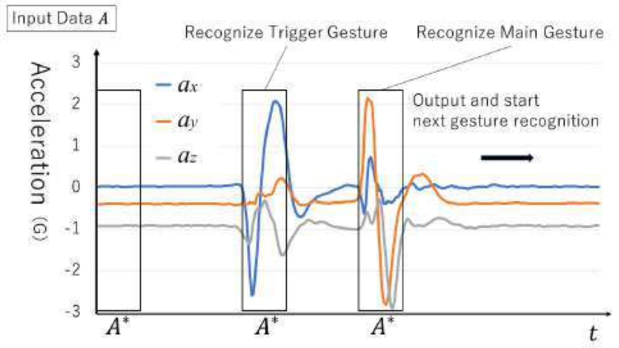

Fig. 6. Gesture recognition in input data

VI. Experiment

A. Experimental purpose

In this paper, we conducted experiments to evaluate the appropriate values of α and β, which are set as thresholds and to confirm whether the proposed method improves recognition accuracy. The environment was assumed to be a gesture-based input using a smartphone indoors. In this experiment, as a comparison method, we considered the input start time and finish time recognition using the total acceleration instead of similarity. This method is a basic recognition method used in vehicle airbags and has been improved to be applied to gesture-based input. As the threshold, the same α as the information extraction of training data was used, and the value having the highest recognition accuracy was found. The value of α obtained at this time was used to find the value of β having the highest recognition accuracy by using the proposed method. Finally, the recognition accuracy of each of the two input patterns in the proposed method was compared.

B. Environment

In this experiment, we assumed a gesture-based input using a smartphone indoors and all acceleration data was acquired indoors with the user stationary and holding a smartphone. The following items were used as experimental equipment.

- Smartphone iPhone8 (Apple A11 Bionic, Built-in 3-axis accelerometer, Sampling rate: 100Hz)

C. Experimental order

The experiments were conducted in the following order.

1) We measured the recognition accuracy by changing the value of α for the comparison method.
2) With the value at α which had the highest recognition accuracy by the comparison method, we measured the recognition accuracy by changing the value of β for the proposed method.
3) With the values of α and β measured in the above two experiments, we compared the recognition accuracy of the input pattern that limits the type of MG by the type of TG with the input pattern that does not limit the type of MG.

D. Evaluation method

As training data, we acquired each gesture shown in TABLE III once. We gave the same sequential acceleration values as input data to both the proposed method and the comparison method. In input data, combinations of TG and MG were performed seven times for each input pattern shown in the TABLE IV and V. While acquiring input data, the time when each gesture was performed was recorded and used as the correct answer label, indicating which gesture was performed. In each method, if there was a time with a correct label between the start time, t_s, and the finish time, t_f, of the gesture, it was assumed that gesture detection was correct. The gestures were recognized by each method, the outputs were classified, and a score was given to each, as shown in TABLE VI. The cumulative score was divided by the number of performed gestures and evaluated as the recognition accuracy.

TABLE VI
Classification and Score of Output

Output	Score
Correct recognition	+1
False positive	0
False negative	0
False classification	-1

VII. Results

A. Evaluate the value of α

The change in recognition accuracy of the comparison method when the value of α was changed by 0.1G is as shown in Fig. 7. When α=0.9G, the maximum recognition accuracy was 78.6%. This value was the best performance of the comparison method.

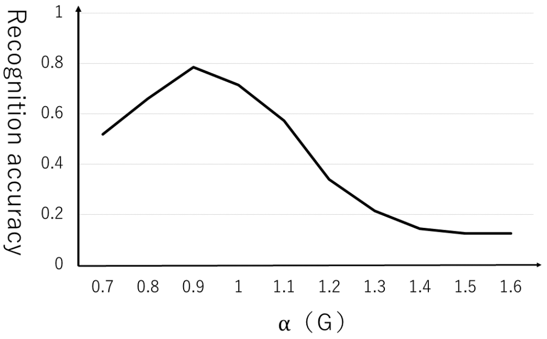

Fig. 7. Graph of recognition accuracy of comparison method

B. Evaluate the value of β

Fixing α=0.9G, the change in recognition accuracy of the proposed method was observed when the value of β was changed by 0.1, as shown in Fig. 8. When β=1.8, the maximum recognition accuracy was 96.4%. The best performance of the proposed method was clarified when the value of α was

0.9G. From the above, regarding the detection method of the time when the gesture was performed, it was confirmed that the proposed method in which the similarity was continuously compared obtained higher recognition accuracy than did the comparison method in which a threshold value was set for the acceleration value.

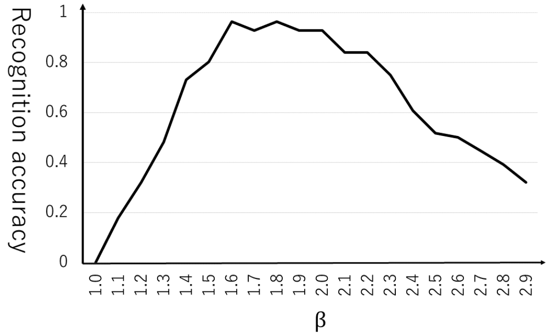

Fig. 8. Graph of recognition accuracy of proposed method

C. Comparison of recognition accuracy in each input pattern

In the proposed method, when α=0.9G and β=1.8, the recognition accuracy in the input pattern that did not limit the type of MG (Input pattern A) was 94.3%. On the other hand, the recognition accuracy of the input pattern that limited the type of MG by the type of TG (Input pattern B) was 97.1% (TABLE VII). The number of misrecognitions was reduced by 49.1%. From the above, it was confirmed that the recognition accuracy was improved by using two consecutive simple gestures.

TABLE VII
RECOGNITION ACCURACY IN EACH INPUT PATTERN

Input pattern	recognition accuracy
Input pattern A	94.3%
Input pattern B	97.1%

D. Recognition accuracy of single gesture

Under the same conditions as in Section VII-C, we calculated the recognition accuracy in the case of only one gesture for input. The average of the recognition accuracy was 95.2%. By comparing with TABLE VII, we confirmed that the recognition accuracy decreased when gesture-based input simply needs a combination of gestures, however, it was improved by limiting the types of gesture candidates even though a combination of gestures was needed.

VIII. Conclusion

In this paper, we proposed a gesture recognition method using two consecutive simple gestures to provide a music player's input operation, using a smartphone's accelerometer. From the comparison between the proposed method and the comparison method, it was confirmed that the recognition accuracy improved more when the gesture was recognized by comparing the similarities than when the gesture was recognized only by the acceleration values. Additionally, it was confirmed that the recognition accuracy was improved by limiting the types of MG corresponding to TG. Using two consecutive simple gestures resulted in complex gesture as a whole input operation, which reduced the recognition accuracy, however, we also confirmed that limiting the types of gesture candidates mitigated the reduction in recognition accuracy. In the future, we would like to calculate and compare the recognition accuracy by experiments on gestures while walking, which are expected to contain a lot of noise. We also expect that it will be necessary to discuss the optimal values of the thresholds, α and β, depending on the difference among users.

***Abstract*—The purpose of this study is to measure the time of tap action on a desk as accurately as possible using a mobile device, such as a smartphone and a tablet PC, placed on the desk. The existing method recognizes a tap based on whether the acceleration exceeds a threshold value. In addition, a waiting time is added after the tap judgment. However, this method often misjudges more taps when the user taps hard or taps continuously at high speed.**

Therefore, in this paper, we propose three new methods to solve this misjudgment problem by using the amplitude of sequential acceleration data and tap sound data: TIA (Threshold and Immediately preceding period for Amplitude), TIAA (Threshold, Immediately preceding period. and Attenuation for Amplitude), and TIAAS (Threshold, Immediately preceding period, and Attenuation for Acceleration and Sound wave). TIA uses the input wave amplitude threshold to find the time at which a tap may occur. TIA then checks the input wave for the last several milliseconds to determine if it was tapped at that time. TIAA uses the amplitude threshold of an input wave like TIA and the degree of attenuation for amplitude after the tap time. TIAAS uses the amplitude threshold of the sound for d seconds after the time the tap is recognized by TIAA for z-axis acceleration.

The experimental results show that TIA for sound amplitude and TIAAS recognize a tap more accurately than the existing method.

***Index Terms*—acceleration, sound amplitude, action recognition, tap**

I. Introduction

There is a rhythm game that scores the timing of the user's actions in response to objects (notes) that appear on the screen in sync with music and users aim for a higher score. The required user actions differ depending on the type of rhythm game, for example, tapping on specified positions the hands, pressing a button, or stepping on panels with feet. In some rhythm games, it is said that if the timing of the action is within about ±0.1, 0.066, and 0.033 seconds of the indicated timing, the score is higher in this order. One game is equivalent to one musical piece that contains several notes. A note indicates one action and its execution timing, and several notes appear in one music. Therefore, users need to perform the right action at the right time many times.

An array of notes that indicate the user's actions is called a chart, and there are various musical pieces and charts. A chart for beginners is low-density and simple, on the other hand, a chart for experts is high-density, complex, and more difficult. Rhythm games often require special large equipment, and many users play them at an amusement arcade. It takes a lot of practice to get a good score on a high difficulty chart. For this reason, players sometimes practice the timing of actions at home by tapping a desk as touch panels or buttons, while watching chart videos on Youtube. However, there is no way to judge if a user taps at the right time during practice.

In order to know if a user taps a desk at the correct time, it needs a method to identify the time when the desk is tapped and a method to determine whether the timing is correct. This paper focuses on the former method and aims to determine the time of tapping a desk as accurately as possible by placing a tablet on the desk in a quiet environment and measuring the shock wave of the tap.

There is already a method for recognizing taps by using the acceleration when a user taps the accelerometer directly. However, since the taps performed in rhythm games are powerful, a sensor may be damaged by tapping directly. Therefore, we placed a tablet on a desk so as not to tap a sensor directly, and measured the acceleration of the shock wave generated by tapping the desk. In this environment, acceleration measured by the tablet is noisier than tapping the sensor directly, which reduces the accuracy of the tap recognition by the existing method. In the existing method, after a tap is recognized, the next tap judgment is not performed until a waiting time. However, since the tap interval in rhythm games can be very short, and if the next tap occurs during the waiting time, the tap will not be recognized. As a result, there is a problem that the accuracy of tap recognition is reduced due to the increase of noise ratio and the inclusion of high-speed continuous taps.

In this paper, we propose the following three methods to determine the tapping time accurately. The first method is TIA (Threshold and Immediately preceding period for Amplitude), which uses amplitude threshold a of input wave to find the time at which a tap may occur. TIA then checks the input wave for the last b seconds to determine if it was tapped at that time. The second method is TIAA (Threshold, Immediately preceding period. and Attenuation for Amplitude), which uses

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

the amplitude threshold a of the input wave and the attenuation for the amplitude of the input wave from the time when the amplitude reaches its maximum. The third method is TIAAS (Threshold, Immediately preceding period, and Attenuation for Acceleration and Sound wave), which uses TIAA for the z-axis acceleration to determine the time of a possible tap, and only determines it a tap if the amplitude of the sound exceeds the threshold c in d seconds just after that time.

In our experiment, we measured z-axis acceleration (acceleration in the vertical direction relative to the desk surface), 3-axis acceleration, and sound with a tablet placed on the desk. For each proposed method and the existing method, we obtained appropriate values of parameters used in each method according to the value of T when the subject taps eight times at equal intervals T through experiments on actual devices and verified the best tap recognition accuracy. The results show that TIA for sound amplitude and TIAAS recognize a tap more accurately than the other methods.

II. Related Works

A. Acceleration-based action recognition

Norieda et al. has proposed a FingerKeypad that allows users to operate a device by tapping a finger around the back of the terminal [1]. FingerKeypad is equipped with nine bone conduction microphones on the backside of the terminal and identifies the tap position on the three parts of each finger and a tap is recognized when the extreme value after the fall of either sensor is below -1.5 V. Although the shape of the sensor is different, the method of identifying the tap time using threshold is the same as those described in this paper. Harrison et al. proposed Skinput, which uses the skin as an input surface by identifying the tap position on the arm, finger, and so on. Skinput uses an armband with 10 vibration sensors attached and is set two threshold values to recognize taps [2]. Murao et al. proposed a motion recognition method using three accelerometers attached to body [3].

In these studies, sensors are attached directly to the body to recognize the behavior. In contrast, in our study, we used a non-contact sensor to recognize the tap. Therefore, we must deal with the effects of strong noise influence and reverberation.

B. Sound-based action recognition

Nandakumar et al. proposed FingerIO, which tracks a finger using an ultrasonic speaker and two microphones [4]. Ishii proposed PingPongPlus, which projects images on the ping pong table according to the position of the ping pong ball hitting the table, using eight microphones on the ping pong table [5].

These methods use a large number of sensors, which make installation complicated and costly. In contrast, in this study, we used one accelerometer and one microphone mounted on a tablet placed on a desk to recognize the tap.

C. Action recognition using mobile devices

Methods of recognizing user behavior by attaching sensors to the body enable highly accurate recognition. However, wearing sensors on the body all the time can interfere with movement and the sensation of wearing the sensor can be stressful. Therefore, research is being conducted on methods for recognizing user action using accelerometers, gyroscopes, and microphones equipped in mobile devices such as smartphones and tablets.

For example, Iso et al. proposed a method for recognizing the following five actions while holding the cell phone: walking, running, going up/down stairs, and walking fast, which are recognized by using data obtained from the cell phone's built-in 3-axis acceleration sensor [6]. Kurasawa et al. proposed a method for estimating the storage location of a cell phone and the user's action by using the acceleration obtained from an acceleration sensor attached to a cell phone and the tilt of the phone [7]. Iketani et al. proposed a method for estimating the user's movement status using a mobile device equipped with an acceleration sensor [8].

Thus, smartphones and tablets can be used in this research because they enable measurements using multiple sensors simultaneously.

D. Action recognition by the combination of acceleration and sound

Ouchi et al. proposed a method to recognize the user's state in real-time using only the accelerometer and microphone of a cell phone [9]. Since the number of sound data increases by more than three orders of magnitude compared to acceleration data, this method avoids continuous use of sound data. It uses the acceleration sensor to roughly estimate the user's state, and then uses sound data according to the estimated state. In our study, considering the complexity of the calculation, acceleration is used to find the tap possibility, and then the sound amplitude is used to determine the tap.

E. Existing tap recognition method

This section describes the existing tap recognition method [10]. This is a method for recognizing two direct taps on an accelerometer. When the acceleration exceeds a threshold value (a_{THT}), there is a possibility of tapping. After that, when the time when the acceleration exceeds a_{THT} is less than or equal to a certain time (T_{DUR}), the tap is finally recognized. Just after the time of tap recognition, the next tap is not recognized during a waiting time (T_{LAT}), when the waiting time has passed, the next tap possibility can be judged.

Fig. 1 shows a graph of acceleration measured on the desk when tapping the desk once, where the horizontal and vertical axes represent time and z-axis acceleration, respectively. We will use this graph to explain how the existing method recognizes tap.

In Fig. 1, the time interval between points in the graph is 0.01 s. Suppose that T_{LAT} is 0.06 s. Since the acceleration exceeds the threshold a_{THT} at time t_1, there is a possibility of tapping. After that, the time when the acceleration exceeds

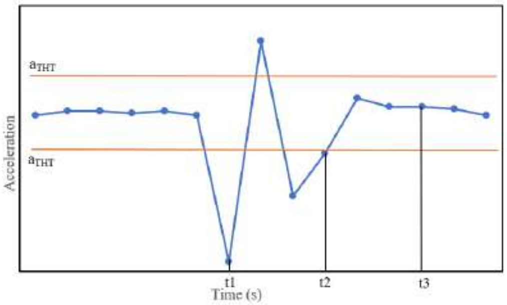

Fig. 1. How the existing method recognizes tap

the threshold is $t_2 - t_1$, so if this time is less than T_{DUR}, it is determined that the tap occurs at time t_1. Since the next tap is not recognized from time t_1 to T_{LAT} seconds, the next tap is not recognized until time t_3 in Fig. 1.

When T_{LAT} is long, the next tap within T_{LAT} will never be recognized. For a rhythm game at 60 fps, the interval between notes is 0.016 s when the notes come in consecutive frames. However, when a strong tap occurs, the amplitude of the input wave swings in the positive or negative direction, and then swings in the opposite direction due to the effect of vibration, so if T_{LAT} is shortened, the acceleration will exceed the threshold even at the time when the effect of vibration is still present, and it will be judged as a tap.

III. Problem Setting

In this section, we describe the assumed environment for recognize a user's tap and the purpose of this study.

A. Environments

A user taps the desk surface that is horizontal to the ground. A tablet is placed on the desk, with the widest side of the tablet parallel to the surface of the desk. When the user taps, a certain amount of vibration and impact generated from the tapping point on the desk are transmitted to the tablet. The tablet device is equipped with a microphone and a three-axis accelerometer. The z-axis of the accelerometer is always at a right angle to the desk surface, while the x-axis, y-axis, and microphone of the accelerometer are randomly oriented to the tapping point.

B. Problem input/output and objective function

Let P denote a set of tapping time $p_1, p_2, \cdots, p_n$. The input for the problem in this study is a time series of vibration and impact sound data detected by a tablet. The output is the set of estimated tapping time Q. The difference between $q \in Q$ and the actual tap time $p \in P$ must be small. If the actual tap time corresponding to q does not exist, it is a false positive, and the number of false positive must be reduced as much as possible. Therefore, the objective function f of the target problem is expressed by the following (1), and the purpose is to maximize f.

$$f = v - u \tag{1}$$

v is an evaluation value whose value increases when taps at a more correct time and u is an evaluation value whose value increases when the number of false positives increases. v is represented by (2). From the set of estimated tap times Q, the element that is closest to the actual tap time p is denoted by q^p.

$$v = \sum_{i=1}^{n} g(|p_i - q^{p_i}|) \tag{2}$$

$g(|p - q|)$ is a function that normalizes the difference between time p and q, and becomes 0 value when $|p - q|$ is greater than a constant value r. u is represented by (3).

$$u = \sum_{i=1}^{n} h(|p_i - q^{p_i}|) \tag{3}$$

$h(|p-q|)$ is a function that binarizes the difference between time p and q. It becomes 0 if the value of $|p - q|$ is less than or equal to a constant r, and w otherwise.

IV. Methods

In this section, we propose three kinds of tap recognition methods: TIA, TIAA, and TIAAS. As mentioned in II-E section, existing tap decision methods using thresholding have the problem of misjudges more taps due to tap vibration reverberation. When the amplitude of the input wave exceeds the threshold at time t, if the amplitude in the immediately preceding period also exceeds the threshold, time t may be the reverberation period. Therefore, TIA uses this mechanism to recognize tap more accurately. However, there are cases where TIA cannot cope with high-speed continuous tapping, because the next tap vibration may start before the reverberation of the previous tap disappears. Therefore, TIAA determines whether the amplitude exceeding the threshold is a new tap or a reverberation by comparing it with attenuation degree of the vibration over time. Since these TIA and TIAA can only be applied to time series data where the input wave is either acceleration or sound pressure value, we propose TIAAS, which recognition tap more accurately by using both of these time-series data. In TIAAS, TIAA is applied to the time series data of z-axis acceleration, and TIAA is also applied to the time series data of sound pressure for the time when there is a possibility of tapping, and when both are judged to be tapped, the tap is recognized. In the following sections, TIA, TIAA, and TIAAS are described in detail.

A. TIA

The amplitude of the input wave remains below the threshold for a certain time and then swings positively or negatively, and tap is recognized when it exceeds the threshold. Let A be the average value of z-axis acceleration when the desk is not tapped, which is measured in advance. Let a (> 0) be the acceleration threshold. Let $r_1, r_2, \cdots, r_{n-1}, r_n$ be the acceleration values detected in the b(b should be set appropriately according to the sampling rate of the device) seconds immediately before the current time t. When these values satisfy (4) and the acceleration value r at the current time t satisfies (5), the tap is recognized.

$$A - a \leq r_1, r_2, \cdots, r_{n-1}, r_n \leq A + a \tag{4}$$

$$a < |r - A| \tag{5}$$

Fig. 2 shows a graph of acceleration measured on the desk when tapping the desk once, where the horizontal and vertical axes represent time and z-axis acceleration, respectively. Using this graph, we will explain how TIA recognizes a tap.

In Fig. 2, the time interval between points in the graph is 0.01 s, the current time is time t_2, and suppose b is 0.05 s. The acceleration value between time t_1 and t_2 satisfies (4). Additionally, the acceleration value at the current time t_2 satisfies (5). So the tap is recognized at the time t_2. If the current time is t_3, the tap is not recognized because (4) is not satisfied at time t_2.

When judging using 3-axis acceleration or sound amplitude, A in (4) and (5) is set to 0.

B. TIAA

For the existing method and TIA, the amplitude of the input wave must not exceed the threshold before and after the time of judgment to recognize a tap. For this reason, both of false positives and false negatives are possible when high-speed continuous taps occur. Therefore, we define the degree of attenuation ratio overtime of the amplitude of the input wave to the maximum value as attenuation and use this attenuation degree (hereafter, we simply describe **attenuation**) to recognize a tap. We will use Fig. 3, which shows the acceleration during tapping, to explain attenuation.

In Fig. 3, the amplitude of the acceleration reaches its maximum at time t_1, and the value is $-1.048-(-1.332) = 0.284$. Let this amplitude be 100%. The amplitude at times t_2, t_3, and $t4$ are 0.132, 0.160, and 0.080, respectively, so the attenuation can be calculated as 46%, 56%, and 28%.

For sampling data where the measurement times of acceleration values are not equally spaced, resample them to make them equally spaced using the linear interpolation method. In this method, the threshold of the input wave amplitude is set to a (> 0), and when the input wave amplitude exceeds a, a tap decision is made by TIA. However, if a tap is recognized immediately before k seconds, the percentage of the amplitude of the current input wave $w_{current}$ to the amplitude of the input wave w_{last} at the previous tap time is calculated using (6).

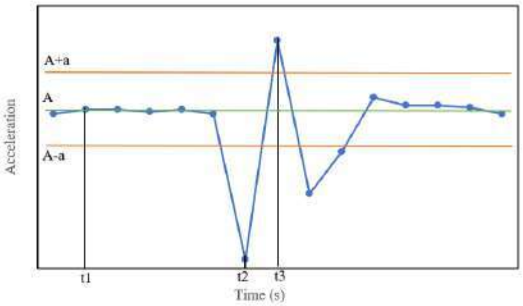

Fig. 2. How TIA recognizes tap

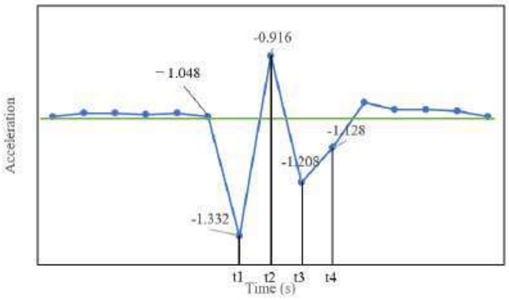

Fig. 3. Calculation of attenuation

$$\text{percentage} = \frac{w_{current}}{w_{last}} \times 100 \tag{6}$$

If the percentage calculated by the (6) is smaller than the predetermined attenuation of the amplitude of the input wave, the tap is not recognized. Fig. 4 shows a graph of acceleration measured on the desk when tapping the desk once, where the horizontal and vertical axes represent time and z-axis acceleration, respectively. Using this graph, we will explain how TIAA recognizes a tap.

In Fig. 4, the time interval between points in the graph is 0.01 s, the current time is time t_a, and suppose k is 0.04 s. At this time, the acceleration value in the k seconds immediately before the current time has not exceeded the threshold a, so the tap judgment is made using TIA. Since the acceleration value of t_1 exceeds a, the tap is recognized at time t_1. Next, when the current time is t_2, since t_1 has been judged as a tap, we move to the tap judgment using the attenuation for t_2. Next, when the current time is t_2, since tap has occurred at time t_1, TIAA recognizes the tap using attenuation. The red graph in the Fig. 4 is attenuation. In a tap recognition using attenuation, the percentage of the amplitude of the acceleration at time t_2 to the amplitude of the acceleration at t_1, the previous tap time, is calculated using (6) and checked to see if it is greater than attenuation. In the case of the Fig4, we check whether the distance from the central yellow-green line at time t_2 is greater in the red graph or the blue graph, and recognize a tap if the distance between red and yellow-green is greater than blue. At time t_2, the distance from the yellow-green line is greater in the red graph, so a tap is not recognized.

C. TIAAS

First, resample the z-axis acceleration data in the same way as TIAA and make the not equally spaced sampled data equally spaced. If TIAA is applied to the z-axis acceleration and recognizes a tap, TIAAS determines that it may be a tap. The same method as in Fig. 4 is used to make the tap possibility decision, and when the distance between the

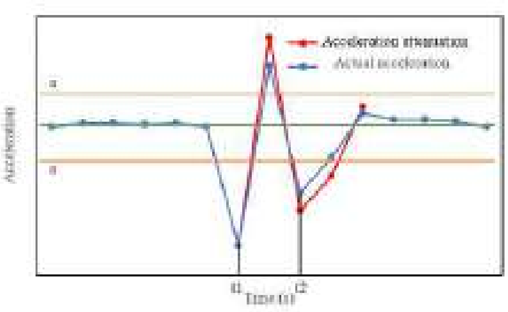

Fig. 4. How TIAA recognizes tap

acceleration value on the red line and the value on the yellow-green line is greater than the blue, the amplitude of the sound for d seconds from the current time is used to recognize the tap. During this time, if the amplitude of the sound exceeds the threshold c, the tap is recognized.

V. Experiment

We used two Nexus 9 tablets. One of them was used to obtain the correct answer data of the tapping time. It was placed lean against an object on the desk and its camera took videos of the tapping on the desk. The other one was placed randomly on the desk and measured 3-axis acceleration with Science Journal (Google app). Acceleration was sampled not equally spaced at about 16 Hz. In TIAA and TIAAS, acceleration was resampled at 16 Hz. Linear interpolation was used as the resampling algorithm. The sound was recorded at 44100 Hz extracted from the video and downsampled to 882 Hz. The time of the actual tapping was identified from the video image and was used as the correct answer data.

As an evaluation criterion for each tap recognition method, we explain the settings of v and u in the objective function described in section III. Let p be the time when the tap actually occurred. When the time when the tap is recognized to be $p \pm 0.033$ seconds (recognition range 1), the evaluation score is 1.01 points; when the time is $p \pm 0.066$ seconds (recognition range 2), the score is 1 point; and when the time is $p \pm 0.1$ seconds (recognition range 3), the score is 0.5 points. We calculate the total score v. However, if more than one score can be obtained, the one with the lower recognition range number is given priority, and no duplicate scores are obtained. If some taps are recognized around the time p, only the one with the earliest time is given a score, and the other tap recognitions are given 0 points. The number of false positives is u, and the number of the tap scored 0 points in the calculation of v is substituted. Each tap recognition method is evaluated by f in equation (1).

Fig. 5, shows how calculate score. Time t is actual tap time and time t_1, t_2 and t_3 are recognized tap time. The yellow, orange, and yellow-green range in Fig. 5 are recognition range 1, 2, and 3, respectively. Recognition range 1, 2, and 3 cover t_1, t_2, and t_3, respectively. In this case, the total score is 0.5 points for t_1, which means that t_2 and t_3 were false positive.

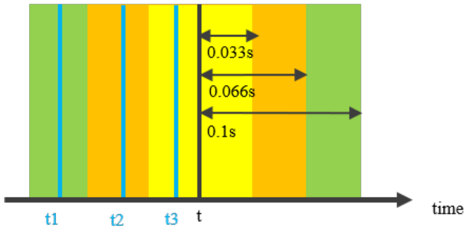

Fig. 5. Example of score calculation

A. Experimental

While increasing the BPM by 10 between 60 and 700, tap on the desk with one hand when the BPM was 60-440 and with both hands alternately when the BPM was 450-700 at equal intervals to the sound of the metronome application for each BPM. The total number of taps is nine at any BPM, one for time synchronization of the acceleration and sound, and eight for recognizing taps. For example, when the BPM is 60, after tapping once to set the time, the second tap is made after sufficient time has elapsed. The third tap is made just one second after the second tap, the fourth tap is made just two seconds after the second tap, and it takes seven seconds from the second tap to the last tap. We set a, b, c, d, T_{LAT}, a_{THT}, and T_{DUR} so that the evaluation value f is closest to the optimal solution of 8.08 for each method.

B. Preliminary experiment

We determined attenuation by measuring the z-axis acceleration, 3-axis acceleration, and sound for 100 taps. Fig. 6, Fig. 7, and Fig. 8 show the maximum and average attenuation values of z-axis acceleration, 3-axis acceleration, and sound amplitude, respectively. Fig. 9 shows a graph of the minimum attenuation of the z-axis acceleration. In TIAA, the percentage of the amplitude of the current input wave to the amplitude of the input wave at the previous tap time is calculated, and if the percentage is larger than the values in Fig. 6, Fig. 7, and Fig. 8, the tap is recognized. In TIAAS, the percentage of the amplitude of the current z-axis acceleration to the amplitude of the z-axis acceleration at the previous tap time is calculated,

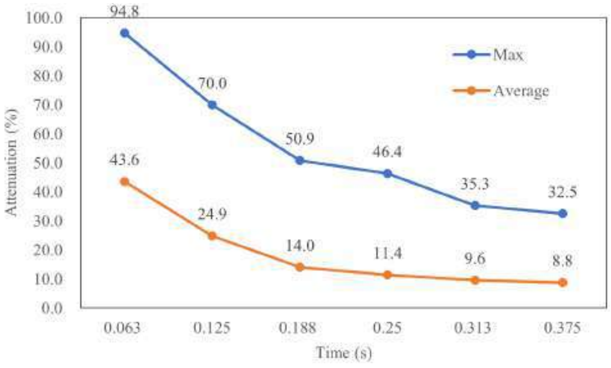

Fig. 6. Attenuation of z-axis acceleration

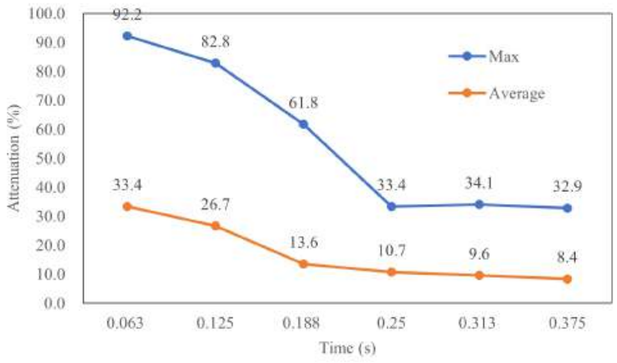

Fig. 7. Attenuation of 3-axis acceleration

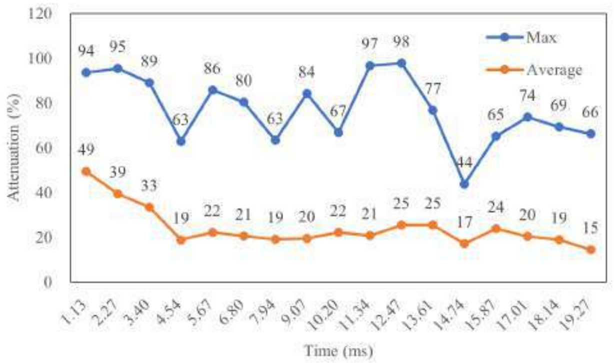

Fig. 8. attenuation of sound amplitude

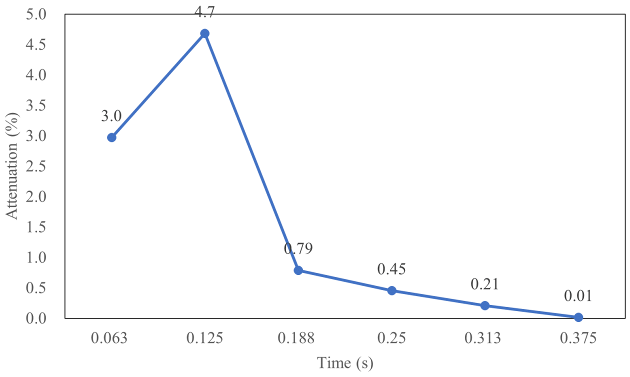

Fig. 9. Minimum attenuation of z-axis acceleration

and if the percentage is larger than the values in Fig. 9, there is the possibility of a tap.

VI. Results

A. Comparison of the results of each method

The result for each method is shown in Table I. The existing method used $T_{LAT} = 0.016s$. TIA used $b = 0.016s$. TIAA used the maximum value of the attenuation is used in TIAA, and when in TIAAS. The average number of false positives and evaluation value f are shown in Table I. Compared to the existing method, TIA was able to reduce the number of false positive for any sensor data and improved the problem of duplicate tap recognitions in a single tap. In particular, when using sound in TIA, f was high. We confirmed that the taps were almost completely recognized. However, TIA using only sound cannot work in a noisy environment. On the other hand, f of TIA using acceleration was lower than the existing method when the BPM was high. This is because recall value is greatly reduced due to the influence of reverberation. TIAA showed worse results than the existing method in terms of the number of false positives and f for recognitions based on z-axis acceleration and sound amplitude. The results using 3-axis acceleration in TIAA were better than the results using 3- acceleration using the existing method, but worse than TIA. TIAAS was able to achieve a higher f than the existing method, TIA using acceleration, and TIAA. Besides, TIAAS was able to reduce the number of false positives when using any sensor data and improved the problem of multiple taps recognitions in a single tap. The details of the results are described in the VI-B section and beyond.

TABLE I
THE NUMBER OF FALSE POSITIVE AND EVALUATION VALUE f IN EACH METHOD

Method		false positive	f
the existing method	z-axis	0.81	6.11
	3-axis	2.80	3.78
	sound	1.73	5.92
TIA	z-axis	0.10	5.82
	3-axis	0.16	5.45
	sound	0.12	7.95
TIAA	z-axis	0.92	3.88
	3-axis	1.46	3.51
	sound	22.55	-15.29
TIAAS		0.27	7.32

B. The existing method

We set T_{LAT} to 0.016 s and T_{DUR} to be long enough to make a tap recognition. The average of a_{THT} when f was the highest for each sensor data is shown in Table II.We set a_{THT} to maximize f at each BPM, and evaluation values when recognizing taps is shown in Fig. 10.In addition, T_{LAT}, T_{DUR}, and a_{THT} were set so that evaluation value would be the highest for each BPM. The evaluation values are shown in Fig. 11.

C. TIA

We set b to 0.016 s. The average of a when f was the highest for each sensor data is shown in Table III. We set a to maximize f at each BPM, and f when recognizing taps is shown in Fig. 12. In particular, when using sound had a high evaluation value. However, f using acceleration was lower than the existing method when the BPM was high. In addition, a and b were set so that the evaluation value would be the highest for each BPM. The evaluation values are shown in

TABLE II
a_{THT} WHEN f IS THE HIGHEST IN THE EXISTING METHOD

z-axis (m/s^2)	3-axis (m/s^2)	sound
0.36	0.52	11992

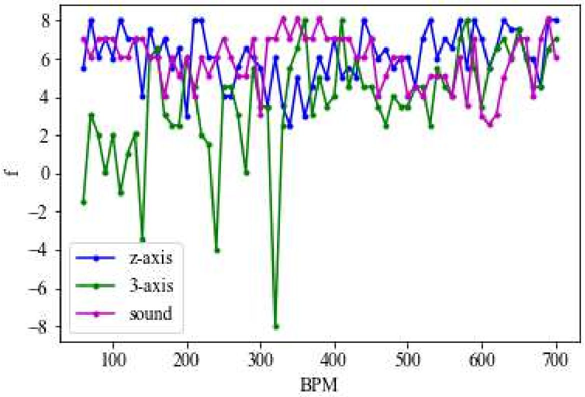

Fig. 10. Results of the existing method

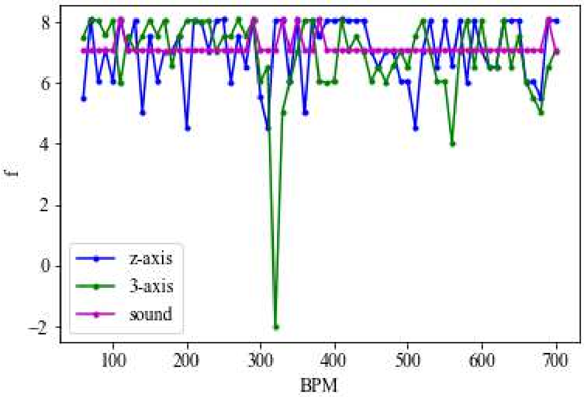

Fig. 11. Results when parameters are set to the optimal in the existing method

TABLE III
a WHEN f IS THE HIGHEST IN TIA

z-axis (m/s^2)	3-axis (m/s^2)	sound
0.37	0.62	7192

Fig. 13. The result is almost the same as when b is set to 0.016 s.

D. TIAA

For recognitions based on acceleration, $k = 0.375s$. For recognitions based on sound amplitude, $k = 19.27ms$. The average of a when f was the highest for each sensor data in TIAA using average attenuation is shown in Table IV. We set a to maximize f at each BPM. The evaluation values are shown in Fig. 14. Using the average attenuation drastically increased the number of times multiple taps recognitions in a single tap, resulting in a low f, especially for recognition using the sound amplitude. The average of a when f was the highest for each sensor data in TIAA using maximum attenuation is shown in Table V. We set a to maximize f at each BPM The evaluation values are shown in Fig. 15. Compared to using average attenuation, the number of false positives was reduced, resulting in a higher f. However, since the number of tap recognitions was reduced, f was lower than that of TIA.

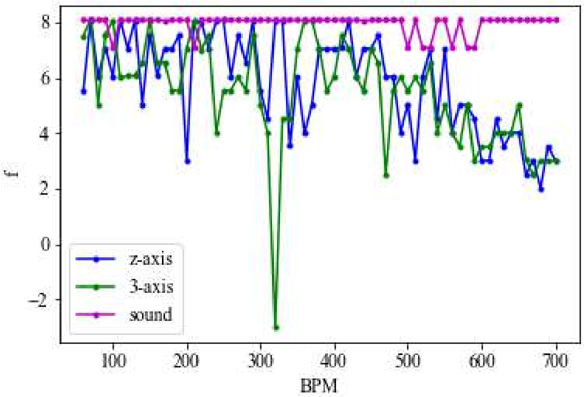

Fig. 12. results of TIA

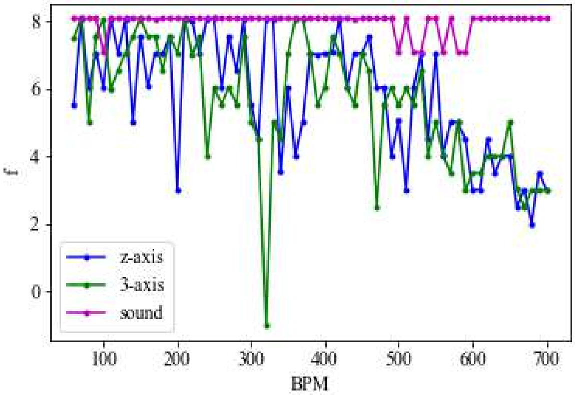

Fig. 13. Results when parameters are set to the optimal in TIA

TABLE VI
a, c, AND d WHEN f IS THE HIGHEST IN TIAAS

$a(m/s^2)$	c	d(s)
0.37	1953	0.021

VII. Conclusions

To solve the problem of duplicate tap recognition by the existing tap-recognition method, we proposed new methods; TIA, TIAA, and TIAAS. The results of the experiments showed that compared to the existing method, TIA was able to reduce the number of false positives and improved the problem of duplicate tap recognitions in a single tap. When using sound, TIA was able to recognize taps almost perfectly, but when using acceleration, the evaluation value was lower than the existing method due to the influence of reverberation. TIAA showed worse results than the existing method for recognitions based on z-axis acceleration and sound amplitude. TIAAS was able to achieve a higher f than the existing method, TIA using acceleration, and TIAA and improved the problem of duplicate tap recognitions in a single tap.

***Abstract*—Covid has killed millions, and millions more are being infected every day. Severe infection causes Pneumonia associated with high pulse and breathing rates, and low blood oxygen. Pulse rate and blood oxygen are two parameters that doctors use to diagnose and measure Pneumonia and Bronchitis. Sensors for their measurement are widely available in developed countries, but their costs are prohibitively high for wide penetration in developing countries. Hardware prototypes incorporated with embedded software and IoT have been developed previously, but their costs have not been brought down sufficiently for wide penetration. We developed and tested the performance of an Atmel ATmega 328P MCU and MAX30100 sensor kit-based pulse rate and blood oxygen monitor. We applied the device on 12 subjects and compared the data with a commercially available, Rossmax SB150 pulse oximeter. A minimal deviation of 0.8175% for pulse rate and 0.425% for blood oxygen was obtained that endorses the accuracy of our algorithm and implementation. Cost analysis shows that implementation can be done at a cheap rate of about US$ 12 only.**

***Keywords*—** *Covid, pulse, blood oxygen, Pneumonia, Bronchitis, monitoring, cheap, oximeter, etc.*

I. Introduction

With coronavirus cases and deaths soaring across the world, the need for monitoring health parameters has increased greatly. Healthcare systems have been operating at their limits worldwide, coping with increasing numbers of patients. Infected patients have a higher pulse rate and lower blood oxygen. Pulse rate and blood oxygen may need to be monitored to prevent death. To make monitoring available to more people, sensor-based non-invasive devices have been developed that can be used at home. Thus researchers have great interest to develop measurement devices for mass production with high accuracy level and lower cost.

Due to the low penetration of health technology, especially in under-developed countries, low-cost oxygen measurement devices have been of interest in the literature [1]. IoT based low-cost remote pulse rate and blood oxygen monitoring has also received attention for telemedicine [2, 3, 4]. Though, most devices obtained good feedback, ensuring the validated performance of devices has great significance for quality assessment and diagnosis [5, 6, 7]. The goal of this study is twofold. One is to develop a low-cost device to measure pulse rate (BPM) and blood oxygen (%SpO2). The other is to compare the performance of the developed device with a standard device, Rossmax SB150.

Infrared (IR) and LEDs have sensor-based applications, known as Photoplethysmography for the measurement of heart rate and blood oxygen saturation. The MAX30100 has integrated Infrared (IR) and Red LED sensors at a low price. While many researchers have developed non-invasive blood oxygen saturation and pulse rate measurement devices [8, 9, 10, 11, 12, 13, 14], we developed a MAX30100-based portable system at the lowest possible cost and analyzed the performance on twelve subjects. A number of sensor-based monitoring systems have already been developed for affordable applications [15, 16, 17, 18], but keeping in mind the issues of sustainability and quality [19, 20], we have conducted a performance analysis after the implementation.

A recent study varied current through the Red LED of MAX30100 to measure blood oxygen, showing that acceptable performance is obtained at 14.2 mA [21]. Another study supported reducing the motion artefact of the sensor kit using an acceleration sensor [22]. A few subjects were assessed showing a high deviation of 5% for oxygen and 7% for pulse rate [23]. This was insufficient for correct estimation and diagnosis and the cost was high at US$ 20. To evaluate the performance of the sensor, a group of researchers analyzed data from 5 subjects and assessed the mean deviation [24]. We developed the device at a lower cost with higher accuracy. We analyzed a set of practical data from 12 subjects finding a deviation of only 0.8175% for pulse rate (BPM) and 0.425% for SpO2 (%). The cost analysis shows that our device costs US$ 12 only, which is cheaper than most previously implemented devices. We found minimal percentage error of the device and sensor data, ensuring a more effective performance than other systems to diagnose Covid.

II. Methodology

The objective was to study the current price of the available systems/devices and implement them at a low cost. Several

MAX30100 interfacing with Atmel ATmega 328P MCU
C/C++ firmware on Ardunio IDE
Data monitor, collection and validation

Fig. 1. Block diagram of pulse rate (BPM) and blood oxygen saturation (%SpO2) monitor

steps were taken for developing a prototype.

- We studied available devices on various e-commerce platforms. We focused on device materials, designs, prices, specifications, availability, and carried out a comparative study.
- We analyzed the cost, quality of the device and listed the components to purchase from online and physical shops.
- We studied previously published papers and focused on the most cited ones on ResearchGate and Google Scholar.
- We simulated the system before implementing the hardware prototype.

Available sensors and tools of acceptable quality and low cost were purchased from online and physical shops. C and C++ coding were applied on Atmel ATmega 328P MCU (Arduino UNO) using Arduino IDE. The same algorithm can be used for extending the prototype i.e. hardware implementation for other parameters. Our implementation steps are illustrated in figure 1.

III. Experimental Hardware Setup

Using the methodology in the previous section, we collected and verified the functioning of the sensors and microcontroller unit. We interfaced MAX30100 with Atmel ATmega 328P MCU. The analog data was observed on the serial monitor. We coded for the ADC to convert the analog data to digital. We calculated blood oxygen saturation (%SpO2) and then pulse rate (BPM) (equation 1).

$$\%SpO2 = \frac{\log(\frac{redACValueSqSum}{samplesRecorded})}{\log(\frac{irACValueSqSum}{samplesRecorded})} x100 \qquad \ldots\ (1)$$

Following a lookup table, we determined the oxygen saturation as (SpO2= SpO2LUT [index]). We observed the data on a serial monitor on the Arduino IDE. We then collected data from 12 subjects of different ages and validated comparing with a commercially available pulse oximeter, Rossmax SB150.

Finally, we calculated the error percentage to analyze the performance of our system. The sensor kit and its functional principle are shown in the following figures 2 and 3 respectively. Figure 2 upholds the sensor and 3 demonstrates how it functions (datasheet). Figure 4 shows the implemented device while being applied on the subject.

IV. Data Analysis: Collection and Validation

We experimented with the implemented device on several subjects of different ages. The collected data verified the accuracy of the sensor. We also validated the data comparing with a commercially available device, Rossmax SB150. Data set on the same parameters were also validated in [21] using NewTech PM100. We found a minimal deviation with an acceptable range of 0.8175% for pulse rate (BPM) and 0.425% for SpO2 (%) as depicted in the following Table I. The error was calculated as the following equation 2.

$$\text{deviation} = \frac{\text{experimental value} - \text{accepted value}}{\text{accepted value}} x100\% \qquad \ldots(2)$$

Figures 5 and 6 illustrate the validation of the collected data from various subjects that compare well with the pulse rate and oxygen saturation from a commercially available pulse oximeter. Figure 5 shows the number of subjects (X-axis) and corresponding pulse rates (Y-axis) collected from

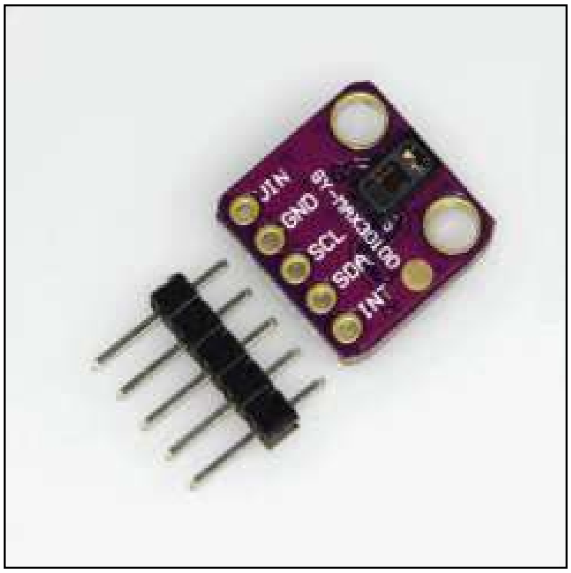

Fig. 2. MAX30100 sensor kit

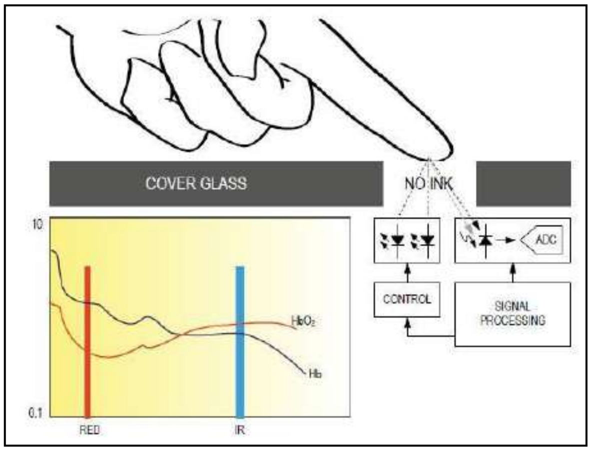

Fig. 3. Functional principle of the sensor (datasheet, 2019)

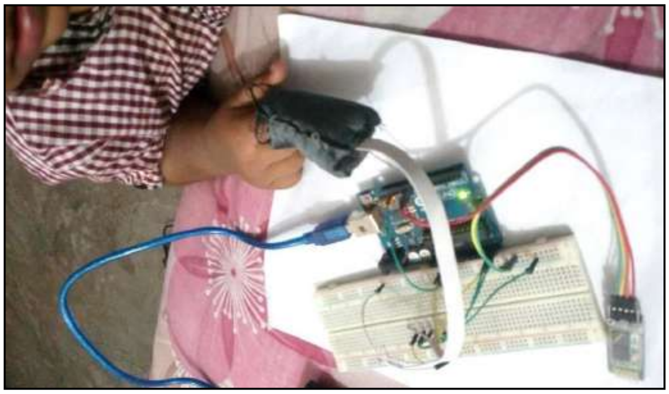

Fig. 4. Application of implemented Oximeter on children that measures SpO2 (%)

the implemented and reference devices, demonstrating a very marginal deviation in the logarithmic scale. Figure 6 shows the number of subjects (X-axis) and corresponding blood oxygen (Y-axis) from the implemented and reference devices, showing very close agreement in the logarithmic scale.

Table I. Collected data with minimal error %

Sub	Age	Heartrate (BPM)		Deviation %	SpO2 (%)		Deviation %
		Experimental	*Accepted*		*Experimental*		*Accepted*
1	29	67	66	1.5	98	98	0
2	24	85	85	0	97	98	-1.02

V. Scopes and Opportunities

While the number of dead and infected from the Covid-19 pandemic soaring across the world, the detection of Pneumonia is a global priority. Pneumonia kills more than 1.5 million children every year. Rural areas across low resource countries do not have enough qualified doctors and resources. People have to travel to cities for proper medical treatment, which they can barely afford. The possible applications may also be extended to the following categories.

A. Patient Monitoring

The developed device can be commercially deployed for monitoring patients. With the availability of telemedicine, wireless health monitoring systems have good potential in healthcare.

B. Telemedicine Application

Several organizations may come up with telemedicine programs. Such a tool has many possibilities to be incorporated as a remote data monitor in telemedicine.

C. Biomedical Innovation for Larger Application

This project can also be expanded as part of larger biomedical applications. Several sensors for other health parameters can be integrated.

VI. Cost Feasibility

As seen in the cost breakdown below, the implemented device is the cheapest among all other available devices. Implementation cost is around US$ 12 including the MCU, sensor and instrumentation.

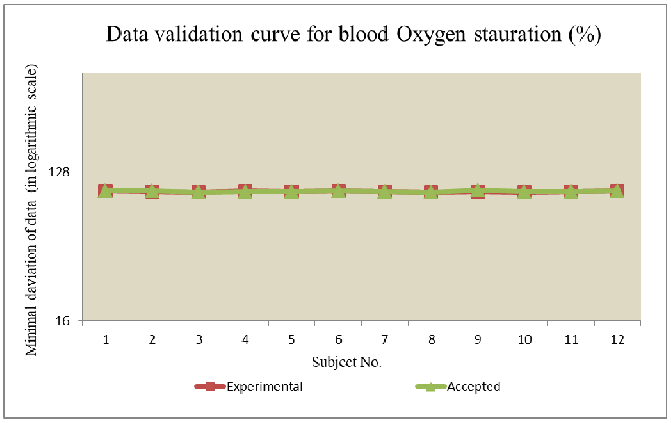

Fig. 6. Minimal deviation in collected blood oxygen saturation (%SpO2) with Rossmax SB150 pulse oximeter.

Table II illustrates the breakdown of cost:

TABLE II. Cost analysis

Apparatus	***Cost (US$)***
Atmel ATmega 328P MCU	4.00
MAX30100	7.00
Others	1.00
Total	12.00

Large scale implementation may greatly reduce the cost, owing to economies of scale. This pulse and blood oxygen data are prerequisites in disease detection and health condition analysis. There are widespread opportunities for further research and development. Some possible applications include remote Covid symptom detection, mobile app-based telemedicine, heart disease detection and analysis, wireless patient monitoring system, biomedical lab applications in universities and low-cost health checkup monitoring system for low resource countries. Research is being done to develop an Artificial Intelligence wearable health device, which can be a breakthrough in the field of healthcare.

VII. Conclusion

A device to measure heart rate and monitor blood oxygen (SpO2) has been developed with lower cost and higher credibility. The results and analysis validate the accuracy of the sensor. There is the possibility of integrating more parameters like breathing rate, chest-in-draw, body temperature etc. to develop even larger monitoring and detection system to fight Pneumonia and Covid. Cost analysis shows that the device is affordable. It is expected that this paper will contribute to the development of affordable technologies for measurement of health parameters.

***Abstract*— This paper presents some limitations of the classical concept of loop gain in many mathematical motion models of the real objects. It is well known that there are some advanced concepts in control theory and a lot of them are very heavy on the loop gain. Therefore, the loop gain is heard in many topics like frequency compensation, phase-gain margins, negative feedback systems. However, the loop gain cannot be used to analyze the overshoot phenomenon in many feedback amplifiers because it doesn't show the operating regions of high-order mechatronic systems. In addition, the theoretical calculation, the laboratory simulation and the practical measurement of loop gain are not unique. As a result, this is the biggest limitation in mathematical models of motion that a lot of engineers have trouble with loop gain. To overcome some disadvantages of the loop gain, the use of the self-loop function allows engineers to do the ringing test simpler because it is easily verified in MATLAB calculator, SPICE simulator, and Network Analyzer. In order to extend the application range of the Nichols chart of self-loop function in high-order mechatronic systems, the feasibility of complex functions and the explanation of overshoot phenomena are described in detail. It is shown that complex functions are useful tools for mathematical motion models of mechatronic systems.**

***Keywords*— Ringing Test, Nichols Chart, Phase Margin, Negative Feedback, Self-loop Function, Loop Gain**

I. Introduction

A. Motivation

Recent researches show that ringing occurs in many high-order mechatronic systems [1]. Ringing or overshoot makes these systems unstable. Hence, a general stability test for mechatronic systems should be introduced. The stability test using loop gain is a valuable tool for analyzing the stable region of high-order mechatronic systems. However, engineers often find the loop gain confusing and difficult to understand because the theoretical analysis and the practical measurement of the phase margin are not unique. In other words, the values of loop gain in these feedback systems are the assumption values. There are some limitations of the concept of loop gain because it is only used in classical control theory [2]. In addition, the operating regions of a high-order mechatronic system are not shown on the Nichols chart of loop gain.

In addition, there are some limitations of numerical methods. Differential equations are normally derived on the basis of a rate of change (velocity) or a second derivative (acceleration) that give a relation based on a physical law such as superposition principle. Expressing the force as a function of time allows one to solve for the acceleration, integrate that to get velocity, and integrate that to get position. Some differential equations are not as well-behaved, and show singularities due to a failure to model the problem correctly, or a limitation of the model that was not apparent. Some differential equations can be solved analytically in closed form, but most have to be approximated by numerical procedures, which can be unstable. Therefore, properties of complex functions are proposed to do the ringing test or overshoot test for high-order mechatronic systems [3].

The characteristics of complex functions give a whole new perspective to math-intensive mechatronic courses at most universities. A mathematical motion model captures the relationship between the signal source and the transmission network [4]. The principal motivation comes from the wide applications of complex function.

It is a main design methodology capable of providing theoretical examination of the operating region of a high-order mechatronic system. In this study, the results here not only provide a theoretical basis for analytically justifying some conventional concepts of existing complex functions but also open up the possibility of investigating the operating regions of high-order mechatronic networks by simply plotting the self-loop function.

B. Objectives and paper organization

Overshoot phenomena can be seen in many mathematical motion models of high-order mechatronic systems [5]. The impact of the overshoot on the mechatronic systems is usually addressed in the term “parasitic elements” [6]. Therefore, it is clearly understood that the occurrence, peak value, additional delay, and other damaging effects cannot be predicted or removed easily [7]. To do the ringing test for high-order mechatronic systems, a square wave is usually used to put in the input port [8]. Depending on the operating region of a high-order system, the output waveforms can be over-damping, or critical damping, or under-damping as shown in Fig. 1. The ringing test will be analysed in detail in section III.

The use of complex functions is an essential theory in many motion models of high-order mechatronic systems. In addition, transfer function is covered in many courses such as control theory, network analysis theory, but the complexity of network topologies requires to develop a specific approach in order to fully analyse a real circuit within the framework of complex function theory [9]. It must be stressed that complex function is present in all systems; therefore, it is important that a good understanding of complex function concepts in mechatronic systems should be developed [10].

This research focuses on the various mechatronic networks, and their operating regions. This paper contains six sections. The research background for some motion models in mechatronic systems is presented in Section II. The limitations of loop gain are discussed in Section III. Several simulation results and some practical measurements of the ringing test are shown in Section IV. Future work and conclusion are presented in Sections V.

II. Research Background

A. Limitations of loop gain

This section points out some limitations of loop gain in some motion models in the mechatronic systems. Many challenges behind the ringing test for high-order mechatronic systems arise from the mathematical models of motion using the term "loop gain" [11]. A simplified transfer function is rewritten as in Eq. (1). Here, Aβ is called loop gain, A is the numerator function and β is the return-ratio. Fig. 2 shows the block diagram of a general control system. The input and output signals of the adaptive feedback systems can be either non-cyclic or periodic with the frequency variable [12].

$$H = \frac{A}{1 + A\beta} \approx 1 \qquad (1)$$

In an adaptive feedback control system, the reference signal and the feedback signal are subtracted as shown in Fig. 3. In general, a comparator is used to calculate the difference between the reference signal and the feedback signal [13]. In other words, the output signal is sampled and then fed back to the input to form an error signal that drives the plant or the actuating system. The actuating system is usually modeled by an open-loop function. The error signal can be used to eliminate or at least considerably reduce the effects of the variations of the actuating system [14].

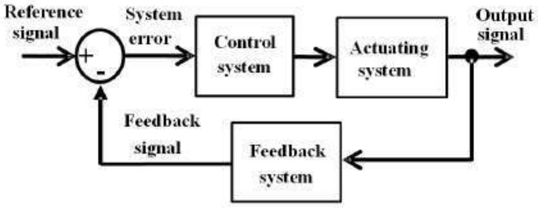

Fig. 2. Simplified model of a general adaptive feedback control system.

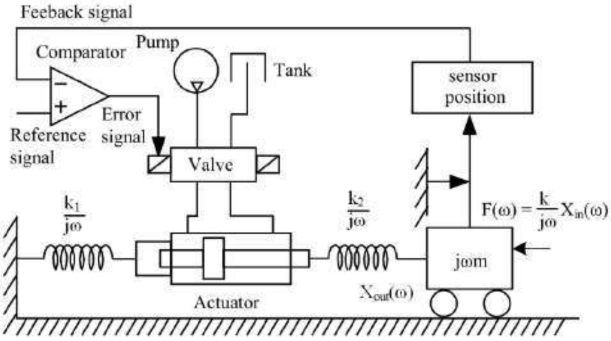

Fig. 3. Block diagram of a mechanical control system.

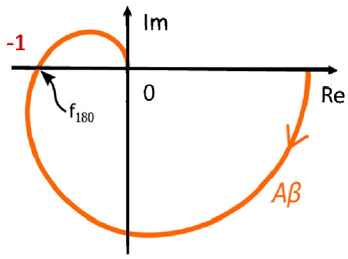

Fig. 4. Nyquist plot of a loop gain in an adaptive feedback system.

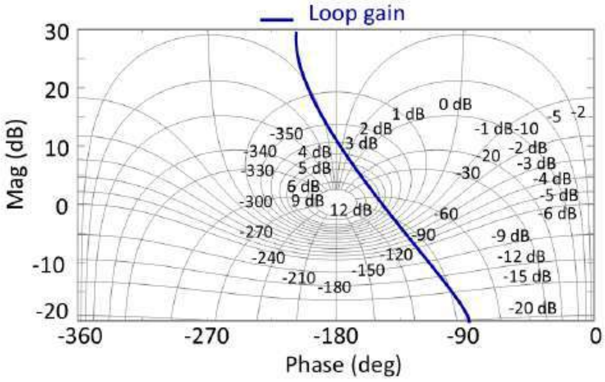

Fig. 5. Nichols plot of a loop gain in an adaptive feedback system.

Fig. 4 shows the conventional Nyquist chart of a loop gain in a control system. As Nyquist's stability condition does not show the operating regions of high-order mechatronic systems, the Nyquist diagram of loop gain cannot be applied for these systems. It is very difficult to derive and measure the exact value of the loop gain because it is an approximation model in MATLAB simulation [15]. In addition, the concept of loop gain is found in many negative feedback systems such as unity gain amplifiers, inverting amplifiers, negative feedback amplifiers while an exact value of loop gain is still not shown [16].

Fig. 5 shows the conventional Nichols plot of a loop gain in an adaptive feedback system. It is not widely used in both SPICE simulations and practical measurements because it is very difficult to predict loop gain when the properties of input and output signals are different. Hence, the characteristics of the control network and the linear network are significantly different [17].

B. Roles of complex functions

Complex functions give various meaningful insights in the motion models of mechatronic systems. They are applied in electrical, electronic, and mechanical systems [18]. Mechatronics in general would involve more physics with the math being somewhat trivial compared to complex functions. The transfer function H(ω) of a mechatronic network is the ratio of the output signal $V_{out}(\omega)$ to the input signal $V_{in}(\omega)$ as a function of the frequency [19]. A simplified transfer function is rewritten as in Eq. (2), where A(ω) is the numerator function, and L(ω) is the self-loop function. The phase margin at unity gain of the self-loop function shows the operating region of a high-order mechatronic system.

$$H(\omega) = \frac{V_{out}(\omega)}{V_{in}(\omega)} = \frac{A(\omega)}{1 + L(\omega)} \qquad (2)$$

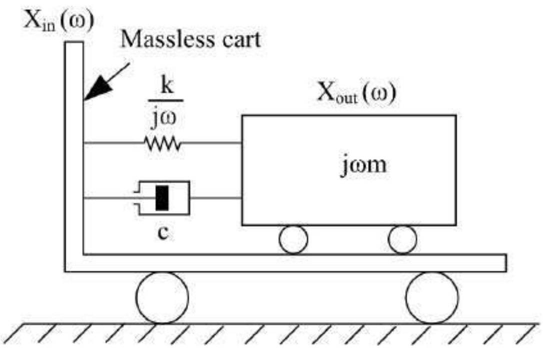

Fig. 6. Simplified model of a spring-mass dashpot system.

C. Behaviors of a second-order mechanical system

This section investigates the behaviors of a second-order mechanical system. A spring mass system is usually used to represent a complex mechanical system as shown in Fig. 6. Based on the superposition principle, Newton's first law points out the relationship between force and motion in a specific transmission space [20]. After applying the superposition principle at the output node for the translational system, the node equation is given in Eq. (3).

$$\left[j\omega m + c + \frac{k}{j\omega}\right] X_{out}(\omega) = \left[c + \frac{k}{j\omega}\right] X_{in}(\omega); \qquad (3)$$

Then, the transfer function and the self-loop function of this system are given in Eq. (4).

$$H(\omega) = \frac{X_{out}(\omega)}{X_{in}(\omega)} = \frac{b_0 j\omega + 1}{a_0 (j\omega)^2 + a_1 j\omega + 1}; \qquad (4)$$

$$L(\omega) = a_0 (j\omega)^2 + a_1 j\omega; \;\; b_0 = \frac{c}{k}; a_0 = \frac{m}{k}; a_1 = \frac{c}{k}$$

The operating regions of a second-order system are over-damping, critical damping, and under-damping as shown in TABLE I. In a 2nd-order mechatronic system, the operating regions are over-damping, critical damping, and under-damping. In case of under-damping, the overshoot will cause the ringing [21]. Three typical cases of a second-order system are given to determine the operating region of the system as shown in Eq. (5). Here, the coefficients of the transfer functions are under-damped (1:1:1), critically damped (1:2:1), and over-damped (1:3:1).

The Bode plot of these transfer functions, the Nichols plot of these self-loop functions are shown in Fig. 7, and Fig. 8, respectively. The phase margin is observed at unity gain of the self-loop function. The simulation results of the transfer functions and the self-loop functions are summarized in TABLE II.

$$H_1(\omega) = \frac{1}{(j\omega)^2 + j\omega + 1}; L_1(\omega) = (j\omega)^2 + j\omega;$$

$$H_2(\omega) = \frac{1}{(j\omega)^2 + 2j\omega + 1}; L_2(\omega) = (j\omega)^2 + 2j\omega; \qquad (5)$$

$$H_3(\omega) = \frac{1}{(j\omega)^2 + 3j\omega + 1}; L_3(\omega) = (j\omega)^2 + 3j\omega;$$

TABLE I. BEHAVIOURS OF 2ND-ORDER SELF-LOOP FUNCTION

Element	Value	
$\lvert L(\omega)\rvert$	$\omega\sqrt{(a_0\omega)^2 + a_1^2}$	
$\theta(\omega)$	$\frac{\pi}{2} + \arctan\frac{a_0\omega}{a_1}$	
Case 1	Over-damping ($\Delta = a_1^2 - 4a_0 > 0$)	
$\omega_1 = \frac{b}{2a}\sqrt{\sqrt{5}-2}$	$\lvert L(\omega_1)\rvert > 1$	$\pi - \theta(\omega_1) > 76.3^o$
Case 2	Critical damping ($\Delta = a_1^2 - 4a_0 = 0$)	
$\omega_1 = \frac{b}{2a}\sqrt{\sqrt{5}-2}$	$\lvert L(\omega_1)\rvert = 1$	$\pi - \theta(\omega_1) = 76.3^o$
Case 3	Under-damping ($\Delta = a_1^2 - 4a_0 < 0$)	
$\omega_1 = \frac{b}{2a}\sqrt{\sqrt{5}-2}$	$\lvert L(\omega_1)\rvert < 1$	$\pi - \theta(\omega_1) < 76.3^o$

TABLE II. SIMULATION RESULTS OF A 2ND-ORDER MECHANICAL SYSTEM

Case	Over-damping	Critical damping	Under-damping
Magnitude (transfer function)	**-12 dB**	**-6 dB**	**1 dB**
Phase margin (self-loop function)	**82° (observed at 98°)**	**76.3° (observed at 103.7°)**	**35° (observed at 145°)**

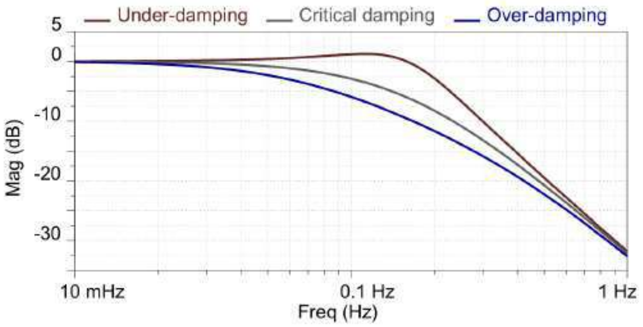

Fig. 7. Bode plot of the 2nd-order transfer function of a mechanical system.

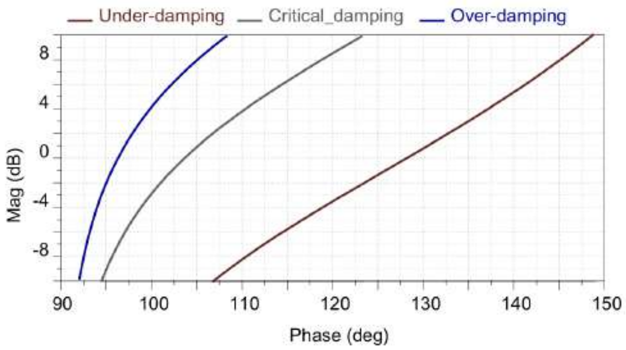

Fig. 8. Nichols chart of the 2nd-order self-loop function.

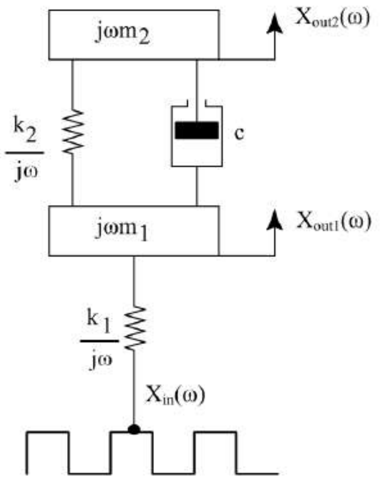

Fig. 9. Simplified model of a suspension system.

D. Operating regions of a fourth-order mechanical system

In this section, the behaviours of a 4th-order suspension system are investigated. In general, three basic types of suspension components are linkages, springs, and shock absorbers [22]. Fig. 9 shows a simplified model of a suspension system. Assume that displacements $X_{out1}(\omega)$ and $X_{out2}(\omega)$ are measured from respective mass positions in the absence of the input $X_{in}(\omega)$. Apply the superposition principle to the present system, the node equations are given in Eq. (6).

$$\begin{aligned}&\left(\frac{k_1}{j\omega}+m_1 j\omega+c+\frac{k_2}{j\omega}\right)X_1(\omega)=\left(c+\frac{k_2}{j\omega}\right)X_2(\omega)+\frac{k_1}{j\omega}X_{in}(\omega);\\&\left(m_2 j\omega+c+\frac{k_2}{j\omega}\right)X_2(\omega)=\left(c+\frac{k_2}{j\omega}\right)X_1(\omega);\end{aligned}\qquad(6)$$

Hence, the transfer functions and the self-loop function of this system are given in Eq. (7). The values of the constant variables of the suspension system are given in TABLE III. The use of Pascal's triangle is a simple way to calculate the binomial coefficients of a high-order mechatronic system as shown in TABLE IV. Three typical cases of a 4th-order system are given to determine the operating region of the system as shown in Eq. (8). Here, the coefficients of these transfer functions are under-damped (1:2:3:2:1), critically damped (1:4:6:4:1), and over-damped (1:9:10:9:1).

$$\begin{aligned}&H_1(\omega)=\frac{X_1(\omega)}{X_{in}(\omega)}=\frac{b_0(j\omega)^2+b_1 j\omega+1}{a_0(j\omega)^4+a_1(j\omega)^3+a_2(j\omega)^2+a_3 j\omega+1};\\&H_2(\omega)=\frac{X_2(\omega)}{X_{in}(\omega)}=\frac{b_1 j\omega+1}{a_0(j\omega)^4+a_1(j\omega)^3+a_2(j\omega)^2+a_3 j\omega+1};\\&L(\omega)=a_0(j\omega)^4+a_1(j\omega)^3+a_2(j\omega)^2+a_3 j\omega;\end{aligned}\qquad(7)$$

III. Behaviors of Feedback Amplifier Networks

A. Loop gain and self-loop function of inverting amplifiers

This section points out the differences between the loop gain and the self-loop function in the inverting amplifiers. Figs. 12 and 13 show the simplified models of two types of the inverting amplifier which are used in many electronic systems [23]. The open-loop function A(ω) of the op amp is described in Eq. (9).

$$A(\omega)=\frac{10^5}{1+j\dfrac{\omega}{2*10^2\pi}}; \qquad (9)$$

Eq. (10) gives the node equation at node V_A in the single-ended inverting amplifier which is derived based on the superposition principle.

$$V_A\left(\frac{1}{R_1}+\frac{1}{R_2}\right)=\frac{V_{in}}{R_1}+\frac{V_{out}}{R_2};\ -V_A A(\omega)=V_{out}\ ; \qquad (10)$$

Then, the transfer function and the self-loop function of this amplifier are given in Eq. (11).

$$H(\omega)=\frac{-\dfrac{R_2}{R_1}}{1+j\dfrac{\omega}{2*10^7\pi}\left(1+\dfrac{R_2}{R_1}\right)+\dfrac{1}{10^5}\left(1+\dfrac{R_2}{R_1}\right)}\approx-\frac{R_2}{R_1}; \qquad (11)$$

$$L(\omega)=j\frac{\omega}{2*10^7\pi}\left(1+\frac{R_2}{R_1}\right)+\frac{1}{10^5}\left(1+\frac{R_2}{R_1}\right);$$

Fig. 14 shows the loop gain in an inverting amplifier. In an inverting amplifier, the loop gain shows the gain reduction from the magnitude of the open-loop function to the magnitude of the inverting amplifier while the phase margin of the self-loop function indicates the operating region of this amplifier as shown in Fig. 15. The phase margin of this inverting amplifier is 90-degrees, this amplifier is absolutely stable.

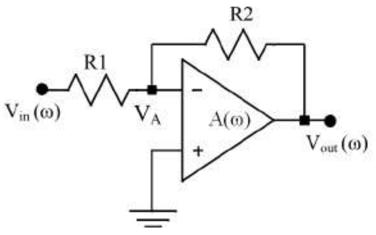

Fig. 12. Schematic of the single-ended inverting amplifier circuit.

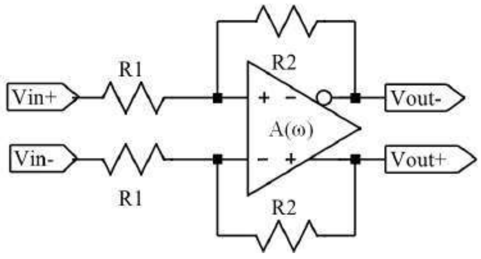

Fig. 13. Schematic of the fully differential inverting amplifier circuit.

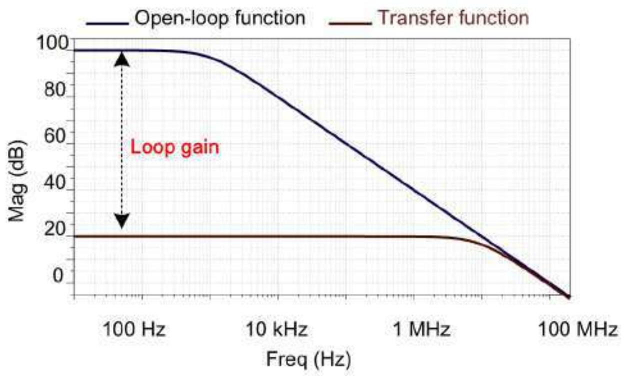

Fig. 14. Behaviour of the loop gain in an inverting amplifier.

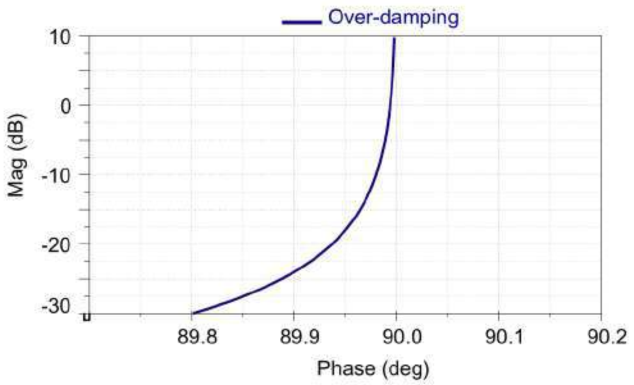

Fig. 15. Nichols plot of the self-loop function in an inverting amplifier.

B. Self-loop function of a 2nd-order inverting amplifier

In this section, the effects of the parasitic capacitor at the negative input of an inverting amplifier are investigated. Figs. 16 and 17 show the simplified models of the single-ended and the fully differential inverting amplifiers with the parasitic capacitors at the input of the operational amplifiers. After applying the superposition principle at node V_A in the single-ended inverting amplifier, the node equation is given in Eq. (12).

$$V_A\left(\frac{1}{R_1}+\frac{1}{R_2}+j\omega C_1\right)=\frac{V_{in}}{R_1}+\frac{V_{out}}{R_2};\ V_{out}=-A(\omega)V_A; \qquad (12)$$

Eq. (13) shows the transfer function and the self-loop function of this amplifier. They are second-order complex functions. TABLE VI presents the values of the constant variables in these complex functions.

$$H(\omega)=\frac{V_{out}(\omega)}{V_{in}(\omega)}=-\frac{b_0}{a_0(j\omega)^2+a_1 j\omega+a_2+1}; \qquad (13)$$

$$L(\omega)=a_0(j\omega)^2+a_1 j\omega+a_2;$$

TABLE VI. Values of Given Variables of Inverting Amplifier.

Variable	Value	Variable	Value
b₀	$\frac{R_2}{R_1}$	**a₀**	$\frac{R_2C_1}{2*10^7\pi}$
a₁	$\frac{1}{10^5}\left[R_2C_1+\frac{1}{2*10^2\pi}\left(1+\frac{R_2}{R_1}\right)\right]$	**a₂**	$\frac{1}{10^5}\left(1+\frac{R_2}{R_1}\right)$

The parasitic capacitor caused by the transmission line will change the operating region of the inverting amplifier. Assume that value of the parasitic capacitor $C_1 = 200$ pF, and values of resistors R_1 and R_2 are 1 kΩ and 10 kΩ. Figs. 18, 19 and 20 show the Bode plot of the transfer function, the Nichols plot of the self-loop function, and the transient response, respectively.

At around 1 MHz, the magnitude of the transfer function is greater than 20 dB and the phase margin at unity gain of the self-loop function is quite small 50-degrees (observed at 130-degrees). This amplifier works in the under-damping region; therefore, the ringing happens in the transient response.

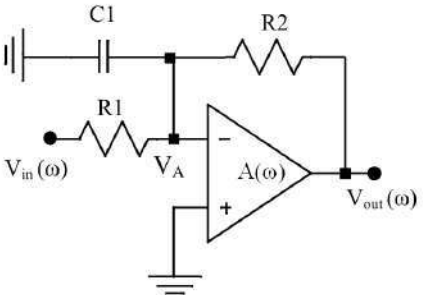

Fig. 16. Simplified model of the inverting amplifier circuit.

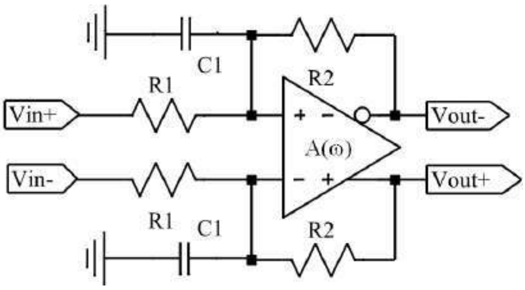

Fig. 17. Simplified model of the inverting amplifier circuit.

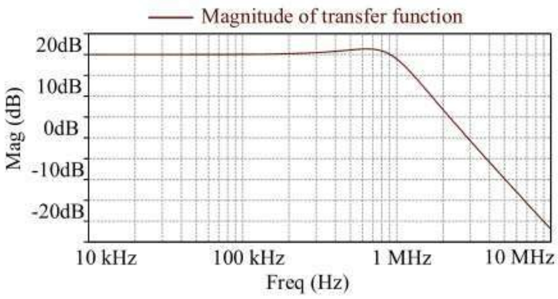

Fig. 18. Bode plot of the transfer function in the inverting amplifier.

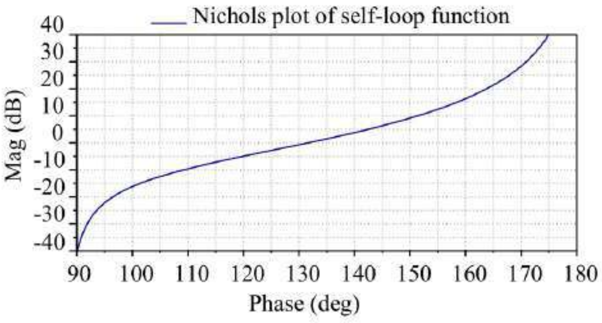

Fig. 19. Nichols plot of the self-loop function in the inverting amplifier.

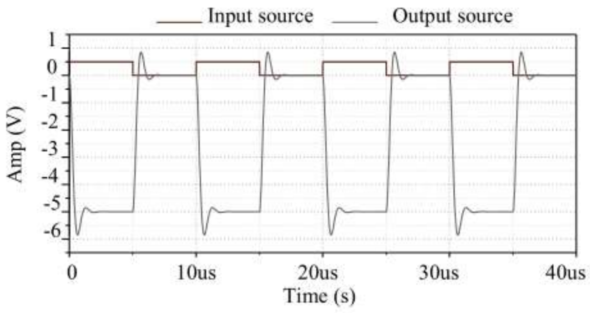

Fig. 20. Transient responses of the inverting amplifier.

C. Self-loop function of a 2nd-order non-inverting amplifier

In this section, the effects of the parasitic capacitor at the negative input of a non-inverting amplifier are investigated. From the view point of complex function, this non-inverting amplifier is also called negative feedback network. The term "positive feedback" is only used to indicate an oscillator or a signal generator network [24].

Fig. 21 shows the simplified model of the single-ended non-inverting amplifiers with a parasitic capacitor at the input of the operational amplifier. After applying the superposition principle at node V_A in the single-ended inverting amplifier, the node equation is given in Eq. (14).

$$V_A\left(\frac{1}{R_1}+\frac{1}{R_2}+j\omega C_1\right)=\frac{V_{out}}{R_2};\ V_{out}=A(\omega)\left(V_{in}-V_A\right); \quad (14)$$

Eq. (15) provides the transfer function and the self-loop function of this non-inverting amplifier. They are also second-order complex functions. The values of the constant variables in these complex functions are given in TABLE VII.

$$H(\omega)=\frac{V_{out}(\omega)}{V_{in}(\omega)}=\frac{b_0 j\omega+b_1}{a_0\left(j\omega\right)^2+a_1 j\omega+a_2+1}; \quad (15)$$
$$L(\omega)=a_0\left(j\omega\right)^2+a_1 j\omega+a_2;$$

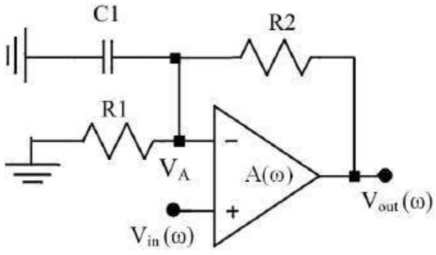

Fig. 21. Simplified model of the non-inverting amplifier circuit.

TABLE VII. VALUES OF GIVEN VARIABLES OF NON-INVERTING AMPLIFIER.

Variable	Value	Variable	Value
b_0	R_2C_1	**b_1**	$1+\frac{R_2}{R_1}$
a_0	$a_0=\frac{R_2C_1}{2*10^7\pi}$	**a_2**	$a_2=\frac{1}{10^5}\left(1+\frac{R_2}{R_1}\right)$
a_1	$\frac{1}{10^5}\left[R_2C_1+\frac{1}{2*10^2\pi}\left(1+\frac{R_2}{R_1}\right)\right]$		

Here, values of the passive components are capacitor $C_1 = 200$ pF, resistor $R_1 = 1$ kΩ, and resistor $R_2 = 1$ kΩ. Figs. 22, 23 and 24 show the simulation results of the non-inverting amplifier with a parasitic capacitor.

On the Bode plot of the transfer function, the magnitude is greater than 15 dB at around 3 MHz. And, the phase margin at unity gain of the self-loop function is very small 30-degrees (observed at 150-degrees). This amplifier also works in the under-damping region; so, the ringing occurs in the transient response.

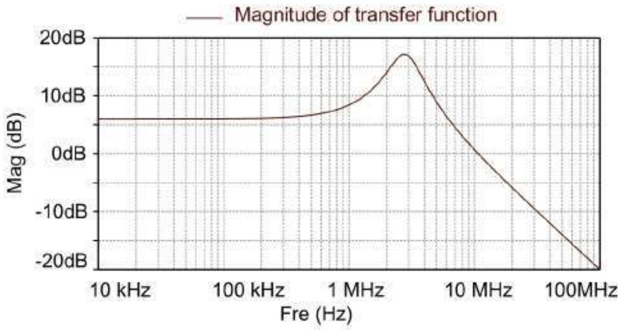

Fig. 22. Bode plot of the transfer function in the non-inverting amplifier.

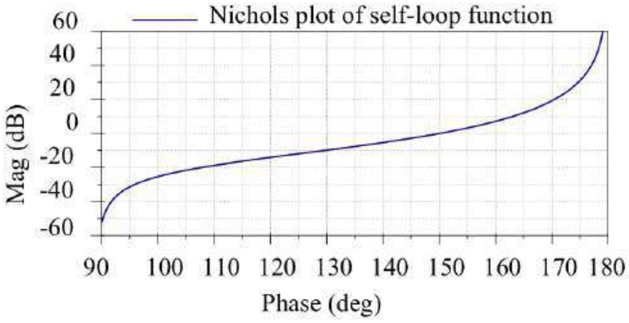

Fig. 23. Nichols plot of the self-loop function in the non-inverting amplifier.

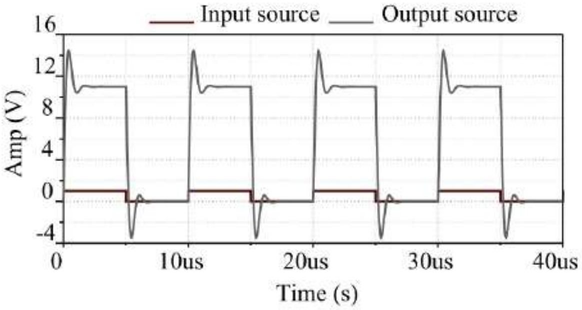

Fig. 24. Transient responses of the non-inverting amplifier.

D. *Self-loop function in shunt-shunt feedback amplifiers*

In this section, the properties of the shunt-shunt feedback amplifiers are investigated. Gain, gain stability, distortion, noise, input/output impedance and bandwidth and gain-bandwidth product will affect the behaviour of a negative feedback amplifier [25]. It is known that the conventional concept of loop gain is used to analyse four types of negative feedback amplifiers called shunt-shunt, shunt-series, series-shunt, and series-series. However, the approximated loop gain does not show the entire behaviour of these amplifiers.

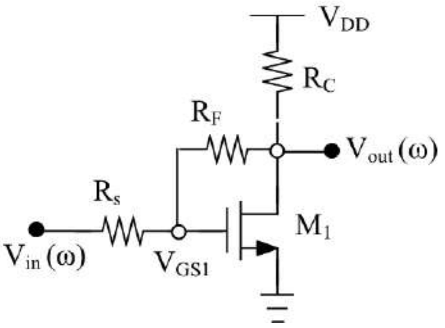

Fig. 25. Schematic of a CMOS feedback amplifier.

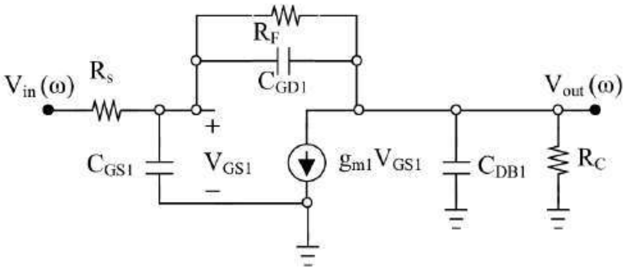

Fig. 26. Small signal model of a CMOS feedback amplifier.

Fig. 25 shows the schematic of a shunt-shunt CMOS feedback amplifier. The structure of this amplifier is also called self-bias common-gate CMOS feedback amplifier [26]. To derive the transfer function of this network, the small signal model is drawn in Fig. 26.

After applying the superposition principle at nodes V_{GS1} and V_{out}, the output voltage is given in Eq. (16).

$$V_{GS1}\left(\frac{1}{R_s}+\frac{1}{Z_{CGS1}}+\frac{1}{R_F}+\frac{1}{Z_{CGD1}}\right)=\frac{V_{in}}{R_s}+V_{out}\left(\frac{1}{R_F}+\frac{1}{Z_{CGD1}}\right); \tag{16}$$
$$V_{out}\left(\frac{1}{Z_{CGD1}}+\frac{1}{Z_{CDB1}}+\frac{1}{R_F}+\frac{1}{R_C}\right)=V_{GS1}\left(\frac{1}{R_F}+\frac{1}{Z_{CGD1}}-g_{m1}\right);$$

Eq. (17) shows the transfer function and self-loop function of the shunt-shunt CMOS feedback amplifier. The values of the constant variables of this circuit are given in TABLE VIII.

$$H_{CMOS}(\omega)=\frac{b_0 j\omega+b_1}{a_0(j\omega)^2+a_1 j\omega+1}; \tag{17}$$
$$L_{CMOS}(\omega)=a_0(j\omega)^2+a_1 j\omega$$

TABLE VIII. VALUES OF GIVEN VARIABLES OF A SHUNT-SHUNT CMOS FEEDBACK AMPLIFIER.

Parameter	Value
b_0	$R_F R_C C_{GD1}$
b_1	$R_C - R_F R_C g_{m1}$
a_0	$R_S R_F R_C\left(C_{GD1}C_{GS1}+C_{GD1}C_{DB1}+C_{DB1}C_{GS1}\right)$
a_1	$\left(R_C R_F^2+R_S R_C R_F g_{m1}+R_S R_F^2\right)C_{GD1}$ $+R_C R_F\left(R_S+R_F\right)C_{DB1}+R_S R_F\left(R_C+R_F\right)C_{GS1}$

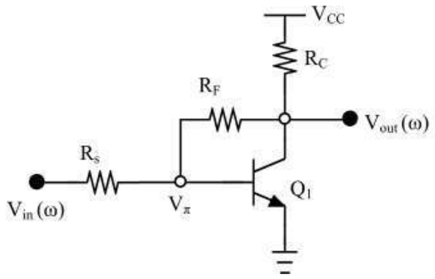

Fig. 27. Schematic of a BJT feedback amplifier.

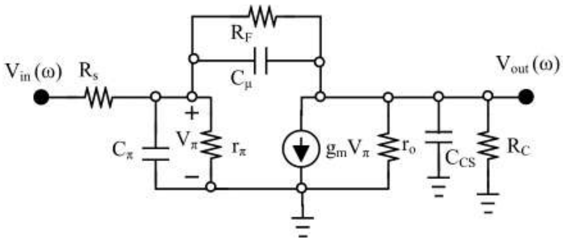

Fig. 28. Small signal model of the BJT feedback amplifier.

A self-bias common-emitter feedback amplifier is also called a shunt-shunt BJT feedback amplifier [27]. Figs. 27 and 28 show schematic and the small signal model of the shunt-shunt BJT feedback amplifier. The superposition theorem is also used to analyze this circuit. After applying the superposition principle at each node in the small signal model of this amplifier, the transfer function and the self-loop function of this amplifier are derived in Eq. (18).

$$H_{BJT}(\omega) = \frac{b_0 j\omega + b_1}{a_0 (j\omega)^2 + a_1 j\omega + 1}; \qquad (18)$$
$$L_{BJT}(\omega) = a_0 (j\omega)^2 + a_1 j\omega;$$

The values of the constant variables of this circuit are given in TABLE IX. A feedback resistor R_f = 1 kΩ is used to reduce the gain of the the shunt-shunt BJT feedback amplifier. Values of the chosen resistors R_C and R_S are 10 kΩ and 950 Ω, respectively. Fig. 29 shows the Bode plot of the transfer function of the common-emitter BJT feedback amplifier.

The simulated DC gain A_0 is 20 dB, and the simulated gain-bandwidth is 260 MHz at unity gain of the transfer function. The phase margin at unity gain of the self-loop function is 86 degrees at the unity gain of the self-loop function as shown in Fig. 30. The behaviour of this amplifier is over-damping.

TABLE IX. VALUES OF GIVEN VARIABLES OF A SHUNT-SHUNT BJT FEEDBACK AMPLIFIER.

IV. Ringing Test for Adaptive Feedback Networks

A. *Signal flow graph of DC-DC buck converter*

In this section, a switching DC-DC buck converter is considered as a control network. A step-down switching DC-DC buck converter is also called a dynamic load network. The propagated power at output will be changed regarding the actuating load. In other words, the variation of load will change the operating region of the power stage [28]. Therefore, a feedback loop is required for some switching power supplies because some parameters of the desired processing operation are changing as shown in Fig. 31. In this control system, a comparator is used to compare a referent voltage (DC voltage) with a feedback voltage, which is extracted from the output node [29]. The behaviours of the switching power supplies rely on negative feedback to maintain the output voltages at the specified values.

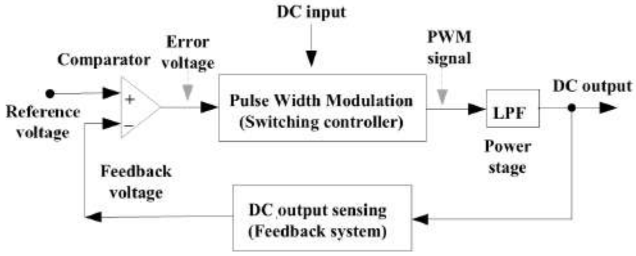

Fig. 31. Block diagram of a DC-DC buck converter.

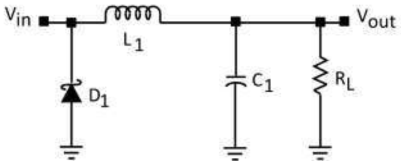

Fig. 32. Simplified model of the power-stage of the DC-DC buck converter.

B. *Behaviors of the power-stage of the buck converter*

In this section, the characteristics of a simplified model of the power-stage in a control system are analyzed. The power stage of the converter is an RLC network which is also called a 2nd-order low-pass filter in Fig. 32.

The function of this actuating system is to convert a multi-harmonic signal or a switching source into DC voltage [30]. Therefore, the transfer function and the self-loop function of the power stage are proposed to predict the maximal value of overshoot in this control system. The transfer function and the self-loop function of the power-stage are given in Eq. (19).

$$\begin{aligned} &H(\omega)=\frac{1}{a_0(j\omega)^2+a_1 j\omega+1};\\ &L(\omega)=a_0(j\omega)^2+a_1 j\omega;\\ &a_0=L_1C_1;a_1=\frac{L_1}{R_L}; \end{aligned} \tag{19}$$

To generate a maximal power, the balanced charge-discharge time condition for the power-stage of this control system is defined in Eq. (20).

$$\omega_{2RC}=\omega_{LC}\Leftrightarrow\omega=\frac{1}{\sqrt{LC}}=\frac{1}{2RC} \tag{20}$$

C. *Phase margin of the power-stage*

This section presents the measurement of the phase margin of the implemented circuit. Fig. 33 shows the schematic of the proposed design of a DC – DC buck converter circuit. In this implementation, the chosen passive elements are L_1 = 530 µH, C_1 = 220 µF, R_1 = 4 kΩ, R_2 = 2 kΩ, R_L = 5 Ω, C_2 = 470 pF, and L_2 = 50 µH.

The measurement setup for the implemented circuit is shown in Fig. 34. The performance of the proposed design of a 12 V – 5 V buck converter has been verified by the practical measurements.

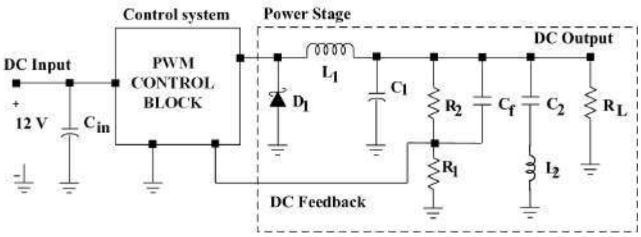

Fig. 33. Schematic diagram of a 12 V – 5 V buck converter circuit.

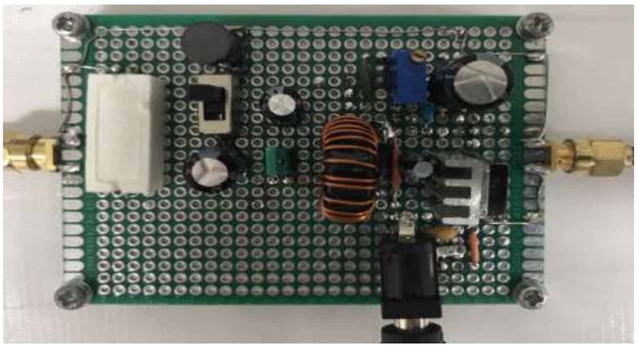

Fig. 34. Implemented circuit of a DC-DC buck converter.

Fig. 35 shows the measurement results of the Bode plot of the power-stage. The measured magnitude of the transfer function of the power stage at around the cut-off frequency is 2 dB. The chosen components in the implemented circuit make the power-stage of this control system always work in the under-damping region because there is a trade-off between the cost and size of the printed circuit board of the DC-DC buck converter circuit [31].

The measured phase margin at the unity gain of the self-loop function is 49 degrees (observed at 131 degrees) as shown in Fig. 36. The output ripple of the implemented DC-DC buck converter is kept very small 5 mVpp which is compared to the desired output voltage of 5 V as shown in Fig. 37.

This work overcomes some limitations of loop and the conventional Nyquist stability criterion and Nichols plot of loop gain in the control systems. The measurement of the phase margin at unity gain of the self-loop function at the actuating system is proposed to evaluate the quality of an adaptive feedback system [32].

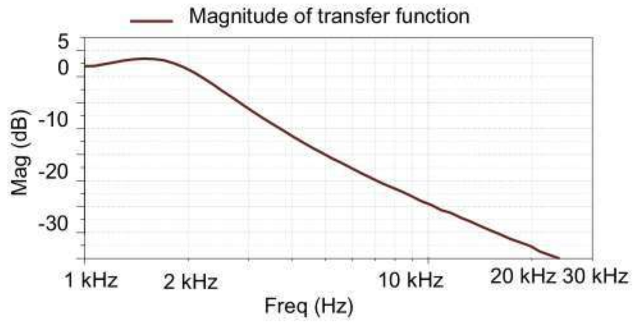

Fig. 35. Bode plot of the transfer function of the power stage.

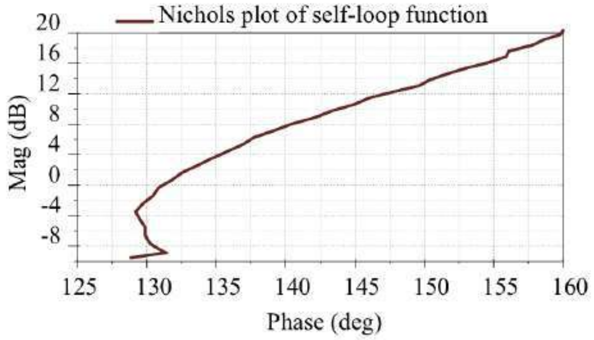

Fig. 36. Nichols plot of the self-loop function of the power stage.

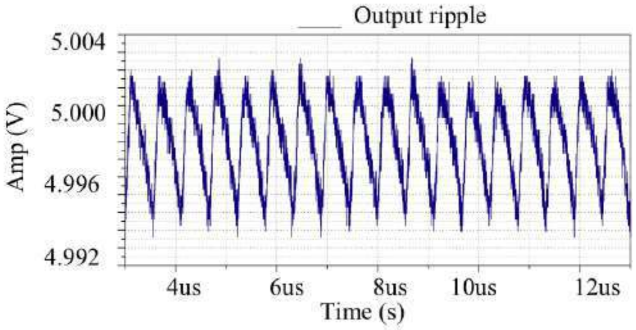

Fig. 37. Waveform of the output ripple of the DC-DC buck converter.

V. Conclusions

This paper has shown some limitations of the classical concept of loop gain in the negative feedback networks and investigated some motion models of high-order mechatronic networks. Loop gain cannot be used to analyze the overshoot phenomenon in high-order mechatronic systems because it doesn't show the operating regions of many high-order mechatronic systems. In addition, it is very difficult to derive the loop gain in many multi-loop feedback amplifiers such as unity gain amplifiers, inverting amplifiers, active filters, negative feedback amplifiers because loop gain is just a predicted value. In an inverting amplifier, loop gain only shows the gain reduction from the DC gain of the open loop function to the defined gain which is calculated by the ratio of two resistors.

The use of phase margin at unity gain of the self-loop allows engineers to do the stability test in high-order mechatronic systems. The Nichols plot of self-loop function is simpler than the Nichols plot of loop gain and the measurement of phase margin is easily verified by laboratory simulation and practical measurements. In case of under-damping, the overshoot or ringing makes the network unstable. This work also describes the approach to do the phase margin test for power-stage of a DC-DC buck converter. The phase margin of the power-stage is 49 degrees, and the output ripple is small 5 mVpp. Hence, the phase margin of the actuating system can be used to evaluate the quality of an adaptive feedback control system. In future works, ringing caused by the parasitic elements in other mechatronic systems will be investigated.

***Abstract*— For many years, a manned mission to Mars has been a challenge for humanity. However, the recent technological advances in human factors and space systems engineering may overcome these limitations. Thus, there are some strategies to face various medical emergencies autonomously due to long distances and hostile conditions in order to develop healthcare monitoring and ensuring the safety of the astronauts. For this reason, an innovative research has been conducted from 2020 to 2021 under the supervision of the Bioastronautics & Space Mechatronics Research Group, resulting in this proposed project, which is a sensorized glove for medical emergencies controlling the rover developed by the Team "Tharsis" from the Universidad Nacional de Ingeniería, winner of the Technology Challenge Award for Wheel Design and Fabrication at the 7th Annual NASA Human Exploration Rover Challenge. In addition, the glove has a soft robotic hand exoskeleton with the purpose of fracture stabilization and to prevent future complications. This study presents a mechatronics conceptual design based on biomechanical fundamentals of the hand, where Fusion 360 was used for 3D mechanical systems development and Eagle for electrical and electronic circuit technical schematics, besides telecommunications and telerobotics protocols are analyzed. The "BIOX-GLOVE" is pretended to be applied on the Martian surface during extravehicular activities-EVA and also, on Earth in a Mars environment analogue and rehabilitation hospitals. In conclusion, favorable results were achieved; consequently, the next step of this project is to start the detailed engineering design in July 2021, and it is proposed to develop the prototype and perform the first test in a Martian analog.**

***Keywords*—Mars, Rover, Sensorized Glove, Medical Emergencies, Exoskeleton, Mechatronics, BIOX-GLOVE**

I. Introduction

This decade, 2020-2030, an age of space colonization will begin. The Artemisa project plans to explore the Moon to extract resources and establish a human base as a rehearsal for future Martian missions [1]. Mars human exploration is the next step; therefore, it is required to develop previous colonization activities [2]. The physical and psychological risks for the astronauts on this trip will be very crucial [3]. It is also essential to offer countermeasure alternatives to avoid body damage by the effects of microgravity, radiation [4] and the environmental conditions on the Martian surface [5]. (Fig.1)

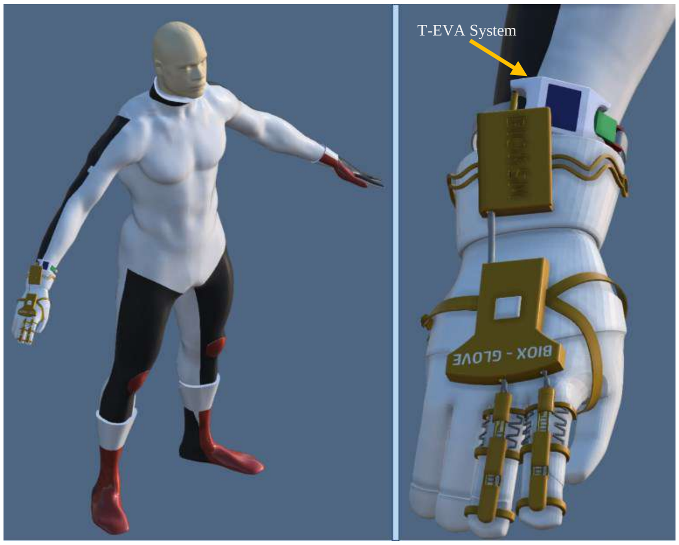

Fig.1. BIOX-GLOVE and Astronaut

Working outside the spacecraft represents a health risk for an astronaut due to environmental factors such as the vacuum in space, radiation, extreme temperatures, and micrometeorites [6]. To solve this, Extravehicular Mobility Unit-EMU, was designed to provide the necessary functions to keep the user alive [7] during exploration activities-EVA.

Gloves are considered one of the most important and complex wearable accessories to operate because specific skills must be developed and in addition, when the suit is pressurized, the mobility of the hands becomes challenging due to the stiffness [8]. Previous studies state that wrist fractures could be caused due to the axial forces [9]; therefore, mechatronics engineering is currently working on designing robotic gloves and tools that allow the astronaut to enhance work performance [10]. Thus, National Aeronautics and Space Administration-NASA, through its “Evolvable Mars Campaign” program, is seeking to make human exploration on Mars surface pioneering and sustainable [11].

The long-term goal is to send astronauts to live on the red planet [12]. Currently, many satellites on Mars are analyzing the surface to find landing candidates places. The first human exploration missions will need to cover a big area for sampling in situ. In this scenario, the use of rovers will be necessary, same as the Apollo 17 mission on the Moon [13]. In this context, for NASA and manned space programs, the lives of astronauts are a priority considering that there is a permanent risk of suffering illnesses and accidents when exploring not-known areas such as the surface of Mars [14]. The gravity on Mars (1/3 g of the Earth) can be considered potentially dangerous, causing increasing object’s acceleration in the environment, and thus, producing injuries [15].

The estimated probabilities of an emergency outside the Earth are on average 0.06 per “crew member/year-of-space-flight-expedition” [14, 15]. For example, with a crew of 6 astronauts on the surface of Mars and a mission duration of 900 days, it would be expected that at least one emergency would occur [16]. EVA and continuous exposure to extreme environments add debilitating effects that predispose to severe traumatic injuries [17] such as bone fractures [18], hemorrhages, thoracoabdominal injuries [14], decompressive diseases [19] as well as contusions involving the digits of the hand, peripheral nerves and generalized fatigue due to the working hours [20, 21]. Prompt medical care for the injured astronaut could be problematic due to the distances between the exploration and Command Center. Therefore, the decisions must be taken quickly in situ because the communication time to the Earth is often between 8 to 56 minutes [19] [22].

Due to this context, BIOX-GLOVE is proposed as a medical wearable robot [23, 24] in order to activate an emergency system on the Martian surface [25, 26] during extravehicular activities, using telecommunications and control protocols applied in a rover (ambulance vehicle) to transfer the astronaut to the Command Center [27]. In addition, it has a hand exoskeleton designed with soft materials to improve the physical capabilities, this innovative technology will be used on Earth for patient’s hand rehabilitation [28]. The research is based on T-EVA project [29] developed by Bioastronautics and Space Mechatronics Research Group (BIO&SM). (Fig. 1)

1.1. Research Objectives

The research requirements are aligned with the NASA’s Journey to Mars [12] and the Agreement on the Rescue of Astronauts, the Return of Astronauts and the Return of Objects Launched into Outer Space [30]. One of the challenges is to integrate human and robotic missions to achieve a successful task [12]. The exploration needs tools to control rovers during accidents and emergency situations in order to come back to the Command Center for medical attention [31, 32, 33].

The BIOX-GLOVE is an accessory that will be placed above the EVA suit and must be comfortable, ergonomic, and able to withstand the environmental conditions on Mars, such as temperature, radiation and dust; therefore, it will be used in case of partial or total motor impairment of the lower extremities. This technology is suggested to be used during any Extravehicular Activities.

The astronaut will turn on the glove in 2 ways during emergency situations [34]:

a) First, by performing a sequence of programmed gestures to control the Rover.

b) Second, by pressing the activation button (located on the back of hand). The exoskeleton will stabilize the musculoskeletal system of the wrist and hand.

1.2 Research and Development Methodology

The steps where elaborated based on 3 key points: a) Define the problem and the scope of the objectives. b) Define the main requirements necessary for the project execution. c) Modeling through 3D design software and the proposed validation test of BIOX-GLOVE. (Fig. 2)

II. Biomechatronics Foundations of Human Factors

Biomechatronic applications have been made for more than three decades to overcome several limitations; research related to biomechatronics and medical robotics cover a diverse aspect in interdisciplinary areas inspired by industrial, military, and medical applications. This area provides new methodologies and tools to design and build devices to cooperate with humans [35-38].

Gloves have long taken importance in the workplace, for the purposes of providing protection and safety against physical injury to the hands. However, they are even more important in space exploration when performing hand tasks in high-risk operations [39]. Over the years, the designs have been improving, and along with this, the most relevant points are that now it can resist cuts, breaks, perforations, slides, and abrasion [40]. At present, mechanical and electronic subsystems are being incorporated to improve the performance of the kinematic synergies of the hand, in order to provide a support that ensures the correct interaction of movements to counteract the rigidity of the pressurized suit during EVA [6].

These devices will make it easier for people to expand work areas and while guaranteeing their safety in highly dynamic hostile places such as space and planetary exploration [41]. However, these instruments are not only for hand protection and safety purposes, their sensors are capable of recognizing predetermined hand signals [42] are also added to BIOX-GLOVE to activate the medical emergency system [41].

2.1. Antropometric Analysis of the Hand

The hand is one of the most complicated biomechanical systems for study and application due to the multiple combinations in the reproduction of movements used to perform simple to complex activities. There are many kinematic interactions between the position of the wrist joint and the digits´ efficiency [8]. A detailed analysis of the pseudo-kinematic restrictions affects certain degrees of freedom due to the disposition of the tissues and tendons of their anatomical structure [8], [43].

For glove sizing, it is necessary to determine the hands' anthropometric dimensions to make a bio-inspired anatomical design with great precision of the movements [44], providing great flexibility and comfort when performing various tasks [39]. Likewise, it is recommended that these devices reflect the morphological characteristics of an astronaut's hand to achieve adequate performance without excessively affecting the control of force and holding of objects [45, 46].

The glove was designed considering morphological differences, ethnicity, and gender [47]. Due to the anthropometric variability and heterogeneity of the population groups, the measurement of the hands differs between Latin Americans [48], North Americans [43, 44], and Europeans [45]. These values are generally represented by percentiles; that is, for smaller people (5th percentile) and older people (95th percentile); therefore, it has been decided to obtain the estimated numerical average of the anthropometric measurements of the authors' hands in a referential way. (Fig. 3.a) For this analysis the following measurements have been noted: wrist circumference (WH), hand length (HL), palmar length (PL) hand width (HW), palmar width (PW), Wrist width (WW), and the total lengths for each digit (TLDi) in Table I.

TABLE I. Hand Anthropomorphic Measurements

Hand Measure (cm)	**A1**	**A2**	**A3**	**A4**	**A5**	**A6**	**A7**	**A8**	**A9**	**X**
Hand Length (HL)	19	19	18	16.5	18	17.9	19	18.8	18	18.5
Palmar Length (PL)	11	10.5	11	9	10.6	10.5	11	10.6	10	10.4
Hand Width (HW)	9.7	10	10	9	10.2	10.3	10	11	10	9.9
Palmar Width (PW)	7.4	8.8	8.5	7.5	8.9	7.5	8.8	10	8.5	8.6
Wrist Circumference (WC)	16.4	16	18	17	18	15.2	16	17.8	15.5	17.0
Wrist Width (WW)	6.1	6	7	6	6.4	6.6	7	6.9	6	6.3

Based on Authors Data (Ai: Random Sequence, X: Average of hand measurements)

The total lengths of each digit (TLDi) is obtained by calculating the lengths of the metacarpals (MCLi) "palm" and the lengths of the digits (DLi) according to the plane of the anatomical description (i = D-I for the first digit (thumb); D-II for the second digit (index); D-III for the third digit (middle); D-IV for the fourth digit (ring) and D-V for the fifth digit (pinky)). Before the measurement, 3 reference points were considered: first, the skinfold lines of flexion of the wrist on the palmar side; second, the digitopalmar skin fold lines [49]; and third, the edge of the distal end of each finger. Subsequently, it has been measured at the intersection of the points following the direction of each digit in extension. With this result the dimensions of LTDi are obtained, and it is represented mathematically with the following formula:

TLDi = MCLi + DLi. (Figure 3.b)

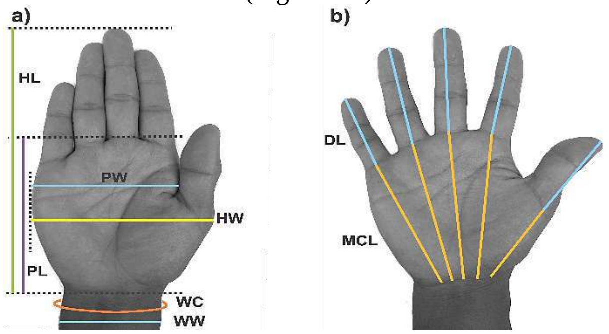

Fig. 3. Anthropometric Sizing: a) Measurements; b) Total length for each digit

Due to the complexity of the kinematic and dynamic model and the high number of degrees of freedom of the hands [8] [50], the gloves have been adapted trying to maintain similar characteristics by replicating hand movements with little interference. The movements have multiple functions such as ergotic, epistemic and semiotic [51]. For this case, the study is focused on the semiotic aspect to correctly size the sensors and characterize the hand gestures following a sequence of images called: M1, M2, ..., Mx, (M1 is the initial posture and Mx is the final posture). The sensors that BIOX-GLOVE has, allow it to capture information of the movement trajectories of the digits (dynamic gestures), characterized by the configuration of the hand digits. Gestures are contents of movements that start from a resting position (initial position), continue with a phase of substantial increase in speed and end by returning to the initial position [51].

2.2. Biomechanical Protocols

The device must follow protocols to verify the integrity and correct operation of the upper limb for the device handling (A); additionally, contain a series of pre-established characterizable movements to translate the biomechanical signals into vehicle movements (B). For this study, only D-II and D-III are characterized since their flexion and extension influence others [52]. Therefore, it is established the activation protocol and the usage protocol.

A) Activation Protocol

Based on the upper limb anatomical and biomechanical considerations, the activation protocol (M1 – M7) must be executed to ensure the correct state of this limb; that is to say, the nervous and muscular structures of the astronaut's upper limbs are capable of performing complex manipulation activities [53].

First, the hand must be extended (Fig. 4.a), avoiding the formation of the proximal and distal transverse and longitudinal arches (PTA, DTA and LA) [54]. This first step is to set up the hand and wrist in a neutral position; the device can be started from there. Second, a complete circumduction of the hand must be performed (Fig. 4.b). This movement, composed of flexion, extension, abduction, and adduction of the hand, verifies that the distal radiocarpal and radioulnar joints are functioning correctly [52]. Likewise, correct functioning of both the epitrochlear and epicondylar muscles and the forearm supinators and pronators is required [52] [54]; in this way, it is verified their full functionality. Third, the hand must return to the neutral position (Fig. 4.c.1), then clench the hand for 5 seconds (Fig. 4. c.2) and return to the neutral position (Fig. 4.c.3). With this movement, it is verified that the metacarpophalangeal (MCP), proximal, and distal interphalangeal joints (PIP and DIP) of all digits are capable of fully flexing and extending [52, 53], as well as the correct functioning of muscles activated by the radial and ulnar nerves [53]. Finally, active flexion at 70° (Fig. 4.d.1) and active extension 60 ° (Fig. 4.d.2) of the hand is executed, then return it to the neutral position. The device will be activated when it has verified the correct execution of the movements. For the user's safety, if any of these movements cannot be executed correctly, the device will not activate; since it would be a sign of a biomechanical malfunction in the upper limb, it would not be able to control the vehicle correctly.

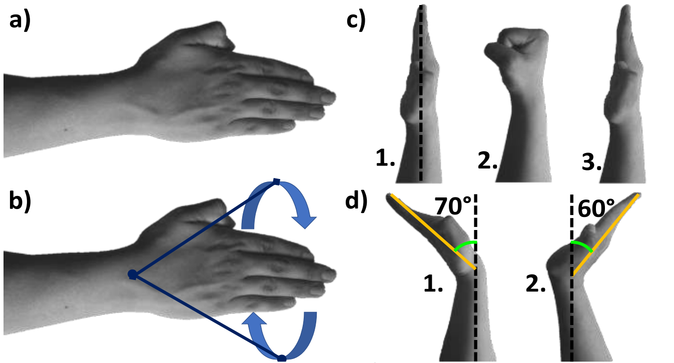

Fig. 4. Activation protocol. a) Top view of the neutral hand position with the fingers and palm extended (M1). b) Circumduction movement of the hand (rotation around the wrist) (M2). c) Lateral View of 1. Extension (M3) - 2. Flexion (M4) - 3. Full extension of the hand (M5). d) Side view of 1. Flexion (M6) - 2. Extension (M7).

B) Usage Protocol

The use of the device depends on a series of hand movements, which represents a specific action in the vehicle's control. These must be interdependent among themselves since their execution must not affect or be confused with another, but in turn, they must work together to execute the activities in the vehicle. Likewise, these movements are based on the upper limb's biomechanics, specifically on the angles formed by joints. The movements required in the vehicle are forward, backward, stop, turn right, and turn left. Therefore, the usage protocol consists of the following steps.

First, in the neutral position, start the device to begin remote control of the vehicle. To advance, flex the hand 70° [52], then close the hand into a fist and only leave D-II extended (Fig. 5.a). In this way, all DIP, PIP and MCP joints of each digit, except D-II, will be fully flexed, allowing them to be easily identified by the flexion sensors and avoiding some error in the algorithm. Likewise, as the wrist joint is flexed, it will be possible to ensure correct recognition of the vehicle's biomechanical gesture to move forward.

On the other hand, to move back, the hand is required to be hyperextended 60° [52], then all the PIP and DIP joints of each digit must be flexed (Fig. 5.b). In this way, it is verified by partial bending of D-II and D-III that the action is being executed correctly and would be free of confusion errors. Likewise, as the wrist joint is hyperextended, it will be possible to correctly recognize the biomechanical gesture for the vehicle to move backwards.

For left and right turns, the hand must be in the neutral position. Then, to turn to the right, radial deviation (abduction) must be performed at 20° [53] (Fig. 5.c.1); while to turn to the left, ulnar deviation (adduction) must be performed at 30° [53] (Fig. 5.c.2).

Eventually, to activate the braking system, it is required to close the hand into a fist, in such a way that all DIP, PIP and MCP joints are fully flexed (Fig. 5.d); while the wrist joint is at the neutral position (0°). This configuration was determined as it is quick to execute, requiring emergency braking.

III. Mechatronic System Design

This research involves fields of engineering such as mechanical, electrical, electronics, telecommunications and telerobotics. It consists of using a sensorized glove to control a manned rover in the case of a medical emergency (body harm) on Mars. BIOX-GLOVE has flex sensors on the fingers, and gyroscopes placed between the wrist and forearm to perform programmed hand movements. Besides, it has a button to activate the exoskeleton as an external fixator, stabilizing the radiocarpal joint in case of traumatic injuries due to falls, thus avoiding further complications.

3.1. Mechanical Design

A) Glove

The design was made using Fusion 360. The glove wraps around the back of the user's hand with a JST SMP connector to make sure it doesn't fall off. The emergency button is located right in the center of the main body, where the main board and a gyro box is located. As it was mentioned, on D-II and D-III, 2 flex sensors are located. Meanwhile, a second gyro box and the battery are located on the back side of the wrist, inside another box, held by a band (Fig. 6). For astronaut's glove manufacturing, it is recommended to use VECTRAN (aluminized and Teflon coated) because it's characteristics such as: abrasion resistance, high radiation exposure and property retention at high/low temperature [55, 56].

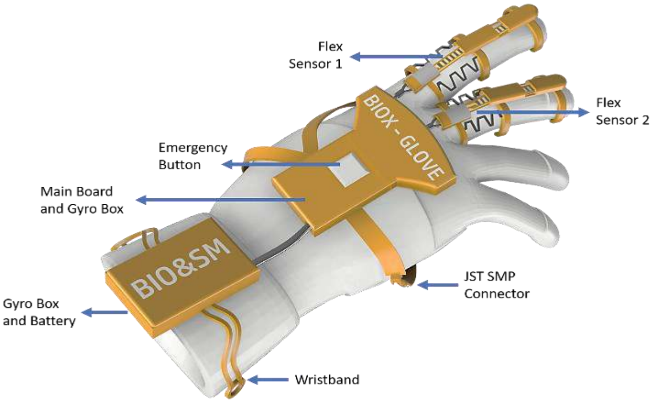

Fig. 6. Components of BIOX-GLOVE, Isometric View

The glove's bands and holders are meant to be made of 3 layers of materials, since it is one of the most vulnerable parts of the suit [40]. An inner bladder, a restraining polyester intermediate one and an outer thermal micrometeoroid garment. The boxes should be fabricated by 3D printing using Polylactic Acid (PLA), since it would make it easier to assembly and the material is durable and has a relatively low density.

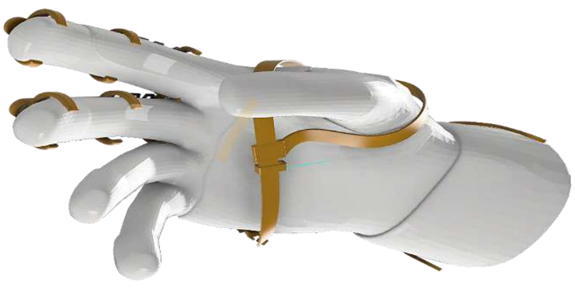

Fig. 7. BIOX-GLOVE, Bottom View

B) Exoskeleton

The exoskeleton [57, 58, 59, 60] is composed of 3 main modules, whose operation is interdependent. Module 1 (Fig. 8.a) has 12 submodules which are found between the PIP (a.1 - a.3), DIP (a.4 - a.7) and MCP (a.8 - a. 12) of each digit; reducing their degrees of flexion and extension. Module 2 (Fig. 8.b) has 4 submodules found in the palm of the hand to restrict the MCP joint flexion and to induce the formation of the DTA and LA (D-II and D-III mainly). Finally, Module 3 (Fig. 8.c) is located on both thenar and hypothenar eminence to ensure the formation of the PTA; likewise, this module completely covers the wrist joint, limiting its ranges of movement at all angles.

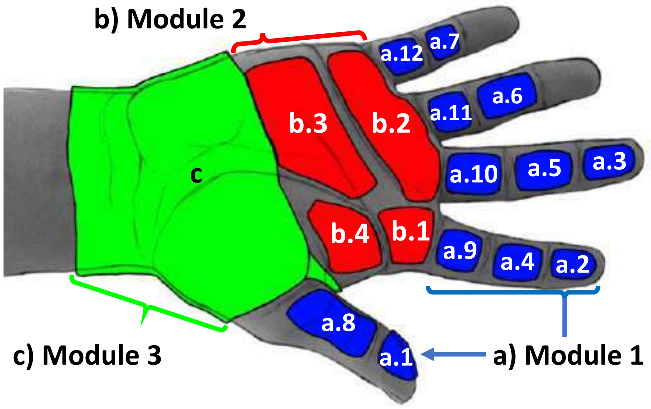

Fig. 8. Palmar View of the exoskeleton and its main modules

When the exoskeleton is activated, each of the sub-modules increase their volume through the inlet of pressurized air into their internal chambers; returning the injured hand to its natural configuration. Fig. 9 shows the hand with the 3 main modules of the exoskeleton activated; but for this conceptual design proposal, only the D-II sub-modules will be shown. The sub-modules of 1 and 2, working interdependently, will generate a controlled change in their volume, for which it will be possible to modify the angles of the MCP, PIP and DIP joints [60, 61, 62, 63], limiting their mobility. Besides, note that module 3 completely covers the wrist, partially restricting its mobility and keeping it parallel to the arm (0 °).

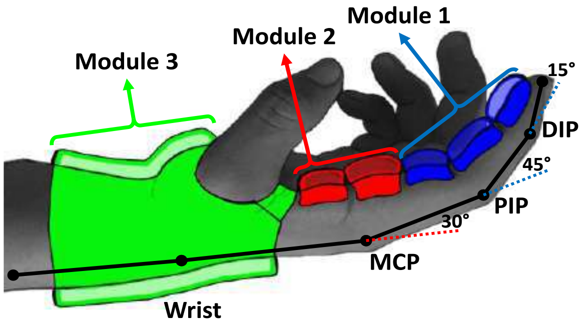

Fig. 9. Lateral view of the exoskeleton and its main modules activated

Therefore, the exoskeleton would not only partially restrict the mobility of the injured hand joints, keeping its natural relaxed configuration, but would also form an additional soft neumatic protection to ensure their safety, allowing the user to control the vehicle.

3.2. Electronics and Electrical Design

A) Glove Sensors and Circuits

The system's electronics are focused on the trajectory of the movement of the digits (from D-II, D-III): pronation, supination, and position of the hand and forearm. There are 2 signals for processing:

a) The first: SEN-FLEX 2P2I sensor (resistivity: 45k to 125k ohms), which works when the finger is flexing projected in motion and gestures for the activation and start-up protocols, sends a voltage range between 0V and 3.3V to the control unit (Fig. 10).

b) The second: MPU6050 gyro sensors (fig. 11a), which provide guidance and reference the Mars Rover's handling. It has the I2C protocol (inter-integrated circuits), which gives less use of pins and a faster data transfer with the control device; when using both same data bus, each one of the sensors will have an address.

The control unit is the STM32F103 ARM Cortex M3 microcontroller with a maximum CPU speed of 72 MHz, 128Kbyte of Flash, it has 26 inputs and 37 outputs. The programming will be carried out in C++ for sensor data processing algorithm, and with the SPI (serial peripheral interface) protocol to send data that contains the configuration, address decoder, and buffer controller, that will be received by the NRF2401L radio frequency module with 2.4GHz using the low power ISM band [64]. Glove-transmitter PCB size: Length 33.26mm, Width 43.31mm. (Fig. 11.b and Fig. 15)

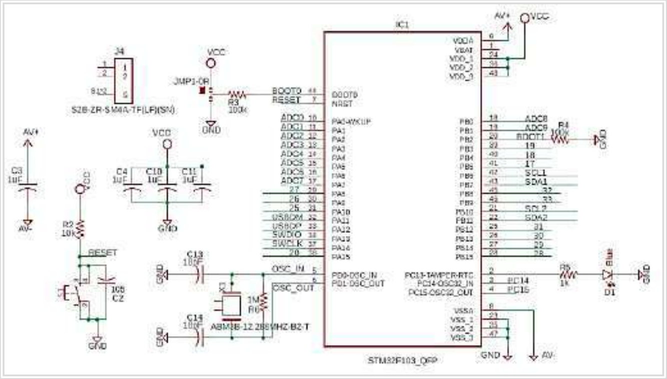

Fig. 10. Microcontroller STM32F103 (Transmitter) - Circuit Diagram

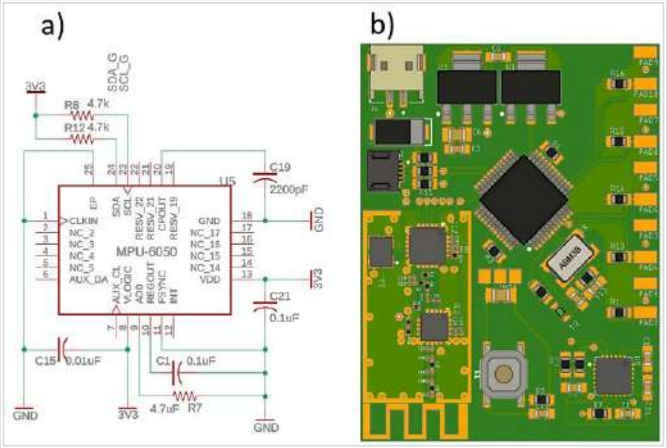

Fig. 11. a) MPU-6050 with connections. b) PCB 3D Design – BIOX-GLOVE

In order to design the circuits, it was required independent grounds planes due to eddy currents [65], where the following components: a) Analog: (SEN-FLEX 2P2I). b) Digital: (MPU6050, NRF2401L, RFX2401C, STM32F103 microcontroller (Fig. 12)), have both grounds planes connected by a 3.3mH inductor; Therefore, two 3.3V voltage regulator circuits will be used on the 1117AMS, delivering a maximum current of 500mA. Furthermore, to prevent EMI (Electromagnetic Interference) or RFI (Radio Frequency Interference), a shield EMC (Electromagnetic Compatibility) is applied on its ground plane [66], whose function is to protect the single-chip, NRF2401L and RFX2401C.

Likewise, the energy subsystem has been divided into 2 sources: a) 85.5mA analog circuit. b) 419.8mA digital circuit, with a total of 505mA, which is why a 3.7V 2S 750mA lithium battery is required.

B) Rover Sensors and Circuits

The receiver board has the following RFX2401C and NRF2401L radio frequency circuits (Figure 13.a) in slave mode; it uses the SPI protocol with the STM32F103 ARMcortex M3 microcontroller, which will process the data received from BIOX-GLOVE and generate the commands for the movement and control of the Mars Rover. The microcontroller will use 2 Serial communication pins (Tx and Rx pins) that will connect with a single-chip CP2102 converter USB (Universal Serial Bus) to TTL (Transistor-Transistor Logic). Rover- receiver PCB size: Length 75.55mm, Width 30.47mm. (Fig. 13.b and Fig. 16)

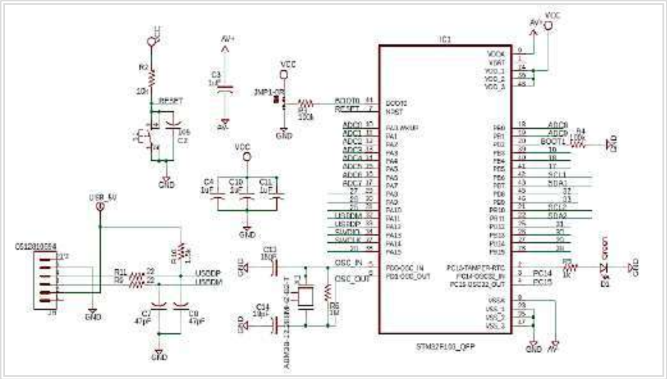

Fig. 12. Microcontroller STM32F103 (Receiver) - Circuit Diagram

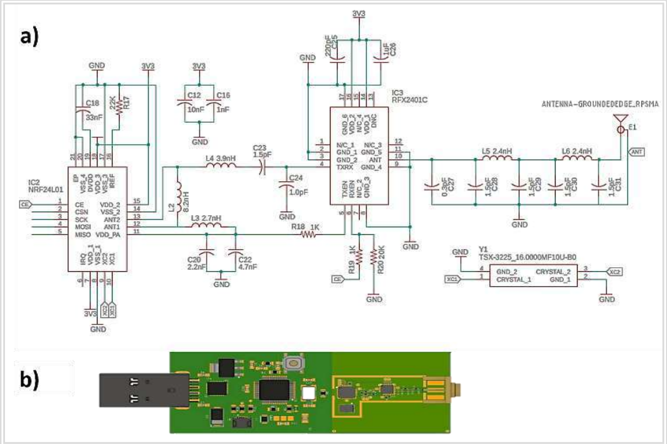

Fig. 13. a) NRF24L01 with connections. b) PCB 3D Design – Rover

3.3 Telecommunications and Telerobotics Technology

The glove's communication with the rover will be unidirectional (master - glove, slave - rover). This research proposes to use: A radio frequency module nRF24L01 Single Chip 2.4GHz Transmitter which operates the 2.4GHz ISM band, with a consumption 11.3mA TX at 0dBm output power and 12.3mA RX at 2Mbps data rate for work in a range of 500 meters in an open field. Also, the RFX2401C a fully integrated front-end module, is used to incorporate all the RF functionality needed for IEEE 802.15.4/ZigBee, with an Auto packet transaction handling wireless sensor network. This component has the lowest power consumption in its category, with only 10.5mA at an output power of -5 dBm and 18 mA in receive-mode.

In addition, the RFX2401C architecture integrates the PA (power amp) and LNA (low noise amp). It is coupled on the transmitter and receiver circuitry, additionally with efficiency +22 dBm output power, low noise with 2.5 dB, and small form factor package, 16-pin (3 x 3 x 0.55 mm).

As shown in the workflow diagram (Fig.14), when the astronaut suffers accidents, he has two ways to activate the glove depending on his health condition:

a) The first way is to perform the pre-established gestures. After the verification, the flex sensors and gyros will provide data according to the protocol of use to the controller to process and transmit it to the rover and command center.

b) The second way is to press the emergency button, which will activate an exoskeleton that works with a system of bags that will inflate and immobilize the hand. The control of the rover will be only with the two gyro sensors.

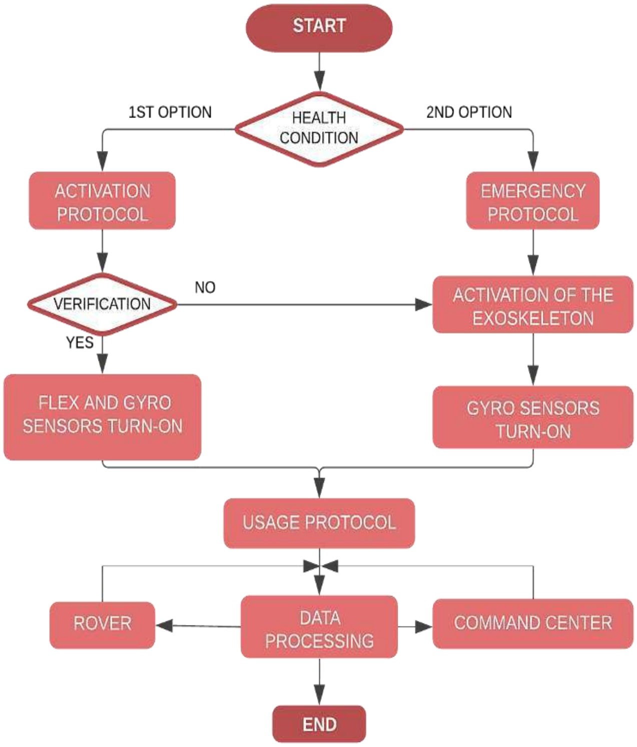

Fig. 14. Workflow Diagram of BIOX-GLOVE

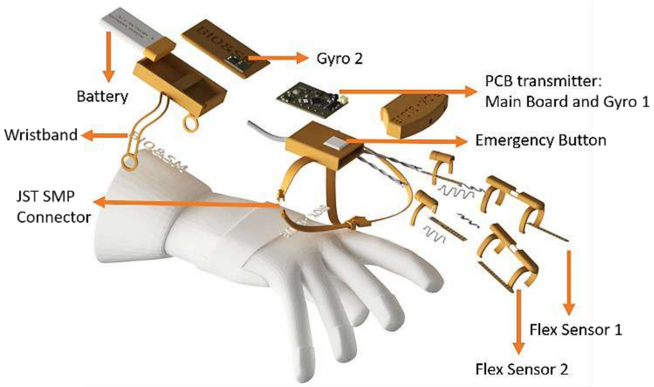

Fig.15. Exploded View of BIOX-GLOVE

When the components of the glove (Fig.15): for Activation Protocol (gyro sensor 1, gyro sensor 2, flex sensor 1 and flex sensor 2), or for Emergency Protocol (gyro sensor 1 and gyro sensor 2), perform the preestablished gestures, the Mars Rover (Fig. 16) will receive the movement order.

a) To start the movement, the user will have to flex the hand 70° [52], leave D-II extended (Fig. 5.a) and close the rest of the hand; the servomotors of the Mars Rover will turn on.

b) All the PIP and DIP joints of each digit must be flexed (Fig. 5.b) when the hand is hyperextended 60 ° [52], then the Mars Rover (Fig. 17a) will move back.

c) To turn left, ulnar deviation (adduction) must be performed at 30° [53] (Fig. 5.c.2); while to turn right, radial deviation (abduction) must be performed at 20° [53] (Fig. 5.c.2); while to turn right, radial deviation (abduction) must be performed at 20° [53] (Fig. 5.c.1) the Mars Rover will turn left or right.

d) All DIP, PIP and MCP joints are fully flexed (Fig. 5.d) when the hand is close into a fist, the Mars Rover (Fig. 17b) activates the emergency brake.

IV. Conclusion and Further Work

4.1 Aerospace Application

Mars has an irregular topography [67] which could generate risks for the operation in the moment of providing medical assistance in emergency situations (Fig.18). In fact, this action requires a series of strategic skills to mitigate existing risks, thus maintaining safety and improving the possibility of survival [68, 69]. These events constantly threaten the well-being of the crew and the success of the mission [68]. Therefore, enough medical and technological resources must be available to maintain good health.

Fig.18. Utopia Planitia on Mars. Date: September 5, 1976. Image Credit: NASA [70]

Gloves are one of the pieces of the spacesuit designed with the goal of providing astronauts with the manual agility to operate tools and interact at the Martian surface. Likewise, they provide insulating protection and are flexible, which allows working for long periods avoiding hand fatigue [40], [71].

The main application of BIOX-GLOVE is to activate an emergency plan on Mars. It is proposed to incorporate this biomechatronic innovation in future medical protocols [72] that activates an emergency system in accident cases, which will facilitate the immediate evacuation of the injured astronaut. In addition, this device, thanks to having strategically placed exoskeletons, is capable of providing stability in cases of bone fractures of the wrist and hand [9, 21].

Currently, unmanned rovers cooperate closely in planetary exploration; the operation of these vehicles is by remote control or semi-automatic [73, 74]. However, it is proposed that they will have a wider application for future missions, even as ambulance vehicles to transport astronauts with severe injuries on the Martian surface. Likewise, these means of transportation would be crucial to resolving various medical events more quickly, with good results and greater chances of rescue [68].

Finally, with this project, new adaptable interfaces could be created (T-EVA)[29] between the systems installed inside the astronaut suit and the base station, incurring in the development of developing new portable electronic technologies allowing assisted interaction and reducing the risk of injuries. Likewise, the glove is made by 3d printing technology for manufacturing in the command center or repair after an emergency.

4.2 Earth Application

A) Medical Background and Proposed Validation Test

Exoskeletons allow medical assistance in physical rehabilitation areas for people with motor impairment[26] by providing help to perform tasks and activities of daily living. These robotic-mediated therapies are helpful for specific and repetitive treatment in order to maximize the recovery process, especially in patients [75] with a history of stroke, associated with functional hand pathologies [76]. The main objective of these systems is to restore basic motor function and improve people's quality of life [77, 78].

Likewise, through artificial intelligence, gloves are implemented with sign language recognition systems based on flexible sensors, capable of obtaining data on the shape of the hand movement in an inertial measurement unit to recognize the gesture and transmit information through speech or text [26] [42] [79] making the most of non-verbal communication skills in patients with language aphasia.

The aerospace industry has provided significant knowledge and technology to improve our patient management on Earth [80, 81, 82]. Therefore, it is proposed that BIOX-GLOVE also have terrestrial applications in a hospital environment, especially in emergency medical services, because it has sensors and can activate a medical emergency system from the place where the event occurred. This action could anticipate the medical team to coordinate the transfer in an appropriate and timely manner. In another area, this device, due to its biomechatronic innovation, can be useful to implement physical medicine and rehabilitation services aiding patients with hand disabilities. This device has the great potential to be part of the complementary treatment of degenerative cartilage diseases such as rheumatoid arthritis.

It will be tested on Martian and Lunar analogs to validate this device's functionality since they have similar topographic conditions. La Joya Desert in Peru is considered a candidate for space exploration simulation due to its isolated location and geographic characteristics. [83-85] (Fig.19).

***Abstract*—One of the main concerns when it comes to contributions to the carbon footprint is the consumption of fuel by vehicles, more specifically that of mining vehicles. One solution to this problem is replacing the combustion engine vehicles with electric vehicles. This also poses the problem of low power density. This paper proposes a solution of using supercapacitors and hybrid capacitors with the aim of investigating how they can affect the performance of electric vehicles. For this purpose, a background of fuel consumption and alternative solutions to the problem are discussed, a prototype was designed and built. It was found that when supercapacitors and hybrid capacitors were used in combination with the battery the system had a notably longer endurance.**

Keywords—Electric vehicle (EV); hybrid energy storage; supercapacitor (SC); hybrid capacitor (HC)

I. Introduction

In recent years it has been noticed that the world is moving into an environmental era where more eco-friendly choices are favoured above the conventional choices that increase the overall carbon footprint [1]. South Africa along with many other developing and developed countries, has signed the Paris Agreement. With this in mind, the DMR (Department of Mineral Resources) of South Africa has increased the importance of each mine decreasing their carbon footprint, as the coal mines in South Africa contribute to 9% [2] of the countries greenhouse emissions alone. The large number of emissions due to the mines is mainly accounted for by the large number of vehicles and the size of these vehicles in operation there. Two additional concerns due to the vast amount of emissions were raised, namely, safety and cost concerns. The DMR raised the concern of safety for the workers, as the magnitude of fumes around these vehicles causes the ventilation to become insufficient, increasing effects of fume inhalations and temperature increases in the vicinity of these vehicles. The cost concerns were raised by the chamber of mines, which include concerns due to increased ventilation costs, increasing fuel price, increasing salary demands and costs to reduce the carbon footprint [3].

The mines are constantly expanding leading to an increased demand for fuel, which has a limited supply. The vehicles that are currently in use in the mining industry, mainly Load Haul Devices (LHDs) and Utility Vehicles (UVs) [2], [4] use either diesel or petrol to operate, which although initially cheaper and more readily available, pose several problems. Firstly, the fuel consumption is too high, and secondly the fuel consumption causes the vehicles to emit extremely poisonous fumes both above and below ground. The ventilation underground is not sufficient for the volume of fumes concentrated in the more confined working areas [5]. This not only poses a threat to the workers' health but also causes the temperature in the vicinity of these vehicles to be much higher than optimal [6]. Therefore, if the mine health and safety act and the fuel costs are taken into consideration, it is beneficial to implement an alternative energy source that will reduce fuel consumption and therefore costs, as well as increasing the health status of the workers.

Although the electric vehicles (EV) do not emit exhaust fumes, they do require electricity to operate, which in itself is also a massive greenhouse gas contributor, as coal is burnt to produce electricity in South Africa [7]. They can be more economically friendly in the long run once solar panels are more widely implemented for electricity production, but this is not in the scope of this research. The electrical vehicles also create a safer environment for the workers in the immediate vicinity. Another huge advantage of the electrical vehicles is that the unnecessary fuel expenses will be reduced [8].

As previously mentioned there are currently multiple solutions available and in place to solve the problem of a too large fuel consumption [9]. Hybridization is currently one of the more preferred solutions to any of these fuel consumption issues as it decreases the consumption significantly with the bonus of adding a couple other advantages to the existing system [10]. The idea of combining batteries with supercapacitors (SCs) is not a new one, it has been researched in depth in a previous research [11], however, it is yet to be implemented to see how it functions in an application.

EVs have emerged as an alternative to combustion engines as they do not emit carbon dioxide, however the extended charge period of the battery packs and the short drive range thereof lead them to still be under-utilized. One option to improve on these downfalls would be to integrate the EV with a hydrogen fuel cell (FC) [12]. The FC has a high energy density but a low power density, allowing it to be able to supply average power for an extended period of time if that time does not include power requirement spikes [13]. Power spikes occur when the load requires peak power, which in turn drains the energy source, to overcome this issue a buffer battery is used to supplement the FC during the spikes, increasing the operational period of the FC. Just like EVs, FC-EVs produce no pollutants during operation, however the production of hydrogen causes its availability to be quite low [14], [15]. The proton exchange membrane fuel cell (PEMFC) is preferred for vehicular use as it offers many advantages over the general FC, including the ability to tolerate air – it does not require pure oxygen.

Hydrogen FCs have their advantages and disadvantages that determine their application. Some advantages include: a driving range and refuelling time comparable to that of conventional vehicles (320-480 km), no tailpipe pollution, hydrogen is a by-product of mining for platinum and therefor relatively freely available, refuelling is limited by the speed of

978-1-6654-4067-7/21/$31.00 ©20XX IEEE

replacing the hydrogen gas, regenerative braking can be utilized to capture lost energy and charge the battery, it is highly efficient with a high energy density and low operating temperature and has a long life span [16]. Hydrogen FCs are however not without their disadvantages, namely, the size and weight of the system can pose a problem when replacing existing systems, the performance is degraded by carbon monoxide [16], the system is currently expensive and the storage of the hydrogen on the vehicle currently poses a challenge [17].

Hybrids use many variations of combinations of alternative power sources with the electric system [18]. Some alternative sources include combustion engines, solar, wind or ultra-capacitors. These sources are combined in many variations (that are sometimes user defined) in order to achieve optimal efficiency [19], [20] . Battery powered EVs use batteries to power an electric motor that puts the vehicle in motion. Batteries are recharged using grid electricity from wall socket or charging unit. These vehicles do not produce pollution themselves, but the production of the electricity required does cause pollution if renewable energy sources are not used [21]. The most common battery used in EVs is the lead acid battery as it is more robust, has comparably high recharge cycles, is generally safer than the other types and has good energy and power characteristics as compared to the other types [22].

When using batteries the advantages associated with them include, increased efficiency compared to combustion engines, no emissions, the possible use of renewable energy, pollution caused by production of electricity is much less than that caused by combustion engines, the long term expenses decrease, regenerative braking and idle-off can be utilized to increase efficiency, the system can be recharged at home, has near instant torque and an extremely fast acceleration [21]. More so, the system is smaller than the others and has an overall decrease in fuel consumption [23]. Although batteries tend to be the more viable option for energy storage in EVs [24] they do however have their downfalls including, an extended charge period, a short driving range (110 – 160 km) [21], low power density and the fuel consumption is heavily reliant on the powertrain characteristics [23].

II. Proposed Topology of Mining EV.

Pure EVs make use of grid power to charge the batteries that then store the power until the vehicle is required. The battery power is used to supply an electric motor, as well as all auxiliary control systems; the electric motor is then used to propel the vehicle. Although this system can sustain moderate power requirements, the battery essentially has a high energy density and low power density. The latter means that the energy of the vehicle will quickly be depleted if high power demands are persistently required. Therefore, another power source is required that will be able to supplement the system during the peak power periods allowing the batteries to have a longer operational period. There are many power sources that can be utilized for this purpose, but ultra–capacitors offer some advantages over the others – they recharge faster, they have much higher power densities and can be used in a variety of kinetic energy storage applications.

For this paper, the focus is on investigating how ultra-capacitors (supercapacitors – SCs, and hybrid capacitors – HCs) affect the efficacy of a battery powered EV. The system that was altered and tested consisted of an electric DC motor powering the vehicle and a windscreen wiper motor powering the steering system of the vehicle. All these components and the control system thereof were powered by the battery, in this case a 12 V, 7 Ah Lead acid battery. The layout of the proposed system is seen in Fig. 1. In altering the pre-existing system, a power switch was used to switch between the power sources when required, this was done using sensors that determined the current requirements of the motor at each stage of a test path. Fig. 1 shows the functional operation of the proposed solution.

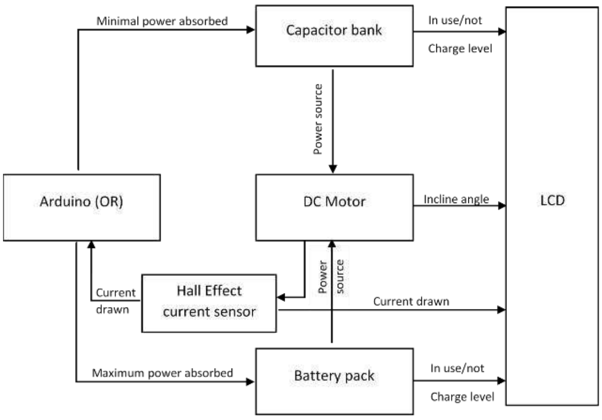

Fig. 1. Functional operation of system.

The power source consisted of a microcontroller that received information from the DC motor, via a sensor, that was used to control the power switch. The information from the DC motor sensors consisted mainly of the power absorption of the motor. When the motor absorbed significantly more power, it was assumed that the vehicle was traversing an incline, or that the motor was starting up and therefore required more power. This need was conveyed to the power switch that then chose the capacitor bank as the main power source. When the DC motor power absorption stabilized, the power switch chose the battery as main power source. When the power absorption remained low or disappeared entirely the capacitor bank stored any energy that the battery would normally waste. When the vehicle was again in motion, the capacitor bank was favoured to allow the vehicle to have a smoother acceleration until the vehicle reached a stable power absorption in which it favoured the battery as main power source. For convenience of the user, a Bluetooth module received the sensor values (current drawn by the motor, state of charge of current power source, incline level) and stored them to be analysed when desired. Different combinations of the power sources were used in order to compare the results and the results were used to determine any changes in efficiency of the vehicle.

For the integration of the power source with the vehicle and the remainder of the circuit, a DC/DC buck-boost converter was designed, a buck for the battery (12.5 V< battery voltage < 13.8 V) and a buck-boost for the capacitor banks (4 V < capacitor bank voltage < 16 V). This ensured that the motor received a continuous 12 VDC supply. Only one power source was used to power the drive motor at a time, therefore only one DC/DC circuit was required. The same h-bridge design that was used to control the servo motor and wiper motor was used for the buck-boost DC/DC converter for the energy storage hybridisation.

III. Results

The final circuit built and used can be seen below in Fig. 2, the design of the vehicle in Fig. 3(a), and the final vehicle implemented in Fig. 3(b). The SCs and HCs used can be seen in Fig. 4. A specific path was chosen with a specified length and varying levels of incline to compare the various combinations. First, the battery was connected as the sole power source, second was the SC bank, third was the HC bank and finally all three were used as a combination. Fig. 5 shows the incline of the path that was used to test the vehicle with the respective power sources and the amount of current drawn by the motor at each point.

To compare the energy sources the distance and time it took each source to traverse along the path until they were depleted was recorded. The discharge period of the batteries was recorded for individual use and when combined with the capacitor bank. Fig. 7 shows the results obtained from these respective tests. From the figure when the battery was used in combination with the capacitor bank the voltage thereof dropped at a slower rate than when used on its own. This allowed the vehicle to become more efficient over the long term. The discharge period of the capacitors was recorded for individual use and when combined with each other and the battery, this is shown in Fig. 7. The combination of the capacitors causes the discharge rate to be slightly higher than the SCs but significantly lower than the HCs. This caused the system to, again, be more efficient than when the sources were used individually.

In Fig. 8, there are two graphs, the current drawn by the EV and the state of charge of the EV (showing the state of charge of the power source in use), thus also showing when the sources were switched.

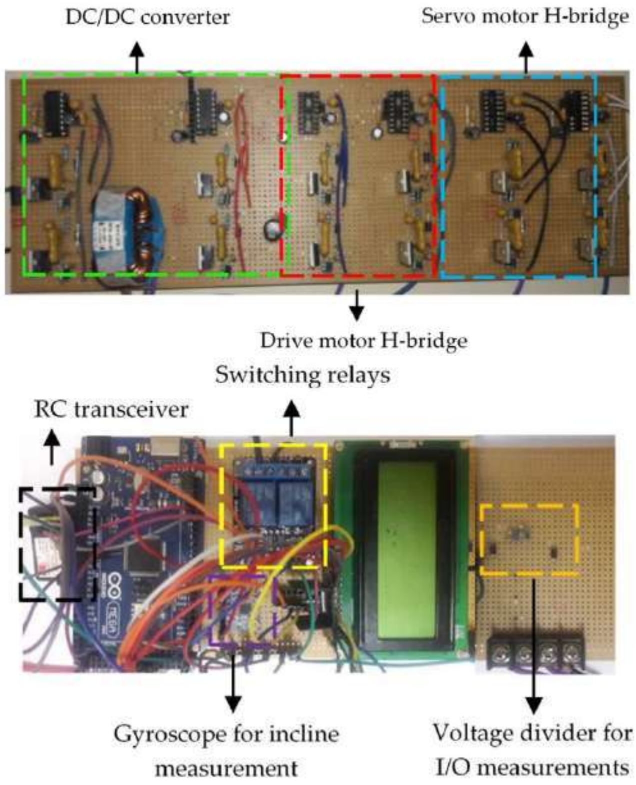

Fig. 2. Final circuit design.

The red blocks represent the sections where the capacitors were in use and the sections in between represent the use of the battery as primary source of power. The system was set to switch to the capacitor bank when the motor would draw current above 7.5 A. This was chosen after evaluating the results obtained from the individual use of power sources on an incline. After the measurements were taken the runtime of the vehicle with the individual power sources and the combination of the sources was documented. The battery lasted 2134 seconds, the SCs lasted 473 seconds, the HCs lasted 100 seconds and finally the combination of all three sources lasted 2849 seconds.

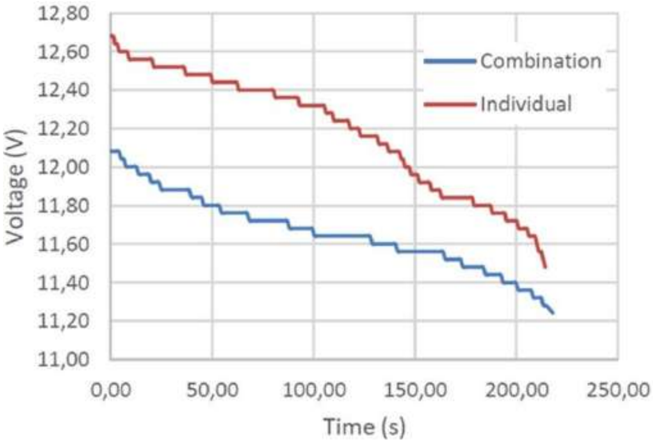

Fig. 6. Battery discharge with and without capacitor bank.

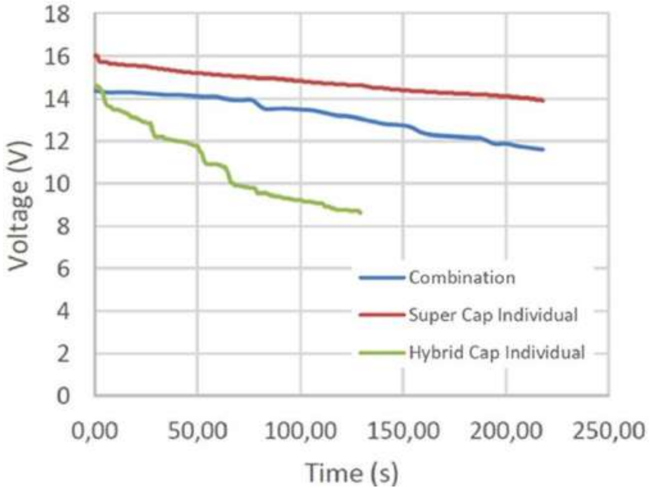

Fig. 7. Supercapacitor, hybrid capacitor an capacitor combination discharge on test path.

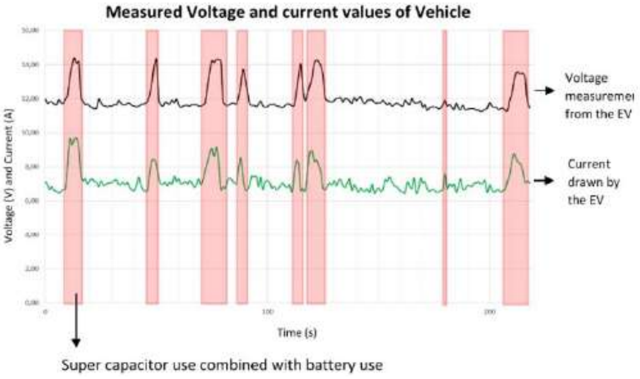

Fig. 8. Battery, supercapacitor and hybrid capacitor combination performance on test path.

Summarily, it was seen that the parallel combination of the capacitors in conjunction with the battery did result in a more efficient system. However, the benefit of the use of HCs was silenced due to the switching system not switching between the capacitor banks. It is therefore suggested to implement the switching between the SCs, the HCs, and the battery. For this research, the motor on the vehicle was replaced with a more efficient version, but the motor used could be further improved if it were to have a larger torque ability which would allow for the traverse of a steeper incline as well as giving the system more power to allow for a more inclusive testing environment. As a Bluetooth module had already been implemented in the circuit to increase ease of use the next step would/could be to implement a Neural Network onto the vehicle. This would further optimize the system and reduce complications due to human error.

IV. Conclusion

The super- hybrid capacitor EV was initiated to research the combined use of SCs and HCs along with batteries to reduce the fuel consumption and increase the efficiency of mining vehicles. The mining vehicles currently in use consume extreme amounts of fuel and emit equally extreme amounts of hazardous fumes into the environment. This vehicle would allow the eradication of the need for fossil fuels on the mines and create a healthier environment for its workers. The proposed solution, a vehicle that combined the use of a battery with SCs and HCs, was evaluated. After these elements were examined the design of the solution was simulated, built, and tested. It was found that the vehicle required a battery as the capacitors could not supply a constant voltage over an extended period. However, the battery lasted much longer with the use of the capacitors, as they supplemented the power source when the current drawn exceeded a certain current. The capacitors were used in this way as they provided a large current (and therefore power) burst, when required. This knowledge allowed for the optimal use of the capacitors and the maximum amount of operational time. Further research and testing would focus on the switching method between the sources, the construction of the vehicle used and the use of an intelligent controller, which could extend the endurance further.

hayman.salih@uniroma1.it

***Abstract*—Internet of Things (IoT) is a relatively new concept in computer science that connects devices with constrained resources to insecure internet through different technologies. IoT's fundamental components, including the wireless sensor networks and the internet, have an unsecured foundation that leads to DoS attacks, namely, sinkhole, blackhole, and grey hole attacks. To maintain the integrity and security of the IoT networks, many researchers implemented distributed ledgers in IoT environments. In this paper, we designed a hybrid framework between blockchain and IoT devices; the aim is to secure data transmission in IoT networks using blockchain technology to defend against DoS attacks. Our framework is called HFSDT-IoT. The method proposed in this paper consists of two phases to maintain security in the IoT. In the first phase, both a list of attackers and a safe list based on the Ethereum Proof-of-Stake (PoS) protocol is used, which complemented by utilizing the proposed IDSs Intrusion Detection System to discover malicious things. In the second phase, to decrease the obstacles in facilitating communication between blockchains, the inter-blockchain communication model creates a network of multiple blockchains with secp256k1 encryption used for heterogeneous blockchains. The experimental results of simulated scenarios show the HFSDT-IoT strategy can achieve better results when DoS attacks were launched compared to other blockchain-based methods, namely Bubble of Trust and Credibility Verification Method.**

***Index Terms*—Blockchain, Security attacks, Proof-of-Stake, Ethereum, Internet of Things (IoTs), HFSDT-IoT, Intrusion Detection System IDS**

I. Introduction

INTERNET OF THINGS (IoTs) is a network infrastructure that connects multiple computers, machines, and software services. IoT enhances human life and represents an essential part of today's urban lifestyle, packed with mobile devices and technologies [1]. Since IoT systems are having resource-constrained and ad-hoc in design, cyber-attackers may infiltrate them [2].This emphasises the need for research and development to design a safe and stable IoT system to tackle the problems and prevent attacks. Several attacks, including DoS attacks, are entering the machine illegally [3]. Since the attack affects IoT, it is a laborious task to eliminate the threat and get the device back online. Arraising the DDoS threats in the IoT environment makes the traditional information security measures, such as encryption or detection of intrusion, not enough for the system protection [4]. To elaborate, encryption and intrusion detection do not consider the sensor and actuator measurements or its compatibility factor with the IoT's physical process and control mechanism, and these process and control mechanisms are substantial to the protection scheme. Previously, IoT systems' problem was the mere attempt to eliminate a single type of attack and were only resistant to protect themselves against such an attack. If the system were subject to a combined attack, it would be practically inoperable, and the act of the intrusion operation would fail the IoT system quickly. Due to the vast network and sensing data produced by IoT devices and systems, cryptographic authentication is highly effective in continuous monitoring and analysis for IoT systems' security. The blockchain technology was proposed by Nakamoto Satoshi in 2009 [5] [6].

To maintain integrity and provide a more robust security propensity to the IoT environment, we designed a hybrid framework using a blockchain-based approach. The designed security framework uses ethereum smart contracts alongside the Intrusion Detection System(IDS). The designed framework contains two phrases, the first of which will establish a list of safe systems and attacker systems, while the second phase relies on blockchain network encryption. In the first phase, we designed a discovery and detection system using the PoS protocol of Ethereum alongside IDSs. The system divides the areas into different regions, and each region has its IDS. The IDS nodes are responsible for categorizing all the things or nodes into specified lists of attack and safe and updating these lists into a smart contract. The second phase of the system aims to decrease the obstacles in facilitating blockchain connections by employing an inter-blockchain connection model for heterogeneous blockchains to create a network of multiple blockchains with secp256k1 encryption. In this model, the blockchain system can communicate with other blockchain systems, and once the two systems are connected, the data and the messages get shared.

For method evaluation, a list of attackers, along with a safelist, is used to evaluate the process of discovering new

attacks and internal protection systems that have been deployed. The result has been compared with the other IoT-blockchain based systems, namely Bubbles of Trust proposed in “A decentralized blockchain-based authentication system for iot” [7] Furthermore, the Credibility Verification system proposed in “Blockchain based credibility verification method for IoT entities” [8]. The simulation was carried out using an NS2 environment with the same simulation scenarios. The results showed that our proposed method could detect 93 percent of the attacked nodes while the bubble of trust method can detect only 85 percent, and the credibility verification method is 78 percent.

The paper presented here is organized as follows: Section 2 introduces some relevant terms regarding application scenarios, security attacks, and detection schemes, section 3 discusses the proposed HFSDT-IoT security strategy and how it works under such circumstances. Section 4 focuses on performance evaluation parameters, investigations, and simulation of the results, while section 5 concludes the paper.

II. Relevant Terms

This section provides an overview of this research work’s fundamental parameters: application scenarios, security threats targeting IoT, and detection schemes to protect IoT.

A. Security Attacks

As IoT systems rely on wireless networks for connectivity, they are vulnerable to active and passive security threats and functional decomposition. Figures 1 and 2 show a vulnerability threat to IoT. The following vulnerabilities are of concern in this paper:

Sinkhole Attack: One of the primary attacks threatening the user agent server (UAS) is a type of attack known as the Sinkhole (SH) attack. In this attack, a malicious node broadcasts illusory information to the IoT about the routing path to impose itself as a legitimate route towards specific nodes for incoming connections and thus attract all incoming and outgoing traffic data. The Sinkhole attack’s objective is to draw all the traffic on the network towards the sinkhole node and alter the data packets or silently drop them altogether. Sinkhole attacks can increase the network overhead and consumption of energy while decreasing the functionality and lifetime of the network before ultimately annihilating the network system all together [9].

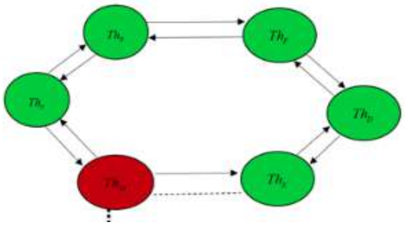

Fig. 1. Simple gray hole attack.

Black Hole Attack: This type of attack acquires when a Routing Request (RREQ) packet is sent, and as a response, the black hole node transmits a forged routing response (RREP) with a claim that it is a short and unexpired path even when the destination entry from the routing table is absent. When the constructed RREP packet enters the source node, it is possible to delete all valid RREP messages sent from other mediums and destination nodes from this mishap intermediate node. The black hole node effectively attracts the traffic to the target destination by misleading a source node, and instead of sending inbound RREP messages, all the data packets are dropped in the black hole node to prevent detection. The black hole node resets the hop count to a low value when a propagation path is forged, and the number of destination sequences to a high value maximises its probabilities to appear at the source node. The black hole attack also appears from the source node by forging fields-source sequence numbers in RREQ packets and hop counts, resulting in the poisoning of routing tables in intermediate and destination nodes [9].

Simple gray hole attack: In this kind of gray hole attack, a malicious node foists itself as a medium node that belongs on the shortest route to the final destination. Regardless of the routing table, the gray hole node is always accessible to reply route requests and it may receive data packets but will drop the packets instead of forwarding them as directed by the RREQ. In the flooding-based protocols, before sending a reply by healthy nodes, the gray hole node sends a reply to the requesting node. In this way, the selected route will contain a malicious node which drops the packets or send them to incorrect nodes. The process of a gray hole attack is shown in Fig. 2. As seen in this figure, the data packets should be transferred from a source $Th_S$to a destination Th_D. For this purpose, a proper route from the source to the destination should be detected. So, if Th_M is malicious, it fakes itself as a node present in the shortest path to the destination. Then, it will respond to the request by sending a reply to the Th_S sooner than other nodes. This way, the Th_S will send the data packets to Th_M and discard the replies received from other nodes [9].

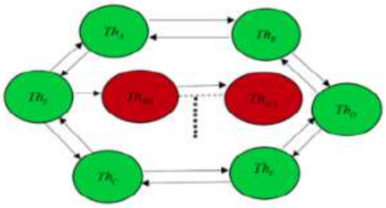

Fig. 2. Cooperative gray hole attack.

Cooperative gray hole attack: another way to implement a gray hole attack is known as cooperative gray hole attack in which multiple malicious nodes cooperate together in the attack to violate the routing protocol and security system. As depicted in Fig. 3, when malicious Th_{M1} and Th_{M2} act together, Th_{M1} refers to Th_{M2} as its next hop. Following the scenario of the source $things_S$ sends a Further Request packet $FReq-packet$ to Th_{M2} through another route other than Th_{M1} (e.g.$Th_S - Th_C - Th_E - Th_{M2}$). The $things$ asks Th_{M2} if it is the next hop ofTh_{M1} and if it has a valid route to the destination Th_D . Since the Th_{M2} is cooperating with Th_{M1}, following Reply $FReq-packet$ will be positive. Consequently, the source Th_s assumes that the route i$Th_S - Th_{M1} - Th_{M2}$s is secure, and starts sending the data packets. Once intercepted, the packets will be dropped by Th_{M1} . [9]

B. Detection schemes

Several studies developed and employed various security metrics to detect security attacks and secure IoTs from misbehaviour attacks. This is not a recent problem and has been previously studied extensively. Researchers currently propose several techniques to deal with misbehaviour attacks. Below, we focus on some recent studies and research on blockchain and IoT networks to enhance security. In the proposed framework in [5], blockchain stores all IoT devices communications as transactions, resulting in a more straightforward and more robust chain of custody process. Blockchain ensures the integrity of the data analyzed and strengthens the security while preservation is more reliable through a decentralized method. Furthermore, the forensic investigation participants (e.g., the device users, the manufacturers, the investigators, and service providers) can transparently confirm the investigation process as the ledger is publicly distributed. Paper [7] proposed a decentralized system named bubbles of trust using Etherum blockchain for IoT networks. The approach creates virtual secure zones to authorize the devices to be a part of the network, and they communicate securely. The system's security parameters are designed in a secure way where data integrity and availability considered for different scenarios. Besides, the authentication scheme in the system and security properties are resilient toward incoming attacks. Paper [10] invented a framework for IoT networks using a blockchain approach where the new framework improved the security and self-defence capability against cyber attacks. Moreover, the study provides an intensive discussion to enhance the power grid's security by using meters as nodes in a distributed network. The authors also claim that their proposed method can be considered a promising solution for data security in modern power systems. In the research [11], due to the limited security prosperities of IoT devices, the authors used the blockchain Ethereum based algorithm to enhance security. They implemented their idea using the whitelisting application alongside with consensus protocol of Ethereum. In this paper [12], the design of a novel architecture is proposed by combining these technologies introducing new opportunities for flexible and efficient DDoS mitigation solutions across multiple domains. The main advantages are the deployment of an already existing public and distributed infrastructure to advertise white or blacklisted IP addresses and the usage of such infrastructure as an additional security mechanism to existing DDoS defence systems, without the need to build specialized registries or other distribution mechanisms, which enables the enforcement of rules across multiple domains. In [13], the authors investigated the issues related to data integrity in wireless networks and the challenges to design a secure system. In their study, a new method has been proposed using the filtering techniques in public wireless networks. Before starting the transmission process, the safety devices register the IP and MAC address in the router for security and a safe network design. This way, it protects the system's information, and unsecured devices can not be a part of the communication process. Software-Defined Network (SDN) as a new centralized network controller has been recently applied using Openflow protocol. In the study [14], the authors investigated the SDN controller and the policy of filtering the MAC and IP address to give stronger security proprieties to the system. Besides, they proposed the use of a firewall for the SDN networks for MAC filtering. Their study checked the performance in terms of packet delay for MAC and IP filtering technique. In the paper [15], the authors proposed a discovery tool to detect spoofed Mac attacks. These kinds of attacks appear in the system when the address resolution protocol ARP pairs false IP/MAC address. Moreover, the proposed discovery tool the authentication to the new pairs confirms only when the proposed method checks all possible spoofing causes. This way, the checking process guarantees security before paring. In the research [16], the authors investigated the security issues available in IoT networks. In order to enhance the security parameters and give more robust prosperity to IoT networks, SDN Software Defined Network) Edge Computing has been used. Using this combination is to benefit from the SDN filtering mechanism and enable the IoT networks for better security and access control proprieties. To enhance the security in blockchain nodes, the authors in [17] used SDN to filter network traffic. For that, a firewall and ChainGuard utility for blockchain applications has been used. This change guarantees the packets from illegitimate sources cannot affect the blockchain. ChainGuard provides access control functionality and can effectively mitigate flooding attacks from several sources at once.

III. Proposed hybrid framework

In the following section, we design a DoS-security threats-immune schema by employing the blockchain approach. The HFSDT-IoT consists of three sections, such as the overview of the proposed framework is discussed in Sect, 3.1, architecture of the proposed hybrid framework is discussed in Sect, 3.2, and encrypted connection between different blockchains is discussed in Sect, 3.3.

A. Overview of proposed HFSDT-IoT framework

The internet of things (IoT) has a big advantage in various fields and industries which is that its growth and adaptation speed is very high. Very soon billions of connectable devices will spread through smart homes and cities, collect data, transmit them to huge databases for analysis and processing, and run the commands sent from smart applications and learning-device-based systems. These technologies have been proven for connections among generic computer devices for years and already answer the needs of small IoT ecosystems like smart homes. However, with the growth of IoT, centralized networks will soon become the system bottleneck and because of the network traffic overload and latency and sudden interruptions in sensitive transactions, they need hubs and communication hardware suitable to these situations for more investment. A solution is decentralized IoT networks for improving the speed and connectivity. In many cases, replacing the internet connection with local inter-device connections leads to increases speed and efficiency. Fortunately, the lack of decentralization has been solved in another popular technology: Bitcoin. The famous encrypted currency which is designed using the less known (but very exciting) blockchain technology. Blockchain is a data structure which allows for the creation and maintenance of a ledger of transactions which is shared among the distributed network nodes. Blockchain through encryption allows the participants to skillfully manage the ledger without having a central reference. When blockchain gets adapted for IoT, it will use the same mechanism used in Bitcoin transactions for creation of an unchangeable record of the smart devices and the transactions between them. Doing so enables independent smart devices to connect directly and check the transaction credit without the need for a centralized force. The devices are registered in the blockchain once they enter IoT networks and can process the transactions after that. The transactions are signed digitally using public key encryption which uses two keys including the public key and the private key. These two keys are mathematically related to each other. Considering the utilized mathematical complexity, it is almost impossible for these keys to be guessed and this makes hacking the transactions almost impractical. The public key is used to sign and encrypt a message for sending and the specific receiver can decrypt the message using its private key. In fact, it can be stated more simply that blockchain is a distributed database which is identified as a distributed ledger. In this technology, the network is able to preserve the information integrity of the database content despite the existence of several users which record and correct data simultaneously and the possibility for the data to interfere with each other. Considering the encrypted data structure that the blockchain has, integrity is preserved without any central controller. Although the popularity of blockchain is rising by the day, the increase in the number of cyber-attacks might damage this process. Since perpetrators seek to attack and perform malicious operations in all networks, due to the exchange of data between the things these perpetrators also exist in the internet of things in the present world. One cyber-attack is the DoS attack which causes huge computing resources to be wasted by sending lots of fake requests. In these attacks where one or two main computers get attacked, the service becomes unavailable by sending fake requests and extensive attacks. Performing the DoS attack on a blockchain-based network is difficult as the attacker need to reach consensus or agreement in more than half of the nodes. Therefore, using blockchain to increase the security in the internet of things is addressed. When blockchain adapts to IoT, it will use the same mechanism used in Bitcoin or Ethereum transactions for creating an immutable record of the smart devices and the transactions between them. Doing so enable the smart devices to connect directly and verify the validity of transactions without the need for a centralized force. The devices are registered in the blockchain once they enter IoT networks and can process the transactions after that. The process of a DoS attack is shown in Figure 3

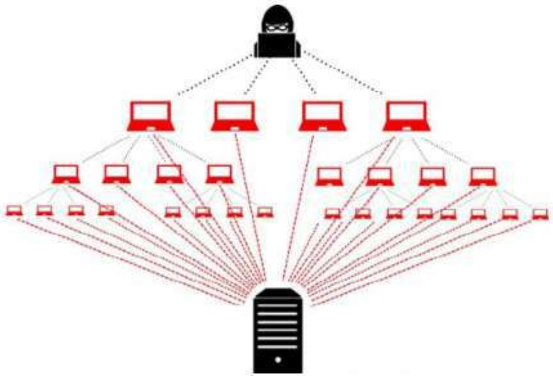

Fig. 3. Cooperative gray hole attack.

In the following section, we study a method based on blockchain for detecting and preventing DoS attacks in the internet of things. In the proposed method, a list of attackers along with a safe list for discovering attackers based on the smart contracts in the PoS protocol of Ethereum which is completed by utilizing IDSs. Also, in order to decrease the obstacles in facilitating blockchain connections, an inter-blockchain connection model is presented for heterogeneous blockchains by creating a network of multiple blockchains with secp256k1 encryption. In this model, the blockchain system is able to communicate with other blockchain systems. After two systems are connected, the data and the messages get shared.

B. Phase 1: Architecture of the proposed hybrid framework

In the proposed method, the PoS protocol of Ethereum is used. Ethereum is based on a smart contract where the smart contracts are applications that run exactly as specified by the creators and Ethereum allows the developers to create various smart contract applications. The architecture of the proposed system is presented in Figure 4. The web server might undergo a DoS attack by the hosts in several domains. These attacks are identified in the proposed method using the Intrusion detection system IDS and the considered list of attackers which are placed in the smart contract. The users in the proposed system first need to create a safe list which is of the smart-contract-based type. However, once the attackers affect the web server, the under-attack users receive the IP address of the attackers from the IDS and save them in the list of attackers. In the Ethereum blockchain, once every 14 seconds a new block is created. Therefore, the common domain of the updated lists receives the addresses which must be blocked and verify the attack authenticity by analyzing the traffic statistics and validity of the target address. Each IDS node covers the region in the network that it watches. Different number of IDSs affects the region being covered and also the attack identification area.

There are three hypotheses regarding this matter:
• The IDS node is placed in an area where it can put the BLOCK messages in the list of attackers in order to identify the DoS attack.
• The authentication mechanism has set of rules applied by IDS in order to detect or delete malicious things.
• Each intrusion detection system (IDS) must check its own area.

As soon as other domains receive the list of attackers from the IDS, retrieved it, and verified the attack, various reduction strategies can be employed based on the existing policies and mechanisms in the area. Also, it can block the malicious traffic near its source.

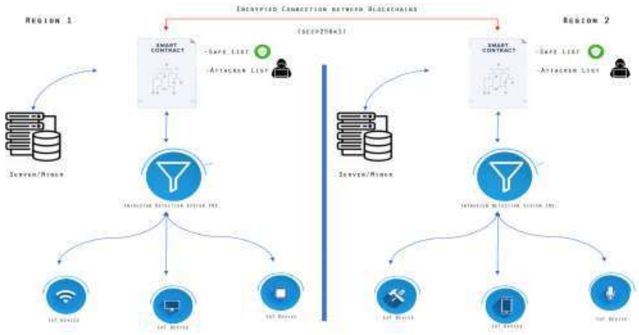

Fig. 4. HFSDS-IoT system model

The architecture and system model of the proposed system shown in figure 5. The system consists of the following three components:
Users : they might update the IP addresses located in the safe list or the list of attackers in the Ethereum blockchain.
IDSs: They propagate the IP addresses located in the list of attackers, retrieve the lists containing the propagated IP addresses, and execute the DoS reduction mechanisms. In the proposed method, the things participating in the blockchain network have IDS units for monitoring and evaluation that perform one or both operations at the same time (which usually perform both simultaneously). Furthermore, the raw warning data generated by the IDSs is saved in a blockchain through a series of transactions which are repeated among the things participating in the network.
Smart contract: This is the regulatory body of the system which is responsible for authorizing the devices and ensuring that they do not operate beyond their gas limit.
Server/Miner: The IoT-Ethereum network includes multiple volunteers acting as the servers/miners. These entities are responsible for verifying the transactions and data exchange through smart contracts using high computational and processing capabilities.

1) Detection of the IP address of the malicious thing by the IDS: Detection of a malicious thing is carried out based on the requested transactions of a thing. The transactions in Ethereum are includes the following important items:
Signature: signature that authenticates the sender and specifies their intention for sending the message for the receiver through the blockchain.
Value: specifies the value intended to be sent by the sender to the receiver.An optional option for information; which can contain a message that is sent by convention.
Gas limit; specifies the maximum number of computational steps that the transaction execution is allowed to pass.
Gas price; specifies the fee that the sender expects to be paid for each fuel unit.
The IDS in the proposed method checks each one of these items and in case these items do not match in a transaction, it introduces the transaction as malicious and adds it to the list of attackers in the smart contract. The communication among the things takes in two separate logical layers, namely the layer for alert exchange and the layer for consensus. In the layer for alert exchange, our proposed method carries out the process to propagate the warning data, which includes the malicious IP addresses. In specific, the IDS nodes are responsible for exchanging and gathering the data for the alerts data according to their role as units for monitoring or analysis. Moreover, the operation to evaluate the data is carried out using IDSs via running an agreement protocol and reaching a consensus on the transactions that have to be present in the ledger. What results in intensifying the extreme participants' responsiveness and guaranteeing the data integrity, is the connection existing between the two layers, the result of the layer for consensus, and the fundamental blockchain structural properties. The engaged things run a consensus protocol to guarantee the validity of the transactions before adding them to a block. This process, which will be introduced in the next phase, guarantees that only the alerts that are formed correctly and soundly are included in the intended blockchain, the alert data transactions are resistant to any manipulation, and each participating entity has a global perspective of the alerts. List of attackers: the general Ethereum blockchain is the executor of smart contracts that use logic to report the IP addresses of the attackers and the alert data obtained by the IDSs in the blockchain. The considered architecture has been built according to the following principles:

1) The DoS discovery and reduction countermeasures which have been presented by the attackers or the users.
2) The attack information reception report which is discovered by the IDSs. Also, the IDSs can encrypt the special alert data in two layers and also the distributed ledger and the keys will only be available to the participating things. This way, the things or other devices which are not a member of this collaborative group and do not have the specific private key, cannot see the alert information exchanged and processed among the

verified participants. Therefore, the peers can cooperate in multiple groups without revealing any confidential alert information to external things while remaining in the same network.

3) In order to prevent the attack, the blockchain DoS reduction modules are run on the users and report their IP addresses and listen to the blockchain.
4) The IDSs report the malicious addresses to the list of attackers by proving the IP address ownership of the users.
5) Different areas, different security policies, and also different fundamental management systems are run. Immediately after being notified of a DoS attack where a customer verifies its validity, some countermeasures get defined based on the security policies of the domain and the existing actions.
6) Consensus is controlled by a pre-selected set of things. In this case, the verifiers are known and the risk of several malicious peers connecting to the system simultaneously (DoS) and eliminating the validity by the IDSs is decreased. Furthermore, if a peer has malicious behavior, i.e. starts sending fake alerts, it will be discovered by the IDSs and added to the list of attackers. Then, the blockchain rules will be altered and the fake transactions will be undone which will be described in length in the next phase.
7) The next important item is related to the alert data and malicious IPs during the sharing process at each one of the two communication layers (alert exchange and blockchain consensus). For this purpose, our suggestion is to use a compressed representation, using bloom filters for example, for communications in the consensus layer in order to decrease the overload and the size of the blockchain. On the other hand, in the alert exchange layer, where the data exchange can potentially occur immediately after the request, raw data exchange presents the highest validity level to the system.
8) In the proposed method, regarding the alert information about the IP of the malicious things and confidential information (exchanges in the consensus layer), it is important to provide a mechanism that keeps the privacy of the participating sides. One of the solutions can be the encryption of alert data using symmetric-key encryption and creating keys be only for participants that have the right to read them. This allows each peer to remain in the same network but be able to decrypt and only check the alert data which they have access to. However, this creates overload in the form of key management and distribution. As mentioned before, in the proposed method, the keys are only available to participating things. This way, the peers which are not a member of this collaborative grout and do not have the specific key cannot see the alert information exchanged and processed among the verified participants.

Therefore, in the proposed method, at first each domain, the participating users or customers for example, need to create a safe list containing the IP address or an address range verified by a source. Then, the discussed safe list is registered as a register-based contract such that the participation can be easily tracked. Therefore, the corresponding safe list can be identified. Then, the input traffic in the customer and user area is analyzed by IDSs and malicious IPs are filtered using this monitoring tool. In the proposed method, the completed blockchain smart contract, which can be deployed as a complementary security features for any system in danger of malicious DoS attacks, uses the IP addresses placed in the list of attackers or the safe list. Since the connection might be among multiple blockchains, in the next phase of the proposed method, an inter-blockchain communication model for heterogeneous blockchains through the creation of a network of multiple blockchains is introduced to decrease the obstacles of facilitating blockchain communications. In this model, the blockchain system is able to establish connection with other blockchain systems. After the two systems are connected, the data and the messages get shared.

C. Phase 2: Encrypted connection between different blockchains

When a blockchain transaction from a user is transmitted to the blockchain system, the system concludes the received transactions and stores the results in the ledger. The agents transfer among the accounts existing in the system as well. Managing the transactions that need asset transfer among two different blockchains is not the same, however. First, the trajectory for delivering the transactions to the target blockchain system should be identified by the source system. Second, there have to be similar answers from the two chains participating in the transaction, following the completion of the cross-chain transaction. The method to move cross-chain assets presented here not only provides the account balance on two chains for having reliable transfers (i.e. resulting in an attack-free method) but also considers the account balance for transfers within the blockchain. In our proposed method, the information on the blockchain address is recorded in a standard format. During the cross-chain transactions execution process, once the decryption is concluded, to ensure the stability of both considered systems, three steps are employed. Guaranteed transfer restricts unreliable participants from making payments. In each blockchain, there exists a public guaranteed address that functions and a reliable mediator for payment within the chain. Based on the routing table available in the router blockchain, the transactions are then transferred. We define the transformation process between a local transaction and a standard cross-chain transaction as two functions. These functions consist of the package and the package removal functions. The responsibility of the package functions is to wrap up a local transaction into a standard cross-chain transaction while the package removal function is responsible for parsing a standard transaction to a local transaction. The assets can be transferred from a chain to another chain through transfers using the connection between blockchain systems. In the inter-blockchain connection model of the proposed method, the transaction needs to be a series of atomic, consistent, durable, and isolated operations. In order to ensure system durability, after a transaction is completed, it is recorded in the ledger and will be immune against system failures. For separation, the writing and reading operations in a transaction need to be serialized, meaning that the transactions are completely separate from each other. In order to guarantee transaction consistency, the cross-chain blockchain method with elliptic curve cryptography is proposed. In our proposed method, three steps are carried out which lead to an agreement between two chain sets. This way, the receiver can make the final decision on whether to perform the extra phase or disconnect. Specially, the ledger is also used in order to eliminate the need for a third party.

1) Performing inter-blockchain transactions based on the secp256k1 encryption: After discovering the malicious thing and removing it from the network which is done in the first phase using the IDSs where each malicious and safe IP becomes a part of the smart contract by being placed in the list of attackers or the safe list, the transmission of the assets is carried out using the elliptical curve cryptography (ECC), which is known as secp256k1 in Ethereum and through a crossover blockchain in order to send the assets safely and as a correct transaction from a blockchain to another. The security of the transactions based on secp256k1 is used in order to ensure that the sent transaction is safe. The Elliptical Curve Cryptography (ECC) is a public key encryption method which is designed based on an algebraic structure of elliptical curves on finite fields. The Elliptical Curve Cryptography (ECC) is used to ensure complete immunity against security risks like confidentiality, integrity, privacy, and authentication. An elliptical curve E is described as presented in Eq. (1).

$$Y^2 = \left(X^3 + AX + B\right) \tag{1}$$

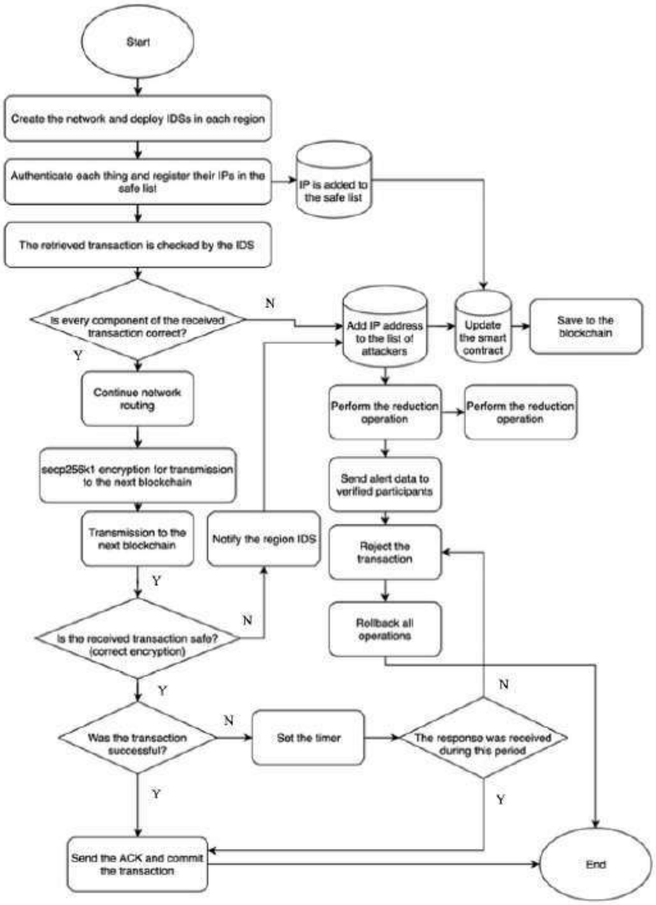
The highest degree in this equation is 3. In order to perform higher levels of encryption and decryption, the standards proposed by NIST must be met. If the root of both sides is taken, the equation will become the as presented in Eq. (2).

$$Y = (\pm\sqrt{X^3 + AX + B}) \tag{2}$$

The elliptical curve cryptography algorithm used by Ethereum is called secp256k1. The secp256k1 equation is as presented in Eq. (3).

$$Y^2 = \left(X^3 + 7\right) \tag{3}$$

This cryptography needs a smaller key compared to other cryptography methods based on Galois fields.When a blockchain wants to transfer some transactions to the next blockchain, we use the secp256k1 algorithm in order to protect the information. Using this algorithm, the transactions get encrypted before the actual routing process. After encryption, the main data are protected against malicious and unauthorized nodes. The SHA-1 method is a hashing method which is used to verify the validity of the data. The SHA-1 algorithm is considered a safe algorithm for the hashing operation. In fact, Hash is a unique string where based on an input string data, an output hash is created which is unique. The transactions created in a blockchain are encrypted using the secp256k1 cryptography algorithm. The hash value used to encrypt the generated transactions is created by the SHA-1 hashing algorithm. This way, the network sends the encrypted transactions and the corresponding hash value through the next chosen blockchain and each blockchain has its own safe list and list of attackers in its Ethereum smart contract. The receiving block in the next blockchain calculated the hash value for the received encrypted packet. If the new hash value is equal to the received hash, the data were protected which demonstrates that the previous block was not an attacker. If the hash value is conflicting, the thing sends the IP of the sender block to its nearest IDS. Then, the IP address of the malicious node is added to the list of attackers found in the smart contract and the malicious node gets separated from the network. In case there are no malicious nodes, the packets get sent all the way to the destination this way and no damage occurs to the transmitted data because they are encrypted. The exchange process in the cross-blockchain in the proposed method is described briefly in Figure 5:



Start
Create the network and deploy IDSs in each region
Authenticate each thing and register their IPs in the safe list
IP is added to the safe list
The retrieved transaction is checked by the IDS
Is every component of the received transaction correct?
N
Y
Add IP address to the list of attackers
Update the smart contract
Save to the blockchain
Continue network routing
Perform the reduction operation
Perform the reduction operation
secp256k1 encryption for transmission to the next blockchain
Send alert data to verified participants
Transmission to the next blockchain
Notify the region IDS
Reject the transaction
Y
N
Is the received transaction safe? (correct encryption)
Rollback all operations
Y
N
Was the transaction successful?
N
Set the timer
The response was received during this period
Y
Y
Send the ACK and commit the transaction
End

Fig. 5. Flowchart of the HFSDT-IoT

Parameter	Value
Coverage area (m x m)	First scenario: 3000 x 3000 Second scenario: 4000 x 4000
Simulation tool	NS-2
MAC	IEEE 802.11
Transport	UDP/IPv6
Range of communication	220 m
Bandwidth	2 Mbps
Traffic type, rate	CBR, 25 packets/sec
Model of mobility	Random way point
RX and TX ratio	95%
Number of nodes, and Packet size	500, 256 Kbps
Number of connections, and Pause time	50, 100 sec
Maximum mobility (varying)	5 m/sec - 25 m/sec
Percentage of malicious nodes	0% - 30%
Simulation time (varying)	500-2000

TABLE I
SETTING OF SIMULATION PARAMETERS.

IV. Evaluating the Performance

In the following section, the performance of the HFSDT-IoT is evaluated to prevent DDoS attacks.

A. Performance metrics

The feasibility and efficiency of our proposed HFSDT-IoT solution were carefully tested in this section using extensive simulations. The results are compared with Bubble of Trust and Credibility Verification Method, approaches proposed in [7], and [8] respectively. The detection ratio, and packet delivery rate are evaluated.

Detection rate:Detection ratio is the division of the number of IoT things that have been misbehaved into the cumulative number of real things. This means that it is likely that all the security threats will be identified effectively. The formula is then shown in the below detection rate of Eq 4.

$$DR = \left(\frac{TPR}{TPR + FNR}\right) * 100 \qquad (4)$$

PDR is the percentage division of total data packets collected at the destination Thing to total data packets sent by the source Thing. Eq. 5 shows the average PDR collected for tests.

$$PDR = \frac{1}{n} * \frac{\sum_{i=1}^{n} X_i}{\sum_{i=1}^{n} Y_i} * 100\% \qquad (5)$$

B. Simulation setup and comparing algorithms

The key benefit of simulation is that it simplifies research and protocol verification, particularly in large-scale systems. Our proposed solution's efficiency is evaluated using NS-2 as the simulation method in this section, and the findings are discussed further. It is worth noting that both HFSDT-IoT, Bubble of Trust, and Credibility Verification Method parameters and settings are treated the same.

C. Simulation results and Analysis

This section analyses the security performance of HFSDT-IoT under the two DoS attacks scenarios outlined in Table 1. The simulations carried out using 500 IoT things consistently expanded in the network area initially.

The detection verification rate has been examined for HFSDT-IoT compared to two other methods, namely, Bubble of Trust and Credability Verification Method. Figure 6. represents the summarized results for the number of things examined. The represented scenarios in Figure 6 (A, B and C) are the number of malicious things set as 10%, 20% and 30%, respectively. The detection performance for both compared methods is reduced, mainly when the number of attacks is high, as seen in the diagrams. This decrease is even greater in creditability verification comparing to the Bubble of Trust method. The detection performance in our proposed algorithm is much higher than the other algorithms, and the detection rate can reach up to 93.5 %.

The obtained results show that when the number of normal things and the rate of malicious things are equal to 500 and 20, respectively. When there are 30 malicious nodes in the IoT network using HFSDT-IoT, the detection rate decreases to 87.13%. Employing the same scenario for the Bubble of Trust and Credability Verification Method decreases the detection rate to 75% and 70%, respectively.

Figure 7 demonstrates the node's ratio of detection against DoS attack with differing misbehaving ratio. As can be seen, there is an inverse proportional relationship between the node's detection rate and the misbehaving ratio. With a misbehaving ratio of less than 0.1, the detection rate exceeds 94, while in the misbehaving ratios of greater than 0.1, the node's detection rate surpasses 93 compared to the other two methods.

The comparison results of the HFSDT-IoT proposed scheme, with the Bubble of Trust, and Credability Verification Method in terms of packet dilevery rate PDR at different percent of DoS attacks is provided in Figure 8.

V. Conclusion

With an expansion in IoT and frank implementation of these networks, a need for securing the communications among IoT nodes recognised as essential. A stable, intelligent agent-based strategy must be developed to meet the challenges, which achieves both immense safe mode and the efficiency of the desired networks. In this paper, a hybrid method consisting of two phases was proposed for maintaining security in the IoTs systems using blockchain technology. In the first phase, the Ethereum PoS protocol was used to discover DoS attacks. In this phase, the smart contracts found in the Ethereum protocol improved using safelists and the list of attackers that the IDSs discover. In the second phase, secp256k1 encryption with cross-blockchain transmission has been used to execute inter-blockchain transactions safely.

The performance HFSDT-IoT investigated using NS-2. The obtained results in the simulation demonstrated that the HFSDT-IoT was very robust against DoS attacks, and It presented that it has a high level of security. The detection rate is more than 93.50 %, and the packet delivery rate is more than 95.76 % compared to current approaches.

Understanding the Information Disseminated Using Twitter During the COVID-19 Pandemic

Jorge Torres[1], Vaibhav Anu[2], Aparna S. Varde[3]
Department of Computer Science
Montclair State University, Montclair, NJ, USA
torresj44@montclair.edu[1], anuv@montclair.edu[2], vardea@mail.montclair.edu[3]

***Abstract*—Twitter, with its ever-growing influence, has continued to serve as a means of spreading information and often providing early warnings to the situations that the world is encountering. The COVID-19 pandemic is no exception. With this disease resulting in hundreds of thousands of deaths, it is valuable that an analysis is conducted regarding the source of information posted on social media sites such as Twitter. In this study, we specifically analyze the source-URLs being posted by influential Twitter accounts. Our main goal in this study is to understand the kind of online materials, i.e., external weblinks that Twitter users prefer to promote/share about COVID-19.**

Keywords—Data analytics, Coronavirus, COVID-19, Pandemic, Social media, Twitter informatics

I. Introduction

With the rise of COVID-19 many people across the globe are looking to the Internet for information related to aspects such as symptoms, remedies, and precautions. As in many of the global disasters of the past, this pandemic came with early warnings. News of the virus was believed to have started late December 2019 and by late January 2020 it had already reached the United States and had become recognized as an emergency by the World Health Organization (WHO) [1][2]. It still had not become a pandemic until March 11, 2020 thus giving the world about 90 days of preparation. While governments across the globe were preparing their own approach to deal with the pandemic, their citizens were dependent on the global coverage of COVID-19 and the experiences from the pandemic's past victims to find more information.

One such approach used by the general public to discover COVID-19 information was through visiting the social media site Twitter. Despite its 280-character limit, Twitter has been used to spread information of all kinds ranging from what someone has eaten today to the personal opinions of those who have a large Twitter following. In addition, *Twitter also allows users to provide external links (URLs - Universal Resource Locators)* which connect to websites outside of Twitter. These links can be used to direct a Twitter user's followers to a website more relevant or useful to the topic at hand. In the case of the pandemic, these links were used to provide information about COVID-19 directly from government websites, webpages of medical organizations (e.g., Johns Hopkins), and informational websites maintained by other organizations/individuals across the globe. A pertinent question that needs to be asked however is: how much of that data is safe to use (i.e., whether the data is trustworthy or not). After all, when used incorrectly, the wrong information could result in disastrous and in the worst case fatal situations for many people across the globe [3].

To that end, the intention of this article is to investigate what kind of information has been spread through social media regarding COVID-19. Twitter is a popular resource for such a data informatics task due to its easy-to-use application programming interface (API) which allows for researchers to easily collect data from Twitter without endangering the users who frequent Twitter. Such data can then be grouped and analyzed depending on the researcher's intentions. While simply viewing tweets might not seem significant on its own, it is the sheer quantity and influence of tweets collected that results in analyzations being vast and diverse. Via this data we can now observe the websites (URLs) that were promoted by Twitter users during the first days of the pandemic announcement. This allows for further analysis of whether these websites contain misinformation and if that misinformation can potentially harm others. Unfortunately, being able to determine if a tweet is indeed factual requires significant analysis and will not be the focus of this paper. Instead, this article is created to ask and answer two significant questions.

1. RQ1: What kind of website links (i.e., URLs), related to COVID-19, were shared most frequently by verified Twitter users during the start of the pandemic?
2. RQ2: What type of Twitter messages/posts related to COVID-19 garnered the most social media attention during the initial days of the pandemic?

These two questions represent two distinct viewpoints on Twitter. These include: (1) the viewpoint of the "99%" which carry very little influence individually, but through sheer numbers can bring certain information into focus, and (2) the viewpoint of the "1%" which already have a large influence but contain less posts overall due to the small number of these individuals that exist. Both these viewpoints are significant.

We believe this study is valuable since using Twitter to predict flu trends and tracking public reactions has been done in the past with other sicknesses like the swine flu [4]. However, this study is unique given COVID-19's largely divided opinions regarding its threat potential. Therefore, it is beneficial to find people's information sources.

The rest of this paper is organized as follows. Section II provides a discussion on related work, followed by Section III

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

that provides our research methodology and Section IV that provides data analysis and results. Section V provides a discussion on the implications of our results, followed by a brief conclusion in Section VI.

II. Related Work

This is not the first time that Twitter has been used in such a prolific manner. Prior to COVID-19 there was the swine flu which also circulated through various social media websites [4]. During this time an important method that researchers deployed was to use Twitter as a live-tracking tool by having programs detect when certain keywords were frequently used and what terminology was used. In the study by Chew et al. [5], we see that as time progressed Twitter authors gradually began to use WHO terminology regarding H1N1 which implies that as awareness created by the WHO increased, so did the correct usage of terminology related to the disease.

Such facts were taken from earlier years, but are relevant with respect to COVID-19 data today, e.g., with misinformation. During the pandemic, countless tweets were created with positive intentions however not all of that data was correct. As per Kouzy et al. [7] in a study of about 650 tweets, 1 in 4 tweets contain some form of misinformation. This could include data such as whether the pandemic has spread to a given local area, but it can also include data such as wearing the wrong type of mask. Both types of information can cause direct and indirect harm as that knowledge can now be spread by the readers.

Additionally, Twitter can also be used to bring attention to conspiracies spread by users. During COVID-19 pandemic, a popular conspiracy was how 5G towers were contributing to the pandemic. According to research we can see that these users who tweeted about the subject consisted of isolated groups lacking authoritative figures (e.g. government organizations) to prevent misinformation [3]. This shows that there are several other methods of analysis used to see how information is spread among Twitter users and the general public.

While the location detection feature from Twitter is only viable when posting from a mobile phone, Twitter also records other important data. The data attributes most valuable to this study for filtering purposes are the tweet dates and the hashtags pertaining to removing unrelated or old tweets that might have created noise in our dataset. In addition, the author of each tweet, the number of followers of the author, whether the author is verified by Twitter, and the link to the tweet itself is provided through Twitter's API. This enriches the dataset which allows for researches to find useful information.

III. Methodology

This section provides the details about the data source from which we obtained tweets related to COVID-19, the data analysis tools/instrumentation used in this study, and the data filtration and cleaning process used during this study.

A. Data Source

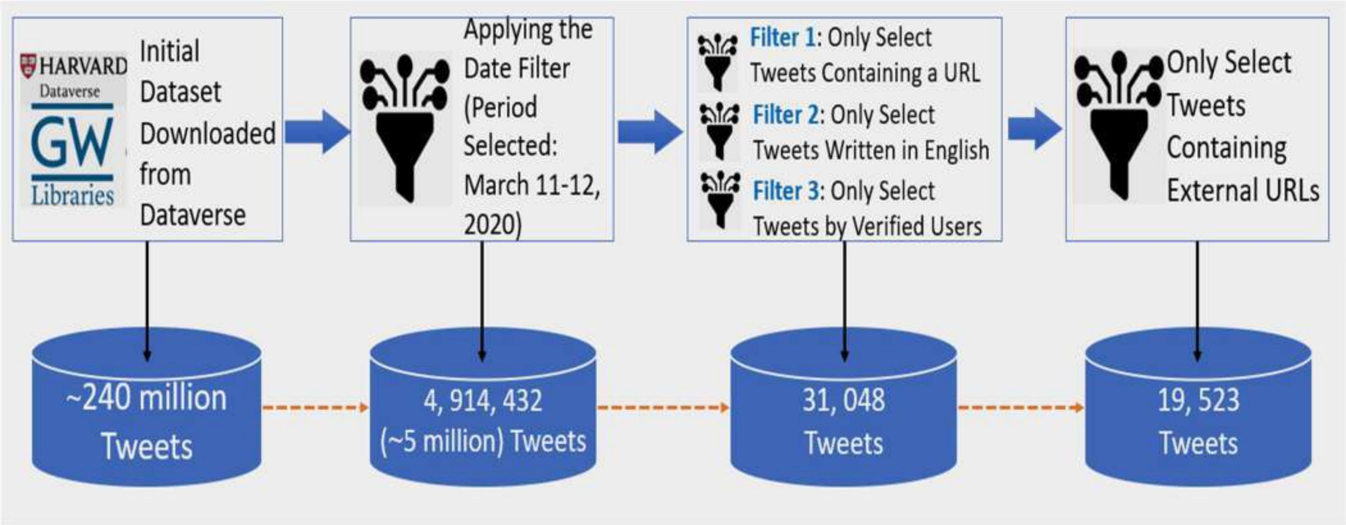
We first started by accessing the tweets stored as a dataset in the George Washington University (GWU) Libraries Dataverse [8]. When we accessed this dataset, it contained 239,861,658 (~240 million) tweet-ids related to COVID-19. Please note that the dataset has been updated since then and more tweet-ids have been added. The authors of this dataset have collected the tweet-ids using Twitter Stream API's POST filter/statuses method. Furthermore, the dataset authors have used the track parameter with the following three keywords: #COVID19, #Coronavirus, and #Coronaoutbreak.

Please also note that the dataset from GWU Dataverse contains only tweet-ids, which are unique ids that Twitter assigns to every tweet. We first downloaded the tweet-ids from above-mentioned dataset [8], and next used a process called rehydration [10]. Rehydrating tweet-id dataset involves sending the tweet-ids up to Twitter's live site to retrieve the full tweets.

B. Data Analysis Instruments

We used the following tools for rehydrating, viewing, and analyzing the data:

DocNow Hydrator: Hydrator is a Python-based, open-source desktop application that provides a user-interface to rehydrate tweet-id datasets [10]. Hydrator accepts tweet-ids and



HARVARD Dataverse
GW Libraries
Initial Dataset Downloaded from Dataverse
Applying the Date Filter (Period Selected: March 11-12, 2020)
Filter 1: Only Select Tweets Containing a URL
Filter 2: Only Select Tweets Written in English
Filter 3: Only Select Tweets by Verified Users
Only Select Tweets Containing External URLs
~240 million Tweets
4, 914, 432 (~5 million) Tweets
31, 048 Tweets
19, 523 Tweets

Fig. 1. Data Filtering and Cleaning Process

returns the corresponding data in the form of JSON files, which can be converted to CSV format (the conversion to CSV format is an added feature that Hydrator provides to its users).

Tad CSV Viewer: Tad is a powerful data engineering tool that can be used to open large CSV files [9]. We selected Tad because it is an open-source tool (MIT Licensed). Tad provides a robust filtering and sorting system when dealing with large amounts of data. After applying the necessary filters on the dataset using Tad, we then transferred the filtered data from Tad to MS Excel for further analyses.

Authors note that, apart from above-mentioned tools we used, there are several big data analysis techniques and machine learning tools [17-21] that have been used successfully for analyzing large amounts of data.

C. Data Filtering and Cleaning

In this sub-section, we describe our data cleaning and filtration procedure, an overview of which is provided in Fig. 1. As previously mentioned, our initial dataset contained 239,861,658 (~240 million) tweets related to COVID-19. Of the 240 million tweets, we narrowed the search down to the tweets posted on March 11th and 12th (of the year 2020), which were the first two days when the World Health Organization (WHO) declared COVID-19 as a pandemic. This, in addition to narrowing the tweet count to 4,914,432, also allowed us to focus on the particular days when the pandemic was at its objectively most critical point.

Furthermore, we were only interested in those tweets that contained links (i.e., URLs), since those links can support any claims the tweet author might have mentioned in their tweet. For example, if the author believes their followers should wash their hands, they will most likely link a website that supports their beliefs which improves the credibility of the tweet author. Additionally, we also limited the analysis in this study to tweets that were in English language. The easiest way to achieve this was to filter by the language in which Twitter classified their tweets and select only the English language tweets. Next, we narrowed the tweets again by considering the *verified Twitter users only*. This ensured that the users considered in this study are at least somewhat credible (as deemed by Twitter), which lowers the chance of the researchers clicking on malicious links or having our research data be skewed by users spamming tweets. These three restrictions narrowed our tweet count from 5 million to 31,048. The next issue we faced when analyzing this data was that a large percentage of users would post links that were still within the Twitter domain (i.e., the source-URL was www.twitter.com and not an external URL). In the current study, we specifically focused on external URLs posted by the verified Twitter users. Please note that, while posts containing links within the Twitter domain were not harmful in any noticeable way, they were not useful for our data analysis and thus these links were removed. This exercise brought the tweet count further down to 19,523.

IV. Data Analysis and Results

This section is organized around the two research questions (RQs) that we described in Section I.

RQ1: What kind of website links (i.e., URLs), related to COVID-19, were shared most frequently by verified twitter users during the start of the pandemic?

The objective for this research question (RQ) was to determine the primary source from where users were getting their COVID-19 related information (and sharing it with their social media audience). In order to answer this RQ, we started by evaluating domain-names of URLs found in the 19523 tweets that we identified during our data filtration and cleaning process (see Fig. 1). As an example, a URL posted in a tweet might be: "https://www.cdc.gov/coronavirus/2019-ncov/index.html". The URL provides the link to a unique/specific page and such a URL is called an *absolute-URL*. However, for our initial analysis, we were just interested in the domain-name (i.e., source) of this URL, which in this case is "www.cdc.gov".

In order to extract only the domain-names from the 19523 URLs, we used an Excel formula on our tweet dataset. After

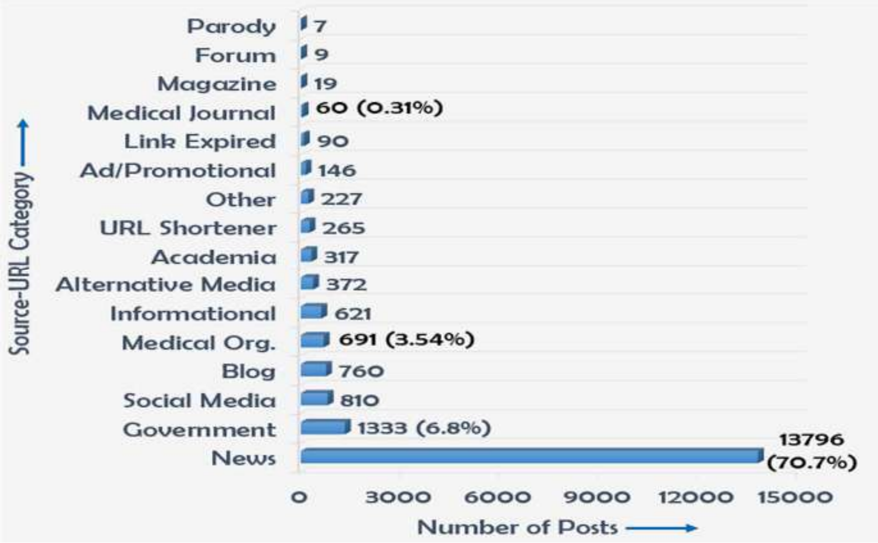


Fig. 2. Domain-name (or Source-URL) Distribution by Category

extracting the domain names, the next step was to classify the domain-names into intuitive categories so as to help enable us in answering RQ1. The researchers agreed upon 16 categories that best described the various domain-names. The distribution of source-URLs (or domain-names) appear in Fig. 2.

As observed in Fig. 2, many of the 16 categories are self-explanatory, e.g., social media links directing to Facebook or Instagram. We describe some of the categories here for reader's reference. The first category of note is Informational: this covers any website that is not directly related to COVID-19 but would like to spread awareness of their business status or general safety tips to the public as relevant to the pandemic. This also includes statistical websites that allow for viewing of the total case count of COVID-19. The next is Alternative Media which covers any form of audio or video media. Another category is 'Other' which is worth mentioning as this fits everything else that cannot be categorized properly, e.g., forms and surveys.

Fig. 2 provides several interesting observations on RQ1:

- Out of the 19523 URLs, most (about 70%) belonged to the category *News* outlets, i.e., websites such as CNN, ABC News, BBC, etc.
- A very small number (only 60, i.e. around 0.31%) was associated with the *Medical Journal* category. This was interesting as we anticipated that a significantly larger number would be associated with this category. It was concerning as it showed that users were not relying on scientific journals for their information about COVID-19.
- Another category titled, *Medical Organizations*, where researchers expected to do well, also had a very small number of posts (only 3.54% of the total posts). The *Medical Organizations* category is related to healthcare facilities such as Johns Hopkins, Mayo Clinic, etc.

The aforementioned analysis (depicted in Fig. 2) specifically looked at the source-URLs (i.e., domain-names) of the links posted in the 19523 tweets we analyzed. We performed another analysis, wherein we focused on the *absolute-URLs*. This secondary analysis was conducted on the complete URLs posted on Twitter. Absolute-URLs are quite literally the addresses of the Internet. Just as providing our address can be useful to find our home, clicking on an absolute-URL is useful to find the very page that is linked or referenced.

Table I provides a list of those absolute-URLs that were found to be most frequently shared. We have only provided the top 10 most popular absolute-URLs (related to COVID-19) posted by users. After ranking the absolute-URLs (as shown in Table I), we proceeded to check whether these links provided accurate and/or valuable information about COVID-19. Please note that Table I was created based on individual tweets containing specified URL and does not account for the number of people who viewed a specific tweet. This could, for example, imply that while 192 people tweeted a URL to medium.com (which is ranked #1 in Table I), it is possible that thousands of users just viewed the cdc.gov website (which is ranked #8) while the table does not account for that.

Table I. Top 10 Absolute-URLs Posted by Verified Twitter Users

RQ2: What type of Twitter messages/posts related to COVID-19 garnered the most social media attention during the initial days of the pandemic?

The data analysis for RQ2 provided insights related to the question: "what type of messaging (i.e., information) about COVID-19 was trending during the initial days of the pandemic and what type of users were behind this messaging?"

Please note that when performing the data analysis for RQ2, we did not focus on the tweet containing URLs. Instead, the focus of this analysis was more on the users and the content they posted. A major challenge here was to make sure that we separate a user's popularity during the pandemic and outside of the pandemic. In order to ensure this, we could not rely on users' followers, favorites, and friend counts as those could be attributed to having been earned prior to COVID-19 and thus would skew the data. It was decided that one way of preventing the skew of the data was to simply view the retweet counts and see what was being retweeted most frequently (as shown in Table II). The reason for this strategy was that it accounts for both the majority of users with very little influence and the minority of users with a lot of influence as the majority can still increase the retweet count through their sheer quantity and the minority can use their influence to draw users to the tweet thus increasing the retweet count further.

In order to understand the type of messages related to COVID-19 that were retweeted most frequently, we observed the top 7 most retweeted messages. Table II summarizes this data on COVID-19. From this table, we observe that the top 7 most frequently retweeted posts amounted to 85581 retweets. We find this to be a sizable count for our data analysis. Likewise, Table II provides several interesting observations on RQ2:

- The World Health Organization (WHO) appears twice in the list, which signifies that, in general, people trusted WHO to provide valuable or useful information about the COVID-19 pandemic.

- The tweets posted by medical practitioners: Dr. Trish Greenhalgh and Dr. Dena Grayson, as well as the well-known epidemiologist Dr. Anthony Fauci, appear in this list. This could be because people look towards qualified individuals for getting their COVID-19 information.

V. Discussion and Implications

This section provides a discussion on the implications of the data analysis shown in the previous section.

Considering RQ1, we can use data from Fig. 2 and Table I to view the kind of URLs (related to COVID-19) that users frequently shared on Twitter. As can be seen in Fig. 2, out of 19,523 tweets containing URLs, 70% of the tweets pointed to News websites, 4% pointed to Blogs, and 4% pointed to social media websites excluding Twitter. This might create the notion that most people are individually tweeting News websites over websites like blogs, government websites, and other social media websites. However, Table I highlighted that the top most frequently shared absolute-URL was a website by the name of medium.com which is a blog (an absolute-URL from medium.com was shared 192 times, as shown in Table I).

Furthermore, in Table I, the second most frequently shared absolute-URL was from a government website (nhs.uk), whereas the Government category (see Fig. 2) represented only about 6.8% of the total websites posted. Although Fig. 2 showed that URLs belonging to the Government category or the Social Media category were not popular, data in Table I highlighted that these categories still did get enough attention from the public. When we visited the top three absolute-URLs shown in Table I, we found that the information presented in these URLs was backed by or linked to the Centers for Disease Control and Prevention (CDC) or the World Health Organization (WHO) implying that they had a large influence when America announced COVID-19 as a pandemic. It is also noticeable that a majority of the frequently shared absolute-URLs in Table I are from News websites, which was clearly predicted by Fig. 2.

With regards to RQ2, we refer to Table II, which contains the most frequently retweeted (i.e., re-shared) messages/posts during the time of the pandemic announcement in America. It is clear from the list shown in Table II that the most retweeted messages included either statistical information about COVID-19, region specific news, or safety tips. Data in Table II also showed that, in some cases, the most frequently retweeted messages also contained political commentary or information related to political events (which we have hidden for the purposes of this study). It also included posts from doctors.

VI. Conclusion

This study presented a systematic analysis of a sample of Twitter data related to COVID-19 during the start of the pandemic. Our analysis showed that Twitter users had a clear preference promoting online materials (i.e., URLs) surrounding COVID-19. Users promoted COVID-19 articles published in quality News websites such as CNN and BBC. They also preferred to promote materials from well-known healthcare agencies such as WHO, CDC, and NHS. It is worth highlighting that users generally were not inclined to promote/share COVID-19 materials directly from Medical Journals such as The Lancet or British Medical Journal (BMJ). Interestingly, only about 0.31% of the URLs shared by Twitter users were scientific journals (belonging to the *Medical Journal* category).

TABLE II. MOST FREQUENTLY RETWEETED COVID-19 POSTS

Retweet Count	Message (i.e., the text in the post)	User Screen Name
34153	These are 7 simple steps to protect yourself and others from #COVID19. #coronavirus	WHO (World Health Organization)
13423	This is the best article I've read on #COVID19. "Countries that are prepared will see a fatality rate of 0.5-0.9%. Countries that are overwhelmed will have a fatality rate of 3-5%". Let's act to flatten the curve.	trishgreenhalgh (Dr. Trish Greenhalgh)
9403	AWESOME #Minnesota now offers curbside #coronavirus testing! Call ahead, drive up, and your samples will be taken in just a few minutes with results provided the next day. EVERY state should offer this. #COVID19 #CoronavirusPandemic h/t @kris_lovaas	DrDenaGrayson (Dr. Dena Grayson)
8732*	[redacted]	TeamTrump
7930	RT @WHO: Media briefing on #COVID19 with @DrTedros. #coronavirus	WHO
7282*	[redacted]	tedlieu (Ted W. Lieu)
4658	Dr. Anthony Fauci: "It is ten times more lethal than the seasonal flu." Watch full #Coronavirus hearing here: cs.pn/2W3IjV2	cspan (Cable-Satellite Public Affairs Network)

******Please note that any messages (i.e., posts) that provided political commentary have been hidden / masked in the above table.*
