Since public opinion on social media is significant as found in many works, e.g. [11] – [15], and since COVID-19 receives much attention in computational research, e.g. [2], [3], [16], [22], [23] our study in this paper contributes to such paradigms. Overall, this study has revealed some interesting insights into the social media psyche of the public about the COVID-19 pandemic. We intend to extend this study by considering a larger sample of Twitter data and addressing other research questions, e.g. on epidemiology and vaccinations, in our future work.

***Abstract*—Currently, risk assessment is more of an art than a science. In this paper, we demonstrate how a previously proposed theoretical risk assessment framework that focuses on making risk assessment more scientific can be implemented and applied to cloud networks. Our work offers a practical risk assessment implementation for cloud networks where disparate network owners can directly measure network risks in an objective, uniform and repeatable manner across networks by allowing the network owners to collaboratively agree on risk metrics and continuously monitor their cloud networks with the same tool, which employs these agreed upon metrics. The end result is a science-based risk metric (SBRM) based on the global impact of the vulnerabilities in the network. Specifically, we demonstrate the feasibility of implementing this SBRM by: (1) imposing real vulnerabilities on realistic cloud networks built from real hardware (multi-core 3 Ghz Xeon Deterlab servers), (2) demonstrating the operational use of our risk assessment implementation to measure risk across several emulated cloud networks, and (3) describing our approach.**

I. Introduction

Cloud networks face the same risks as traditional networks and even more. Typically, in cloud networks, enterprises share physical machines with many different types of users. This means that even if one user or enterprise is security conscious, other users may not be, and thus pass along their risk to the entire cloud network. Therefore, in addition to the risks that traditional enterprise networks face, cloud networks also have to defend against network virtualization risks, which target the virtualization layer between users in cloud computing.

Furthermore, because enterprises no longer have full control of their resources in a cloud network, they must set up controls to ensure that the cloud providers do not somehow gain access to their data. Additionally, they will have to rely on the cloud network provider for availability. Thus, part of the enterprise must incorporate the cloud network provider as a factor when managing risk. Despite these extra risks, an increasing number of enterprises are switching to cloud networks, because of their flexibility, reliability, and cost savings, which make the need for risk management greater than ever.

Our contributions include: (1) designing and implementing a science-based risk assessment implementation for cloud networks and (2) demonstrating the operational benefit and applicability of the implementation to cloud networks. The rest of the paper is organized as follows. In Section 2 we discuss the motivation for our work, and in Section 3 we detail related work. Next, in Section 4 we describe risk management in cloud networks, and in Section 5 we layout the need for a Global Impact Database. In Section 6 we discuss the vulnerabilities used in our experiments. Then, in Section 7 we detail our experimental evaluation, and in Section 8 we discuss results. Finally, in Section 9 we conclude and discuss future work.

II. Motivation

Unfortunately, many enterprises have come up with their own methods for measuring risk; therefore, there is no established standard. One way of measuring risk is the frequently used Common Vulnerability Scoring System (CVSS). Even though frequently used, this system has deficits. One example was pointed out by Watkins et al. [6], where they compare ShellShock (CVE-2014-6271), a widely publicized vulnerability, and an unspecified Java vulnerability (CVE-2014-4227). The highly impactful Shellshock affected 20% to 50% of global web servers [8], and the Java vulnerability was only exploitable in a sandbox. Yet both have scores of 10.0 under CVSS. Clearly, this presents an issue when determining which vulnerability is a greater threat. This is just one example, among many others. There must be some way of distinguishing the differences between the two vulnerabilities when assessing risk.

Watkins et al. [6] propose a method of modifying the CVSS score based on additional criteria, including creating an Overlay Score and allowing for a more nuanced view of the risk presented by vulnerabilities. Rather than having a static score like CVSS, the Overlay Score is more dynamic and is reactive, as some vulnerabilities take the forefront relative to impact while others fade into the past. The Overlay Score is derived from the collaborative 5 Layer Cyber Maturity Model as explained by Watkins et al. [6], (1) collaborative management leads meet to agree on the criteria to rank vulnerabilities, (2) collaborative management leads agree on the impact the criteria will have on their risk model and thus identify criteria weights, (3) technical collaborative leads identify a scientific approach to assessing the global severity of vulnerabilities identified in the network, (4) technical collaborative leads agree on the implementation details of this scientific risk assessment approach, and (5) collaborative management leads agree on the minimum risk-level necessary for their continued collaboration. In a case-study, the authors apply this model by choosing a set of example criteria, as required by the the Analytic Hierarchy Process (AHP) to determine a ranking for these criteria. They also propose the notion of a vulnerability global impact database (with impacts of high-1.00, medium-0.05, or low-0.01). Finally, the Overlay Score for a specific vulnerability results from multiplying each criteria ranking by the vulnerability's global impact database score for that criteria and adding up the products (which yield a real number no greater than 1). This Overlay is then multiplied by the CVSS base score, which essentially serves as a way of scaling down the CVSS base score for less impactful vulnerabilities.

Our work puts these concepts from Watkins et al. [6] into practice and demonstrates their feasibility and practicality. We use actionable resources like yearly malware reports (e.g., Symantec, Mcafee) to extract customizable criteria like age of exploit, exploit availability, and global impact. We use this approach to build a database, which can be queried to enhance risk analysis. The full details of our approach are given in Section 5.

III. Related Works

There are many tangentially related experimental works that speak to cloud network risk metrics. We believe our work is unique in that our approach is based on dynamic science-based risk metrics that are customizable. We also demonstrate the feasibility of our approach through experiment on real hardware.

A. *Risk Management Suite of Tools*

Cloudcover is a suite of tools that can be used for risk management in cloud networks. It provides a cloud-diagnostic tool that uses proprietary analytics to determine weaknesses in security. It also presents real-time findings based on Confidentially, Integrity, and Availability (CIA) and analysis using continuous monitoring [5] [4]. Similarly, MetricStream provides software for enterprise governance, risk management, and compliance (GRC). Essentially, risk assessment is accomplished via continuous monitoring for internal vulnerabilities coupled with external data feeds, which are combined via key performance and risk indicators [2] [3]. Although our work is similar in that we perform continuous monitoring of vulnerabilities, we instead base our effort on augmenting CVSS scores such that they are more representative of the impact of the vulnerability and operationalizing to demonstrate the practicality of our approach.

B. *Qualitative Risk Management*

The authors in [9] introduce a qualitative risk assessment approach for cloud networks based on ISO 31000 for logistics companies. The basis of the measured risks are responses to a questionaire given by human employees. The authors in [15] base their risk assessment framework on ISO27005. They modify the risk assessment step in ISO27005 to allow the cloud client to evaluate the risk factors. Also, they limit their scope to Software-as-a-Service models only. Similarly, the authors in [11] base their risk management on ISO 27001 cloud computing risk assessment use cases. Specifically, the authors use 7 ISO 27001 compliant risk assessment use cases to help answer the question ”What are the risks of deploying my software (Software-as-a-Service), tools (Platform-as-a-Service), and/or infrastructure (Infrastructure-as-a-Service) in the cloud?” Our work is similar in that it is based on the analytical hierarchical process (AHP), which allows for the fusion of qualitative and quantitative information. However, the end result of our work is a numerical science-based risk metric that demonstrates the deployment feasibility of this approach.

C. *Artificial Intelligence and Risk Management*

The authors V. Malik et al. [10] see risk management as identifying several risk factors across many different risk categories and using statistical or artificial intelligence algorithms to minimize these risks. However, the authors do not mention the data sources that should be used to derive training data for the above mentioned algorithms or the feature vectors that should be used to extract patterns out of this data. Similarly, A.D. Kozlov et al. [12] developed a cloud risk management system based on fuzzy logic. Specifically, the authors use MATLAB to develop a fuzzy inference system based on identifying assets, identifying threats, defining vulnerabilities, analyzing risks, and processing risks. Our work is different in that we show the operational practicality of a method that uses the AHP to fuse statistical and qualitative data into a repeatable risk metric.

IV. Cloud Networks and Risk Management

Years ago when the authors in [6] developed their approach, there was need for enterprises with their own private networks to collaborate. Though this requirement still exists, networks are now mostly cloud-based. In fact, most companies use cloud networks in many aspects of their business [13], whether they be private (enterprise owned infrastructure, managed by provider like like HP or IBM), public (infrastructure totally owned and managed by provider like Amazon or Google), hybrid (enterprise and cloud provider share aspects of hosting network) network. Even though these networks are now likely cloud networks, the collaborative approach mentioned in [6] is still applicable. However, this approach is most likely only applicable to private and hybrid cloud network providers, since the necessary hardware vulnerability monitoring would likely only be possible in these types of cloud networks. Below in Section 5 we discuss how we implement the science-based risk management theory from [6] and demonstrate its feasibilitiiy in real networks.

V. Science-based Risk Assessment Design

Our design is based on 4 key aspects taken from Watkins et al. [6] First, the collaborative design of risk assessment metrics. Second, the vulnerability monitoring of the nodes within the network. Third, the creation of a global impact database based on global assessment data. Fourth, the continuous vulnerability monitoring of the cloud network and calculation of the Overlay score.

A. *Global Impact Database*

The global impact database serves as a way to make the chosen criteria actionable. It draws its data from published annual threat data (i.e., Symantec threat reports), which we use as an authoritative source of information on the global impact of certain vulnerabilities. Actually, the global impact database has a rating for each of the criteria, i.e., global impact, exploit availability, and age of exploit. This information was manually extracted from published annual threat data.

For global impact rating, we sifted through the report and assigned four levels of impact. A vulnerability would have a global impact rating of 1.00, if it was deemed to have high global impact. An example of such a vulnerability would be ShellShock. The vulnerability would be given a rating of 0.50, if it had moderate impact, such as some of the vulnerabilities in Adobe Flash Player. A lower rating of 0.25 would be given, if the vulnerability was mentioned in the report, but stated as not having much impact. Finally, if a vulnerability was not in the report at all, it would be given a score of 0.10. We chose these impact ratings based on the approach in Watkins et al. [6]. However, to actually be able to implement this approach, we made modifications (e.g., added the option of making a low rating 0.25 or 0.01 based on if it were mentioned in the report or not).

We used a 3 level rating for exploit availability: (1) an exploit would receive a score of 1.00, if there was an exploit readily available (e.g., exploits readily available for usage in Metasploit or some other scripting tool), (2) a vulnerability would be given a score of 0.50, if an exploit required other vulnerabilities to be present on the target system, and (3) all other vulnerabilities would be given a score of 0.25.

In terms of age of exploit, the scores were calculated in a cumulative manner. The score would increase by 0.10 for each year the exploit existed, with a maximum score of 1.00 for any exploit 10 years or older.

After the criteria rankings were calculated from the analytic hierarchical process, we then multiplied these rankings by the scores for each factor and added the resulting numbers to obtain a unit-less weight with which to multiply the CVSS score. The end result is the Overlay score.

To illustrate the the influence of the global impact database on the Overlay score, we offer the following example: consider the ShellShock (CVE-2014-6271) versus Oracle database (CVE-2010-0071) vulnerabilities, the CVSS base scores for each is 10.00. However, the Overlay scores for ShellShock is 8.91 since there is an exploit available along with a high global impact score, and an exploit age of 3 years old. The Oracle vulnerability has an Overlay score of 2.84, mostly since it does not appear in the global impact database and thus has a minimum rating for global impact.

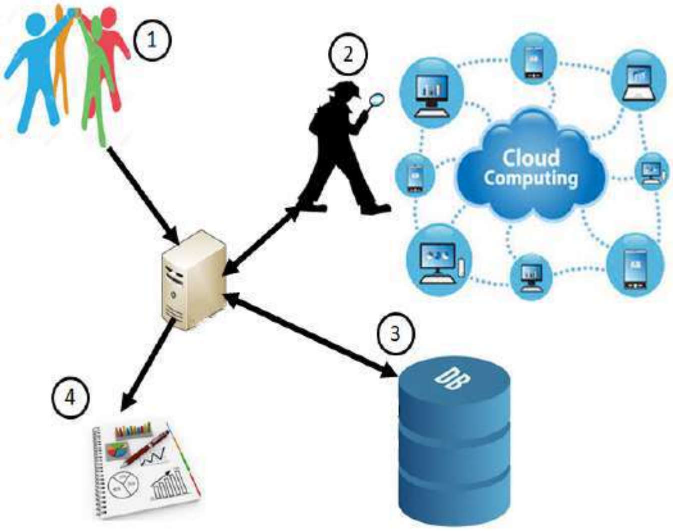

Fig. 1. Science-based Risk Metric Implementation Design: (1) accepts as input the relative importance of one criteria over another, (2) feeds in vulnerability information from each node in each network, (3) queries from the global impact database per vulnerability, uses all of this information to calculate the Overlay score, and finally uses the Overlay score to calculate the Overlay Science-based Risk Metric

B. *Science-based Risk Metric Implementation*

The SBRM implementation design is illustrated in Figure 1. In this section, we elaborate on this design. The python code written to calculate the SBRM takes as input, the relative importance of one criteria over another, which then is used to calculate the criteria ranking. The product of the criteria ranking and the database score (queried from the global impact database per vulnerability) is used to calculate a unit-less weight. The Overlay score is derived from the product of this unit-less weight and the CVSS score. Finally, the Overlay score is used to calculate the science-based risk metric (SBRM) score as specified by [6]. Note, we also calculate the SBRM using the CVSS score just as a comparison to the Overlay SBRM score. The SBRM defines the number of nodes expected to be compromised in the next year.

VI. Emulating Security Risks in Cloud Networks

We chose 5 different types of vulnerabilities to induce on the nodes in our test networks. All of these software packages could realistically be used in a cloud network. These vulnerabilities are invoked by either installing vulnerable software or by using an old Linux image. The Apache Server 2.4.18 was chosen to emulate the hosting of a webserver on the cloud network. The vulnerability associated with this is CVE-2016-8743. This is essentially a whitespace parsing defect. Oracle MySQL is another piece of software used, which could mimic database hosting in a cloud network environment. This software has several vulnerabilities associated with it such as: CVE-2016-5584, which allows remote administrators to affect confidentiality, CVE-2016-6662, which allows local users to bypass certain protection mechanisms, and CVE-2017-3331, which allows low privileged attackers to essentially crash the server. Adobe Flash Player is software that could also be found in a cloud network to stream video. This software is associated with vulnerabilities CVE-2015-0311 and CVE-2015-0312. Java is a commonly used programming language in software development. As software engineering companies offload their processing power onto cloud networks, it is common to find packages like Oracle's JDK. There could be a number of vulnerabilities associated with this software. Similarly, there could be quite a few vulnerabilities associated with the old Linux image Ubuntu 8.02 that we used. Some of the packages that were included were: OpenSSH 4.7p1, Apache Server 2.2.8, MySQL 5.0.51a, Samba 3.0.20, PostgreSQL 8.3.1, ProFTPD 1.3.1, and VNC 1.2.9. These packages could emulate the existence of legacy systems that may be used to support older products.

VII. Experimental Evaluation

The nodes used in our experiments were hosted in DeterLab [14], which allows users to reserve tens of physical nodes for several hours at a time. We used this environment to automate our experiments.

A. Experimental Setup

We setup 3 Linux networks composed of 25 nodes each using 3 GHz Xeon processors with 4 GB of RAM. To emulate vulnerabilities in these networks each node either had a vulnerable application installed or executed an Ubuntu 8.02 image with old, vulnerable software. The nodes running the Adobe Flash Player ran Ubuntu 14.04. The remaining nodes ran Ubuntu 16.04. The vulnerabilities were randomly distributed across the nodes in the 3 networks. In this paper we focus on 1 run where the first network had a total of 64 vulnerabilities, the second network had 323 vulnerabilities, and the third network had 529.

B. Procedure

Python scripts were used to randomly distribute vulnerable software on each network. Specifically, the vulnerable software chosen were: (1) Adobe Flash Player 11.2.202.438, (2) Oracle Java Development Kit 8u74, (3) Oracle MySQL Server 5.7, (4) Apache 2.4.18 and (5) an old Linux image containing several vulnerable software packages (i.e., Apache 2.2.8, Oracle MySQL 5.0.51a, Samba 3.0.20, PostgreSQL 8.3.1, Proftpd 1.3.1, and VNC 1.2.9). The selection of these vulnerabilities was done to reflect software that would be found on an enterprise cloud network. Next, the nodes were scanned using the Vuls vulnerability scanner. Then vulnerability information for each vulnerability in each network was fed into the python risk assessment implementation along with the inputs from the user on the criteria weighting, and the database scores from the global impact database to calculate the Overlay score and then the science-based risk metric (SBRM).

TABLE I
Total Vulnerabilities Per Network

Cloud Network	Total Number of Vulnerabilities
Network 1	64
Network 2	323
Network 3	529

TABLE II
Distribution of Vulnerability Categories Networks

Cloud Network	Apache Server	Oracle MySQL	Adobe Flash Player	Vulnerable Linux Image	Oracle JDK
Network 1	8	12	5	0	0
Network 2	0	11	12	2	0
Network 3	0	12	0	4	9

VIII. Results and Discussion

We demonstrated the feasibility of our implementation by arbitrarily choosing exploit availability as 5 times as important as global impact, 3 times as important as the age of exploit, and the global impact as 2 times as important as the age of exploit. Recall from the Cyber Maturity Model proposed by Watkins el al. [6], this would be agreed upon by the leaders of the organizations that want to collaborate and connect their networks. Next, we ran our scripts to randomly distribute vulnerabilities on the 3 networks, and the results are listed in Tables 1 and 2. The data in Table 1 illustrates the total number of vulnerabilities across all 3 networks, and Table 2 lists a breakdown of vulnerability categories across networks. The results of the SBRM calculations for both the CVSS scores and the Overlay scores are listed in Table 3. Note that even though network 3 has the most vulnerabilities, both the CVSS and Overlay SBRM state that network 2 is the most vulnerable. This particular run of our risk implementation yields results where both the CVSS and Overlay SBRM agree; however, this does not always happen. The main point here is that the Overlay SBRM reflects the global impact of the vulnerabilities in the network and is more informative than the SBRM calculated using the CVSS scores. This point is made even clearer in Tables 4 - 6. For instance, in Table 4, the top 5 most impactful vulnerabilities in network 1 are identified by their CVSS scores, but only yield a score of 10 for each of them. However, the corresponding Overlay score identifies CVE-2015-0311 as the most impactful and CVE-2016-6662 as the least impactful in the table. The scaling of the vulnerabilities based on their global impact by the Overlay score clearly provides the necessary information for network owners to be able prioritize the vulnerabilities that should be patched in their network. Not only does the Overlay score provide vulnerability priortization information, but it also allows owners to directly compare risks (via the Overlay SBRM) across networks. We believe that these results support our premise and demonstrate that it is feasible and practical to implement the SBRM as a risk assessment resource for cloud networks.

TABLE III
TOTAL NUMBER OF NODES EXPECTED TO BE COMPROMISED

Cloud Network	CVSS SBRM	Overlay SBRM
Network 1	17.08	4.62
Network 2	25.00	12.27
Network 3	16.09	4.34

TABLE IV
TOP 5 MOST IMPACTFUL VULNERABILITIES IN NETWORK 1

CVE	CVSS	Overlay
CVE-2015-0311	10.00	8.76
CVE-2015-5122	10.00	4.21
CVE-2015-0312	10.00	2.07
CVE-2015-5123	10.00	2.07
CVE-2016-6662	10.00	1.91

TABLE V
TOP 5 MOST IMPACTFUL VULNERABILITIES IN NETWORK 2

CVE	CVSS	Overlay
CVE-2015-0311	10.00	8.76

TOP 5 MOST IMPACTFUL VULNERABILITIES IN NETWORK 3

CVE	CVSS	Overlay
CVE-2007-2446	10.00	3.31
CVE-2010-0425	10.00	2.84
CVE-2012-1182	10.00	2.53
CVE-2013-1902	10.00	2.38
CVE-2013-1903	10.00	2.38

IX. SUMMARY AND FUTURE WORK

We have demonstrated via a python implementation, the efficacy and usefulness of a theoretical risk metric system proposed by Watkins et al. [6]. We have shown that it is practical for cloud network owners wishing to collaborate to be able to directly compare their network risks and that the information used for this comparison can also be used to prioritize vulnerability patching. Although this implementation serves as a good proof of concept, it is limited in its capability and could be improved. The major limitation is the global impact database has to be updated manually. To improve this, natural language processing could be used to extract the necessary information out of the annual malware reports. In future work, we would like to extend this implementation beyond enterprise networks to ICS networks, and also automate updates to the global impact database.

***Abstract*—The steadily developing number of users has achieved the test to distinguish an advantageous strategy for different access in upcoming wireless communication. It has been seen that non-orthogonal multiple access (NOMA) method gives far superior execution than orthogonal multiple access (OMA) procedure while exploiting the accessible assets. Interferences can be limited enough using successive interference cancellation (SIC) when actualized broadly, however it is normal situation in NOMA. But enormous usage increments the complexity of the framework and as a result energy effectiveness is decreased. To balance the detriments of NOMA procedure, interest in hybrid NOMA strategies has developed. Numerous new papers have proposed hybrid NOMA schemes as a reasonable alternative to moderate the disservices of NOMA. This paper plays out an investigation of the exhibition between hybrid NOMA systems such as CR-NOMA, U2X-NOMA, RIS-NOMA, HS-UAV NOMA, SCMA-NOMA and GFDM-NOMA. An examination of every one of these methods is led to recognize the best hybrid NOMA procedure for 5G and beyond wireless communication. The articulations for sum rate and outage probability have been determined for all the procedures. Through examination and reenactment results it is found that U2X-NOMA gives the best exhibition regarding sum rate and outage probability among the six discussed schemes.**

***Index Terms*—CR-NOMA, U2X-NOMA, RIS-NOMA, HS-UAV NOMA, SCMA-NOMA, GFDM-NOMA, Outage Probability, Sum Rate**

I. Introduction

Non-orthogonal multiple access (NOMA) has gained a prominent impact in establishing wireless networks of the next generation 5G and beyond wireless communication. To support various applications, a high data rate and stable communication would therefore be needed [1],[2]. The main aim is to be able to extend the channel capacity in the architecture of the cellular networks [3]. For instance, multiple access is an useful approach for next generations to accommodate as many cells as feasible at a given bandwidth with a fair extent of service quality [4],[5]. Non-orthogonal multiple access (NOMA) is considered to be a revolutionary multiple access framework for fifth generation (5G) and beyond 5G (B5G) cellular networks that can significantly improve the efficiency of application distribution [6]-[8]. In cooperative networks with buffer-aided power control, hybrid NOMA-OMA has been discussed in [9],[10] and the machine productivity of the computer is increased relative to other existing state-of-the-art heterogeneous network bandwidth management protocols [10]-[13]. SIC is used at the ends of the receiver for inter-user interference cancellation [14],[15]. In[16]-[18], several researchers proposed different but rather powerful methods to power distribution in order to efficiently disperse power to NOMA structures. For full duplex (FD) and half duplex (HD) switch supported cognitive radio NOMA (CR-NOMA) networks, the author provided a performance analysis in[19]. A NOMA improved unnamed aerial vehicle to everything (U2X) network, where stochastic geometry instruments were used to model the spatial randomness of several receivers, $R_x s$ is discussed in [21]. To establish reconfigurable intelligent surface NOMA (RIS-NOMA) in [24]-[26], the framework of a high-speed internet infrastructure and cost-effective data coverage offshore is shown. The efficiency of the hybrid satellite unnamed aerial vehicle NOMA (HS-UAV NOMA) infrastructure over the Rician fading channel is studied in [27]. How user message is stored using sparse code multiple access NOMA (SCMA-NOMA) is supplemented with encoder access and various power levels are assigned depending on channel conditions in[28]. In[29], they collaborative generalized frequency division multiplexing with NOMA (GFDM-NOMA) strategies to expand the multi-carrier NOMA network framework. The survey was carried out in the aforementioned paper strongly inspired us to make more effort on the hunt for an optimal NOMA hybrid system to significantly improve efficiency and verify its quality with extant NOMA hybrid systems. In this paper, six exceptional hybrid NOMA systems are analyzed and their usefulness in the outage and sum rate interplay. The aim of the investigation is to demonstrate intuitive perspectives in order to highlight the best hybrid NOMA system to meet the need for 5G and beyond wireless communications.

II. System Model

The system model of six most modern hybrid NOMA schemes such as CR-NOMA, U2X-NOMA, RIS-NOMA, HS-UAV NOMA, SCMA-NOMA and GFDM-NOMA has been clarified in this section.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

A. CR-NOMA

It takes into consideration a modern uplink/downlink relay-assisted method developed for CR-NOMA as in [19]. The restricting influence of interference from the starting point to the relays during the relay recruitment process is known to make the model more realistic. To pick the relay for transmitting the message to the destination, the partial relay selection (PRS) technique was being used. A relay-aided CR-NOMA network with a main source MS and multiple distribution switches $\{R_k|k = 1, 2, \ldots, K\}$ using conveying protocols as shown in Fig. 1. In just the same frequency spectrum, there are two separate pairs, $G_1 = \{S_1, D_1\}$ and $G_2 = \{S_2, D_2\}$ using the NOMA technique [19]. For the reliable information S_1 and S_2, we assume a worst-case communication case. In addition, we presume that there is a deep fading of the direct connection between secondary data pairs and that communication is only possible through intermediary relays. Quite importantly, uplink-downlink CR-NOMA communication has two stages. First one is the uplink process suggested that S_1 and S_2 could create a pair of NOMA [20] to relay the R_k simultaneously.

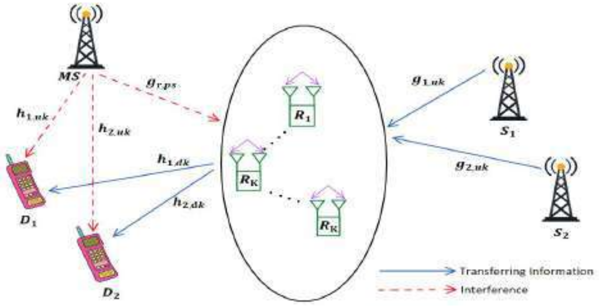

Fig. 1. Uplink Downlink Framework of CR-NOMA

The other one is R_k will simultaneously send an overlaid composite signal composed of transmitted patterns sent to D_1 and D_2 by sources in the downlink process. Restricting interference in CR-NOMA is visible because MS interferes with numerous R_k relays and two routes. In this case, with respect to full achievable device power, both uplink and downlink require SIC to work equally at both source destination pairs as in [19]. Both S_1 and S_2 relay signals x_1 and x_2 periodically during the designated time slots, following the concept of uplink NOMA. In NOMA, $\alpha_1 P_s$ and $\alpha_2 P_s$ are part of the assigned capacity for two x_1 and x_2 signals, respectively. Here, $\alpha_1$and α_2 are the power allocation coefficient and P_s is the total transmit power.

B. U2X-NOMA

We suggest an upgraded NOMA downlink U2X network, where several $R_x s$ installed with a single omni receiving antenna are communicated by a UAV installed with a single omni transmitting antenna as in [21]. With only a single UAV, Fig. 2 shows the wireless networking framework. The UAV-T_x is located in the middle of a circle with a distance radius of D [21]. In conjunction with the homogeneous poisson point method (HPPP) with the density, two $R_x s$, the close R_x w and the far R_x v, are distributed. Therefore, two $R_x s$, one close R_x and one outside R_x, are paired in each cluster to execute NOMA. From [22],[23], we assume the circular area is divided into two power regions. One is a tiny domain (Blue zone) and the other is a big hollow domain(Green Zone). The close $R_x s$ are believed to be located with radius R in the tiny domain, while the far $R_x s$ are located with radius R to D in the big hollow domain. d_w denotes the length between the T_x and the nearest R_x, and d_v denotes the range between the T_x and the nearby R_x. The variance in received signal of the paired NOMA $R_x s$ is needed to ensure the consistency of decoding [21]. Therefore, one close R_x and one outside R_x, are coupled in each cluster to execute NOMA. In reality, large-scale fading and small-scale fading are commonly found in the fading model. The path loss in between UAV-T_x and R_x is expressed by large-scale fading. Large-scale fading and small-scale fading are considered to be determined simultaneously and completely identical. Since the conventional Rayleigh fading channels can only model powerful scattering situations, which is not a possible option for the communication of UAV [22]. The small-scale channel benefits for R_x w and R_x v, respectively, are shown by h_w and h_v for terminology convenience.

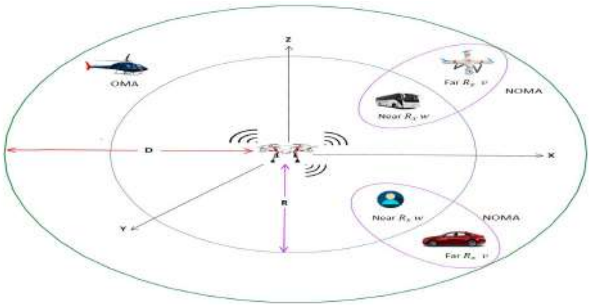

Fig. 2. U2X-NOMA Model

C. RIS-NOMA

As seen in Fig 3, we interpret the RIS-NOMA, in which the base station aims to connect with two locations. Location users are identified as the close user (CU) and the faraway user (FAU). We presume that all nodes have a single-antenna in order to achieve low complexity and low cost because even a RIS contains of N meta-surfaces as in [24]. The baseband identical fading channels from BS and the ith component in

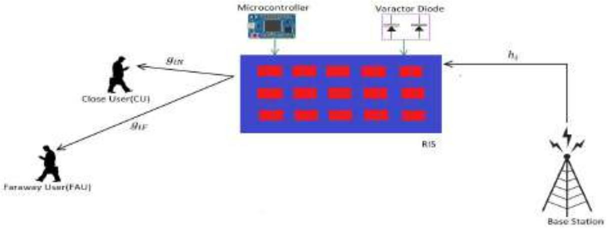

Fig. 3. System Representation of RIS-NOMA

the RIS are h_i, g_{iN} and g_{iF}, signals from the ith component in the RIS to CU and FAU, respectively. These pathways are supposed to be distinct, equivalent, changing smooth, dwindling. In this context, we considered the framework of two FAU and CU users that will obey Rayleigh correlations of various parameters of size. The signal reproduces through the RIS to two types of users from the transmitter, which helps to increase the efficiency of the signal at these locations as in [24]. Ideally, we expect that the channel state information (CSI) of such users can be accomplished by the RIS [25]. Surprisingly, such a CSI may be used by the RIS to optimize the SNR obtained at these locations. The BS sends an overlaid signal in the form of NOMA containing signals s_1, s_2 that are aimed at the user CU and FAU, respectively. Higher power level a2 is allocated to user FAU in order to have separate quality of service (QoS) for applications, such allocation scheme must be fulfilled, $\alpha_1 + \alpha_2 = 1$.

D. HS-UAV NOMA

In Fig. 4, the entire interaction is broken into two schedules. The first one is satellite to UAV and the other one is UAV to mobile users. We suggested an HS-UAV NOMA downlink network, where one satellite as seen in Fig. 4, aims to connect with terrestrial NOMA users with the assistance of a DF UAV relay U as in [27]. A consistent height h is used to install the UAV. The UAV and all users are believed to be running in half-duplex mode and all nodes are fitted with individual antennas. All served users are divided into two categories, A_1 and A_2, depending on the ranges between the UAV and the NOMA mobile users. We claim that in group $A_1$the close user D_n is located in the loop with both the radius R_n and in group A_2 the far user $D_f$is situated in the inner radius R_n and outer radius R_f loop $(R_f > R_n)$ [27]. We also assume that due to the barrier or extreme large-scale fading, the direct connections between the satellite and the users are missing. Random user matching is known to achieve greater efficiency gains. We will concentrate on the paired user's results in the following, and using the same approach, other pair performance can be extracted.

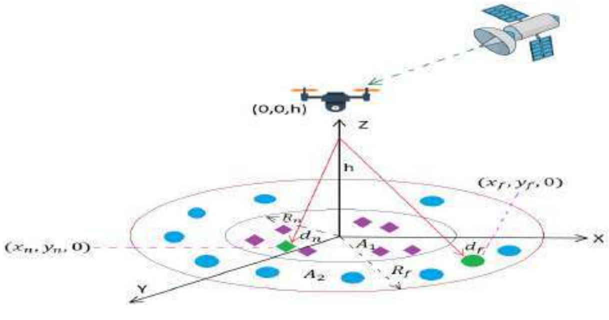

Fig. 4. Framework of HS-UAV NOMA

E. HS-UAV NOMA

We assumed one base station and J users as a downlink system. Suppose users of J_1 face stronger channel conditions than other users of $J_2 = J - J_1$, as seen in Fig. 5. The strongest and weakest users are respectively represented by $\{s_1, s_2,,.... s_{j1}\}$ and $\{w_1,w_2,,....w_{j2}\}$ as in [28]. The strong and the weak users are also attributed to as the near and far users, respectively, without damage of generalizability. The channel dimensions encountered by the strong and weak users respectively are denoted by $^{s}_{i}\}^{j_1}_{i=1}$ and $\{h^w_j\}^{j_2}_{j=1}$. Assume the number of orthogonal asset components like K Consider a solid user's $J_1 \times KSCMA$ algorithm focuses on codebookC_1. For weak users $J_2 \times KSCMA$ algorithm focuses on codebook C_2. MPAD1 and MPAD2 signify an MPA(Message passing algorithm) detector of weak and strong user respectively. The detection is exemplified in the second part of Fig. 5 of the ith strong user s_i. Before extracting the data from s_i, the SIC of the far users is carried out as in [28]. Initially, MPAD2 generates the approximate code words $\{x^{w_i}_j\}^{j_2}_{j=1}$ with y^s_i as input. The superscript 'i' here indicates that the detection operation is done at the position of s_i by the ith receiver [28]. These projections are only used for the identification of s_i data.

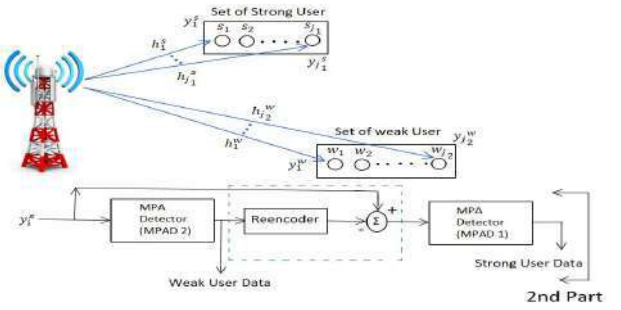

Fig. 5. System Model of SCMA-NOMA

F. GFDM-NOMA

In Fig. 6, we integrate GFDM waveforms with NOMA schemes to broaden the multi-carrier NOMA system model. In NOMA systems enabled by downlink GFDM, the situation with one BS and four users is presumed. Each conversion efficiency block is shared by four users, unlike conventional GFDM systems as in [29]. It is assumed that a close user with less assigned power and a much more transmitted power for far user is assumed. Due to the larger share of total power in NOMA networks, U_2 is first decoded by comparison to the U_1 signal as interference. The received U_1 signal on the

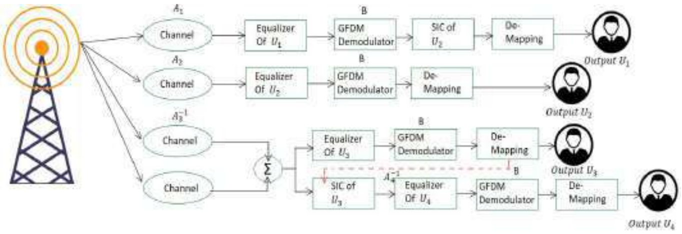

Fig. 6. Downlink Scenario of GFDM-NOMA

U_2 side is in most situations, entirely regarded as interference. Nevertheless, whenever two users endure from the same fading channels and decoding processes, from the point of view of theoretical study, the signal power of U_2 is enhanced or diminished by that of U_1, with a 50 percent chance. For U_3 and U_4 case, we use the same technique as hold on U_1 and U_2.

III. Numerical Analysis

In this section we will discuss among predefined six hybrid NOMA schemes where we calculated the outage probability and sum rate arrangements.

A. Outage Probability Analysis

For CR-NOMA, R_1 and R_2 are considered to be the specified target rate thresholds of G_1 and G_2, respectively, according to the necessary level of operation. Thus, the signal to noise ratio (SNR) thresholds are γ_{th1}^{FD}, γ_{th2}^{FD}. As in subsequent sections, the precise outage probability of G_1 and G_2 is determined as in [19].

$$\begin{aligned} OP_{G_1}^{FD} = 1 - &\sum_{i=1}^{K}\sum_{j=1}^{K}\binom{K}{i}\binom{K}{j}(-1)^{i+j-2} \\ &\times \frac{j\rho R\lambda_{1,\mu k}\lambda_{1,\mu k}\lambda_{1,dk}}{\left(i\alpha_2^{FD}\lambda_{2,\mu k}+j\lambda_{1,\mu k}\right)\left(i\alpha_3^{FD}\lambda_{r,PS}+\lambda_{1,\mu k}\right)} \\ &\times \frac{\left(a_3-\gamma_{th1}^{FD}a_4\right)}{\left(\gamma_{th1}^{FD}\rho P\lambda_{1,PS}+\left(a_3-\gamma_{th1}^{FD}a_4\right)PR\lambda_{1,dk}\right)} \\ &\times exp\left(\frac{-i\alpha_4 FD}{\lambda_{1,\mu k}}-\frac{\gamma_{th1}^{FD}}{\left(a_3\rho R-\gamma_{th1}^{FD}\alpha_4\rho R\right)\lambda_{1,dk}}\right) \end{aligned} \tag{1}$$

In which, $\gamma_{th1}^{FD}=2^{R_1}-1$, $\alpha_1^{FD}=\gamma_{th1}^{FD}\left(I_R+1\right)$, $\alpha_2^{FD}=\frac{\gamma_{th1}a_2}{a_1}$, $\alpha_3^{FD}=\frac{\gamma_{th1}^{FD}\rho P}{a_1\rho S}$ and $\alpha_4^{FD}=\frac{\alpha_1}{\alpha_1\rho S}$.

$$\begin{aligned} OP_{G_2}^{FD} = 1 - &\sum_{i=1}^{K}\sum_{j=1}^{K}\binom{K}{i}\binom{K}{j}(-1)^{i+j-2} \\ &\times \frac{j\lambda_{2,\mu k}\lambda_{2,\mu k}}{\left(i\beta_2^{FD}\tau_1\lambda_{1im}+j\lambda_{2,\mu k}\right)\left(i\beta_3^{FD}\lambda_{r,PS}+\lambda_{2,dk}\right)} \\ &\times \frac{\lambda_{2,dk}\lambda_{2,dk}}{m_1^{FD}\tau_2\lambda_{2im}\lambda_{2,dk}} \\ &\times \frac{\left(a_3\rho R-\gamma_{th1}^{FD}a_4\rho R\right)\lambda_{2,dk}}{\left(\gamma_{th1}^{FD}\rho P\lambda_{2,PS}+\left(a_3\rho R-\gamma_{th1}^{FD}a_4\rho R\right)\lambda_{2,dk}\right)}\times \\ &exp\left(\frac{-i\beta_4^{FD}}{\lambda_{2,\mu k}}-\frac{m_3^{FD}}{\lambda_{2,dk}}-\frac{\gamma_{th1}^{FD}}{\left(a_3\rho R-\gamma_{th1}^{FD}\alpha_4\rho R\right)\lambda_{2,dk}}\right) \end{aligned} \tag{2}$$

In which, $\gamma_{th2}^{FD}=2^{R_2}-1$, $\beta_1^{FD}=\gamma_{th2}^{FD}\left(I_R+1\right)$, $\beta_2^{FD}=\frac{\gamma_{th2}a_2}{a_2}$, $\beta_3^{FD}=\frac{\gamma_{th2}^{FD}\rho P}{a_2\rho S}$, $\beta_4^{FD}=\frac{\beta_1}{\alpha_2\rho S}$, $m_1^{FD}=\frac{\gamma_{th2}^{FD}a_3}{a_4}$, $m_2^{FD}=\frac{\gamma_{th2}^{FD}\rho P}{a_4\rho P}$, $m_3^{FD}=\frac{\gamma_{th2}^{FD}}{a_4\rho R}$.
For U2X-NOMA, first, we concentrate on evaluating the Outage probability (OP) of the faraway R_x v. At the UAV-T_x , where the spectrum sharing variables α_w^2 and α_v^2 are unchanged during transmission, the fixed channel assignment technique is configured. R_w and R_v, respectively, are considered to be the target levels of R_x w and v. Outage probability (OP) is defined as the tendency that the transmit power is lower than the aim rate needed, therefore given to the OP of v$^{\text{th}}$ close R_x is as [21], where, $\alpha_v^2-\varepsilon_v\alpha_w^2>0$.

$$\begin{aligned} OP_v = 1 - &\frac{3\left(mM_v\sigma^2\right)^{\frac{-3}{2}}}{\alpha\left(D^3-R^3\right)}\sum_{n=0}^{m-1}\frac{1}{n!} \\ &\gamma\left(n+\frac{3}{2}+1, mM_v\sigma^2 D^\alpha\right)-\gamma\left(n+\frac{3}{2}+1, mM_v\sigma^2 R^\alpha\right) \end{aligned} \tag{3}$$

Here, $M_v=\frac{\varepsilon_v}{P_u\left(\alpha_v^2-\varepsilon_v\alpha_w^2\right)}$, $\varepsilon_v=2^{R_v}-1$, γ is the significantly reducing inadequate gamma function. Recollect that when using SIC technology, the OP of the close Rx w relies on two decoding processes. First one is R_x w compiles the R_x v input. Secondly, R_x w decodes the signal of by its own. So, the close R_x w can be defined as [21]

$$\begin{aligned} OP_w = P&\left(\log_2\left(1+\frac{P_u|h_w|^2 d_w^{-\alpha}\alpha_v^2}{\alpha^2+P_u|h_w|^2 d_w^{-\alpha}\alpha_w^2}\right)<R_v\right)+P \\ &\left(\log_2\left(1+\frac{P_u|h_w|^2 d_w^{-\alpha}\alpha_v^2}{\alpha^2+P_u|h_w|^2 d_w^{-\alpha}\alpha_w^2}\right)>R_v, \log_2\right. \\ &\left.\left(1+\frac{P_u|h_w|^2 d_w^{-\alpha}\alpha_w^2}{\alpha^2}\right)<R_w\right. \end{aligned} \tag{4}$$

Although, $a_w^2 < a_v^2$ is followed by the channel assignment variables of the paired NOMA $R_x s$ and the paired NOMA $R_x s$ are chosen from two power areas, the encoding can therefore be consolidated.
In the case of RIS-NOMA, if CU is unable to identify the signal from FAU, the outage probability will be as [24].

$$OP_{CU} = P_r\left(\frac{|A|^2 a2}{|A|^2\left(k_t^2+k_r^2\right)+\frac{1}{P_s}}\leq\rho_{th1}\right) \tag{5}$$

Here, $A=\sum_{i=1}^{N}|h_i||g_{iN}|$, ρ_{th2} is the SINR threshold. The outage probability of FAU can be determined as [24]

$$OP_{FAU} = P_r\left(\frac{|B|^2 a2\rho_s}{|B|^2\left(k_t^2+k_r^2\right)+P_s+1+a2\rho_s}\leq\rho_{th2}\right) \tag{6}$$

Here, $B=\sum_{i=1}^{N}|h_i||g_{iF}|$, $\left(k_t^2+k_r^2\right)$ is the interference phrase.
For HS-UAV NOMA, the following three scenarios, the outage activity will occur in the far user D_f . Firstly, the switch would not be able to correctly decipher x_1 . Then, x_2 can not be correctly deciphered by the switch. The switch will effectively decipher x_1 and x_2, although its signal can not be decoded successfully by D_f . So, the OP of the Faraway user, D_f can be expressed as in [27]

$$OP_{D_f} = P_r\left(\min\left(\frac{\gamma_{x_1}^{SR}}{\gamma_{th,f}}, \frac{\gamma_{x_2}^{SR}}{\gamma_{th,n}}, \frac{\gamma_{x_1}^{RD_f}}{\gamma_{th,f}}\right)<1\right) \tag{7}$$

Where, respectively, the outage thresholds at D_f and D_n are th_f and th_n [27]. For close user D_n , outage events will not occur until x_1 and x_2 are effectively deciphered by both the relay and close user Dn. So, the OP of close user will be as [27]

$$OP_{D_n} = P_r\left(\min\left(\frac{\gamma_{x_1}^{SR}}{\gamma_{th,f}}, \frac{\gamma_{x_2}^{SR}}{\gamma_{th,n}}\right) < 1\right) \\ + P_r\left(\min\left(\frac{\gamma_{x_1}^{SR}}{\gamma_{th,f}}, \frac{\gamma_{x_2}^{SR}}{\gamma_{th,n}}\right) \geq 1, min\left(\frac{\gamma_{x_1}^{RD_n}}{\gamma_{th,f}}, \frac{\gamma_{x_2}^{RD_n}}{\gamma_{th,n}}\right)\right) \tag{8}$$

For the case of GFDM-NOMA, the situation with one BS and four users is planned in downlink of the proposed scheme. Increasing time-frequency resource block is shared by four users, separate from conventional GFDM systems. Considering a closer user with less power delegated and a much more power transmitted to far user. Due to the larger share of total power in NOMA networks, U_2 first deciphered by treating the U_1 signal as interference. Same case happened for U_3 and U_4 [29]. Nevertheless, whenever two users endure within the same fading channels and decoding processes, from the point of view of theoretical study, the signal power of U_2 is enhanced or diminished by that of U_1, with a 50 percent chance. So, the outage probability for $U_1 and U_2$ will be considered as in [29]

$$OP_{U_1} = Q(\sqrt{\frac{\alpha.\gamma}{\xi_1}}) \tag{9}$$

Here, ξ_1 is derived with $\theta = 1$ in (31) and the same power management technique is considered in [32].

$$OP_{U_2} = \frac{1}{2}Q(\sqrt{\frac{T_1.\gamma}{\xi_2}} + \sqrt{\frac{T_2.\gamma}{\xi_2}}) \tag{10}$$

Here, ξ_1 is derived with $\theta = 1$ in (31) and In addition, the factor of power enhancement T1 and the factor of power impedance T2 are represented as [29]

$$\{\begin{matrix} T_1 = (\sqrt{1-\alpha} + \sqrt{\alpha})^2 \\ T_2 = (\sqrt{1-\alpha} - \sqrt{\alpha})^2 \end{matrix} \tag{11}$$

here, $0.5 > \alpha > 0$.

$$OP_{U_{3,4}} = \frac{1}{2}Q(\sqrt{\frac{\gamma_3}{\xi}} + \sqrt{\frac{\gamma_4}{\xi}}) + \frac{1}{2}Q(\sqrt{\frac{\gamma_3}{\xi}} - \sqrt{\frac{\gamma_4}{\xi}}) \tag{12}$$

Here, $\gamma_3 = \frac{P_3}{\sigma_v^2}$ and $\gamma_4 = \frac{P_4}{\sigma_v^2}$ indicates U_3 and U_4 SNR on the receiver side.

B. Sum Rate Analysis

For CR-NOMA, with the symbol x_1,the sum rate capacity for S_1 to D_1 can be expressed as [19]

$$C_{G_1}^{FD} = \sum_{i=1}^{K}\sum_{j=1}^{K}(\begin{matrix}K \\ i\end{matrix} \quad)(\begin{matrix}K \\ j\end{matrix} \quad)(-1)^{i+j-2}\frac{1}{\ln 2} \\ \times \int_0^{\frac{a_3}{a_4}} \frac{q_1+q_2+q_3}{1+x} exp(\frac{-i\epsilon_3^{FD}x}{\lambda_{1,uk}} \\ - \frac{x}{(a_3\rho R - a_4\rho Rx)\lambda_{1,dk}} - \frac{x}{(a_3\rho R - a_4\rho Rx)\lambda_{2,dk}}) \tag{13}$$

$$q_1 = \frac{j\lambda_{1,uk}\lambda_{1,uk}}{(i\epsilon_1\lambda_{2,uk}x + j\lambda_{1,uk})(i\epsilon_2\lambda_{r,ps}x + \lambda_{1,uk})} \tag{14}$$

$$q_2 = \frac{(a_3\rho R - a_4\rho Rx)\lambda_{1,dk}}{\rho P\lambda_{1,ps}x + (a_3\rho R - a_4\rho Rx)\lambda_{1,dk}} \tag{15}$$

$$q_3 = \frac{(a_3\rho R - a_4\rho Rx)\lambda_{2,dk}}{\rho P\lambda_{2,ps}x + (a_3\rho R - a_4\rho Rx)\lambda_{2,dk}} \tag{16}$$

Using the symbol x_2, the capacity from S_2 to D_2 can be expressed as [19]

$$C_{G_2}^{FD} = E(\log_2(1+H_2)) = \frac{1}{\ln 2}\int_0^\infty \frac{1-FH_2(x)}{1+x}dx \tag{17}$$

Here, $H_2 = min(\gamma_{x2}^{S1-RK}, \gamma_{x2}^{RK-D2})$.

$$FH_2(x) = Pr(\min(\gamma_{x2}^{S1-RK}, \gamma_{x2}^{RK-D2}) < x) \\ = 1 - (1 - F_{\gamma_{x2}^{S1-RK}}(x))(1 - F_{\gamma_{x2}^{RK-D2}}(x)) \tag{18}$$

The sum rate in the U2X-NOMA networks is a prominent parameter that is necessary calculating for assessment process. Consequently, we have closed-form representation in the following consequence in terms of the ordinal ergodic rates of individual U2X R_xs. It is possible to express the attainable sum rate of the close R_x as follows [21].

$$C_w = \frac{3}{\alpha\ln(2)(R^3 - r_0^3)}\sum_{n=0}^{m-1}\frac{1}{n!}\sum_{k=0}^{\infty}\frac{\Gamma(\varphi_2 - 1)\Gamma(n+1+k)}{\Gamma(\varphi_2+k)} \\ \times C^{n+k}(R^{\varphi_1}exp(CR^\infty)\Gamma(k-n, CR^\infty) - r_0^{\varphi_1}exp(Cr_0^\infty) \\ \Gamma(-k-n, Cr_0^\infty)) \tag{19}$$

Here, $\Gamma(.)$ signifies higher unfinished gamma function. $C = \frac{m\sigma^2}{P_u\sigma w^2}$, $\varphi_1 = (\alpha n + 3 + \alpha k)$ and $\varphi_2 = n + \frac{3}{2} + 1$.

To express the attainable sum rate of the faraway R_x as follows [21].

$$C_v = \log_2(1 + Q_1 - Q_2)(2 + \frac{\alpha_v^2}{\alpha_w^2}) \tag{20}$$

Here, $Q_1 = \frac{3(D^{\alpha n+3} - R^{\alpha n+3})}{(D^3 - R^3)(\alpha n+3)}\sum_{n=0}^{m-1}\frac{1}{n!}(\frac{m\alpha^2}{P_u})^n$ and $Q_2 = \frac{3(D^{\alpha(n+1)+3} - R^{\alpha(n+1)+3})}{(D^3 - R^3)(\alpha(n+1)+3)}\sum_0^{m-1}\frac{1}{n!}(\frac{m\alpha^2}{P_u})^{(n+1)}$.
In this case, we consider the time limit communication sum rate for the NOMA system supported by RIS. The sum rate of the entire system corresponding to the set bit rate R1, R2 for various service specifications for CU and FAU users can be determined as a further output variable, and such sum rate can be measured by [24]

$$C_{CU,FAU} = R_1(1 - OP_{CU}) + R_2(1 - OP_{FAU}) \tag{21}$$

For HS-UAV NOMA, the services rely under a flat amount in the time limit transmitting mode, and the wireless faded streams specify the system throughput. So, the sum rate can be calculated as [27]

$$C_{HS-UAVNOMA} = \sum_{i=1}^{M}(1 - PD_m) \times R_{th,m} \tag{22}$$

Here, $R_{th,m}$ signifies D_m's rate of propagation period and can be described as $R_{th,m} = \frac{1}{2}\log_2(1+\gamma_{th,m})$. The constants $\frac{1}{2}$means that the communicating method is split into two time slots. The outage rate of user D_m is implied by $\gamma_{th,m}$.
The sum rate of SCMA-NOMA can be expressed as [30]

$$C_{SCMA-NOMA} = \sum_{i=1}^{F}\sum_{n=1}^{N}\sum_{k=1}^{K} s_{k,n}\log_2(1+\Gamma_{k,n}^{FUE,i}) \quad (23)$$

Here, the factor $s_{k,n}$ is a device management with $s_{k,n} = 1$ indicating that a relation occurs between user dataset $s_{k,n} = 0$ indicates that the it has not been connected to any data.
The achievable rate of GFDM-NOMA can be represented as [29]

$$C_{GFDM-NOMA} = \log_2(1+\frac{\alpha.\gamma}{\xi_1}) + \log_2(1+\frac{(1-\alpha).\gamma}{\alpha,\gamma+\xi_2}) \quad (24)$$

IV. Simulation Results

Simulations in this portion have been shown to verify the results generated in Matlab. In the simulations described in section III, we make sure that all users have the very same standard rate criteria and total transmission power specifications. Fig. 7 highlights the differences of outage reliability between the top sections addressed by the hybrid schemes of NOMA. It must be noticed that the study of the necessary outage matches well with the U2X-NOMA schemes at a high SNR rates. In order to highlight U2X-NOMA, we offer small-scale channel advantages for near and distant consumers in the contract. It is an evident from the outcome that the probability of outage for U2X-NOMA is dramatically lower than other discussed schemes and also theoretical outage performance. On the reverse, CR-NOMA places a very low SNR(5dB) in a better position than all other methods described here.

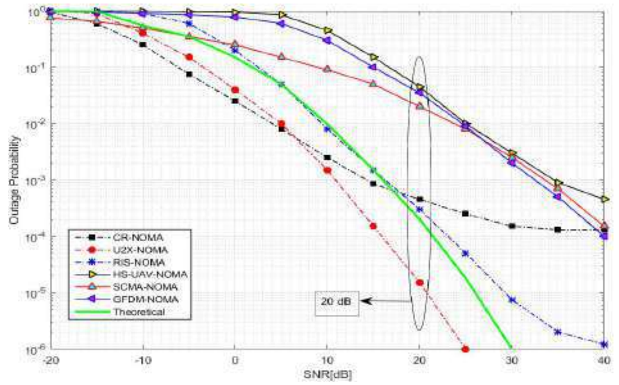

Fig. 7. Outage Probability performance among six hybrid NOMA schemes

In Fig 8 of the proposed hybrid NOMA schemes, the utility of the sum-rate is calculated in the next context. In this portion, due to its benefits of the small scale fading for all users, it is noticeable that U2X-NOMA perform better than the other schemes for high SNR.

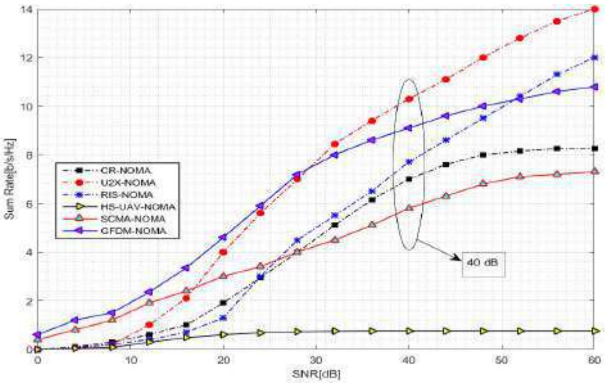

Fig. 8. Sum Rate Comparison among six hybrid NOMA schemes

V. Conclusion

For the hybrid NOMA structures discussed in this paper, we give a comparative theoretical framework as well as a measured structure. We use closed-form calculations for the sum rate and outage probability from the frameworks above. All derived phrases are checked through calculations. U2X-NOMA, considering all performance metrics, outperforms the other hybrid NOMA schemes underlying the configuration of outage and sum rate. The reason behind U2X-NOMA out forming the other schemes described here is U2X-NOMA uses the large scale fading. As a result, it can depict the path loss between transmitter and receiver side users. For future research, combination of UAV and STBC(Space time block coding) in terms of NOMA could be a better solution for next generation wireless communication.

***Abstract*—With the tremendous growth of IoT application,providing security to IoT systems has become more critical.In this paper, a technique is presented to ensure the safety of Internet of Things (IoT) devices. This technique ensures hardware and software security of IoT devices. Blockchain technology is used for software security and hardware logics are used for hardware security. For enabling a Blockchain, Ethereum Network is used for secure peer-to-peer transmission. A prototype model is also used using two IoT nodes to demonstrate the security logic.**

***Index Terms*—Internet of Things, Blockchain, Security.**

I. Introduction

In recent years the security issue of the IoT ecosystem has become subject of discussion which often troubles the end-users.The internet of things has become one common solution for better and scalable automation technologies. The deployment of the IoT technologies is now in limited applications but soon it is going to be included in every day-to-day activities. With the increase in the application areas of IoT technology, there is a high chance of misuse of these technologies. Therefore, there is an urgent need of ensuring the safety of these devices and make them such that they are effective to deal with all the threats in the future. Existing technology will be not enough to protect the devices.

With the increase of involvement of IoT system in human life there is exponential increase of cyber attacks on the IoT systems [1].Various IoT specific malware are being formulated to perform DOS attacks,eavesdropping attacks on the system [2].Due to it's open structure and involvement of third part, access,leaking the information out of the IoT nodes is not very much difficult.The IoT system is not only attacked at software level rather it is being compromised at the hardware level also.Since sometimes these IoT devices are installed remotely some foreign objects or a leakage path is being formed at the hardware of the IoT system by authorized persons [3].

In order to have a secure communication between IoT nodes,we have to provide security at every level of system i.e from hardware level to the software level.For providing hardware level security we can use dummy or fake logic to make the circuit more complex to understand by other and also we can install self-assessment test to check the proper working of the hardware before configuring it as IoT node. Now if we look for software level security(data transmission level) we can use blockchain technology in order to have secure peer to peer communication along with cryptographics method.The Blockchain has gained so much attention from the world since its launch. Fig 1 shows the basic components of the blockchain technology. Blockchain has the ability to optimize the global structure of the technologies connected with each other through internet [4]. It has mainly two fields that are going to be affected which are:

- It creates a decentralized system which removes the interference of the central server and provides peer to peer interaction.
- It creates a fully transparent and open to all database which brings transparency

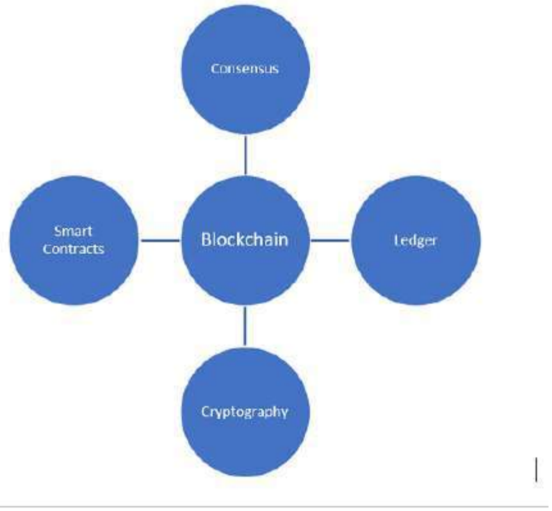

Fig. 1. Basic components of Blockchain

Block has 4 components, first of which is consensus which provides proof of work (PoW) and it verifies the actions occurring around the networks, second is ledger which provide the details of the transaction that occurred between the nodes. Third is cryptography, it make sure that the data on the network and the ledger is safely encrypted and only authorized user can have the access of it and the last one is smart contract which are termed as the verification and validation of the connecting nodes [5].

II. IoT Security Concerns

IoT has tremendous amount of application for example in making smart city, improving health, autonomous vehicle and many more. But with kind of connection on which the foundation of IoT is built has many issues so if an unwanted person(hacker) gets access to the system by exploiting the issues can compromise the privacy of users and can also harm them [6].

Thus, while implementing IoT, the security of the systems should be strengthened. Keeping these systems secure is a difficult task because the actual sensor is sometimes placed remotely. Various cluster of the security [7] is shown in the fig 2. Now the security of these device needs a robust solution right from the hardware level to the application layer. Existing technology is not enough for the security of the vastly implemented technology.

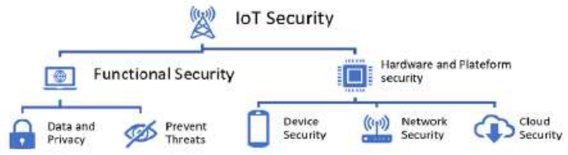

Fig. 2. IoT Security

Here the smart technology called Blockchain will give us a suitable solution to provide end-to-end security to the IoT system. Blockchain provides a decentralized system that stores the database of every transaction made in a network. Rather than having a traditional central database like that of the government, it has a ledger distributed over a network of nodes.

Now blockchain can provide the security for the application layer or we can say it will provide the way to share data between nodes securely, so we have to also look for the threats due to the hardware. Since the IoT specific hardware are generally third-party build so there is a chance that the third-party person may tamper with the circuit and provide a leakage path (Trojan). And also, since it is devices are remotely installed it is rather easy to install foreign materials on the IoT circuitry.

So, end to end security is a must for the IoT environment to provide a seamless experience.

III. Overview of Blockchain

Blockchain's decentralized cryptographic model allows users to trust each other and make peer-to-peer transactions, eliminating the need for intermediaries. This technology is not only affecting the way we use internet, but the global economy is also being revolutionized.

Following are the main parts of the blockchain which helps in completing the infrastructure:

1) Network Node: All the connected nodes maintain a database of transactions made on a blockchain network. The authentication process is also done by mutually decided the function so it eliminates the involvement of the third-party validation process. When a transaction is done, its records are added to the ledger of past transaction, this process is known as 'mining'. The proof of work has to be verified by the other nodes present on the network.
2) Distributed database: The database composed of blocks of information and each block has following data in it:
   - A list of transaction
   - TimeStamp
   - Information which links it to previous chain of the blocks
3) Shared Ledger: The ledger is updated when the transaction is made. It is available for all and it is incorruptible which brings the transparency.
4) Cryptography: The data is secured using crypto mechanism and unauthorized users cannot alter or tamper the data.

The blockchain network can be visualized as shown in fig.3

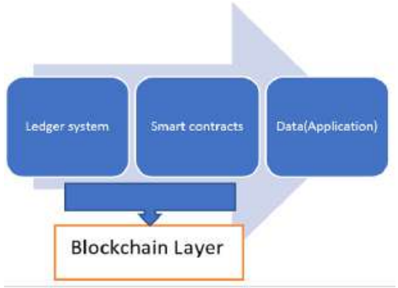

Fig. 3. Blockchain Network

The best example of implementation of blockchain is the Bitcoin and the transaction system in it.

Blockchain is implanted in 3 domains:

1) Public Domain: No-Permissioned area and each and every node send, read data without requiring any permission. Bitcoin and Ethereum are the examples for it.
2) Consortium Domain: Partial permissioned. Only defined nodes can take part in process and permission to read, write data may or may not be made public.
3) Private: Permissioned domain. Only the members whom the network belongs can write transaction. Reading can be made public or restricted to few nodes.This kind of private domain is applied in the industries.

IV. Architecture of IoT Based on Blockchain

The internet of things can have many nodes which will be communicating with each other, so we can build an architecture which would have a distributed connection.

Multiple models for communication:

1) Fundamental function of blockchain network can be used.
   - Peer to Peer messaging
   - Distributed data sharing
   - Differential coordination with the device

But there will be issues while implementing the model like Slow processing due to low end CPU because blockchain requires more memory and high CPU.

Also, the size of the ledger will increase day by day thus making the process slow.

In fig. 4 shows the basic architecture of the blockchain network implementation of technology i.e. mining, cryptography, ledger ,etc. Each IoT node is the member of the network participating in the transaction. Validation is done through mining and node can be a computer, cloud. These IoT devices are the client and theses clients will interact with each other with APIs. Devices create transaction and these transactions are sent to the blockchain nodes for storing and processing data into distributed ledger.

REST-APIs can be used to make communication with the IoT devices and the blockchain. Each of them will have different set of APIs.

Various attacks like "man-in-the-middle" attack can be avoided by establishing the trust between node and IoT devices.

Now while implementing this technology we have to take into the consideration of the delays caused due to blockchain [8] .Therefore we have to adjust our system in order to sustain the data transition delays.

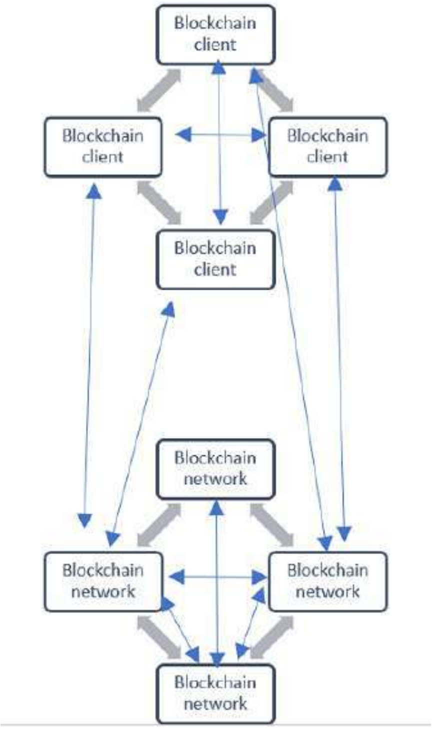

Fig. 4. Distributed Data Sharing

- Various recent research shows that future IoT environment will have multiple blockchains with having distinctive features and services.Also, the implementation of Artificial Intelligence will be there along with the blockchain. So, this kind of arrangements will be robust to outcome the vulnerably.

V. Enhancing the Security of IoT

A. Hardware Security

First line of security has to be implemented on the hardware level. Generally, the threats are known as Hardware trojan i.e. unwanted circuit which is leaking the data.

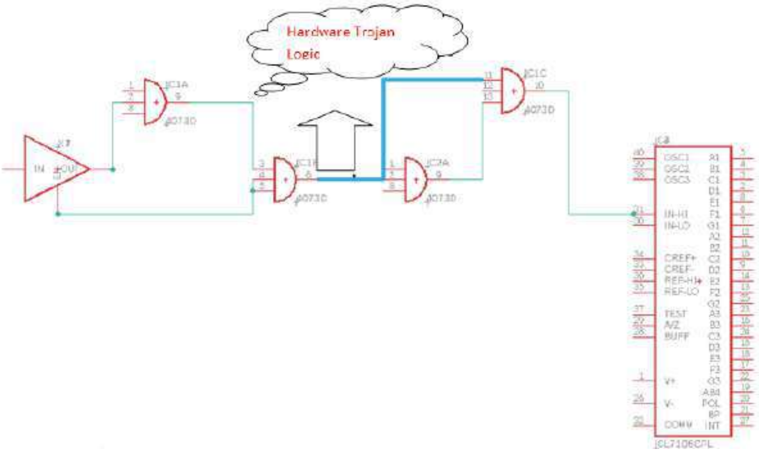

Fig. 5. Hardware Trojan

To avoid this kind of malpractice we can use following methods:

- Installing or fabricating a fake or dummy logic to create confusion to another person.
- Also adding multiple functioning mode of operation like normal mode and malfunction node and as the circuit designer we only know how to configure for normal mode operation.
- Also, often the attackers exploit the empty spaces on the PCB, so installing a Built-in-self-test circuit will help us to determine whether there has been any alteration to original circuit.

Now above will give us some extent of security to the devices because these devices are installed remotely.

B. Securing Data transmission

Now the next aspect and most important one is to provide secure data transmission. In this area there always maximum attack happens.

Following are the area through which we have to ensure for security:

1) Secure Transmission (Communication):Here the blockchain features will come into effect. The IoT devices will utilize a ledger to store the encryption key

in order to send encrypted data.
IoT devices sends the encrypted message using the Public Key of the receiver which is stored in the blockchain network after asking for it.
Then the legal or authenticate receiver can only decrypt the message using its Private Key. So, no third person can have the access of that data.

2) Authentication of the Legal IoT nodes: In this system the sender will digitally sign the message before sending to anyone. Then the receiver will obtain the public key of the sender to verify the signature of the received message.
The process will be as follows:
a) Sender calculates the hash of the message and encrypt it with it's Private key.:
b) This constitute a digital signature and it is transmitted along with the data.:
c) The receiver will obtain the Public Key of the sender through ledger and calculate the hash of the message.:

C. Configuring the legitimate IoT node:

Everyday large number of IoT devices are to be added so there should be ability to differentiate between legitimate and non-legitimate nodes.
As soon as the new device is switched on, this device register itself on the root server of that network. Then the exchange of information takes place and it sends its information to other devices and also receives the same from others.
Now an attack called "Spoofing" can happen at this stage. To avoid that we can use Domain name security extension to provide name resolution of root server.
In Private networks to make sure legitimate Node is connected, root server must authenticate the device before starting any bi-directional communication. This can be done in following ways:

- The credential can be generated by blockchain network and we can install these at the device setup.
- Some credential can be given to user and after initializing the process the device can be registered.

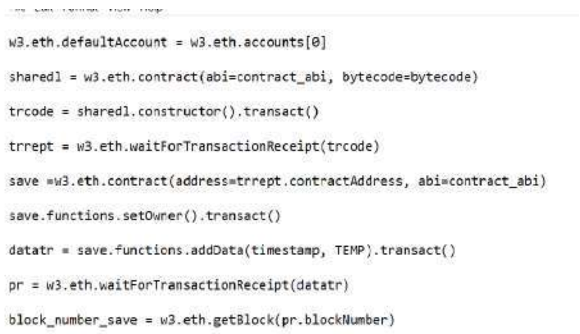
Thus, the blockchain features really help in securing and establishing the IoT environment. The properties of the devices, configuration details are securely stored on the ledger.The hash value feature also helps us to validate the received message. So, having a network of Blockchain connected device i.e. a decentralized system each and every node will have the copy of data. Whenever any device node user wants to access it, all the other nodes must validate it. After the validation then only a transaction can happen.

VI. Implementation

For implementation of the architecture with respect to above section, we have used a Raspberry pi and a laptop.We will use Ethereum's based system library Web3.py Python library and we will set a private Ethereum Blockchain network between Raspberry pi and a laptop.

A. Raspberry Pi configuration

We have to configure the pi in order to run the Blockhain network.Required operating system is "linux/Raspbian GNU" and Python3 must be installed.Also the Pi is connected to internet and a fixed IP address is assigned to it.A default account is created in the network using web3 module and also the IP of the connected node is stored in Pi address book.A part of code is referred as in fig.6
Also a pair of Public and Private key will be generated for each node and the public key of each node is shared along the shared ledger of nodes and private key is being kept safe.



```
w3.eth.defaultAccount = w3.eth.accounts[0]

shared1 = w3.eth.contract(abi=contract_abi, bytecode=bytecode)

trcode = shared1.constructor().transact()

trrept = w3.eth.waitForTransactionReceipt(trcode)

save =w3.eth.contract(address=trrept.contractAddress, abi=contract_abi)

save.functions.setOwner().transact()

datatr = save.functions.addData(timestamp, TEMP).transact()

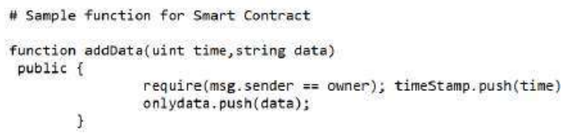
pr = w3.eth.waitForTransactionReceipt(datatr)

block_number_save = w3.eth.getBlock(pr.blockNumber)
```

Fig. 6. Web3(Ethereum)

B. Blockchain Smart Contract

Now we will use the laptop 2 node of the network. Now a smart contract a formed using senders information condition .The data part in the contract referred in fig. 7 which will be message to be transmitted is encrypted using the public key of node 2 and only the node 2 will able to decrypt the data using its private key.Both the laptop and the pi will use this smart contract in order to transfer data.



```
# Sample function for Smart Contract

function addData(uint time,string data)
 public {
                require(msg.sender == owner); timeStamp.push(time)
                onlydata.push(data);
        }
```

Fig. 7. Important Function of Contract

C. Integration using Python

In order to connect both we will use node id and IP address of the nodes and we will use "addPeer" command and mining will be done at a node.
Once the connection is established,the smart contract is being called and the message is stored at the node2.The message is

decrypted using the private key of the node 2. Each block of message is stored with a time stamp of reception along with the data.Alternatively the data can be appended into a .json file for better transparency.

VII. Conclusion

In this paper we have discussed the security vulnerability of IoT communication and growing need for a robust solution.A prototype of blockchain component is implemented using raspberry pi.The proposed hardware security methodology will help us to counter the hardware trojans and blockchain has been used as a solution to the application/software level security.In this way a decentralized communication system is being established without interference of third party for the validation and the data is transmitted securely between the nodes.This system demonstrates the important features of blockchain in terms of provide a secure environment for communicating between the nodes.

***Abstract*—Bangladesh is one of the top five rice-producing and consuming countries in the world. Its economy dramatically depends on rice-producing. Rice leaf disease is the biggest problem in the agriculture sector. This is the main reason for the reduction of the quality and quantity of the crops. The spread of the disease can be avoided by continuous monitoring. However, manual monitoring of diseases will cost a large amount of time and labor. So, it is a good idea to have an automated system. This paper presents a rice leaf disease detection system using a lightweight Artificial Intelligent technique. We are applying the edge computing concept here. Our edge device is Raspberry Pi. We have processed all our data in Raspberry Pi. We consider three rice plant diseases, namely Brown Spot, Hispa, and Leaf Blast. They are the most common type of rice leaf disease in Bangladesh. We have used clear images of healthy and infected rice leaves with white background. After applying the necessary preprocessing, we have extracted the necessary features from the images. Then we have made an image classification model with various machine learning algorithms by feeding these features. We have learned that the Random Forest algorithm performed the best. By using our image classification model, we have achieved 97.50% accuracy on our edge device.**

Keywords*—*Edge Intelligence, IoT, Machine Learning, Rice Leaf Disease Detection, Image Classification

I. Introduction

As an agricultural country, about 135 million people of Bangladesh consider rice as their staple food. In this region, rice considers as low cost and most nutrient food. More or less, 48% of rural employment is the blessings of it. Besides, half of the agricultural GDP comes from the rice sector. The Rice sector contributes to one-sixth of the national income of Bangladesh. Around 80% of the total irrigated area is under this sector [1]. The livelihood of the people in rural areas depends mostly on rice cultivation. To ensure stable economic growth and maintain desired goals, disease-free rice cultivation can play an important role. So, it is evident that the proper cultivation of rice is a primary concern for Bangladesh.

Therefore, we have come up with an automated system, which will contribute to the development of Bangladesh's agriculture sector. Our proposed system will automatically detect if a leaf is healthy or infected from the leaf's image. Our system is based on the edge computing concept. Edge computing places networked computing resources as close as possible to where data is created. Edge computing is associated with the Internet of Things and the application of small computing devices like Raspberry Pi [2].

We are using Raspberry Pi as our edge device. We process all of our data in Raspberry Pi. Raspberry Pi is a credit-card-sized single-board computer. It is very low in price. It has some GPIO pins to communicate with external components. Its default operating system name is Raspberry Pi, which is based on Debian [3].

We are detecting three rice leaf diseases, namely Brown Spot, Hispa, and Leaf Blast, because these are the most common rice leaf disease in Bangladesh [4].

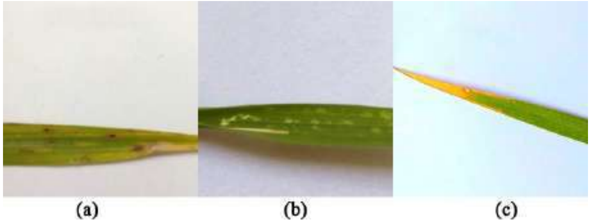

Fig. 1. Infected Leaves (a) Brown Spot, (b) Hispa, (c) Leaf Blast

Brown Spot is caused by Cochliobolus miyabeanus fungus. It causes a prominent spot on the leaves [5]. A species of leaf beetle named Dicladispa armigera is the reason for Hispa. It scrapes the upper surface of leaves and causes white patches [6]. Magnaporthe oryzae is a fungus that causes Leaf Blast disease in rice leaves. It causes grey-green or white spots with dark green or reddish-brown border [7].

We have taken images of healthy and infected leaves with white backgrounds [8]. After preprocessing the images, we have applied machine learning algorithms to make our image classification model. We have tried different machine learning algorithms, but random forest turns out to be the most efficient.

A. Internet of Things:

Internet of Things (IoT) refers to devices embedded with sensors and technologies that are connected to the internet

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

for exchanging information. It can be a self-driving car, an automatic door, a coffee maker, a wearable device, or a washing machine connected to the internet for collecting and sharing information. Most of the time, this information exchanging happens without the interference of humans. In some cases, these devices make use of artificial intelligence [10].

B. *Edge Computing:*

Edge computing is a distributed computing system that processes data on an edge device instead of a data center. It makes real-time data processing effective. This reduces problems with latency and connectivity. It ensures that only critical data will be sent over the network, and no-critical data will be processed on the edge device. This reduces latency for time-sensitive devices [11]. Since edge devices process data themselves, the latency is almost zero.

C. *Machine Learning:*

Machine learning is a method that enables systems to learn automatically from data and improve their accuracy over time from experience without being programmed to do so. It is a branch of artificial intelligence. In machine learning, training data is given to the learning algorithm. Then learning algorithm generates a set of rules from the pattern and feature of the data. Based on these rules, it makes a prediction on new data. The quality of the algorithm defines the accuracy of the prediction. [12].

D. *Random Forest Algorithm:*

Random forest algorithm is a supervised learning technique. This is a popular machine learning algorithm for classification. However, it can be used for regression problems also. It consists of a combination of multiple decision trees. It uses the bagging method for training. The prediction of random forest is based on the majority of all the decision trees. Random forest eliminates the risk of overfitting and it takes less time for training [9].

E. *Motivation:*

Bangladesh is the fourth-largest rice producer. Rice is grown on about 10.5 million hectares. Almost all of the 13 million farm families of Bangladesh grow rice [1]. So, it is essential to produce good quality and quantity of rice. But the main problem is the disease of rice crops. Detection of rice plant disease has always been challenging. It requires constant human observations. But it is much more time-consuming and requires more labor.

This research presents an automatic rice leaf disease detection system. It detects if any of the crops are infected by disease or not. This will make the life of farmers easier, reduce the cost of labor and save time. Our proposed system is cost-friendly also, as we are using Raspberry Pi, a cheap microcomputer.

F. *Research Paper Outline:*

Our research paper has six sections. The sections and their contents are as follows:

- Section 1: Introduction. This section gives the overview, objectives, and motivation of our research report.
- Section 2: Literature Review. This section presents a concise survey of different image processing and machine learning operations applied in rice leaf disease detection.
- Section 3: Methodology. This section gives an overview of the working process.
- Section 4: Implementation. This section presents our proposed work for rice leaf disease detection. It describes the detailed methodology of our proposed work.
- Section 5: Results and Discussion. This section presents the results we have achieved.
- Section 6: Conclusion. The summary and scope of our research report has been discussed here.

II. Literature Reviews

In [13], the image is treated as a matrix of M rows and N columns. Their work extracted color texture using chromatography concepts of CIE XYZ color space. They have extracted color features using CIE L*a*b* color space. They used those features to form a simple metric indicating the roundness of the spot. They have achieved 70% accuracy with 50 sample images.

Authors in [14] divided their work into two phases. First, they prepare the healthy leaf image using HS histogram, and then they prepare diseased leaf image by extracting significant colors. After that, they have used image segmentation to apply the outlier detection method.

Q. Yao et al. [15] used Support Vector Machine (SVM) for detecting rice diseases. The achieved accuracy is 97.2%. After segmenting the diseased spot from the image, shape and texture features were extracted from the spot. Bacterial leaf blight, rice sheath blight, and rice blast disease were classified using SVM.

Orillo et al. [16] used 55 images for Bacterial leaf Blight, 37 images for Brown Spot, and 42 images for Rice Blast. After reducing noise and contrast adjustment, image segmentation was done for feature extracting. Then the back-propagation neural network is applied for the classification.

In this [17], 300 images were used for classification. After converting the image to HSV color format, K-Means clustering is used for image segmentation. Statistical features such as Mean Value, Standard Deviation, and GLCM are calculated for feeding to artificial neuron network (ANN). 90% and 86% accuracy achieved on test dataset for the infected and healthy images, respectively.

Research work in [18] used two datasets. One has 48 images, and another has 23 images. They have used the Simple Linear Iterative Clustering (SLIC) algorithm for over-segmentation of images. They extracted three features, namely color, shape, and texture. They have extracted texture from Gray Level Co-occurrence matrix (GLCM). They have used Random Forest classifier for classification.

The authors of this [19] paper used K-means clustering for the segmentation of the diseased area of the rice leaves. For classification, they used the Support Vector Machine (SVM). They achieved 93.33% accuracy on the training data set but 73.33% accuracy on the test dataset.

The author in [20] used fermi energy-based segmentation to extract the infected parts from the images. The shape of the infected part was extracted using the DRLSE method. To reduce computation time, they have used rough set theory.

III. Methodology

The methodology of the research work can be divided into five steps. They are image preprocessing, image segmentation, feature extraction, training model, and detecting healthy and infected leaves in Raspberry Pi. Block diagram of the system is shown in Fig. 2.

The system architecture of our proposed system is shown in Fig. 3.

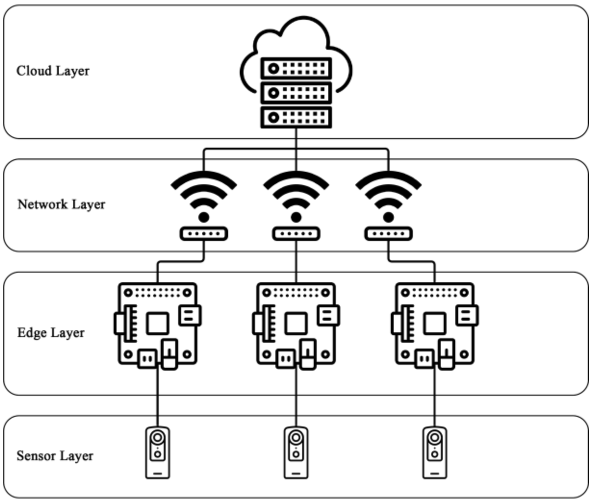

Fig. 3. System Architecture

IV. Implementation

We are working with an image dataset [8] from Kaggle. The dataset is not well sorted. In the healthy folder, there are some infected leaf images, and in the infected folder, there are some healthy leaf images. After separating them, we discovered a lower number of healthy leaf images than infected leaf images. Furthermore, the picture sizes are not consistent.

As we have to make an image classification model which can be run on Raspberry Pi, we are not classifying individual diseases. We will just find out if the leaf is infected or not. That is why we have labeled our dataset in two classes called infected and healthy. For the training dataset, we have taken 310 infected leaf images and 190 healthy leaf images. Furthermore, we have taken 50 infected leaf images and 30 healthy leaf images for the testing dataset. All of the images were selected at random.

A. Components

1) Raspberry Pi 3 Model B v1.2: We are using Raspberry Pi as our edge device. It is packed with Quad-Core 1.2GHz 64bit CPU. It comes with 1GB of RAM. The classification of the leaves is done on Raspberry Pi.

2) Raspberry Pi Camera Board v1.3: We will use a camera module to capture rice leaves images for detecting purposes. It is a 5MP resolution camera. The camera module can be connected to Raspberry Pi through the CSI Camera Port of Raspberry Pi.

B. Creating Model

We are creating an image classification model which can be run on Raspberry Pi. For that reason, we are not going to use complicating filters and image processing methods. Our goal is to get higher performance with a lesser computational load.

1) Image Preprocessing: For reducing computation time, we have resized the images to 256 × 256 pixels. Then we have changed the color format of images from RGB color format to HSV color format. Because it is easier to separate colors in HSV color format. HSV represents Hue, Saturation, and Value part of an image. The output is shown in Fig. 4.

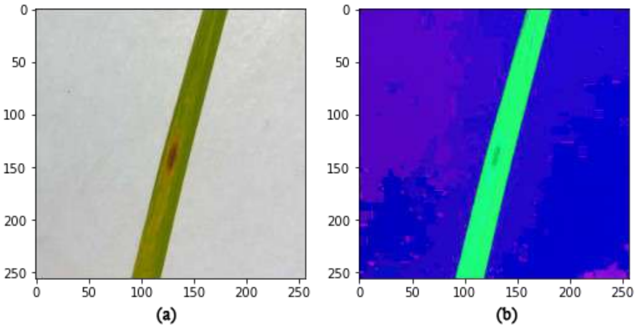

Fig. 4. (a) Image in RGB Format, (b) Image in HSV Format

2) Image Segmentation: After that, we have removed the background from the images. For that, we have performed image segmentation. In segmentation, we have first made a mask that will extract green color from the images, shown in Fig. 5.

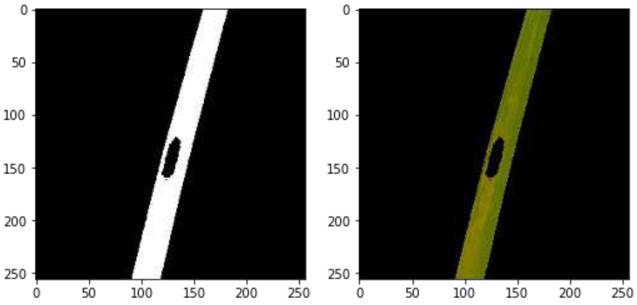

Fig. 5. The output of the green mask

Then we have made another mask that will extract brown color from the images, shown in Fig. 6.

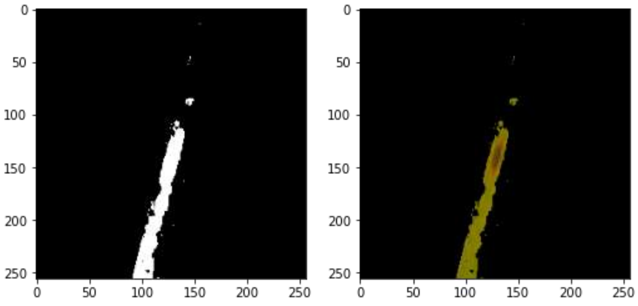

Fig. 6. The output of the brown mask

After that, we have combined these two masks, which will extract leaf from the images. After applying segmentation, the output image becomes like in Fig. 7.

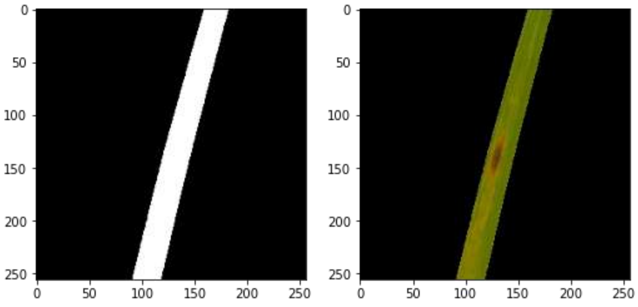

Fig. 7. The output of the final mask

3) Feature Extraction: We have used three feature descriptors to extract features from the images. For extracting color features, we have used Color Histogram. The color distribution in an image is represented by a histogram. Calculating an image's histogram is extremely useful because it offers insight into some of its properties, such as total range, contrast, and brightness. We have used Hu Moments for extracting shape features. A weighted average of the image pixel intensities is used to measure the image moment. Hu moments are moments that are not affected by translation, scaling, or rotation. Texture features were extracted using Haralick. A Gray Level Co-occurrence Matrix, or GLCM, is used to compute Haralick texture features. Haralick Texture is a texture-based approach for quantifying images.

4) Training Model: We have trained our model with six machine learning algorithms. All the models are validated using the 10-Fold Cross-Validation technique. The algorithms are,

a) Random Forest [RF]

b) Naïve Bayes [NB].

c) Decision Trees [DT].

d) Logistic Regression [LR]

e) K Nearest Neighbors [KNN].

f) Support Vector Machine [SVM].

A comparison of the machine learning algorithms is shown in Fig. 8. We can see that Random Forest has performed the best. That is why we have trained the whole dataset with the Random Forest algorithm.

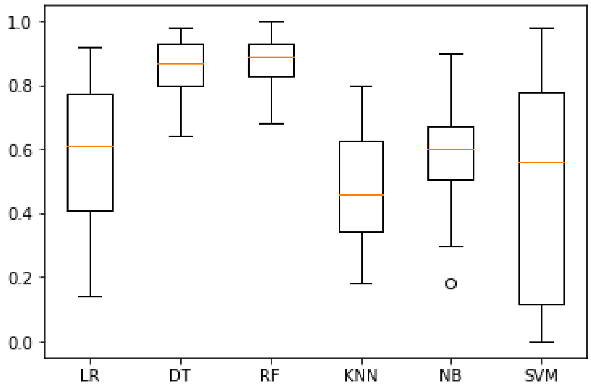

Fig. 8. Comparison of machine learning algorithms.

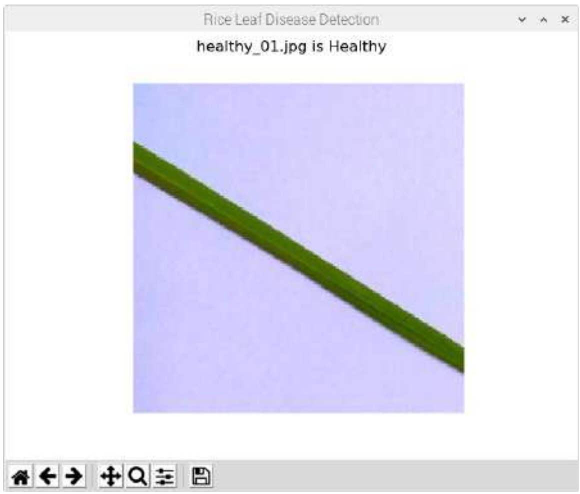
5) Detecting Healthy and Infected Leaves: Our main focus of this research is to implement edge computing concept in rice leaf disease detection. That is why after training our image classification model, we have exported the image classification model. Then we have transferred the image classification model to our Raspberry Pi. Then we have executed our program. We could detect healthy and infected leaves with our system without any hassle. We have shown in Fig. 9 and Fig. 10.



Rice Leaf Disease Detection

Rice Leaf Disease Detection

infected_01.jpg is Infected

Fig. 10. Classified as Infected

V. Results and Discussion

A. Model Accuracy

After performing prediction on our test dataset, we achieved an impressive 97.50% accuracy. The classification report of our image classification model is given in Table I.

TABLE I. Classification Report

	precision	recall	f1-score	support
healthy	0.94	1.00	0.97	30
infected	1.00	0.96	0.98	50
micro avg	0.97	0.97	0.97	80
macro avg	0.97	0.98	0.97	80
weighted avg	0.98	0.97	0.98	80

The confusion matrix of our image classification model is shown in Fig. 11.

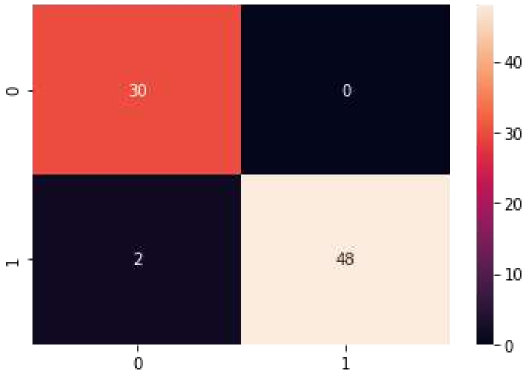

Fig. 11. Confusion Matrix

B. Raspberry Pi Performance

As a microcomputer, the performance we are getting from Raspberry Pi is pretty good. A total of 80 images were used to test the performance. We compared the performance of Raspberry Pi with a computer having a Hexa-Core 3.6GHz 64bit CPU and 8GB of RAM. Comparison of performance between Raspberry Pi and Computer is shown in Table II.

TABLE II. Performance Comparison

	Average time to classify one image
Raspberry Pi	0.20 sec
Computer	0.02 sec

C. Discussion

This paper has introduced the use of edge computing in agriculture. To the best of our knowledge, we are not aware of any other work in this field relating to edge computing. We are able to successfully identify healthy and infected leaves with the help of our system. We have got a good amount of accuracy from our image classification model. As an edge device, the performance of our system is promising. As we are classifying the images in our edge device, it will reduce the problems related to latency and connectivity.

We have randomly taken 30 images. Out of 30 images, only 4 images were the image of infected leaves. So, it can be said that our system can reduce approximately 86.66% of data transmission cost which will improve the latency.

VI. Conclusion and Future Scope

A. Conclusion

Rice leaf diseases can cause a significant amount of loss to the agriculture sector. This paper presents a system that will detect healthy and infected leaves automatically.

Many types of research have been done on detecting rice leaf diseases. But most of them use server-side data processing. The cost of a server is not cheap. That is why we have proposed a system that will classify the images on an edge device. We are using Raspberry Pi as our edge device, which is low in cost and power consumption. Our system can classify a leaf within 0.18 sec to 0.25 sec, and the accuracy of our image classification model is 97.50%. We are pleased with the performance of our system.

We hope our system will contribute a little to the advancement of the agriculture sector. The work has significant economic importance for Bangladesh.

B. Future Scope

Our current image classification model is built with machine learning. In the future, we are thinking of implementing deep learning for detecting leaf diseases. Currently, we are classifying all diseases as infected. Nevertheless, for future work, we plan to classify each disease by its name.

***Abstract*— Many protocols have been proposed to reduce energy consumption in wireless sensor networks and extend their lifetime. One of the most efficient class of these protocols is known as cluster-based routing protocols. In this paper, we consider a key issue that impacts the performance of this class of protocols. We call it Intra/Inter-Cluster Event-Reporting Problem (IICERP). We show that IICERP significantly degrades the performance of cluster-based routing protocols. Accordingly, we propose an efficient solution for IICERP (SIICERP). Thorough simulations have been conducted to show the performance of different cluster-based protocols with and without SIICERP. The simulations showed that SIICERP significantly improves the performance of cluster-based routing protocols.**

Keywords—Cluster-based networks; Routing protocols; Wireless sensor networks; SIICERP

I. Introduction

Wireless Sensor Networks (WSNs) consist of a large number of tiny and smart devices called sensor nodes [1-3]. Sensors are randomly deployed in remote areas for monitoring purposes [4]. In WSNs, the main task of deployed nodes is collecting data from the sensed region and transmitting it to the base station (BS) or the sink node through predefined channels [5-6]. Energy constraint is considered as the most disturbing issue to many researchers in the field of WSNs [7-8]. Sensor nodes consume a lot of energy due to sensing information, processing data, transmitting and aggregating data. Indeed, the main source of power in these nodes is the battery which is almost impossible to be changed or recharged after the nodes deployment in the network [9-10]. Therefore, well-designed protocols for data collection in WSN are needed to reduce the energy consumption in the network and so extending the lifetime of the network [11-13]. Different energy-aware data collection schemes (i.e., routing protocols) have been proposed for WSNs. These protocols can be classified into three main categories; flat-based routing protocols [14-16], tree-based routing protocols [17-18], cluster-based routing protocols [19-26]. In this paper, we mainly considered the cluster-based protocols which have proven to be the most energy efficient routing protocols [19-26]. In this type of protocols, there are some nodes that have a unique identification over the others. There are two types of nodes: normal nodes and Cluster Head (CH) nodes. The network is divided into many groups called clusters. Each cluster contains one CH node and a number of normal nodes. All of the normal nodes in any cluster transmit their sensed data to their CH which is responsible of aggregating the overall data and transmitting it to the BS. Clustering may be fixed or variable. In fixed clustering protocols, the clusters are formed after the deployment of the nodes and they still the same until the end of the network lifetime. The role of CH is rotated among all nodes in each cluster. In variable clustering protocols, the lifetime of the network is divided into multiple rounds. New clusters are formed in the beginning of each round. There are some protocols that use a third type of nodes called Relay Nodes (RNs) which are responsible of receiving data from CH nodes and then transmitting it to BS. Cluster-based routing protocols efficiently save the energy in WSNs.

All cluster-based routing protocols have a key issue which severely drains the batteries of the nodes. We call this problem as Intra/Inter-Cluster Event-Reporting Problem (IICERP). This problem appears on two levels; intra transmission and inter transmission levels. In first one, if an event occurs in a certain region in the network, then more than one node from the same cluster or different clusters may report on this event by sending similar data packets to their CHs. In the second one, if an event occurs in a certain region in the network, then more than one CH node may report on this event by transmitting similar data packets to the BS.

In this paper, we propose an efficient solution to IICERP problem (SIICERP) which improves the performance of cluster-based routing protocols. SIICERP aims at reporting on an event by no more than one normal node and no more than one CH node. SIICERP is compatible with cluster-based routing protocols. In order to evaluate the performance of SIICERP, we integrate into two cluster-based routing protocols. One of them uses fixed clustering scheme and the other applies variable clustering scheme. The simulation results show that SIICERP significantly saves energy and so extends the lifetime of the network. However, the rest of the paper is organized as follows. Section II presents some related work. Section III presents and explains SIICERP. In section

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

IV, we conduct simulations to evaluate the performance of SIICERP. Finally, concluding remarks are drawn in section V.

II. Related Work

Many cluster-based routing protocols have been proposed in literature [19-26]. However, in our work, to show the effect of the proposed solution, we consider only two cluster-based protocols proposed in [19] and [20]. We select these protocols since one of them is based on variable clustering scheme [19] and the other is based on fixed clustering scheme [20]. In [19], the authors proposed the first and the most popular cluster-based routing protocol called Low Energy Adaptive Clustering Hierarchy (LEACH). The overall network lifetime in this protocol is divided into time slots called rounds. Each round contains one short setup phase followed by one long steady state phase. In the setup phase, selecting CH nodes and forming clusters take place. Selecting CH nodes is done in randomness probabilistic form. Each node in the network generates random number between 0 and 1. Then by comparing this generated number with predefined threshold value, this node will be either a CH or normal node. Then, CH nodes send advertisement messages for all nodes in the network based on carrier sense multiple access (CSMA) protocol to inform them that they were elected as CHs. These messages contain the locations of elected CH nodes. Normal nodes will choose their CHs based on the strength of the received message signals. Each node sends join message to the nearest CH to inform it that it is a member of its cluster. Accordingly, the clusters are formed. In general, the clusters contain different numbers of member nodes. In order to organize data transmission of member nodes in each cluster, CH nodes create time division multiple access (TDMA) schedules. Then, they broadcast these schedules for their member nodes to tell them when each node must transmit its sensed data. Each TDMA schedule is divided into equal time slots. The number of time slots equals the number of member nodes in the cluster and the duration of each slot is the time needed by each node for transmitting its data packet. By this step, the setup phase ends and the steady state phase starts. The steady state phase is broken into time slots called frames. The number of these frames equals the largest number of member nodes exist in a cluster. Each member node in any cluster transmits its data packet to its CH node in its own frame. The CH then aggregates these packets with its own sensed data and transmits the aggregated data packet to the BS. CHs transmit data towards BS based on CSMA protocol.

In [20], an energy efficient routing protocol named Load Balancing Cluster Head (LBCH) was proposed. This protocol uses fixed clustering scheme where each cluster contains one RN, one CH node, and member nodes. The CH collects data packets from member nodes, aggregates them, and transmit these packets to the RN. In a multi-hop routing, RNs transmit to the BS the collected data in each cluster. The network lifetime in this protocol is broken into one short setup phase and one long steady state phase. In setup phase, the BS broadcasts a hello message for all nodes in the network. Then, each node sends its location and energy level to the BS. The BS then divides the network area into equal size subfields called clusters. The length and the width of each cluster are no longer than a predefined threshold distance. After that, the BS selects for each cluster one RN and one CH node (i.e., initial CHs and RNs). The role of RN requires consuming a lot of energy since it receives the overall data packets in the cluster and transmits them to the next RN. Hence, to minimize the energy consumption of these nodes, selecting RNs is done by calculating the magnitudes of nodes in each cluster. The magnitude of a node is linearly proportional to the node's energy and inversely proportional to its distance to the BS. The node that has the largest magnitude in each cluster will be selected as RN for that cluster. After selecting RNs, the BS defines the routing paths and sends to each RN the next hop RN. Choosing a CH for each cluster is done by the BS based on the weight of each node. For the following rounds, the role of RNs and CHs rotates among all nodes in the cluster which ensures load balancing between nodes. The node that was selected as RN in the previous rounds will not be selected as RN in the current round. Moreover, the node that was selected as CH in the previous rounds will not be selected as CH for the current round. After that all nodes in the cluster have played the role of RN and CH for once and consequently the same procedure for choosing RNs and CHs will be repeated. After that, the BS creates TDMA schedules for the nodes in each cluster in order to organize data transmission between nodes and CH. Moreover, to organize data transmission between each cluster and the BS, the BS assigns a unique CDMA code for each cluster. By this step, the setup phase ends and the steady state phase starts. The steady state phase is divided into equal frames called rounds. Each round is divided into number of time slots that is equal to the largest number of sensor nodes exist in a cluster plus an extra time slot that is reserved for controlling purposes of the following round. Each member node transmits its data packet in its time slot to the corresponding CH. The CH aggregates the overall data packets and transmit them to the corresponding RN in its cluster. In a multi-hop routing manner, RNs transmit the collected data from their clusters to the BS. In the extra time slot, the BS chooses a new CHs and RNs for the following round and broadcasts them for the nodes before the starting of the next round.

III. The proposed solution: SIICERP

A) Main Idea

The SIICERP is mainly based on the fact that if there is a group of sensor nodes that their sensing regions are overlapped, then they will unnecessarily send similar packets to report on an event occurs in the intersection region. The sensing region of a node is the region around the node where if an event occurs within it, the node will sense that event. The radius of the sensing region is called the sensing range Rs of a node [27]. Figure 1 shows a group of sensor nodes that will generate similar data packets while sensing the same event.

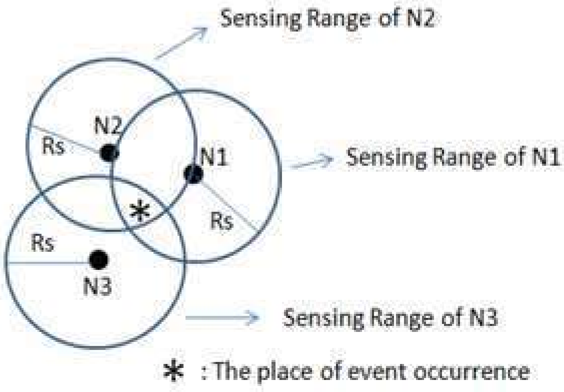

Figure 1. Group of sensor nodes generate similar data packets to report on the same event

Accordingly, SIICERP aims at reporting on any event by only one packet generated by one node such that saving energy in the network as well as achieving the load balancing in the network. To achieve the objective of SIICERP, firstly, it requires that if an event occurs in a certain region, then the node with the highest energy (among all the nodes from the same cluster or different clusters that sense the same event) will report on this event by sending a packet to its corresponding CH. Secondly, the transmission of this packet should be done over at least 2Rs range such that all the possible nodes that could sense this event will know that there is a node has higher energy than them and it reports this event instead of them. This means that a well-designed TDMA schedule is needed to satisfy the following requirements that are considered in the design of SIICERP:

- The sensor nodes (from the same cluster or different clusters) that may sense the same event should be assigned different time slots. This is required to allow these nodes to hear the transmission of each other and hence avoid sending similar packets and so reducing the energy consumption.
- The sensor node that has higher residual energy should be assigned the lower time slot index. This is required to ensure that the event is reported by the node that has the highest residual energy among its neighbors so load balancing is satisfied.

B) *Design of SIICERP*

SIICERP can be integrated into any cluster-based protocol as follows:

- In the setup phase of each round, the CHs are chosen and the clusters are formed based on the used cluster-based routing protocol. Each CH informs the BS the position and the residual energy of each member of its cluster.
- To prevent interference between transmissions from different clusters, the BS generates a unique CDMA code for each cluster. All the nodes of one cluster use the same code for transmission.
- The BS runs an efficient TDMA scheduling algorithm (discussed in the next section) that determines the transmission time for each node in the network.
- Finally, the BS announces the generated TDMA schedule to all nodes in the network using a predefined CDMA code. This TDMA schedule must be followed by all the nodes during the steady state phase. Based on this TDMA schedule, each node will know at which time slot (call it sending slot) and on which CDMA code it should send packets. Additionally, it will know at which time slots (call them listening slots) and on which CDMA codes it should listen. Now, if a node senses an event and the time of its sending slot becomes without receiving any announcement about the same event, then the node will report this event. Otherwise, at the moment of receiving any announcement about the event, the node ignores this event and turns off its transceiver electronics to save its energy.

In a nutshell, SIICERP is compatible with cluster-based routing protocols since it only requires a modification on the TDMA schedule of the routing protocol such that each node knows its sending slot and listening slots.

C) *TDMA Scheduling Algorithm (TSA)*

The TSA is illustrated in the following steps:

Step1: The BS creates for all nodes in the network an initial TDMA schedule based on the residual energy in each node whereas the first time slot is assigned for the node that has the highest energy level in the network and the second time-slot is assigned for the node that has the second energy level and so on. The length of the initial TDMA schedule is impractical; it equals to the number of the nodes in the network. Therefore, in the next steps, the length of the initial TDMA will be reduced by assigning one time-slot for different nodes.

Step2: Initially, each node is assigned a Flag Number (FN) equals to the index of its time-slot assigned in Step1.

Step3: Starting from the node with FN=1, the FNs of all its neighbors (within 2Rs range) are changed to 1. Similarly, for the neighbors of the node with FN=2, their FNs are changed to 2. This process is done for all nodes and the FN of a node should not be changed more than once in this step. In this step, for example, the first time slot is assigned for the node that has originally FN=1 and no one of its neighbors (that their FNs changed to 1) can use this slot for transmission.

Step4: Starting from the second time-slot, if the node in the second time-slot and the node in the first time-slot are not neighbors and not members of the same cluster, then the node in the second time-slot is moved to the first time-slot and its FN is changed to 1 as well as the FNs of all its neighbors are changed to 1 instead of 2. This process is repeated for all nodes. To generalize this step, there are two cases should be clarified:

- If the node has FN equals to the index of its time-slot, this means that its FN was not changed and no neighbor in the previous time-slots. Therefore, it checks if it is possible to move to one of the previous time-slots (starting from the first one); if there is no member from the same cluster in the checked time-slot, then it can be move to it. Otherwise, it cannot be moved.
- If the FN of the node does not equal to the index of its time-slot, this means that there is a neighbor in the time-slot of index equals to FN (that has higher energy). Therefore, the checking process should start from the time-slot of index equals to FN+1.

IV. Performance Evaluation

In this section, we analyze and evaluate the performance of our proposed solution, namely, SIICERP. We evaluate the performance of the protocols proposed in [19] and [20] with and without SIICERP. Thus, respectively, we use the names SIICERP-LEACH and SIICERP-LBCH to refer to the LEACH and LBCH protocols with SIICERP. Table I presents some common simulation parameters used in [19] and [20].

TABLE I. The common simulation parameters

Parameter	Value
Data packet size	1024 bits
Control packet size	176 bits
Initial energy	2.4 J
ETX (Energy for transferring one bit)	50 nJ/bit
ERX (Energy for receiving one bit)	50 nJ/bit
EDA (Energy for data aggregation)	5 nJ/bit
Transmit amplifier energy in free- space	10 PJ / bit / m^2
Transmit amplifier energy in multi-path	0.0013 PJ / bit / m^4
Simulation area	100 m x100 m
Distribution of nodes over the simulation area	Random
Base-station location	(50 m, 125 m)
Sensing range for each sensor	10 m

To evaluate and compare the performance of SIICERP-LEACH and LEACH protocols, we conduct several simulation scenarios. Figure 2 shows the result of one simulation scenario. In this scenario, the number of simulation rounds is 1000 and the location of one event is randomly generated per round (i.e., the total number of generated events during the simulation time is 1000 events). In this scenario, we want to focus on one part of IIER problem, which is sending similar packets from normal nodes to their CHs to report same events. Therefore, we change the number of all nodes in the network and keep the average number of CHs fixed. This is done by selecting the proper percentage of CHs (p) for each number of nodes; p=0.1 for 100 nodes, p=0.034 for 300 nodes, p=0.02 for 500 nodes, and p=0.0143 for 700 nodes. Figure 2 shows that, in SIICERP-LEACH protocol, the total number of sent packets to CHs equals to the total number of events (i.e., 1000 events). However, the figure shows that the effect of IIER problem (i.e., sending more similar packets to report one event) on the performance of LEACH protocol severely increases with increasing the number of nodes in the network. This is because increasing the total number of nodes in the network will increase the density of the nodes around each event which means more similar packets will be unnecessarily sent to CHs to report the same event.

Figure 3 shows the results of another simulation scenario. In this scenario, we try to show the effect of the second part of IIER problem (i.e., sending similar packets from different CHs to the BS in order to inform about the same events). Therefore, we fix the number of nodes to be 300 and change the average number of CHs (i.e., by changing the percentages p of CHs). In this scenario, the number of simulation rounds is 1000 and the location of one event is randomly generated per round. It can be shown from this figure that the performance of SIICERP-LEACH is fixed (i.e., total number of sent packets to BS equals to the total number of events). On the other hand, the performance of LEACH degrades with increasing the percentage of CHs. This is because increasing the number of CHs means more overlapped clusters and so more different CHs report the same event. To show the effect of SIICERP on the overall performance of LBCH protocol, we conduct a third simulation scenario. In this scenario, the percentage of clusters is 0.05 and the locations of events per round are distributed on a grid shape. The results of this simulation scenario are shown in Figure 4. From this figure, we can see that SIIER effectively improves the performance of LBCH protocol.

V. Conclusion

In this paper, we proposed an efficient solution for a problem in cluster-based routing protocols for WSN, namely, SIICERP. We called this problem intra/inter-cluster event-reporting problem. By integrating SIICERP solution into cluster-based protocols, only one packet will be sent by one node (with the highest energy) to report on an event instead of reporting on the event by many packets sent by different neighbor nodes. Accordingly, SIICERP results in saving energy and achieving load balancing in WSNs.

Abstract—**Event reporting in Wireless Sensor Networks (WSNs) has always been a major challenge in terms of energy consumption. Event reporting requires sensing the event and sending a reporting packet from the sensor to the centralized base station (BS). However, sensor's energy is limited and stored in a non-rechargeable battery. Therefore, several event-reporting (or data collection) protocols have been proposed to improve energy consumption in WSNs, and consequently, to extend their lifetime. In this paper, we propose an efficient event reporting protocol for WSNs which mainly aims at reporting any event by no more than one sensor node such that energy saving is satisfied in the whole network. To achieve this goal, our proposed protocol is mainly based on the following features: it is a cluster-based protocol, it is a multi-hop routing protocol, it applies distributed data aggregation, and it employs variable clustering and cluster head selection. Simulations show that our proposed protocol significantly extends the lifetime of WSNs compared to other related protocols.**

Keywords—Event Reporting; Cluster-based; Data Aggregation; Multi-hop Routing; WSNs; ERP-DDA

I. Introduction

To monitor a wide region via a WSN, the sensors are randomly distributed over this region [1-2]. The function of the sensors is summarized as follows: sensing the surrounding environment, converting the sensed information into data packets, and sending the data packets over a wireless channel to a base station (BS) [3-5]. Even though WSNs have different important and useful applications, they have many issues and challenges [6-7]. In this paper, we consider the issue of energy constraint in WSNs. In sensors, the main source of energy is a non-rechargeable battery which almost cannot be changed after the deployment of the sensors in the network [8-9]. Accordingly, several energy-aware data collection protocols (i.e., routing protocols) for WSNs have been proposed in the literature [7-12]. The cluster-based protocols have been proven to be efficient energy-aware routing protocols for WSNs [13-20]. Therefore, in this paper, we mainly consider this category of protocols. According to this type of protocols, the nodes are grouped into many clusters. For each cluster, there is one Cluster Head (CH) and different number of normal nodes. The normal nodes in each cluster send their data to their corresponding CH. After that, each CH aggregates the overall data (i.e., removes redundancy in the collected data) and sends it to the BS. The network lifetime is divided into time intervals called rounds. The formation of clusters may be done in a variable manner as in [13] (i.e., it is changed every round) or in a fixed manner as in [14] (i.e., the clustering is done after sensors deployment and it is not changed during the network lifetime).

After studying different event reporting and data collection protocols proposed for WSNs, we have determined some of their elegant features that could be employed to propose a new energy-aware event reporting protocol for WSNs. These features mainly are the cluster-based, the multi-hop, and the variable clustering. In addition to these features, we found that most cluster-based routing protocols (fixed or variable clustering) have a critical problem that severely degrades their performance in terms of energy saving. We call this problem as Intra/Inter-Cluster Event-Reporting Problem (IICERP). This problem appears on intra transmission and inter transmission levels. In the intra transmission level, if an event occurs in a certain area in the WSN, then different nearby nodes from the same cluster or different clusters will unnecessarily send similar packets to their CHs in order to report this event. In the inter transmission level, if an event occurs in a certain area in the network, then more than one nearby CH will unnecessarily send similar packets to inform the BS about the event.

To this extent, we present the works that are quite related to our proposed protocol. In [18], the Load Balancing Cluster Head (LBCH) protocol was proposed. LBCH applies fixed clustering technique. Each cluster has one CH node, one Relay Node (RN), and many member nodes. The member nodes, in each cluster, sense the events and then send reporting packets to their corresponding CH. After that, the CH aggregates the received packets and resends these packets to the RN. In a multi hop manner, RNs send to the BS the received packets. According to this protocol, the lifetime is divided into setup phase and steady state phase that is divided into time periods called rounds. In the setup phase, the BS sends a hello message to all nodes in the network. After that, the nodes send their locations and energy levels to the BS. Then, the BS divides the network area into subfields called clusters. These clusters are fixed over the lifetime of the network. After that,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

the BS, chooses one RN and one CH node for each cluster. The selection of the RN and CH is based on two calculated values called magnitude and weight, respectively. Thereafter, the BS determines for each RN the next hop RN. For the following rounds, the selection process of RNs and CHs is repeated in each round to ensure load balancing in the network. In [19], the Round-Robin Cluster Header (RRCH) protocol was proposed. The RRCH is a fixed clustering protocol which achieves load balancing and a high energy efficiency in WSNs. In the setup phase, clustering process is performed only once. In the steady state phase, there is no RNs selection. However, for each round, the selection of CH nodes for each cluster is done according to round robin method. In [20], the first fixed clustering routing protocol based on a well-known protocol Low Energy Adaptive Clustering Hierarchy (LEACH) was proposed. The new protocol is called LEACH-F. The clusters are constructed during the setup phase by applying a centralized cluster formation algorithm. In the steady state phase, the CHs selection is done in a round robin manner. In [21], the dynamic round time-based fixed LEACH scheme (we call it Adaptive LEACH-F) was proposed. Its main idea is to reduce the problem of the fixed round time in LEACH-F. The round time in the Adaptive LEACH is adaptively changed according to the current energy of the member nodes (not to their initial energy) and the total energy consumption in the cluster for that round. This leads certainly to reducing the possibility of early death of CHs in addition to extending the network lifetime.

In [22], the Adaptive Energy-aware Fixed Clustering Protocol (AEA-FCP) was proposed. This protocol is based on adaptive fixed clustering. In the setup phase, the network is divided into a number of clusters that are fixed during the network lifetime. In the steady state phase, the RNs route over a multi-hop path the aggregated data from the CHs to the BS. The selection of RNs and CHs is performed in each round based on the residual energy in the nodes. The CH and RN in a cluster switch their roles if their residual energy is less than certain percentages of the average residual energy of the cluster when they start working as CH and RN nodes. AEA-FCP is evaluated under two scenarios; continuous availability of data and event-based availability of data. In [23], the Self-incentive and Semi Re-clustering (SISR) protocol was proposed. It is a fixed clustering protocol. In the setup phase, each node in the network elects itself as a candidate CH with probability P and then broadcasts an *ADVERTISE_MESSAGE* with the initial radio range R_i. Then, the node gradually increases R_i until it receives at least one *ADVERTISE_MESSAGE* from other nodes. Accordingly, the node checks the probability (P) values of other nodes. If one of the nodes has higher value of P, it considers this node as its CH. Otherwise, the node gives up the competition. The selected CHs send an *INVITE_MESSAGE* and wait for a feedback from the normal nodes. When the normal node finds its CH, it sends a *JOIN_REQ_MESSAGE* to its CH to inform it about its decision. After the construction of clusters, each CH determines its CH sequence based on the signal strength of *JOIN_REQ_MESSAGE* from the normal nodes in its cluster. In the steady state phase, *HEARTBEAT_MESSAGEs* are broadcasted by the CHs to their member nodes. The member nodes that do not respond by *HEARTBEAT_ACK_MESSAGE* are considered as dead nodes. However, alive nodes send their *HEARTBEAT_ACK_MESSAGEs* that include their incentive values to be CHs.

In this paper, we propose an Event Reporting Protocol Based on Distributed Data Aggregation (ERP-DDA) for WSNs. The design of ERP-DDA is based on the good features of related protocols. In particular, it is a multi-hop and variable clustering protocol as well as it considers and solves the problem of IICERP via distributed data aggregation. For distributed data aggregation, we propose an algorithm which strictly implies that any node senses an event should, first, listen to its neighbors which have higher residual energy and could sense the same event. Then, if the node hears that one of its neighbors reported the same event, it will ignore this event and will not send any packet to report the event. Therefore, the redundancy in packet reporting is removed in a distributed manner (i.e., distributed data aggregation). The process is not as in most cluster-based protocols where data aggregation is centralized (i.e., it is only done by the CH in each cluster). Hence, distributed data aggregation ensures that any event is reported by no more than one sensor. This leads to reducing the energy consumption and extending the network lifetime. Simulation results show that ERP-DDA significantly saves energy and so extends the network lifetime compared to other related protocols. It is worthwhile to mention that the novelty of our work can be summarized as follows: to the best of our knowledge, no previous work considered the integration of multi-hop feature, variable clustering feature, and specifically the problem of IICERP into one protocol. However, the rest of the paper is organized as follows. Section II presents and explains ERP-DDA. In Section III, we conduct simulations to evaluate and compare the performance of ERP-DDA with other protocols. Finally, concluding remarks are drawn in Section IV.

II. ERP-DDA Protocol

The ERP-DDA mainly aims at reducing the energy consumed for reporting events in WSN in order to extend the network lifetime. The main features of ERP-DDA that help in achieving this goal are summarized as follows: it is a variable clustering and multi-hop protocol as well as it considers and solves IICERP problem. These features are explained by presenting the design of ERP-DDA.

A) *ERP-DDA Design*

According to ERP-DDA, the network lifetime is divided into multiple time intervals called rounds. Each round is divided into setup phase and steady state phase. In the setup phase of each round, the following steps are executed:

Step 1: All the alive nodes send to the BS its identification number, residual energy, and position (assuming the nodes have GPS or they apply a localization algorithm).

Step 2: The BS runs the algorithm proposed in LEACH protocol [20] for CHs selection. Other algorithms can be employed but in our work, we select the one proposed in LEACH protocol [20] because it is an energy efficient and satisfies load balancing.
Step 3: The BS runs Dijkstra's algorithm [24] to find the best route (in terms of minimum energy) between each CH and the BS through other CHs.
Step 4: The BS divides the nodes into clusters where each node is associated to the nearest CH. To prevent interference between transmissions from different clusters, the BS generates a unique CDMA code for each cluster. All the nodes of one cluster use the same code for transmission.
Step 5: To solve the problem of sending more than one packet in order to report the same event (we call this problem as IICERP), the BS runs our proposed algorithm called Listening and Sending Scheduling Algorithm (LSSA) that is explained in the next subsection. This algorithm generates a Time Division Multiple Access (TDMA) schedule that is followed by all nodes during the steady state phase. Based on this schedule, each node knows at which time slot (we call it sending slot) and on which CDMA code it will send its packets. Also, it knows at which time slots (we call them listening slots) and on which CDMA codes it will listen to other nodes. At this point, if a node senses an event and the time of its sending slot passes without receiving any announcement from its neighbors about the same event, then the node will report this event. Otherwise, at the moment of receiving any announcement about the event, the node ignores this event and turns off its transceiver electronics to save its energy.
Step 6: Finally, the BS announces to all nodes information about the result of LSSA, the corresponding CH of each node, and the next hop of each CH.

B) Listening and Sending Scheduling Algorithm

The LSSA mainly relies on the fact that if there is a group of sensor nodes where their sensing regions are overlapped, then they will unnecessarily send similar packets for reporting an event occurs in the intersection region. The sensing region of a node is the region around the node where if an event occurs within it, the node will sense that event. The radius of the sensing region is called the sensing range R_s of a node [25]. Figure 1 shows a group of sensor nodes that will generate similar data packets while sensing the same event. Accordingly, LSSA aims at reporting any event by only one packet generated by one node in order to save energy and achieve load balancing in the network. In other word, LSSA aggregates data in a distributed manner.

To achieve the objective of LSSA, firstly, it requires that if an event occurs in a certain region, then the node with the highest energy (among all the nodes from the same cluster or different clusters that sense the same event) will report this event by sending a packet to its corresponding CH. Secondly, the transmission of this packet should be done over at least $2R_s$ range such that all the possible nodes that could sense this event will know that there is a node that has higher energy than them reports this event instead of them. This means that a well-designed TDMA schedule is needed to satisfy the following requirements:

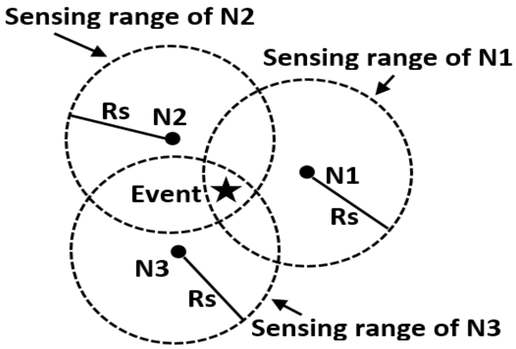

Figure 1. Group of sensor nodes generate similar data packets to report the same event

- The sensor nodes (from the same cluster or different clusters) that may sense the same event should be assigned different time slots. This is required to allow these nodes to hear the transmission of each other and hence avoid sending similar packets, and consequently, reducing the energy consumption.
- The sensor node that has higher residual energy should be assigned the lower time slot index. This is required to ensure that the event is reported by the node that has the highest residual energy among its neighbors so load balancing is satisfied.

These requirements are considered in the design of LSSA. Interestingly, the LSSA is illustrated in the following steps:

Step1: The BS creates for all nodes in the network an initial TDMA schedule based on the residual energy in each node where the first time slot is assigned for the node that has the highest energy level in the network and the second time-slot is assigned for the node that has the second highest energy level and so forth. The length of the initial TDMA schedule is impractical and equals to the number of the nodes in the network. Therefore, in the next steps, the length of the initial TDMA will be reduced by assigning one time-slot for different nodes.
Step2: Initially, each node is assigned a Flag Number (FN) equals to the index of its time-slot assigned in Step1.
Step3: Starting from the node with FN=1, the FNs of all its neighbors (within 2Rs range) are changed to 1. Also, for the neighbors of the node with FN=2, their FNs are changed to 2. This process is done for all nodes and the FN of a node should not be changed more than once in this step. In this step, for example, the first time slot is assigned for the node that has originally FN=1 and no one of its neighbors (that their FNs changed to 1) can use this slot for transmission.
Step4: Starting from the second time-slot, if the node in the second time-slot and the node in the first time-slot are not neighbors and not members of the same cluster, then the node in the second time-slot is moved to the first time-

slot and its FN is changed to 1 as well as the FNs of all its neighbors are changed to 1 instead of 2. This process is repeated for all nodes. To generalize this step, there are two cases should be clarified:

- If the node has FN equals to the index of its time-slot, then this means that its FN is not changed and no neighbor in the previous time-slots exists. Therefore, it checks if it is possible to move to one of the previous time-slots (starting from the first one). If there is no member from the same cluster in the checked time-slot, then it can move to it. Otherwise, it cannot move.
- If the FN of the node does not equal to the index of its time-slot, then this means that there is a neighbor in the time-slot of index equals to FN (that has the higher energy). Thus, the checking process should start from the time-slot of index equals to FN+1.

III. Simulation Results and Discussion

In this section, we conduct simulations to evaluate and compare the performance of ERP-DDA with different protocols presented in Section I. Table I summarizes the parameters used in the simulation. The same parameters were used in [13], [14], and [18].

TABLE I. THE COMMON SIMULATION PARAMETERS

Parameter	Value
Data packet size	1024 bits
Control packet size	176 bits
Initial energy	2 J
ETX (Energy for transmitting one bit)	50 nJ/bit
ERX (Energy for receiving one bit)	50 nJ/bit
EDA (Energy for data aggregation)	5 nJ/bit
Transmit amplifier energy in free-space	10 PJ / bit / m^2
Transmit amplifier energy in multi-path	0.0013 PJ / bit / m^4
Simulation Area	100 m x 100 m
Number of nodes	100
Distribution of nodes over the simulation area	Random
Base-station location	(50 m, 125 m)
Sensing range for each sensor	10 m
Percentage of CHs per round	5%

In our simulations, we consider continuous availability of data; the nodes in the network always have data to send. Therefore, the nodes will consume more energy to send their data packets and so short network lifetime is expected. To setup this scenario in simulation, the locations of events per round are distributed on a grid shape (i.e., the minimum distance between events is one sensing range). As a result, the total number of events per round is 50. This distribution of events is chosen such that each node, in each round, senses the closest event to it and has a packet to report this event. Since the nodes are randomly distributed over the network area, then it is possible that different nodes sense the same event. The performance of ERP-DDA is compared with other protocols that assume the same scenario. Figure 2 shows the total number of nodes alive per simulation round. Interestingly, it can be seen from Figure 2 that ERP-DDA shows a performance superiority over all compared protocols. In the case of applying ERP-DDA, the number of nodes alive in the network is slowly decreasing with time which results in extending the lifetime of the network. This is because ERP-DDA integrates the good features in different protocols in one protocol as well as it has an ability to overcome the weaknesses in all compared protocols. ERP-DDA is mainly based on four features that significantly reduce the energy consumed in reporting events in the network. First, ERP-DDA is a cluster-based protocol. This feature results in preventing the nodes in the same cluster to send the same data to the BS, and accordingly, reducing the consumed energy in the network. Moreover, different research works have shown that clustering is efficient in WSNs in terms of energy saving [13-20]. Second, ERP-DDA is a multi-hop routing protocol. Multi-hop routing between the CHs and the BS reduces the transmission distances, thereby reducing the transmission power and achieving load balancing in the network. It has been shown in the literature that multi-hop routing protocols are more efficient than single-hop protocols in terms of energy consumption [16] [26] [27] [28]. Third, ERP-DDA is based on variable clustering and variable cluster-head selection in each round which result in load balancing in the network, i.e., the task of reporting the events will be distributed over different nodes in the network. Fourth, as discussed before in Section II, ERP-DDA considers and solves IICERP problem such that one packet is sent by one node to report one event. Thus, the consumed energy in the network is significantly reduced.

IV. Conclusion

In this paper, we proposed an efficient energy-aware data collection protocol for improving the lifetime of wireless sensor network. This protocol is called Event Reporting Protocol based on Distributed Data Aggregation (ERP-DDA). This protocol aims at reducing the consumed energy in the network by reporting the event that occurs in a certain region by only one sensor node that has the highest residual energy in that region. Moreover, ERP-DDA applies clustering and multi-hop routing schemes in order to reduce the total consumed energy in the network. Simulation results showed that ERP-DDA protocol, compared with other protocols, achieves higher performance in terms of network lifetime.

Abstract— **In this paper, the design implementation of a two-stage operational transconductance amplifier (OTA) using a passive frequency compensation technique is presented. It is based on the Miller and passive frequency compensation techniques. The use of these techniques achieves the high gain-bandwidth product without an increase in the overall power consumption. It produced a -21.17dB of gain margin with a phase margin of 77° at a 1.8V power supply voltage. A resistor-capacitor pair in feed-forward compensation is connected in the first stage and a Miller compensation capacitor is introduced in the second stage of the circuit. The proposed op-amp design results in 1205 MHz of gain-bandwidth product. It is observed that the presented circuit performs better as compared to existing designed circuits**.

Keywords— ***stability analysis; frequency compensation; Gain-bandwidth product; OTA amplifier Miller compensation.***

I. Introduction

An operational transconductance amplifier (OTA) is the basic building block used in analog large-scale integration systems. However, the design of such a circuit has numerous design challenges to satisfy the performance parameters of circuits. These parameters are gain, bandwidth, and power consumption. In the past years, various researchers have suggested high-performance amplifiers [1]. The parameters such as high slew rates (SR), gain-bandwidth product, and low static power dissipation are required in a variety of applications especially in wireless and battery-powered systems [2]. The OTA can be used to fulfill these requirements. It can be implemented using a cascode topology in which one or two transistors are stack together in series. Using such cascode connections the overall output resistance and especially gain can be increased. However, it has some drawbacks that they suffer from voltage headroom constraints [3] which will limit the closed-loop gain. To overcome these issues, in multiple cascaded amplifiers, gain stages can be realized to attain the high voltage swing as well as high gain. Nevertheless, this design methodology is susceptible to instability. Each stage will introduce a lower frequency pole which causes a reduction in the phase margin thus leading to instability [4]. This issue is improved by adding a suitable compensation network to guarantee stability under the operating frequencies [5]. In closed-loop conditions, Miller compensation techniques are commonly used to provide stability [1]. The basic principle of the Miller compensation technique is splitting the dominant and non-dominant pole to acquire the desirable phase margin (PM). The drawback of this technique is the reduction of a dominant pole which causes the reduction of -3dB bandwidth and unity gain-bandwidth of the OTA [6].

The compensation network can be realized as a nulling resistor, current buffer or voltage buffer, or amplifier [7]. The best choice for moderate and higher capacitive loads are current amplifier and voltage buffer approaches, respectively [7, 8]. Moreover, there are some methods which do not use miller capacitor to compensated multi-stage amplifiers [9].

Classical topologies of two-stage amplifiers were introduced in 1967 [10]. Since then, many efforts were brought up about the stability issue of the two-stage amplifier and a lot of designs with improved performance are reported in the literature [11-14]. Moreover, a variety of high-performance amplifiers have been proposed by several researchers. The scaling of the supply voltage would eventually lead to a reduction in power consumption. Therefore, designers had come up with the idea of cascading, however, still limitations exist. Thus, topologies like inverter-based amplifiers, bulk-driven, and self cascode topologies help to solve the power consumption issue. Although the stability and gain in the above topologies are not considered, it has a variety of applications such as energy harvesting, wireless, IoT sensors, biomedical sensors, and so on. These applications are widely used in recent technologies and modifying different versions of OTA helps to make use of the above technologies effectively and efficiently. However, they did not consider the power consumption issue in the analysis. It is observed from the literature that the existing approaches lack stable output. Therefore, it is very much important to design a circuit with stable output and low power consumption [15]. Therefore, in this paper, a new circuit design is proposed. It consists of a mixture of frequency compensation [16] and miller compensation techniques.

The rest of the paper is divided into the following sections. An analysis of the existing circuits is conducted and

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

various combinations of the compensation networks are drawn and analyzed in Section II. The proposed circuit and analysis are presented in Section III. Moreover, the conclusions and future scope are drawn in Section IV.

II. Study of Existing Circuits

A simple circuit diagram of two-stage OTA is presented in Fig. 1. In this, transistors M_1 and M_2 are the NMOS transistors and M_3 and M_4 are PMOS transistors that form a current mirror circuit in the first stage of the amplifier. The second stage is a common source amplifier and is made up of NMOS and PMOS transistors, M_5 and M_6, respectively.

In Fig. 1, C_e is the capacitance at the mirror node, C_L is the load capacitance, and V_b is the bias voltage. The value of capacitor C_C and C_L should be very small [16]. By increasing C_L, the dominant pole, as well as unity gain frequency, can be shifted toward the origin [18]. Hence, phase margin (PM) can be increased, which improves stability [19-20]. The compensation network R_C and C_C generate a left-hand plane (LHP) zero, which can be represented as

$$Z_1 = \frac{1}{R_C C_C} \tag{1}$$

This zero helps to increase the gain-bandwidth product of the amplifier. Second LHP zero represented as

$$Z_2 = \frac{g_{m3}}{C_E} \tag{2}$$

where g_{m3} is the transconductance of M_3 transistor. Second stage has RHP zero represented as

$$Z_3 = \frac{g_{m6}}{C_{gd6}} \tag{3}$$

where g_{m6} is the transconductance of M_6 transistor. Above two zeros, Z_2 and Z_3 can be ignored as it is seen at high frequency.

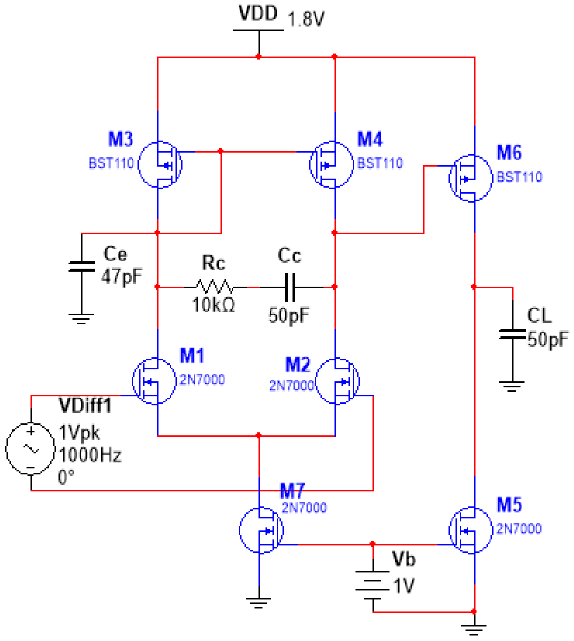

Fig. 1. Two-stage OTA circuit with compensation network.

The voltage gain A_V can be represented as

$$\frac{V_{out}}{V_{in}} = \frac{g_{m1} g_{m6} R_1 R_L \left(1 + sR_C C_C\right)}{\left(1 + sR_L C_L\right)\left[1 + sC_C\left(\alpha + R_C\right)\right]} \tag{4}$$

where V_{out} is voltage across the C_L capacitor and $V_{in} = V_{diff1}$ (1 Volts peak), g_{m1} is the transconductance of M_1 transistor; R_1 is the resistance at the output of the first stage, R_L is the equivalent resistance at the output node in parallel with the load. Moreover, α is a constant given as

$$\alpha = \frac{\left(1 + 2g_{m3} R_1\right)}{g_{m3}} \tag{5}$$

From the transfer function, dominant pole P_1 at the output of the first stage,

$$P_1 = \frac{1}{C_C\left(\alpha + R_C\right)} \tag{6}$$

The second pole at the load can be canceled by the zero with $R_L C_L = R_C C_C$, unless and until phase margin is more than 45° [17]. A two-stage OTA circuit without compensation and with feed-forward compensation is shown in Fig. 2.

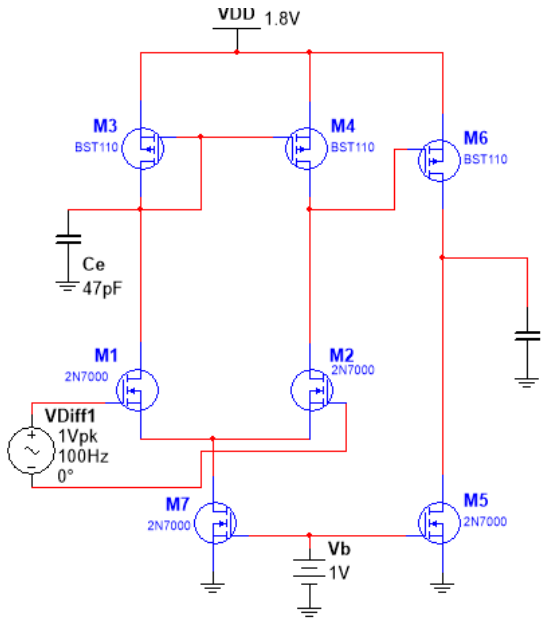

Fig. 2. Two-stage Non-compensated OTA circuit

Adding a capacitor in parallel to the resistor as a compensation network (CN), can further increase the gain-bandwidth product of the implemented circuit as shown in Fig. 3(a). Nodal equations for the circuit shown in Fig.3 are given as

$$-g_{m1} V_{in} = sC_{in} V_{in} + \left(sC_C + \frac{1}{R_C}\right) V_2 + G_1 V_2 \tag{7}$$

$$-g_{m6} V_2 = sC_L V_{out} + G_{11} V_{out} \tag{8}$$

$$\frac{V_{out}}{V_{in}} = \frac{\left(g_{m1} + sC_m\right) g_{m6} R_1 R_L R_C}{\left(1 + sR_L C_L\right)\left(R_1 + R_C + sR_1 R_C C_C\right)} \tag{9}$$

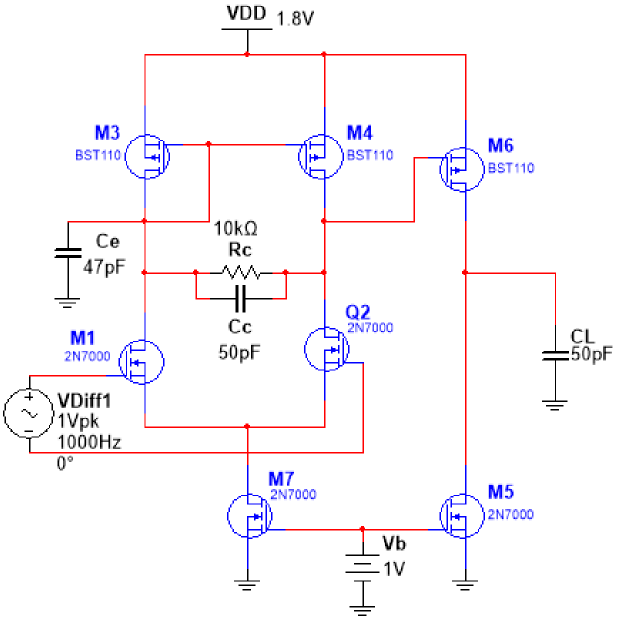

Fig. 3. Two-stage compensated OTA circuit

In Analog VLSI design researchers are continuously trying to reduce the area by using new MOS technology. In this paper, the compensation network components are replaced by MOS technology.

The performance of the OTA further can be improved by adding depletion type of MOSFET in parallel with a resistor as shown in Fig. 4.

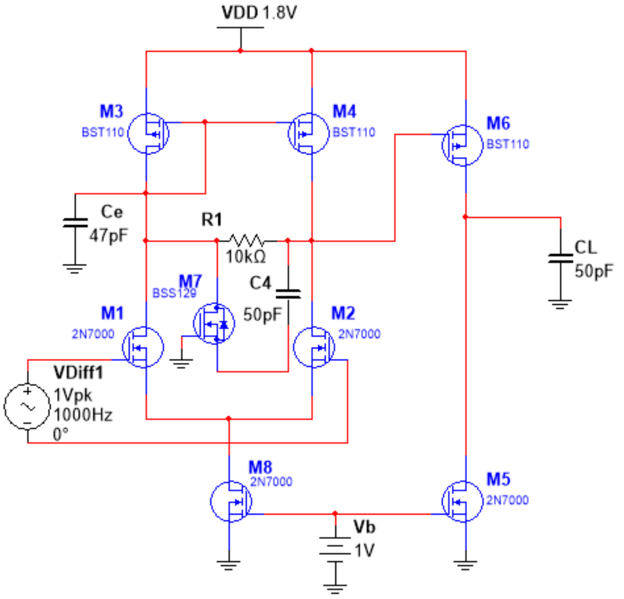

Fig. 4. CN with capacitor and resistor in series and parallel to resistor R_1

The transfer function in the s-domain for circuits can be calculated as

$$-g_{m1}V_{in} = sC_mV_{in} + [{}^{1}\!/_{R_C} + (R_9 + {}^{1}\!/_{sC_C}) - 1]V_2 + G_1 \quad (10)$$

$$-g_{m6}V_{in} = sC_LV_{out} + G_{11}V_{out} \quad (11)$$

$$T(s) = \frac{g_{m6}(g_{m1}+sC_m)R_1R_C(1+sC_CR_9)}{R_1[1+sC_C(R_9+R_C)]+R_C(1+sC_CR_9)}\left(\frac{R_{11}}{1+sC_LR_{11}}\right)$$

(12)

A depletion type transistor M_7 which is diode-connected will act as a resistor connected in series with a capacitor C_4 and this whole connection is in parallel with the resistor R_1.

However, its stability analysis can be improved by replacing the parallel capacitor and resistor with depletion-mode transistors and Miller compensation network. Based on this concept a new design is proposed. The proposed design consists of depletion type of MOSFET connected with capacitor either in series or parallel combination.

III. Modified OTA Circuit

The proposed design and implementation of two-stage OTA with passive frequency compensation in a 200um CMOS process technology, which draws a total current of $0.95mA$ from a $1.8V$ supply. The compensation network can be modified in which a depletion mode transistor, M_7 which is a diode-connected transistor that acts as a resistor. It is connected in parallel with a capacitor. Moreover, Fig.5 shows the performance of OTA can be improved by replacing the capacitor with a depletion mode transistor, M_8 by shorting source and drain terminals. The transfer function can be calculated as

$$-g_{m1}V_{in} = sC_mV_{in} + (sC_C + g_{m9})V_2 + G_1V_2 \quad (13)$$

$$-g_{m6}V_2 = sC_LV_{out} + G_{11}V_{out} \quad (14)$$

$$T(s) = \frac{g_{m6}(g_{m1}+sC_m)R_1R_{11}}{(1+sC_LR_{11})[1+R_1(sC_C+g_{m9})]} \quad (15)$$

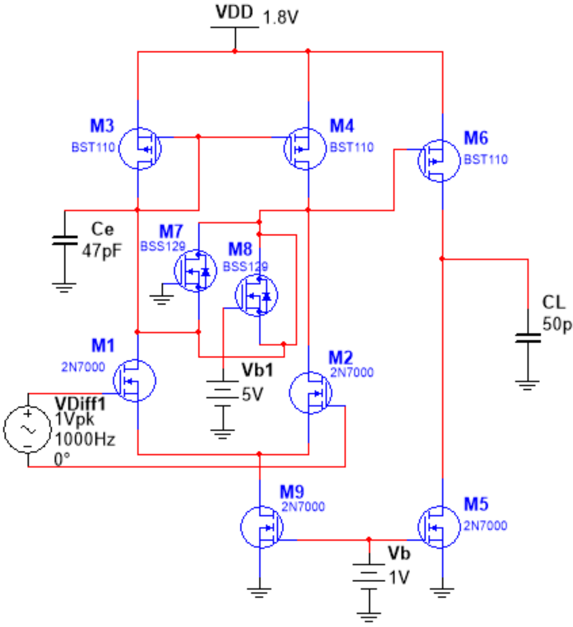

Fig. 5. Compensation network with capacitor and resistor in parallel, both of which is replaced by depletion-mode transistors

However, the proposed circuit can obtain a stable output and high gain. The design consists of a mixture of a feed-forward path technique along with the miller compensation technique. The circuit diagram of the proposed modified two-stage OTA is seen in Fig. 6.

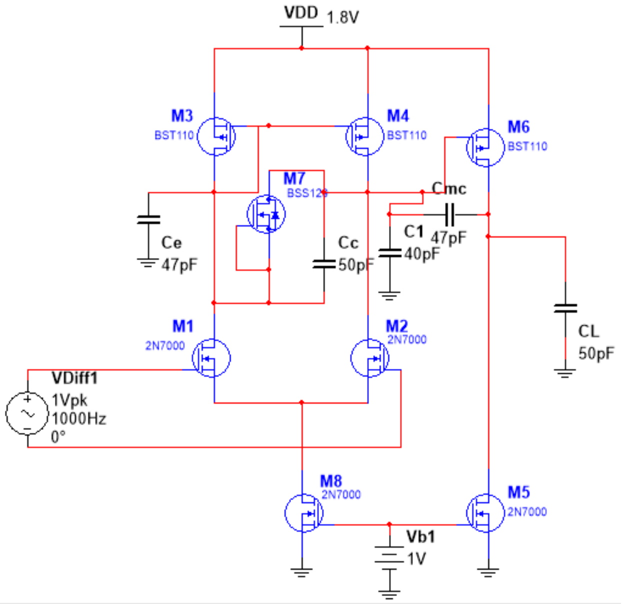

Fig. 6. Proposed two-stage OTA circuit

In this, M_1 and M_2 are the NMOS transistors and M_4 and M_3 (current mirror circuit) are the PMOS transistors in the first stage of the amplifier. These four transistors form the differential amplifier. C_E is the capacitance of the Mirror node. A depletion mode transistor, M_7 is connected instead of the resistor in the compensation network. A capacitor C_C is connected in parallel with M_7. The Miller compensation technique is added to the second stage of the circuit. A bias voltage, V_{b1} is applied at the gate of M_5 transistor, and capacitors C_1 and C_{mc} are the miller compensation capacitors along with C_L is the load capacitor.

The transfer function of the proposed circuit as shown in Fig. 6, is calculated as

$$T(s) = g_{m1}R_{p1}\left(\frac{1}{1+s(C_1+C_{mc})R_{p1}}\right)\left(\frac{1+\frac{sC_C}{g_{m7}}}{1+sC_L R_{11}}\right) \qquad (16)$$

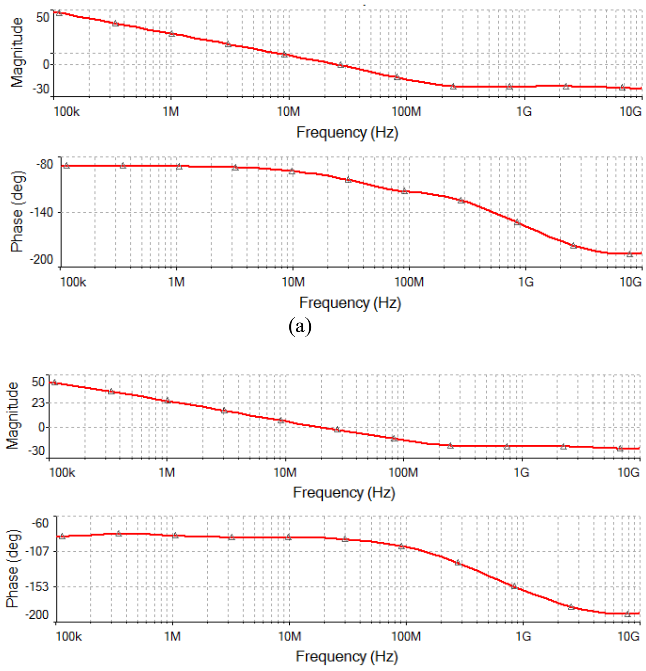
$$\times\left(\frac{-1}{g_{m7}+sC_C}\right)$$

Simulation results of all the circuits discussed will be further discussed in the upcoming section.

Experimentations and Results

A. Compensated Circuit and Non-Compensated Circuit

Fig.7(a) and Fig.7(b) show frequency response of a two-stage uncompensated OTA and a two-stage compensated OTA on simulating Fig.2. and Fig.1 on MULTI-SIM.



(a)

(b)

Fig.7. (a) Frequency response without compensation network, (b) Frequency response with R_C, C_C in series.

The frequency response without the use of a compensation network and with compensation network is shown in Fig.7.(a), and Fig.7.(b), respectively. The circuit simulated in Multi-Sim software and gain-bandwidth product, gain margin, and phase margin has been obtained. The gain-bandwidth product is 33275*MHz*. However, the stability of the amplifier is very less. The phase margin is 99° which is comparatively large. This will push the circuit into instability. Therefore, to improve the phase margin a compensation network should be introduced in the circuit. A compensation network shown in Fig.1, helps to overcome this issue. However, the gain-bandwidth product was reduced to 25360*MHz*. Thus, even though the gain-bandwidth product has decreased but the stability has improved as compared to the circuit without the compensation network. Further, the performance of the circuit can be improved by modifying the circuit shown in Fig.1.

B. Compensated Circuit with Capacitor and Resistor in Parallel

Furthermore, on simulating Fig.3, the below frequency response is observed.

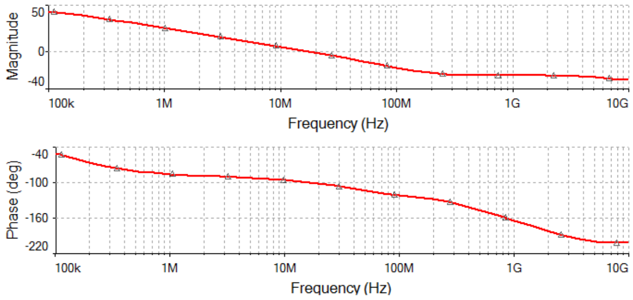


Fig. 8. Frequency response of CN with R_C and C_C in parallel.

Fig.8. shows the frequency response of CN with a resistor and capacitor connected in parallel. The components R_C and

C_C in parallel can further increase the gain margin to 39.3dB and phase margin 39° as shown in Fig. 8. However, the gain-bandwidth product was reduced. Thus, we move forward to another analysis to overcome this issue.

C. Resistor In Parallel With Capacitor And MOSFET In Series Which Are Connected In Series:

Furthermore, on simulating Fig.4, the below frequency response is observed.

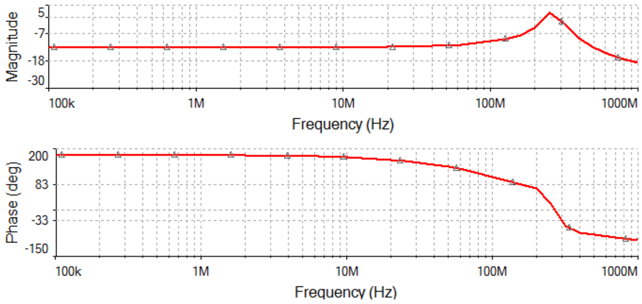

Fig. 9. Frequency response of CN with R_1 parallel with MOS and capacitor C_4

Using the depletion type NMOS and capacitor in series as shown in Fig. 4, provides a phase margin of 142^0. However, the GBW is very less and close to 581*MHz*. Thus, we move forward to another analysis to overcome this issue.

D. Capacitor and Resistor in Parallel, Replaced by Depletion Mode Transistors

Furthermore, on simulating Fig.5, the below frequency response is observed.

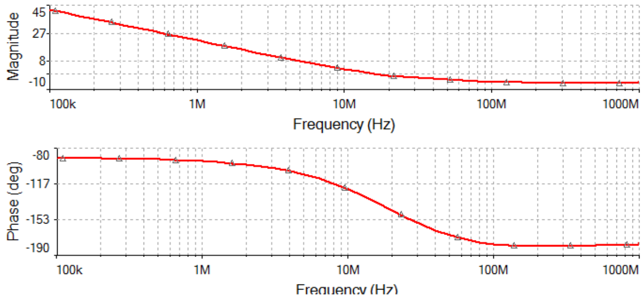

Fig. 10. Frequency response of CN with *Resistor and Capacitor in parallel, both replaced by depletion mode transistors.*

Fig.5 shows the proposed circuit and Fig.10 shows the frequency response of the proposed circuit that directs to its stability analysis. However, the gain-bandwidth product is large and nearly equal to 1181.18 *GHz* which is higher than the other circuits. However, the gain margin is -82.6dB and the phase margin is nearly 131°.

E. The Proposed Circuit

The gain-bandwidth product, phase margin, and gain margin as compared to the previous circuit can be improved by replacing the proposed design. In this capacitor C_1 and C_{mc} are connected as an extra circuitry to the OTA circuit as shown in Fig. 6.

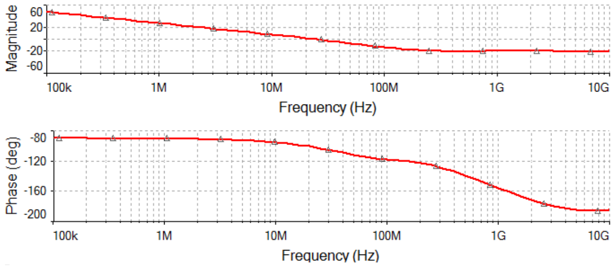

Fig.7. Frequency response of a proposed circuit

The proposed method includes a combination of the miller compensation technique along with the passive frequency compensation technique, which helps to increased stability and gain. This is achieved by introducing a new pole which increased the stability of the system. The Gain-Bandwidth (GBW) product of the amplifier is found to be 1205*MHz*. It is observed from the graph that the Phase Margin of the amplifier is 77°, which has been improved. Moreover, the gain margin is nearly -21.17dB which is good enough as compared to existing methods.

The various combinations with compensation networks connected to the first stage and their performance are summarized in Table 1. It is observed from Table 1 that the proposed design results in a higher gain-bandwidth product, gain margin as well phase margin. Although, the gain margin of the proposed approach is less but overlooked by the higher phase margin and thus the stability.

TABLE I. PERFORMANCE OF THE EXISTING MODELS AND PROPOSED DESIGN MODEL

Circuit Model	Parameters		
	Gain-Bandwidth Product (MHz)	Gain Margin (dB)	Phase Margin (deg)
Fig. 1	25360	-36.7	35
Fig. 2	33275	-30	90
Fig. 3	22560	-39.3	39
Fig. 4	581	-12.7	142
Fig. 6	1181180	-82.6	131
Fig. 7	1205	-21.7	77

IV. CONCLUSION AND FUTURE WORK

A new OTA amplifier with a compensation network is proposed to achieve a higher gain-bandwidth product as well as a stable output. The introduction of a compensation network helped to overcome the stability issue. The proposed circuit achieves a high gain-bandwidth product of 1205 *MHz* without an increase in the overall power consumption. It produced a -21.17dB of gain margin with a phase margin of 77°. The simulation results show that the proposed design is effective in improving the stability and gain-bandwidth product. As stability and gain are attained by using a combination of miller compensation technique and passive frequency compensation technique, it can be used in wireless and battery-powered systems. Moreover, it can be implemented in a variety of applications such as IoT sensors, biomedical applications, and so on. The results obtained from the proposed design can further be used to study and find out the sizes of the optimal transistors (length and width) in order to obtain operational amplifier performances for analog and mixed CMOS-based circuit applications using multi-objective genetic algorithms.

Abstract—**It is well known that the mathematical modeling and manual computations of the transistor design parameters are sometimes impractical and remains a challenge for researchers. In submicron technologies, the basic component of a three-stage operational amplifier such as MOSFET is modeled by various complex nonlinear equations. The modeling equations include parameters such as channel length (L), channel width (W), node voltages, and branch currents. However, the design and analysis of such complex nonlinear equations are depending on the expertise of the designer. In this paper, a Neural network is used to design and implement a three-stage operational amplifier. The channel length (L) and width (W) which are most suitable for circuit characteristics are calculated using neural network training. The Cadence tool is used to simulate the various circuit diagrams. The Neural Network model is developed and trained using MATLAB 2019b software platform. The effectiveness of the proposed neural network model is tested using the various circuits.**

Keywords— ***MOSFET; Artificial neural network; Gain-bandwidth product; OTA amplifier Miller compensation.***

I. Introduction

In recent years, MOSFET design has become an integral part of almost all electronic devices. Therefore, an efficient and implementable design still remains a challenging area for the researchers. It is known that the MOSFET consists of Gate-Source, Drain-Source, and Bulk-Source potentials as inputs and current flow through the drain. We know that the MOSFET is a voltage-controlled device and it is because of the fact that the conduction is started by some minimum gate voltage. So, depending upon the input voltages provided such as V_{GS} and V_{DS} to MOSFET, the channel parameters results into a controlled drain current I_D. The channel length (L) and width (W) parameters provides a non-linear output current relationship with respect to the constant input and output voltages. However, the evaluation of such parameters $(L \text{ and } W)$ is very difficult since the MOSFETS are generally modeled using complex and non-linear equations along with the independent and dependent parameters. Therefore, to overcome these issues neural network-based approach can be used.

In past years, many researchers carried out numerous research work on the MOSFET modeling and design based on the neural network models. Kothapalli in 1995 [1] proposed an approach based on the neural network to design an operational transconductance amplifier (OTA). Moreover, a similar approach is presented by Langeheine *et al.* [2] and it is used for the transistor array design using a genetic algorithm. This model is developed only for the purpose of a single transistor and with constant drain-source voltage which cannot be used the general-purpose approach in analog integrated circuit design. Further, similar work has been carried out using the same process parameters and genetic algorithms in [3].

From literature, it is observed that the neural network model has been extensively used for MOSFET design as well as the various electronic circuits such as current mirror [4], differential amplifier [5], inverter, and logic gates [6]. In 2007, Avec *et al.* [7] has proposed a model which is a general design approach for analog integrated circuits. This model consists of Multi-Layer Perceptron (MLP) neural network with three inputs, two hidden layers, and two outputs. In this, training and testing data are prepared using the simulation of MOSFETs using Cadence software.

The channel length (L) and width (W) are important parameters for the modeling of MOSFET and Integrated circuits. It has been observed that the theoretical calculation of dimensions of MOSFET becomes impractical and complicated due to the other varying and nonlinear parameters. The ratio of channel length and width is called aspect ratio and it can be predicted by using a supervised neural network. Neural networks are mostly one which takes input data and train themselves to build a model and then predict the output for a new set of similar data. The artificial neural networks are made up of layers of a neuron. These neurons are the core processing units of the network. The input layer receives the input and the output layer predicts the final output. The hidden layer performs most of the computations required for the process. In a multi-layer perceptron (MLP) neural network, the modeling of the transistor can be done by providing input voltages and output current [8-10].

In this paper, an artificial neural network model is proposed to design the basic building blocks of the three-stage operational amplifier. The manual calculations of various design parameters of MOSFET are calculated using the Cadence software. These parameters are considered to train the proposed neural network model. In the first stage, basic MOSFETs circuits are simulated and their current-voltage characteristics are studied. Later, the current mirror,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

differential amplifier, two-stage, and three-stage operational amplifier were also simulated and characteristics have been studied in detail. The rest of the paper is organized as follows. The proposed approach is explained in Section II. Experimentations and results are shown in Section III and finally, conclusions are drawn in Section IV.

II. Proposed Neural Network Model

A neural network is generally termed as a system that consists of many neurons. It produces the best possible output though there is a change in the input. Generally, it consists of source nodes which include an input layer, one or more hidden layers, and an output layer. In general, in neural network architecture, the set of sensory nodes called as input neurons constitute the input layer, one more computational hidden layer, and summed output layer. The output of the neural network is decided by the activation function and threshold [11]. It has been observed from the literature that the sigmoidal function can perform better as compared to the binary and step function. The basic neural network with three inputs and one out is shown in Fig. 1. In Fig. 1, x_1, x_2 and x_3 are the input to the neurons and $w_1, w_2,$ and w_3 are the weights to the respective inputs. The activation function is used to calculate the output of the neural network using the threshold value.

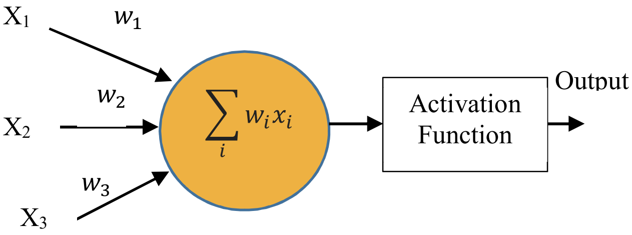

Fig.1. Basic block diagram neuron model.

In this work, the NMOS1 MOSFET model is used for the design and analysis. The input parameters such as gate-to-source (V_{GS}), drain-to-source (V_{DS}) and output drain-current (I_D) are considered as a input to the neural by which the design parameters channel length (L) and width (W) are estimated. The proposed neural network architecture is shown in Fig. 2.

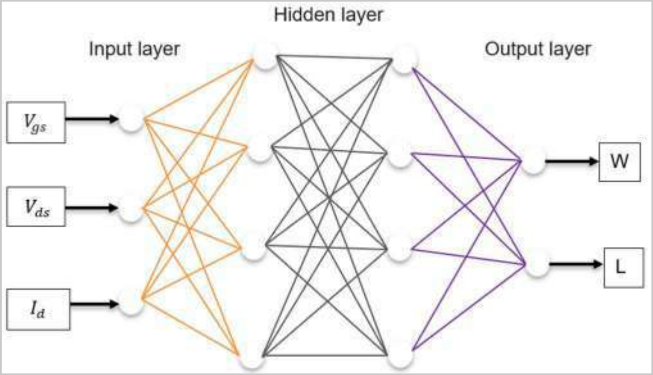

Fig. 2. Proposed Neural network model for circuit design and analysis.

Training and testing data are obtained by various simulations of MOSFET (n-channel and p-channel) in a Cadence software environment. The activation of the hidden neuron is the function of weighted inputs and bias. It can be calculated as

$$x_i = w_1 V_{GS} + w_2 V_{ds} + w_3 I_d + \theta_j \qquad (1)$$

III. Circuit Implementation

The circuit in Fig. 3 shows the design developed for the proposed neural network using Cadence software. The voltage values at different nodes and current are shown in Table II. The value of voltages and currents decides the design parameters length (L) and width (W) of the transistors. The channel length and width are calculated using the simulation of the circuit using Cadence and predicted using the proposed neural network.

7	1.3	1.31	165.3	3.60	1.80	1.688	1.380

TABLE III. SIMULATED AND PREDICTED VALUES OF WIDTH AND LENGTH FOR NMOS 2

S. No.	V_{GS} (V)	V_{DS} (V)	I_D (μA)	Simulated		Predicted	
				W	L	W	L
1	0.35	0.70	0.018	0.36	0.045	0.360	0.046
2	0.51	0.80	0.477	0.36	0.045	0.389	0.054
3	0.67	0.9	1.640	0.72	0.18	0.773	0.156
4	0.81	1.01	8.421	0.72	0.18	2.271	0.438
5	0.98	1.10	47.35	2.16	0.60	2.162	0.598
6	1.14	1.20	72.39	2.16	0.60	2.132	0.602
7	1.3	1.31	163.5	8.00	1.80	8.024	1.786

It is observed from Table I, Table II, and Table III that the channel length (L) and width (W) parameters are fitted well with the simulated values.

Further, using the current mirror circuit, a differential amplifier circuit has been designed as shown in Fig. 4. The node voltages, currents, and design parameters of all MOSFETS are calculated using circuit simulation in Cadence software. In this design, two PMOS and three NMOS are used. All the MOSFETs are simulated and design parameters are predicted using the proposed neural network. The analysis of all MOSFETs are connected in differential amplifier is summarized in Table IV and Table V. It is observed that the simulated and predicted design parameters such as channel length (L) and width (W) are approximately similar which indicates the effectuality of the proposed neural network model.

The three-stage operational amplifier can be designed and implemented using the current mirror, differential amplifier, and two-stage operational amplifier. It is shown in Fig. 5.

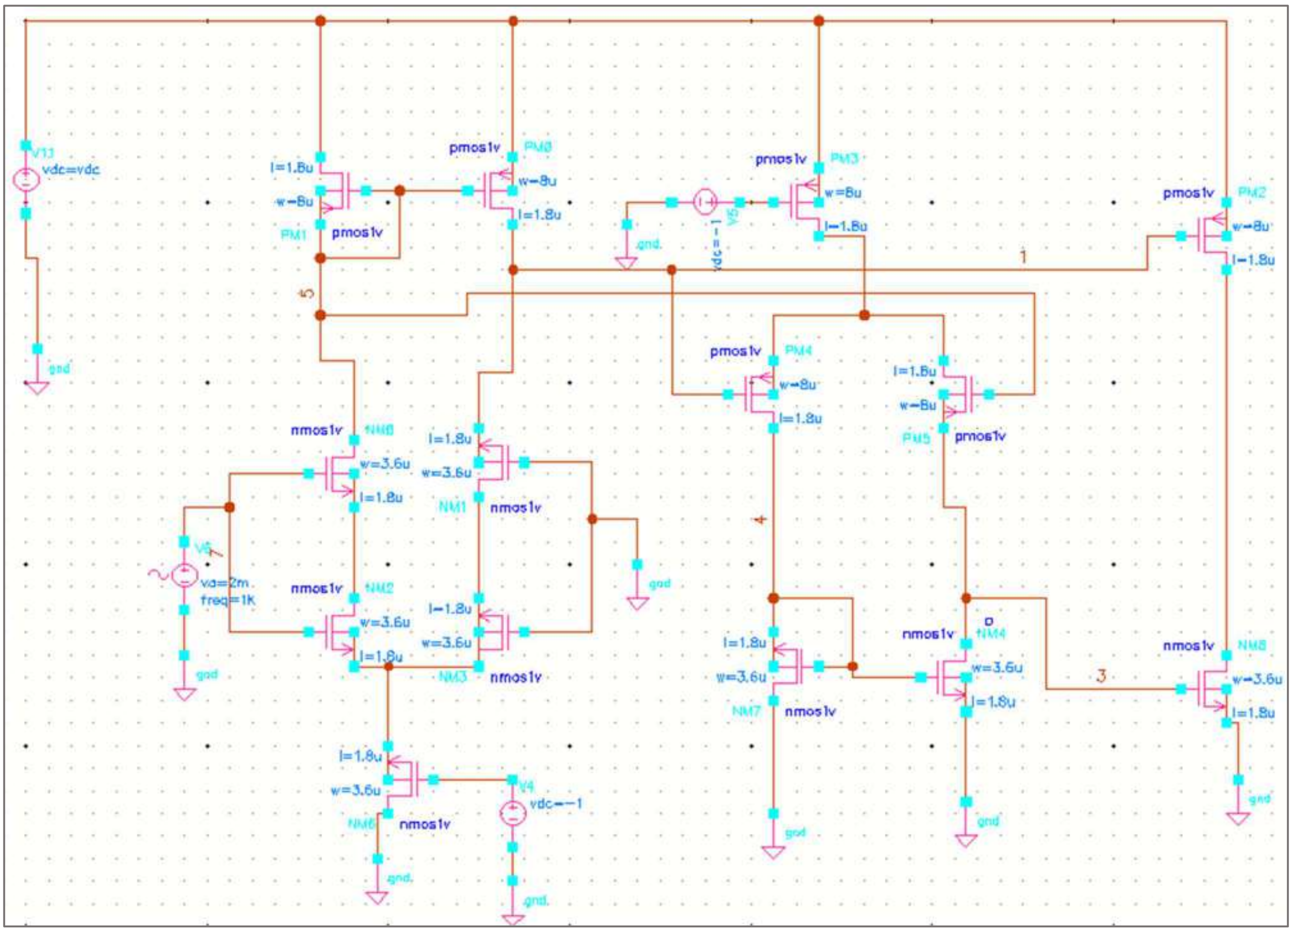

Fig. 5. Design and implementation of three-stage Operational Amplifier

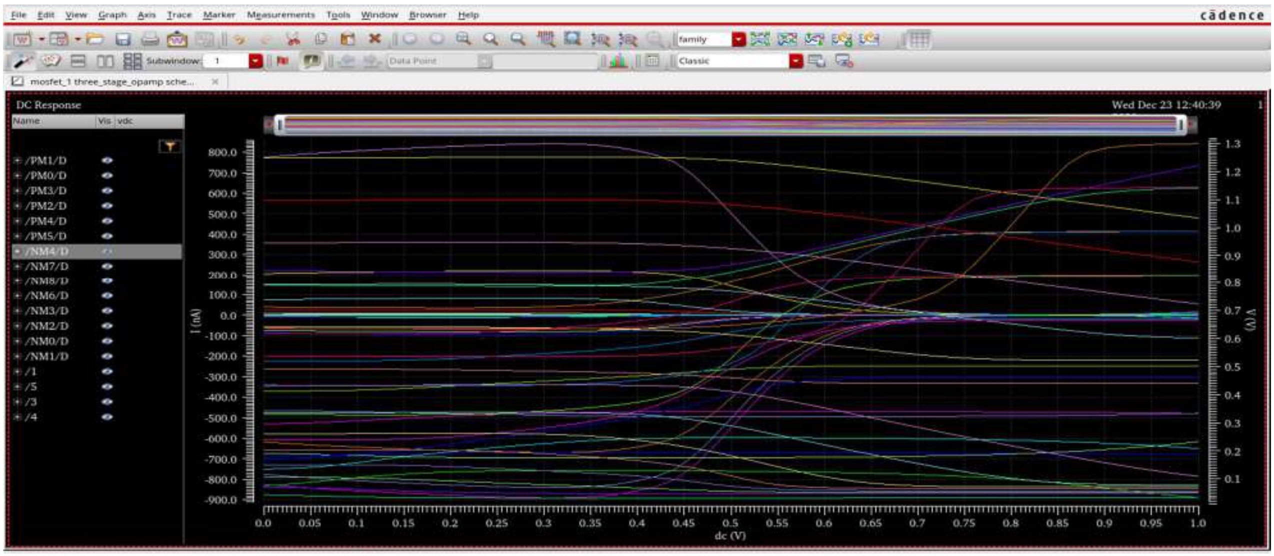

Fig. 6. The simulated output of three-stage Operational Amplifier

The three-stage operational amplifier is simulated using the CADENCE software and the circuit schematic is shown in Fig.5. In this circuit, six PMOS and eight NMOS are used. The analysis of all the MOSFETs has been carried out and design parameters such as channel length and the channel width are predicted using the neural network. However, the limited readings are summarized in Table VI and Table VII, since the test generates huge data which can not be recorded in the form of a table in the paper. Moreover, Fig. 6 shows the characteristics of the three-stage operational amplifier circuit.

IV. Conclusion

The basic building blocks of the operational amplifier are designed and simulated using the Cadence software. The aspect ratio of each MOSFET is calculated using the simulation. Moreover, the channel length and width are designed using the artificial neural network. The various experimentations are carried out using the current mirror, differential amplifier, and three-stage operational amplifier circuits. It is observed from the results that the presented neural network model can predict the design parameters such as channel length and width accurately and it is closed to simulated results. Thus, the proposed approach can be used to design analog and digital VLSI circuits.

Abstract—This work presents the design of a constant, programmable and extremely high (Tera ohm) MOS pseudo-resistor over a wide dynamic range of ± 0.6 V based on MOS transistors operating in the weak inversion region. The major challenge faced by the circuit designers in designing high resistance pseudo-resistor is the linearity problem and it is resolved in this work. The proposed pseudo-resistor is utilized as a feedback resistor in the second stage of the two-stages bio-medical amplifiers in the portable bio-detection system. By controlling the resistance of this pseudo-resistor, the lower cut-off frequency of the amplifier is automatically adjusted and thus allowing the detection of the small frequency range. Simulations in LT-spice using 130 nm CMOS technology under ± 0.6 V supply voltage are performed to validate the realization of the extremely high resistance and its application.

Keywords **— level-shifter, pseudo-resistor, bio-medical amplifier, bio-detection system, BMI.**

I. Introduction

The Pseudo-resistors are enormously essential devices in any bio-medical system. The relevant signals extracted in the biomedical applications having the frequency range of 0.1 Hz – 10 kHz, while the amplitude is ranging between 20µV – 10mV [1]–[4] Therefore, the need for the pseudo-resistors is vital to realize extremely high resistance values that can be reached to kilo-ohms resistance as in [5] and few giga-ohm resistance as in [6], [7], and few Tera-ohm resistance as in [8]–[11]. Besides, it will ensure a smaller chip area despite the usage of the high resistance value, with minimal designing cost and lower power consumption [7]. These resistors are preferred to be utilized over the conventional ones in many important circuit blocks such as the trans-impedance amplifiers, data converters, operational transconductance amplifiers, and multipliers as an integral part of the biomedical application, temperature sensing application and low current sensing application, etc. [12].

Recently, the neurobiologist and neuroscience researchers have devoted much of their research and studies to the field of bio-medical interfacing systems [13], [14]. The industrial revolution, the remarkable development in the Integrated Circuits, and the great achievements of the scientists up to date have been directed the attention towards the bio-medical interfacing systems field. The neural recording implants are the core element in the BMIs which consist of three main blocks, bio-medical amplifiers, ADCs and compressors [15], [16].

The main motivation behind this work is to provide an almost constant high resistance (reach to Tera ohm) pseudo-resistor, applicable for a wide dynamic range of ± 0.6 V. Thus, the performance of the application in the bio-medical analog circuits won't be vitiated and distorted. based on the proposed pseudo-resistor as a feedback element in the second stage amplifier. In this work, the proposed pseudo-resistor circuit will be investigated and designed in section II. The design of the bio-medical amplifier as an application of the proposed pseudo-resistor is thoroughly discussed, analyzed and simulated in section III. A conclusion is presented in section IV.

II. Proposed Pseudo-resistor

The proposed pseudo-resistor presented in Fig. 1. is designed using two series (NMOS- M_{a2}) and (PMOS- M_{b2}) transistors, each connected with a level shifter (PMOS- M_{c2}) and (NMOS- M_{d2}), respectively, which affords the capability to dynamically adjusting the gate to source voltages of the two transistors. This adjustment will maintain a constant V_{GS} on the pseudo-resistor over large output voltage swings. Meanwhile, by controlling the bias currents in the level shifters, the resistance value can be controlled. However, utilizing two different types of transistors (NMOS and PMOS) will be useful in implementing a large and constant R over the wide dynamic range, by ensuring at least one transistor has the proper operation and adjusted V_{GS}. Utilizing one NMOS transistor (M_{a2}) with a level shifter will guarantee that $V_{4,1} = V_{GSa2}$

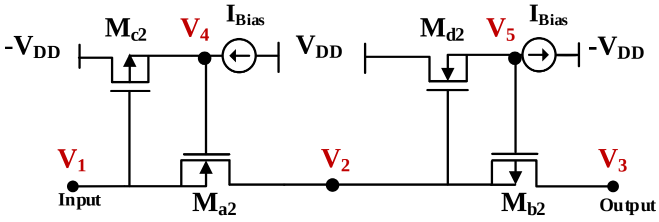

Fig. 1. The structure of the proposed pseudo-resistor

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

= V_{SGc2}, which will maintain a proper and constant V_{GSa2} value, meanwhile ensure that M_{a2} operating in the subthreshold region, thus a constant, linear and large resistance value over the positive voltage swing will be emulated. Knowing that, The I_{DS} expression for the NMOS transistor is given in (1), where $I_{Dn} = 2n\, \mu_n C_{ox} U_T^2\, W/L$, and U_T, V_{To}, n, μ_n, C_{ox}, W and L are defining the thermal voltage, MOS threshold voltage, subthreshold slope factor, mobility of electrons, gate oxide capacitance per unit, channel width, and length of the MOS transistor respectively. Hence, its equivalent resistance is given in (2), where I_{bias} is the biasing current source in the level shifter M_{c2}.

$$I_{DS} = I_{Dn}\left(e^{-\frac{V_{SB}}{U_T}} - e^{-\frac{V_{DB}}{U_T}}\right)e^{\frac{V_{GB}-V_{To}}{n\,U_T}} \qquad (1)$$

$$R_{2,1} = 1/\frac{\partial I_{2,1}}{\partial V_{2,1}} = \frac{U_T}{I_{bias}}.\frac{I_{Dpc2}}{I_{Dna2}}.\frac{1-e^{-\frac{V_{SDc2}}{U_T}}}{e^{-\frac{V_{2,1}}{U_T}}} \qquad (2)$$

On the contrary, utilizing one PMOS transistor (M_{b2}) with a level shifter will maintain a fixed value of $V_{2,5} = V_{SGb2}$ which will guarantee that M_{b2} is operating in the subthreshold region, accordingly preserve a constant, linear and large resistance value over the negative voltage swing. The equivalent R of this pseudo-resistor is given in (3), where I_{bias} is the biasing current source in the level shifter M_{d2}.

$$R_{3,2} = \frac{U_T}{I_{bias}}.\frac{I_{Dnd2}}{I_{Dpb2}}\left(\frac{1-e^{\frac{-V_{DSd2}}{U_T}}}{e^{\frac{V_{3,2}}{U_T}}}\right) \qquad (3)$$

By connecting the two cells mentioned in a series connection, as declared in Fig. 1 the stated drawbacks of using only one cell will be avoided, and thus validate that the cells emulating a constant, linear and high resistance value (1.08 TΩ) over the entire positive and negative voltage swing as demonstrated in Fig. 2. The size of the transistors M_{a2} and M_{b2} is (W= 0.26 μm, L= 65 μm) and M_{c2} and M_{d2} is (W= 200 μm, L= 1.5 μm).

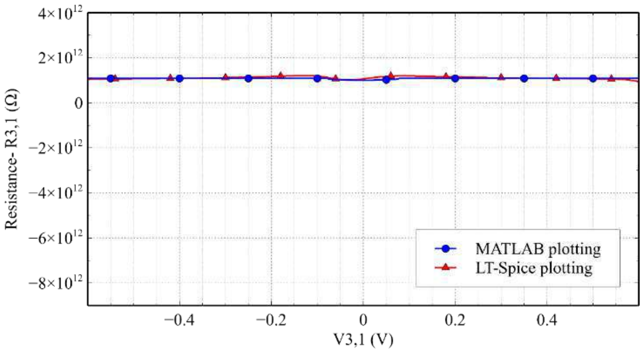

Fig. 2. The $R_{3,1}$ vs. $V_{3,1}$ curve of the proposed pseudo-resistor using both the LT-Spice and MATLAB simulators.

It's demonstrated also from Fig. 2 that $R_{3,1}$ curve plotted using LT-Spice is almost identical to the one plotted using MATLAB. Besides, this fact can be justified by the theoretical analysis, where the derived expression of $R_{3,1}$ under both conditions of $V_3 < V_1$ and $V_1 > V_3$ is expressed by the same equation, presented in (4). However, a small drop in the R reached 1.01 TΩ is observed near $V_{3,1}$= 0V; due to the gap between the realized resistance by NMOS and PMOS pseudo-resistors.

$$R_{3,1} = \frac{U_T}{I_{bias}}\left[\frac{I_{Dpc2}}{I_{Dna2}}\left(\frac{1-e^{\frac{-V_{SDc2}}{U_T}}}{e^{\frac{-V_{2,1}}{U_T}}}\right) + \frac{I_{Dnd2}}{I_{Dpb2}}\left(\frac{1-e^{\frac{-V_{DSd2}}{U_T}}}{e^{\frac{V_{3,2}}{U_T}}}\right)\right] \qquad (4)$$

III. Bio-medical Amplifier Design

As an application of the proposed pseudo-resistor, an op-amp-based bio-medical two-stage amplifier has been designed by employing the proposed pseudo-resistor as a feedback resistor in the second stage of the amplifier while using another non-linear pseudo-resistor as a feedback resistor in the 1st stage of the amplifier.

A. First Stage Amplifier Design and Simulation

This stage presented in Fig. 3 involves input capacitors utilized to block the DC offset voltages which are produced as a result of the electrochemical interaction at the electrode-tissue interface. This voltage considered a huge problem since it can alter and affect the mode of operation of the transistors and saturate the amplifier. The issue is arising since these offset voltages which range between (1 mV – 50 mV) have higher voltages values compared to the brain's signals, thus it is compulsory to get rid of these offset voltages [15].

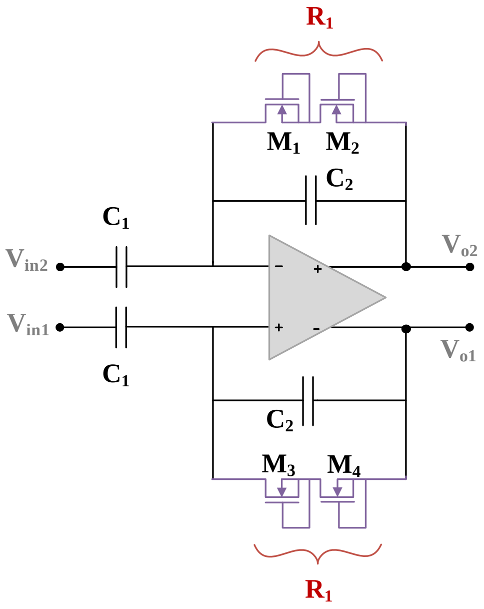

Fig. 3. The structure of the first stage bio-medical amplifier

This stage is also comprising of feedback capacitors along with a feedback resistor R_1 design using two series NMOS transistors at an equal aspect ratio of (1 µm /100 µm) to produce the pole frequency at 0.1 Hz. This pseudo-resistor is based on the symmetrical biasing for the body and V_G of the two NMOS transistors operating in the subthreshold region. This architecture of pseudo-resistor, is able to emulate an extremely high resistance value, reached to tens of Tera ohm but on the contrary, its value is not constant therefore it is not suitable to be used for the last stage of the amplifier due to the high output voltage swing and due to the linearity problem. Nevertheless, using this cell of pseudo-resistor is appropriate to emulate high resistivity in the first stage of the amplifier to achieve a very low cutoff frequency.

The gain of this stage is 31.8 dB which is the ratio between the input capacitor C_1 to the feedback capacitor C_2. Where the active block designed using a fully differential folded cascaded op-amp with A_v of 74.28 dB and ϕ_m of 86.5° [17]. The design structure of this op-amp is presented in Fig. 4.

The simulation in LT-spice has been conducted for verification purposes using 130 nm model, BSIM032, level = 4, ± 0.6 V supply. TABLE I. showed the design specifications and components values of the 1st stage amplifier and its active block. The magnitude and phase responses of this stage are presented in Fig. 5 (a) & (b) respectively.

B. *Second Stage Amplifier Design and Simulation*

The structure of this stage shown in Fig. 6 comprises coupling input capacitors C_3, feedback capacitor C_4 and feedback resistor R_2 which designed using the proposed pseudo-resistor, since it required to design a pseudo-resistor that can emulate a high resistance value reached to T ohm resistance, provided that its linearity is high. Employing the proposed pseudo-resistor in this stage is the best solution to preserve an almost constant resistance value over a wide dynamic range of ±0.6 V, which leads to high linearity and almost constant pole frequency in the bio-

C. Overall Amplifier Design and Simulation

The structure of the two-stages bio-medical amplifier is presented in Fig. 9. It's worth noting that besides the linearity advantage provided by the usage of the proposed pseudo-resistor, it also facilitates controllability to the lower cutoff frequency of the amplifier. Accordingly, by decreasing the biasing current in the level shifter, the lower cutoff frequency will reduce thus, the bio-medical amplifier will be able

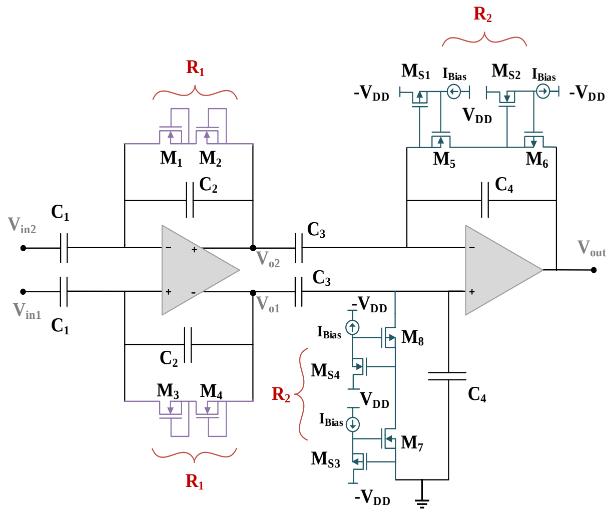

Fig. 9. The structure of the two-stages bio-medical amplifier

to detect the small frequency range. The magnitude and phase responses of the two-stages bio-medical amplifier are demonstrated in Fig. 10 (a) & (b) respectively. The response of the overall op-amp-based bio-medical amplifier is simulated over three different biasing currents; 1nA, 1.5nA, and 2nA as demonstrated in Fig. 11, where the corresponding lower cutoff frequencies are; 1.8 Hz, 2.3 Hz, and 2.8 Hz respectively. The simulated result of the input-referred noise spectral density of the two-stages bio-medical amplifier is shown in Fig. 12. The design parameters of the overall bio-medical amplifier are summarized in TABLE III.

TABLE III. THE DESIGN COMPONENTS AND PARAMETERS OF THE TWO-STAGE BIO-MEDICAL AMPLIFIER

Design parameters	Value
Gain	54.9 dB
Supply voltage	±0.6 V
Bandwidth	678.2 Hz
IRN (above 10 Hz)	$312.8\ \mathrm{nV}/\sqrt{\mathrm{Hz}}$
IRN @0.1 Hz	$41.66\ \mu\mathrm{V}/\sqrt{Hz}$
Power consumption	4.69 µWatt
THD @100 Hz, 1mV$_{pk-pk}$	0.327% (-49.7 dB)
IM3 @50 and 60 Hz, 1mV$_{pk-pk}$	46.49 dB
IIP3	22.94 dBm
Gain	54.9 dB
Transistors of pseudo-resistors	**Value**
M$_1$ – M$_4$	1 µm /100 µm
M$_5$ – M$_8$	0.26 µm /65 µm
M$_{S1}$ – M$_{S4}$	200 µm /1.5 µm

IV. CONCLUSION

A novel CMOS pseudo-resistor using NMOS and PMOS transistors with level shifters is proposed. This cell affords an extremely high and almost constant resistance over a wide dynamic range of ±0.6 V, which leads to high linearity and almost constant pole frequency when it’s used in a bio-medical filter design application. The performance of the resistance is tested and applied in a two-stage bio-medical amplifier and simulation tests are provided and confirm the high linearity performance and the fine-tuning of the lower cut-off frequency.

***Abstract*— A single Active Namenode (ANN) of Hadoop Distributed File System (HDFS) become a bottleneck when we require high-throughput read operations such as large-scale data analysis. Recently, various kinds of namenode schemes are proposed including asynchronous check pointing schemes to address the ANN bottleneck issue. Even if asynchronous schemes offers high throughput reading operations, they suffers in stale read problem where the latest data return is not guaranteed. In this paper, we propose a novel metadata replication scheme with synchronous OpCodes writing to achieve namenode multiplexing, where we can avoid the stale read problem. To reduce synchronization overhead, our proposed scheme conducts reduced replication only for metadata updates such as a write request, using quasi byte-level metadata operation codes. We conducted the empirical experiment to verify the effectiveness of our proposed schemes. The results show that our method reduces by 50.95% in the average required number of NNs when the number of NNs for read-only operation is 100.**

Keywords—HDFS, Metadata Replication, Staleness Elimination, Strong Consistency

I. Introduction

As the size of big data continues to grow, many distributed file systems have been used to store them. The Hadoop Distributed File System (HDFS) [1] became a popular choice for storage because of its high throughput and scalability. Thus, several hundred petabyte-scale data mining and analysis is feasible with HDFS. In data mining, a method to find specific patterns in the data, a mining application queries data to the HDFS. A transaction of those queries usually consist of high ratio of read operations [2] approximately 95% [3-4] of all requests. However, these high read operation ratio causes performance degradations in many cases. For example, Zhang et al. [3] reported a case of significant performance degradation from their experiments, where 500,000 queries to HDFS were produced and 90% of queries took more than 100 seconds. They analyze the experiments results and conclude that the limited read throughput was caused by the HDFS with A single Active Namenode (ANN), which is metadata.

Since the introduction of HDFS to the big data domain, there has been many studies that address the limitation of a single ANN especially for read requests. Shvachko et al. proposed the Observer Namenode (ObNN) in their study [5], which was designed only to process read requests. It is differentiated from ANN that processes both read and write requests. However, in order to use these ObNNs, Journal Nodes (JNs) and Quorum Journal Manager (QJM) are required as well as Standby Namenodes (SbNNs) to improve fault-tolerance of ANN. Thus, as the number of NN is required more and more, we can recognize the HDFS system complexity and cost is higher and higher. Therefore, HDFS needs asynchronous to improve performance. However, asynchronous approach can be occurred stale reads. Stale read problem where the latest data return is not guaranteed happens with high performance asynchronous techniques, and it may be occurring repeatedly that will yield serious performance degradation.

Stale read amplifies synchronizing overheads of the metadata changes. Stale read yields delay in read operations since to obtain the latest data, additional synchronization workload is required and it can be repeated. Additionally, stale read increases read latency and make it difficult to achieve real-time responsiveness. Furthermore, because it affects to other metadata processing operations [4], delay is amplified further. As a result, as the number of node that serves metadata grows, the throughput of metadata read operations is decreased. There are other problems of stale read. Even if a read request arrives after a write request is completed, the time at which the data are available is non-deterministic, which can affect the accuracy of data analysis [8]. Also, because data from stale read violates security requirements, vulnerabilities in data leak are detected [9] or restricted [10] to avoid general reads. Thus, stale reads are a critical problem to be resolved in a large-scale data analysis not only because it affects overall performances but also yields security vulnerabilities.

For better improvement in read throughput, the metadata multiplexing is better choice in many cases. The metadata is a descriptive information of data (e.g., file name, path, size, and created time). Among the all access, the number of accessing to metadata are majority. In the study [6], the metadata access occupies 50%–80% [6] of all accesses of the file system. Therefore, it significantly affects the overall performance.

To achieve metadata multiplexing, the replication technique is critical. Replication technique is well known for improving performance, availability and reliability. However, even if metadata occupies relatively very small (i.e., 0.1%–1% in [6]) the overhead resulting from synchronizing copies of metadata

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

whenever writing operation happens is a serious performance bottleneck. We may alleviate the synchronizing overhead of the metadata changes with a consistency protocol. However, still there will be stale reads problem to be resolved. The consistency protocol is used to maintain the metadata changes between copies of the metadata. Strong consistency [7] of protocols ensures that all metadata changes are applied uses a 'synchronous' synchronization technique. Therefore, there is no metadata mismatch but high overhead has to be endured. On the other hand, both weak consistency and eventual consistency [7] of protocol do not guarantee that all metadata changes are applied. In addition, these two consistency policies use 'asynchronous' synchronization techniques. Thus, the stale reads may occur (i.e., not the latest data is returned for the read request) even with relatively low overhead.

In this paper, we propose a novel read-only metadata multiplexing method to improve read throughput with reduced read latency as well as low metadata synchronizing overhead for changes. To achieve the reduced overhead, we introduce byte-level metadata and replicates only minimum metadata, i.e. we reduce size and the number of replications. We could achieve this by not replicating entire metadata. We also apply strong consistency policy to avoid stale reads.

To evaluate the effectiveness of our proposed method, we implement read-only namenode multiplexing on Hadoop. First, we implement the write operation codes (opcodes) of the metadata for replication in byte-level. Also, we replicate metadata only when they are changed (e.g., write requests occur) to reduce the number of replications. Second, for strong consistency, we use the eager primary-copy model [11]. Based on these two design/implementation, we achieve the increase of the number of ANN and the replication of metadata from the ANN to the ANN's replicas using the primary-copy model. The proposed ANN process both read and write requests. On the other hand, the replicas can process read-only requests.

We identify the main contributions of this paper are as follows:

1. Read-only metadata multiplexing method to maintain read throughput
2. Metadata replication method of byte-level opcodes for reduced synchronization
3. Synchronization technique of in-memory and on-disk metadata for read-after-write in a replica node

The remainder of this paper is organized as follows. Section II describe the related work. Then we describe the proposed scheme in Section III. The evaluation results are presented and analyzed in Section IV, and we conclude in Section V.

II. Related Work

A. Asynchronous checkpointing

Mohan et al. [14] investigated various checkpointing approaches such as asynchronous checkpointing in High Performance Computing. Among those approaches, synchronous checkpointing occurred large checkpoint stalls. The GPU is used for learning, and the CPU is used for checkpointing. In the past, GPU-based learning had to be stopped for checkpointing, but in the proposed technique, the CPU is minimized by pipelining through two-phase checkpointing called snapshot and persist so that the CPU performs as background regardless of learning. However, it may not be effective in CPU-based learning. Because checkpointing must also be performed while learning, the CPU load can be increased and learning may be delayed. Also, HDFS is not suitable because CPU is used, and such asynchronous checkpointing is known to cause stale. Because checkpointing is k-iteration, it must be performed periodically and repeatedly. However, it is necessary to ensure that it is performed only when metadata changes occur so that it cannot be always performed repeatedly.

In ObNN, Journal nodes (JNs) periodically back up the metadata of ANNs using a checkpoint; this is one of the reverse error recovery techniques involving a state-based backup method. However, the ObNN waits for the ANN's metadata to be transmitted to process a read request, and if a read request arrives before synchronization due to metadata inconsistency, then a stale read occurs. To mitigate this problem, the ObNN verifies the JNs for updated metadata before processing a read request. To process read requests that require the latest information, such as the quota usage API for the directory, the synchronization process is repeated until the latest metadata are obtained. ANN's metadata is asynchronously replicated and synchronized in several stages from the QJM's JNs to SbNN to the ObNN. The QJM periodically requests each JN to replicate the ANN's metadata to replicate and synchronize the metadata. When more than half of the odd-numbered JNs complete synchronization with the latest metadata, this cause write delay. Then the metadata are copied to the SbNN. When SbNNs download the metadata, they transmit the metadata to the ObNN. Thus, replicating asynchronously an entire single metadata over several nodes causes significant synchronization overhead.

B. Metadata distribution and replication for fault-tolerance

Niazi et al. [4] proposed a multiple namenode with single leader NN (e.g., ANN). They divided equally the entire metadata of single ANN into a distributed database. However, this causes relatively high network communication and synchronization overhead because this should be searched via network to get the metadata information. To alleviate the overhead, they placed the client side cache. This cause stale cache and the overhead that periodically needs to be updated. Moreover, the node number of distributed database that they used was 48 and recently it has increased to 64. This means that scalability is limited. Wang et al. [16] proposed multiple SbNNs that failover the ANN to remove single point of failure of the ANN. These all SbNNs cannot process read requests. SbNN of existing HDFS also still cannot process read requests.

C. Write delay of strong consistency

In CephFS [12], metadata was synchronized using strong consistency, such as primary-copy model. Therefore, metadata inconsistency due to writing did not occur, but high network traffic occurred between nodes due to metadata discovery and synchronization. Furthermore, owing to communication overhead, the low-latency requirement cannot be satisfied. In a

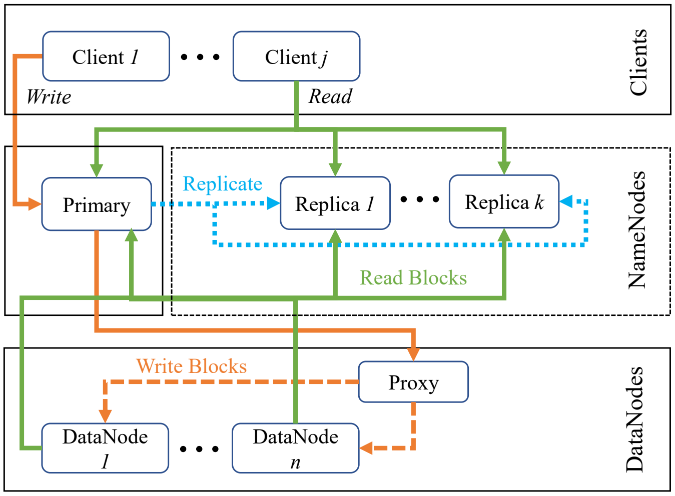

Fig. 1. Our proposed scheme for namenode replication

study by Jiayuan et al. [13], to lower the consistency level from strong to weak, the primary node that committed data asynchronously replicated metadata to the remaining replication nodes using a ring. This reduced the write latency but amplified stale reads. Thus, write overhead needs to be reduced or minimized.

D. Stale reads

In CephFS, stale reads occurred owing to the size of the metadata cache; therefore, reads were repeated to obtain the latest data. To solve this problem, reading was repeated or metadata were reread when the lease expired such that the latest data were updated using read lease [15]. Ho et al. [8] proposed a stale synchronous parallel model that allows stale data in bulk synchronous parallel systems such as Hadoop as a parameter server system for distributed machine learning. However, regarding learning accuracy, even if specific data are not used for learning, accuracy loss occurs, and using invalid data affects accuracy. Therefore, if the data are old or stale, the corresponding parameter and variable values are not used through limiting the maximum age of the stale value. Snavely et al. [9] stated that stale data may violate security attributes, particularly confidentiality-based requirements, may contain sensitive information, and should not be read in general. Accordingly, the vulnerability of real programs, in which sensitive data were leaked due to stale reads, was detected. Aiyer et al. [10] used the quorum system, a malicious scheduler that maliciously delayed messages between the server and client guaranteed an upper bound to limit the insolvency of data read, but stale reads still occurred.

III. Proposed Scheme for Namenode Replication

In this section, we propose a metadata replication with synchronous opcodes writing for namenode multiplexing. For better performance of read throughput, our proposed scheme has a primary metadata and multiple replica metadata. In this paper, we call it an eager primary-copy model. The primary metadata processes both read and write requests. Any of both the primary and the replicas can process read-only requests from clients. This requires all of the metadata to be identical. To reduce synchronization overhead, we synchronize metadata operation codes (described in Table I) only when the metadata are changed (e.g., write requests occur).

For low metadata synchronizing overhead for changes, we replicate the write operation codes (opcodes) of the metadata in byte-level. A write opcode is an operation unit with transaction of storing metadata changes according to write requests. We synchronize the write opcodes are stored between the in-memory (e.g., RAM) and on-disk metadata (e.g., HDD or SSD). This enables read requests from clients to process immediately after processing a write request. Thus, this read-after-write can reduce read latency. Furthermore, the proposed scheme apply strong consistency policy to avoid stale reads. The remainder of this section exhibits the design and implementation of the proposed scheme.

A. Read-only Namenode multiplexing scheme

We introduce our proposed scheme to increase the number of ANNs which can process read requests. These primary and replicas are called the proposed ANNs in this paper. To increase the number of the ANN, we first prepare several nodes and then place identical ANNs on each node. As shown in Fig. 1, in the proposed scheme, each ANN should be able to process read requests from clients. To do that, all of the proposed ANNs should synchronize to keep identical metadata. However, the stale reads can be occurred when we use an asynchronous synchronization. To eliminate the stale reads, we use a synchronous synchronization approach (as shown in Fig. 2). In addition, synchronizing the metadata between the proposed ANNs causes the synchronization overhead. To reduce the overhead, we replicates byte-level metadata operations codes (i.e., opcodes as shown in Table I). We also replicates the opcodes from the primary to the replicas. This enable the

proposed ANNs (i.e., primary and replicas in Fig. 1) and to be identical. Growing the number of the replicas enables better improvement for read throughput as in ObNN of existing HDFS. Thus, Fig. 1 shows the proposed scheme provides replicas to process read operations to achieve higher read throughput as the number of namenodes continues to grow as in ObNN of HDFS.

B. Write opcodes to reduce the synchronization overhead

The write opcodes are used to replicate only when changes are made to the metadata. We replicates only write opcodes that mutate the metadata among metadata opcodes for replicating the metadata in byte-level. This enable size of replications to be reduced. Also, we replicate metadata only when they are changed (e.g., write requests occur) to reduce the number of replications. Table I lists of the write opcodes and brief descriptions related to quasi byte-level changes in the metadata. They can be added according to the length of the file name; however, their size is in fact the size of bytes recorded in the metadata. The write opcodes do not have single-digit as size. Therefore, in this paper, we call it quasi byte-level opcodes. Fig. 3 shows the flow chart of the write opcodes according to write request. Algorithm 1 briefly shows an algorithm that replicates the write opcodes to synchronize metadata from the primary to the replicas.

```
Algorithm 1 Write opcodes replication with strong consistency
Inputs: $Req_{OPCODE}$ : set of metadata opcodes, $Write_{OPCODE}$ : set of write opcodes, $Num_{OPCODE}$ : number of $Req_{OPCODE}$, $Id_{TX}$ : identifier of transaction, $Id_{OPCODE}$ : identifier of $Req_{OPCODE}$, $Id_{NODE}$ : identifier of the primary and the replicas metadata, $Num_{NODE}$ : number of $Id_{NODE}$, $Bool_{\mathrm{ApNN}}$ : boolean whether our proposed scheme (i.e., ApNN) is activated
Output: $\mathrm{Ack}_{\mathrm{SYNC}}$ : result of syncronous synchronization
if ($Req_{OPCODE} \in Write_{OPCODE}$) then
    Set index of $Id_{NODE}$ to 1 as the primary
    for index $i \in \{1, 2, \ldots, Num_{OPCODE}\}$ do
        Get $Id_{OPCODE}$ at $i$ of $Req_{OPCODE}$
        // append $Id_{OPCODE}$ to metadata in the primary
        Append with $Id_{OPCODE}$ with $Id_{TX}$
        if ($Num_{NODE} > 1$ and $Bool_{\mathrm{ApNN}}$) then
            // append $Id_{OPCODE}$ to metadata in the replicas
            for index $j \in \{2, \ldots, Num_{NODE}\}$ do
                Get $Id_{NODE}$ at $j$ of the replicas
                $Ack_{\mathrm{SYNC}} \leftarrow$ Append with $Id_{OPCODE}$ with $Id_{TX}$
                if ($Ack_{\mathrm{SYNC}}$) then
                    // in-memory metadata for appended $Id_{OPCODE}$
                    Sync memory metadata with $Ack_{\mathrm{SYNC}}$
                Else
                    Retry to get $Ack_{\mathrm{SYNC}}$
            end if
        end for
    end if
end for
end if
Return $Ack_{\mathrm{SYNC}}$ from the replicas to the primary
```

IV. Evaluation

To evaluate the effectiveness of our proposed method implemented on HDFS, we evaluate the synchronization overhead for the write opcodes by measuring the write performance of the multiplexed namenodes. To do that, we implemented read-only namenode (i.e., ANN replicas) multiplexing on HDFS. To implement our proposed scheme, we made the ANN replica node by modifying ANN to have functions of ObNNs and SbNNs. We also made ANN primary by modifying ANN to have functions JNs and QJM. To do that, we write 7,000 lines approximately and modify more than thirty files in Hadoop source codes. In this section, we describe the evaluation settings and analyze the results obtained from HDFS.

A. Evaluation Settings

We compare the synchronization overhead, as the number of nodes grow in our proposed scheme compared with the existing HDFS. To do that, we measure write time, write throughput, and average operations per second (ops). Specifically, in case of write time, to compare our proposed scheme with a single ANN of the existing HDFS, we compare the time it take to process write requests according to the file size. In addition, to compare write throughput and average ops, we measure them using

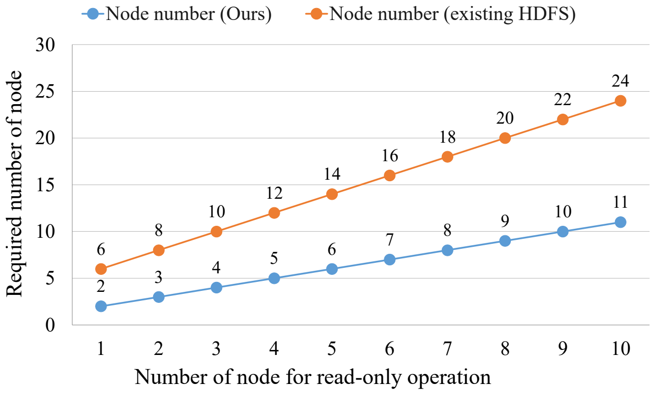

Fig. 4. Required number of namenode

TABLE III
AVERAGE WRITE OPERATION TIME

File size	Naive NN	Our scheme	Ratio
128MB (1 block)	3.786	3.324	113.8%
256MB (2 blocks)	3.412	3.954	86.3%
512MB (4 blocks)	4.502	5.267	85.5%
1024MB (8 blocks)	8.775	8.624	101.7%
2048MB (16 blocks)	12.988	16.178	80.3%
3072MB (24 blocks)	20.449	21.543	94.9%
4096MB (32 blocks)	26.164	29.198	89.6%

benchmark tools in Hadoop. Naive-NN is an existing HDFS with a single ANN. "Proposed-NN" is our proposed ANN and comprises 1 to 10 nodes. "1 Proposed-NN" is the primary namenode, and "2 through 10 Proposed-NN" is the replica namenode. The evaluation environment is presented in Table II. The existing HDFS method and the proposed method were applied separately to form a virtual machine, and each machine had one virtual core, 2 GB of memory, and 30 GB of disk space. An SSD was used in the host server for storage.

B. Evaluation Results

Fig. 4 shows the required number of namenode when the number of node for read operations (i.e., ObNNs) grows from one to ten. Equations (1) and (2) are a way to obtain the required number of node in existing HDFS and our proposed scheme, respectively. ANN and ANN primary is always 1. JNs is 2k+1 because of quorum and assume k to 1. Our proposed scheme does not need JNs and QJM because we do not use asynchronous synchronization. ANN replicas are almost equivalent to ObNNs and SbNNs because our proposed scheme has function of SbNN's ANN failover and ObNN's read operation processing capabilities.

$$\textbf{Number of node} = \textbf{ANN} + \textbf{JNs} + \textbf{ObNNs} + \textbf{SbNNs} \tag{1}$$

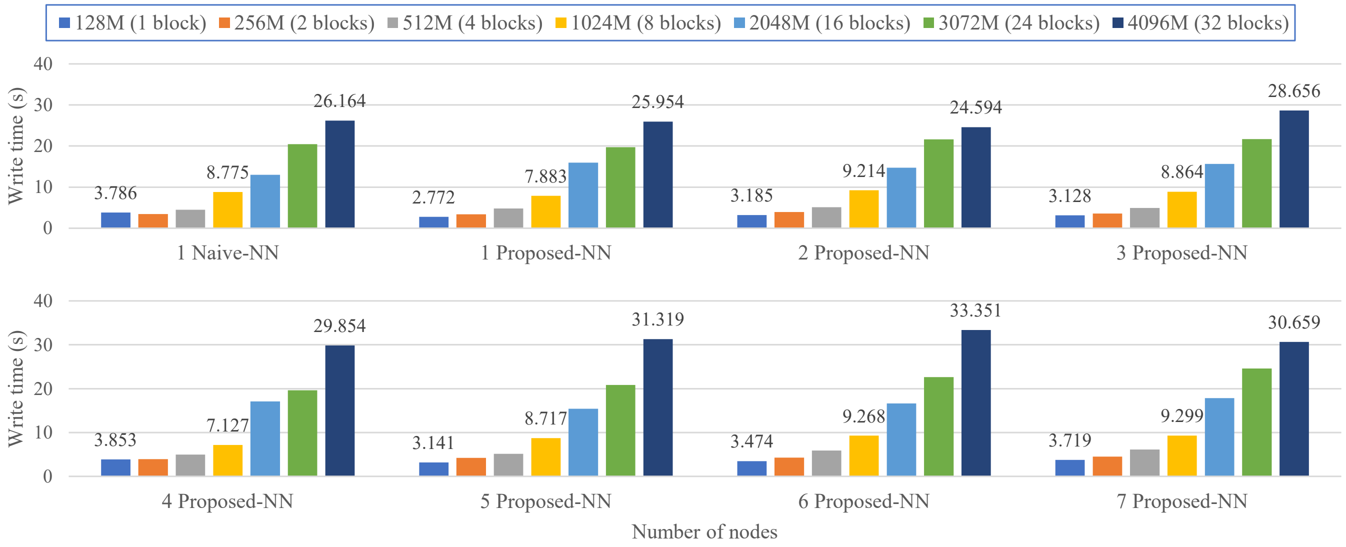
$$\textbf{Number of node} = \textbf{ANN primary} + \textbf{ANN replicas} \tag{2}$$

Therefore, we can obtain the difference between Equations (1) and (2). For instance, when the number of node for read operation is 1 to 10, our scheme needs only 2 to 11 nodes but existing HDFS should have 6 to 24 when JNs are three (as described in equation (1)). This means that our scheme can reduce the required number of node by 58.3%. This can be calculated by the following equations.

$$(\mathbf{2k} + \mathbf{1}) + \textbf{ANN replicas} \tag{3}$$

As shown in Fig. 5, the write time for each file size was measured to compare the synchronization overhead due to the increase in the number of nodes in the proposed scheme compared with the existing HDFS. The result shows that Naive-NN, the existing HDFS, had a write time of 26.164 s for a file size of 4096 MB (32 blocks), and the proposed scheme indicated an average of 29.198 s, differing by 3.034 s. The time required to complete a file upload to HDFS was measured using "-put" among the HDFS commands of Hadoop. The size of one block was 128 MB, the size of the file was the same as that of the block, and the number of DNs was set to one. Fig. 5 shows there was low overhead in given condition. We will analyze actual write time overhead in Table III.

We compared write time between our proposed scheme and existing ObNN. ObNN configuration applied as follows: ANN, SbNN, ObNN, DN is set to 1. JN is set to 3. When 1,000 files are written to existing HDFS, write and read time are 541,654 ms, 1,769 ms, respectively. In our proposed scheme with ANN primary and 1 replica, write and read time are 530,010 ms, 1,790 ms. To measure this, because we assigned one of unique number between 1 to 1,000 per text file, each file's size has from 1 to 3 bytes. Then we verified whether final summation is 500,500 (i.e., summation from 1 to 1,000) or not.

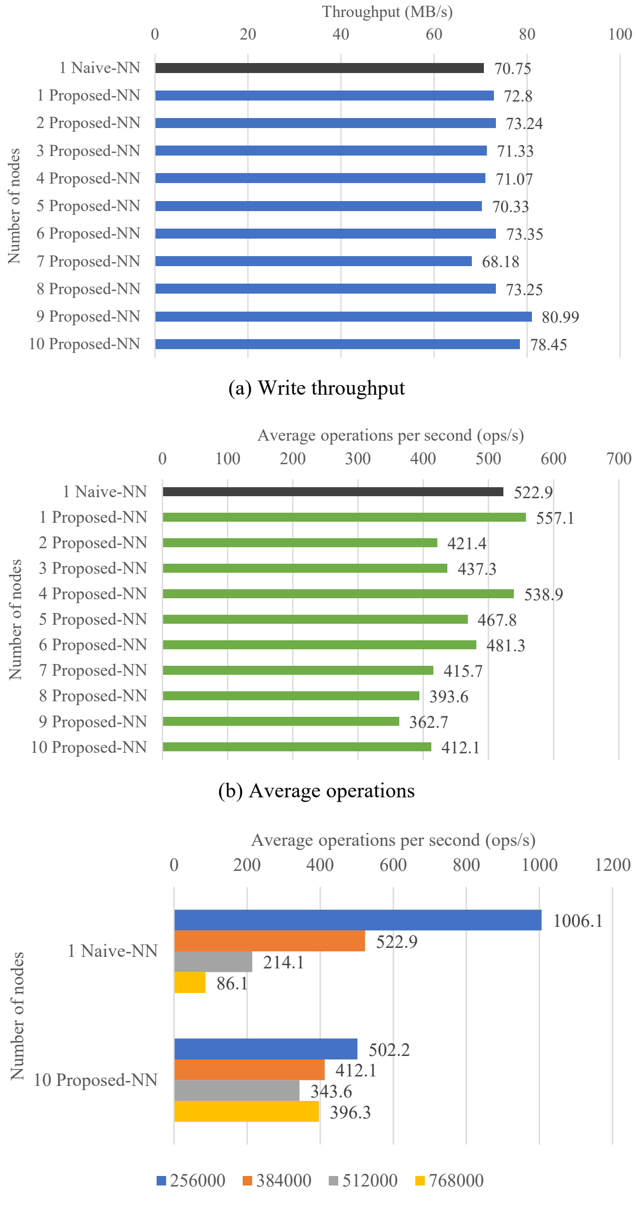


Write operation time for file with various blocks

Fig. 5. Synchronization overhead

Table III shows part of the result of Fig. 5. We can obtain 28 NNs through summation from 1 to 7 NNs. This results show that the write time per node in our proposed scheme took between 80%-113.8%. The average write operation time is 93.17% compared to the naive-NN. Thus, we verified that the overhead for write time is 6.83%.

As shown in Fig. 6(a), the write throughput was measured to compare the synchronization overhead due to the increase in the number of nodes in the existing HDFS and the proposed scheme. The results show that the throughput of naive-NN, i.e., the existing HDFS, was 70.75 MB/s, and the average throughput of the proposed scheme was 73.30 MB/s, which differed by 2.55 MB/s. It was measured using TestDFSIO, a benchmark tool of Hadoop, and the file size was set to 8 GB corresponding to 64 blocks, the buffer size to 10MB, the number of DNs to five, and the replication factor to five. Figs 5 and 6(a) show that the result values are slightly lower or higher than those of naive-NN. This means that the time required to add a block in the DN was slower or faster depending on the DN's disk input/output performance, which differed slightly temporarily.



(a) Write throughput

(b) Average operations

(c) Decrease in average operations

Fig. 6. Synchronization overhead

In Figs 6(b) and (c), the synchronization burden due to the increase in the number of nodes in the proposed scheme is compared with the existing HDFS. We used NNloadGenerator, a benchmark tool of Hadoop that generates workloads for a set time period and measures the average number of operations per second. The number of files was set to 1,000, the number of threads to 1,000, and the file size to 384,000 in Fig. 6(b), from 256,000 to 768,000 in Fig. 6(c), respectively. The file size is a basis value when creating a file for performance measurements and is used to create an arbitrary size (i.e., 10 times) rather than the actual size of the file. Both the number of DNs and the replication factor were set to five. Additionally, the ratio of reading and writing was set to 95% and 5%, respectively.

Fig. 6(b) shows that the existing HDFS naive-NN yielded 522.9 ops/s, whereas the proposed scheme yielded the average of 448.8 ops/s, indicating a difference of 74.1 ops/s. As shown in Fig. 6(d), naive-NN, an existing HDFS, decreased the average processing performance per second significantly as the file size increased. However, in the proposed scheme, even if the file size increased, the average processing performance per second remained constant compared with naive-NN. When the file size was 760,000, the computational performances of naive-NN and the proposed scheme were 86.1 and 396.3 ops/s, respectively. In addition, the lower limit of the file size of naive-NN was 86.1 ops/s, whereas that of the 10 Proposed-NN was 343.6 ops/s. Naive-NN does not intervene with synchronization but, in our proposed scheme, ANN intervenes with synchronization. Thus, Naive-NN can perform faster than ours when the file size is small. But, when the file size is bigger, naive-NN can look like performance degrade because naive-NN should wait for DNs to complete the job.

V. Conclusion

In this study, we proposed a metadata replication scheme with synchronous opcodes writing for namenode multiplexing. As the node number of metadata grows, the synchronization overhead can be high. To reduce the overhead, we replicated byte-level write opcodes. We synchronized in-memory and on-disk metadata so that all of the replicas can process read requests immediately for read-after-write in our proposed scheme. We applied our proposed scheme on HDFS and evaluated. As a result, our method reduces by 50.95% in the average required number of NNs when the number of NNs for read-only operation is 100. As the number of NNs is increased from one to seven, we also verified that the average write operation time for each file size (e.g., 128MB to 4096MB) was 6.83% higher than the existing HDFS with the given condition.

***Abstract*— In the modern era, safety is one of the most concerning issues for people because of the increased rate of harassment, rape, hijacking, etc. For the sake of people's security, a device has been proposed in this paper. This device will help to prevent rape, hijacking, unwanted harassment, etc. The proposed system can be applied to make it smarter, safer, and automated. Flex Force pressure sensor, VR3 module will be used for activating the device automatically as well as artificial intelligence (AI) will be used to assume the attacker's wary behavior. In an unexpected situation, when the device will get activate it will send the location of that place to a pre-defined number through a message. This system will ensure the well-being of people of all gender and ages.**

I. Introduction

Around the world today, human safety has become a vital issue. Not only women, every human being is affected by physical/sexual abuse, hijacking, harassment, and a fear of violence. An organization working to protect women's rights known as Bangladesh Mahila Parishad revealed a statistic that approximately 2083 women and girl child were subjected to sexual violence from the first of 2019 to June 30, 2019, and out of that 731 were raped. From 2014 through 2018, a total of 5,274 women, and children faced different kinds of violence including 3,980 rapes [1]. It is assessed that around 35% of women everywhere in the world have encountered some sort of lewd behavior in the course of their life. Ladies who are between 18 -24 years of age are multiple times bound to be casualties of assault or rape. In Bangladesh assault rate 9.82% out of 11682 incidents [2]. Not only sexual assault or rape human trafficking, but kidnapping also has become a burden for people. Sometimes police can retrieve people from kidnappers sometimes they couldn't. As per figures detailed by the "Daily Star" newspaper, between February 2012 and June 2018, 4,152 instances of kidnappings because of human trafficking were recorded, yet just 25 individuals were indicted [3]. So, considering the safety of the people a model designed which will help to make sure the safety of people. These types of safety devices will lessen the crime rate. Moreover, it helps people to stay safe when needed and enables them to live more independently with greater confidence, peace of mind, and dignity when they are outside of the house .

II. Literature Review

Human security is one of the most significant issues as crime increments. There is some wellbeing device to lessen the crime. Here, some related distributed works are going to be discussed.

A security solution for women [4] developed by authors consists of a smart band and smartphone and both are connected with Bluetooth Low Energy (BLE). The Smart band consists of three sensors which are a temperature sensor, motion sensor, and pulse rate sensor. The app is installed in a smart phone to monitor the data directed by the smart band and to send the location of the victim using the GPS and the GSM system of smart phone. A smart watch [5] is designed by authors through which a woman can seek help by pressing the button of the smart watch. The smart watch module consists of three sub-module which are the Sensing, Control, and Transmission module. These three modules together help to activate the device and send the location of the victim, also the device is capable of giving severe shock to the culprit and generating an alarm. The paper [6] clarifies a gadget, which will work in three different ways, for example, voice, switch, and shock. At the point when the gadget got triggered by the sensor, it will begin working and then it will send location to police and message to the enlisted number through a GSM module and the same will be accomplished by a voice order. In ref. [7] the authors proposed a design which is implemented in the form of a smart ring, smart band, smart belt, etc. for ladies' wellbeing based on the Internet of Things (IoT). It is comprised of Raspberry Pi Zero, Raspberry Pi camera, buzzer, and button to activate the services. It is actuated by the victim by tapping the button. After clicking, the current location via GPS of the victim's and the camera catches the picture of the culprit which is then sent to police or pre-defined contact numbers using the victim's cell phone. This technique further uses the Uniform Resource Locator (URL) of the image and alert message to inform the family and police personnel. In the work [8] authors proposed a design which is a combination of several types of equipment such as IoT module, GPS & GSM, Neuro stimulator, Vibration sensor, Buzzer. In the device, GPS & GSM is used to detect & send the location of the

978-1-6654-4067-7/21/$31.00 ©2021 IEEEIEEE

victim, and the buzzer is used to generate an alarm to aware nearby people, whereas the IoT module is used to track the location continuously and update it on the webpage. For own safety using a Neuro Stimulator victim would be able to give a shock to the attacker. Moreover, a Vibration sensor is used to send the victim's last location if somehow the device gets damaged. In ref. [9] the authors proposed a design capable of self-defense, recording evidence, and tracing the location of a victim. In a critical situation, when the button is pressed nerve stimulator and buzzer is activated for self-defense and the camera is activated for recording evidence simultaneously also victim can send the current location of the victim and contact with a pre-define number through an Application. A wearable device [10] for women's safety and security designed by authors is comprised of an Arduino controller, temperature LM35 sensor, flex sensor, pulse rate sensor, GSM, and GPS. All those sensors help to activate the device. The hidden camera was installed in the victim's dress, when the device gets activated, the camera transmits the live scenario to the registered contacts so that they can be able to see what's happening there. And in the meantime, it will track and send the location of the victim to registered phone number using the GPS and GSM module. The principal objective of the work [11] is to make a wearable IOT gadget for the security and protection of human. This is executed by the measurement of physiological signs in simultaneousness with body motions. The signs are dissected and the internal heat level is estimated by galvanic skin obstruction. This work manages internal heat levels and stresses and skin obstruction and the connection between them. The gadget investigates skin opposition and internal heat level to break down the circumstance of the individual. A lot of research has been done and also running in the improvement of a human security system to decrease our social issues. Though all the device is made for human safety the majority of them are not perfect for human safety. Hence, a human safety system is proposed where some extra features are added to bring the perfection of the safety device.

III. Proposed Model And Simulation

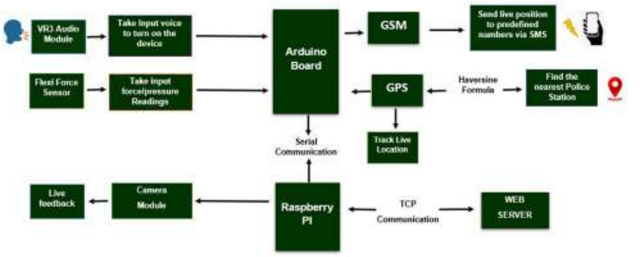

Fig.1. Block diagram of the design.

This paper is based on both Arduino and raspberry-pi. For the real-time recognition and detection process the YOLOv3 algorithm is used hence, raspberry-pi is used as microprocessor. For VR3, FlexiForce pressure sensor, GPS, GSM, Arduino is used as microcontroller. And to connect Arduino and Raspberry pi serial communication is used between them.

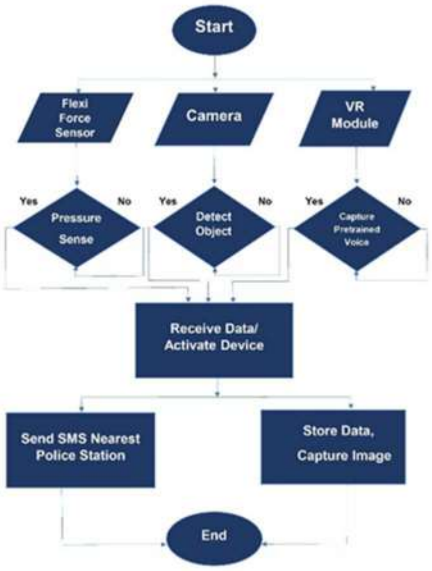

Fig.2. Flow chart of the design.

The device can be activated through the FlexiForce pressure sensor or VR3 module or from camera input. If victims face any critical situation, the device can be activated by saying pre-defined words using the VR3 module. Moreover, if somehow the FlexiForce pressure sensor get unexpected pressure then the device will also be activated. A camera is used to record real-time image and if the image match with pre-trained data set then also the device will be activated. So, when the device will activate, in the meantime it will send the location of the victim to the nearest police station and family members with the help of GPS & GSM.

Simulation of GSM and GPS Module:

Fig.3 shows the connection of both GPS and GSM together. GPS is used for tracing the victim's exact location. When the device will get activate the GPS will track that location. GSM is used for sending the location of victims through SMS to a pre-defined number.

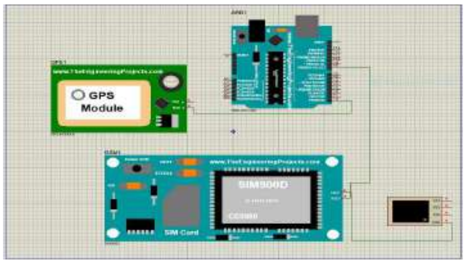

Fig.3. Combined simulation of GSM and GPS

```

Fig.4. Coordinates of GPS

Simulation of FlexiForce Pressure sensor:

The simulation of the FlexiForce Pressure sensor is shown in fig.5. This sensor ranges from 0 to 25lbs of pressure. When the sensor will sense pressure more than the threshold value the sensor will be turned on. Where the threshold value has been set to 0.4lb (around 200gram).

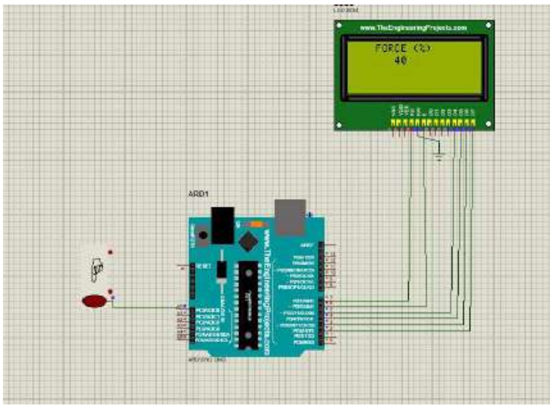

Fig.5. Simulation of Flexi Force pressure sensor.

Simulation of Object Detection:

The YOLOv3 algorithm is used in object detection using the TensorFlow framework. Harmful weapons such as Handguns, knives, and weapons are trained in Google Colab which is shown in fig 6. Around 2400 images were trained with 300 epochs.

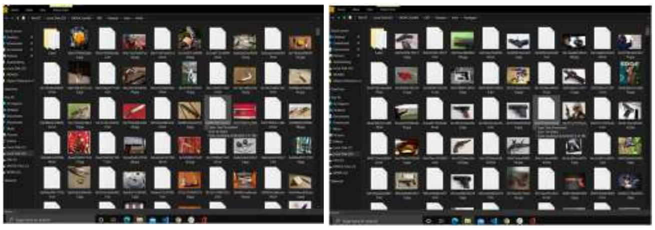

Fig.6. Trained Images of weapons and handguns

IV. Implementation Of The Design

Implementation of the design means the execution of design plans applying compatible processes to reach the utmost goal. It brings an idea to a real-life prototype. The device is made of several types of components such as Voice Recognition Module, Flexi Force pressure sensor, GPS, and GSM where Arduino is used as a microcontroller. The YOLOv3 algorithm is used for detecting the abnormal behavior where Raspberry Pi is used as a main processor. The device can be activated through VR3 module or FlexiForce pressure sensor or by analyzing dubious behavior from camera input.

A. VR3 Module

In this module, any sound could be trained as a command and users need to train the module first before let it recognizing any voice command. From fig.7, a mic is shown that is used to capture the voice and the voice process in the module. If the captured voice match with the pre-trained voice then the device will be activated. Several test has been carried out to check the accuracy of voice command from different distance. It has been found that the module worked accurately when the sound source is within 0-3 meter from VR3 module.

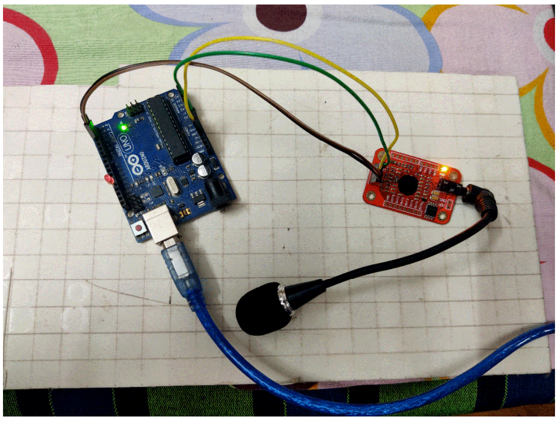

Fig.7. Voice Recognition Module

B. FlexiForce pressure sensor

The FlexiForce Pressure sensor acts as a force-sensing resistor. When there is no force in the sensor then its resistance is very high. When a force is applied to the sensor, the resistance proportionally decreases. If the sensor senses force more than threshold value which has been set to 0.4lb (around 200gram), it will send a signal to Arduino to activate the device.

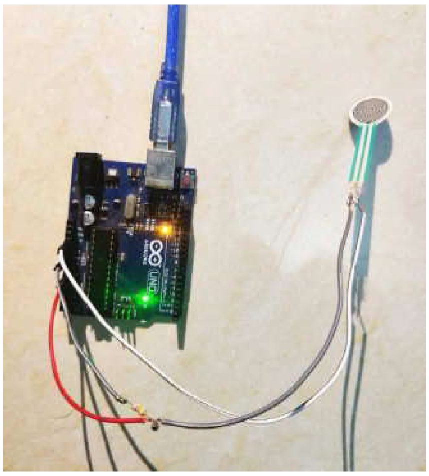

Fig.8. FlexiForce Pressure sensor

C. GPS

It is used for tracing the victim's exact location. A buck converter is used to convert the voltage into 5 voltage. An antenna is added for capturing the signal accurately. Here, "Haversine formula" is used to calculate the shortest distance between two points on a sphere using their latitudes and longitudes measured along the surface. This will find the nearest police station, additionally tracks live location.

Haversine formula:

$$a = \sin^2(\Delta\varphi/2) + \cos\varphi 1 \cdot \cos\varphi 2 \cdot \sin^2(\Delta\lambda/2)$$
$$c = 2 \cdot \operatorname{atan2}(\sqrt{a}, \sqrt{(1-a)})$$
$$d = R \cdot c$$

Where, φ is latitude, λ is longitude, R is earth's radius (mean radius = 6,371km);

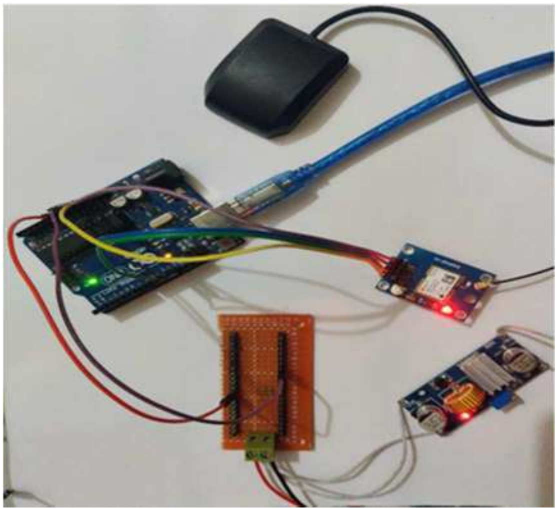

Fig.9. GPS Module

D. GSM

When the device is activated by getting the emergency signal, it sends the location information via SMS to predefined relatives or friend's phone numbers and nearest police station.

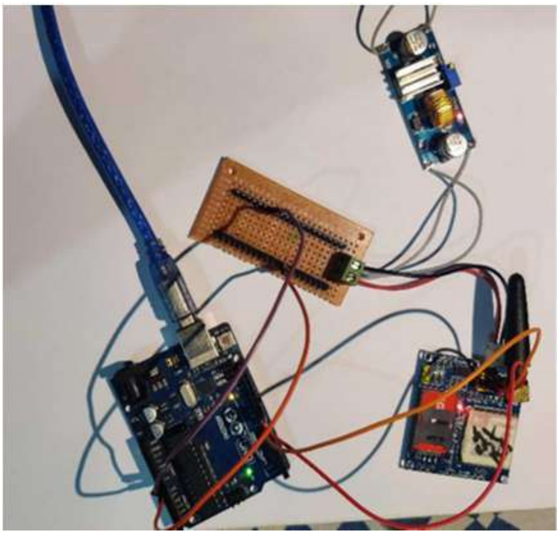

Fig.10. GSM Module

E. Object detection

The camera shown in fig.11 is used for the real-time recognition process. If the camera detects any weapons it will send a signal to the Raspberry pi then the device will be activated.

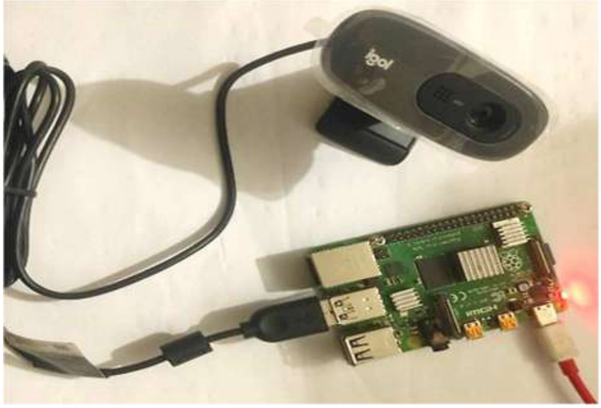

Fig11.Object detection system

F. Implementation of the complete system

A wearable multi-sensory device for human safety is shown in fig.12, where the device can be activated using either Flexi-force pressure sensor or VR3 module or by detecting suspicious behavior of the attacker. As soon as the device will be activated it will send the location of the victim to the predefined number, as well as it will capture the image of the attacker to find out the attacker later.

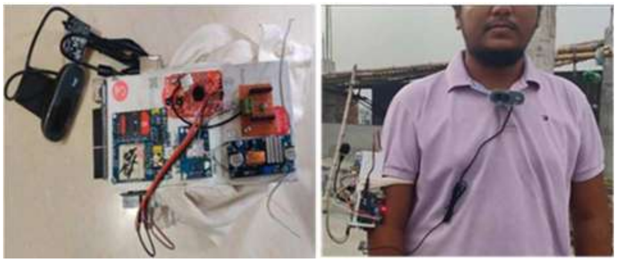

Fig.12. Implementation of Wearable multi-sensory device for human safety.

V. Result And Analysis

Before the implementation of the device, simulation of the component was done. In case of the VR3 module and FlexiForce pressure sensor, the result was quite perfect but for weapon detection through AI, the result wasn't 100% perfect because enough images were not trained. Moreover, sending the victim's location to the predefined number through GPS & GSM was done successfully.

A. VR3 Module

At first, the module is trained with a specific voice command as shown in fig.13 then with that word the VR3 module is checked whether the module worked or not.

Fig.13.Taking Voice command of VR3 module.

As shown in fig.14 when the Module got the voice command same as the trained one then the device got activated which is understood by the red LED cause when the module isn't activated the LED is off but when the device gets activated the LED is on.

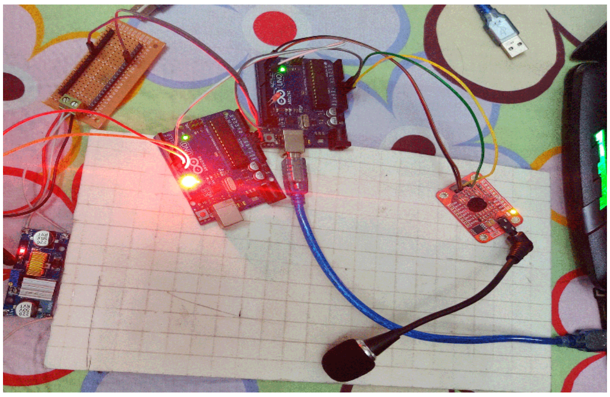

Fig.14. Result of Voice Recognition Module.

B. *Flexi Force Pressure Sensor*

The working of the FlexiForce pressure sensor depends on the pressure sensing on the sensor. From fig. 15, it is shown that pressure is 0 that means it doesn't sense any pressure. Which means device isn't activated.

Fig.18. Vatara police station by utilizing GPS module

From fig.18, the GPS module is initiated and it is showing the Vatara police station. That means when the device got activated at that moment the victim was near Vatara Thana. And Vatara Police station will get a message of the victim's location so that they can easily find out the victims and the attacker from that location.

D. *GSM*

When the system will activate it will send the victim's location to a pre-defined number through the GSM module. Fig.19 shows that, a message including the location of a place received by a person.

E. *Result of object detection method*

From fig.20 shows that a person showing different kinds of weapons and the system detects the weapon along with the name of the weapon. As soon as it detects a weapon it will send a command and the device will be activated. For the detection process thousands of weapons images such as Hand Gun, Knife was trained.

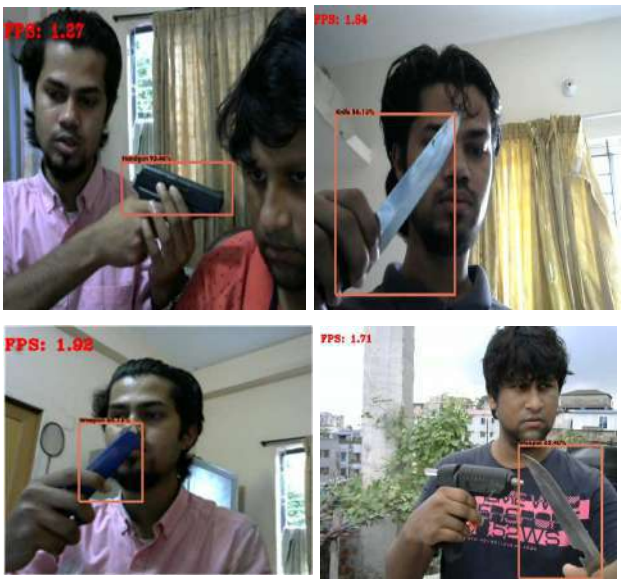

Fig.20. Weapon detection and recognition

At the moment of system activation, it will capture the image of the attacker. Here, fig.21 shows the captured image of the attacker at the time of device activation which is stored in the webserver.

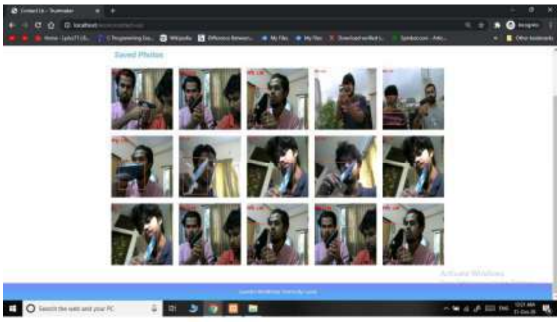

Fig.21. Stored image in Webserver

Fig.22 shows different confidence values in several detection periods. For handgun detection event the frame's confidence value is achieved more than 50%.

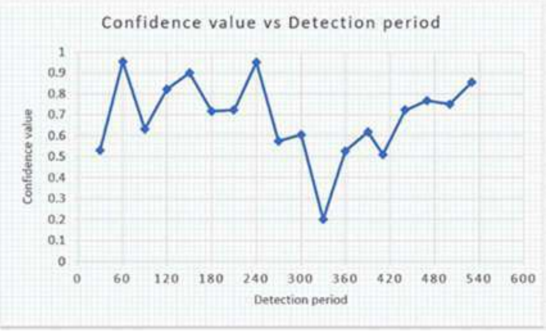

Fig.22: Values of Confidence ratio over total detection period

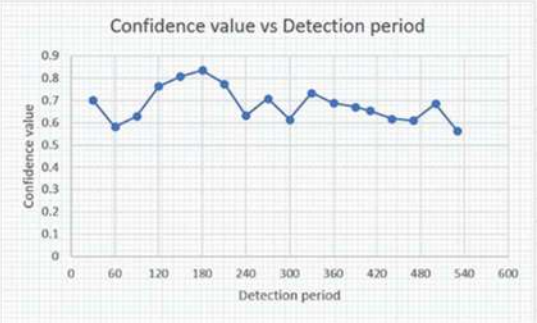

Fig.23: Values of Confidence ratio over total detection period

Fig.24. shows loss vs. epoch graph. In the event of weapon detection highest loss at epoch 10 is achieved 0.53. When the frames are ended at 300 epochs the loss came near 0.41.

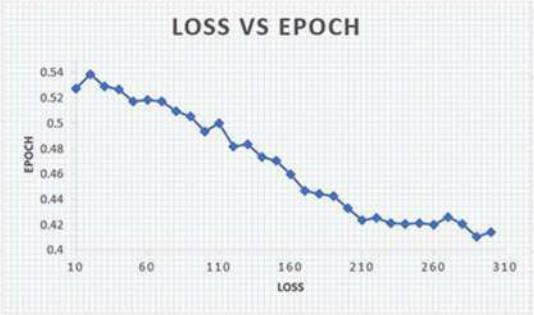

Fig.24: Loss Vs. epoch ratio for weapon detection event

VI. Conclution And Future Work

Statistics say that rape, kidnapping, hijacking, harassment, molesting, etc. is increasing day by day but very little progress has been made to find a noteworthy solution to the problem. Hence, a prototype is designed to make people safer in such situation and the purposes of the design have been achieved. Because using this smart device people can secure them, protect them, can take help in emergencies. Moreover, this device will capture the photo of the attacker which will help the authority to find the attacker easily. There is some scope for further improvement of this device. In the future, a 360-degree viewing camera can be used instead of a one-sided camera so that it can analyze all sides of the surrounding. If a huge dataset of the weapon can be trained then the efficiency of the weapon detection will be increased. Moreover, in future besides weapons, the suspicious behavior of a person can be analyzed to detect the culprit.

`MiniCon`: Automatic Enforcement of a Minimal Capability Set for Security-Enhanced Containers

Haney Kang, Jinwoo Kim, and Seungwon Shin
Department of Electrical Engineering
Korea Advanced Institute of Science and Technology (KAIST)
Yuseong, Daejeon, South Korea
{haney1357, jinwoo.kim, claude}@kaist.ac.kr

***Abstract*—Nowadays, containers have been widely adopted not only for clouds but also for individual users. On the one hand, containers provide much more light-weight virtualized infrastructure, but on the other hand, it is unavoidable to handle security issues since the isolation of containers is relatively weak, compared to the legacy VMs. Under the container architecture, adversaries are able to exploit kernel vulnerabilities to escalate privilege to gain root privilege, and leak system, privacy critical information. Although previous solutions provide strong security protection, unfortunately, none of them do provide a way to apply policies. Therefore, in this paper, we present an eBPF-based capability enforcement system, `MiniCon`, that automatically generates and enforces a minimal capability set by using Seccomp Filter. It monitors capability requests from containers, merges those requests to create a minimal capability set, and enforces capability policies through Seccomp Filter.**

***Index Terms*—Cloud, Virtualization, Capability, Container**

I. Introduction

Recently, cloud has been emerging technology because of its flexibility and ease of management. Service providers (or tenants) are now shifting their service environment from their local servers to cloud to benefit by flexibility and management of cloud. Thanks to the on-demand resource allocation policy of the cloud, service providers now can request exact amount of hardware resources they required, and also they are able to request reallocation of resources in any time they need. Moreover, hardware resources are already physically installed at data centers, the only thing service providers have to do is just to follow simple configuration steps so as to set up their environment. Therefore, service providers can effectively reduce huge amount of cost for managing and purchasing resources.

However, to allocate resources to different users, resources should be properly isolated as like they are in separate hardware. This is important because it may cause security issues if users are available to access others tenants' resources. To address this issue, virtualization techniques have been adopted to isolate resources.

Virtualization can be implemented by two different architecture. Virtual Machine (VM) is the traditional way to virtualize entire software stack including kernel, which has been employed as the most popular approach over the last decade. Under the VM environment, each user has their individual kernel, and their applications are executed on top of the isolated kernel stack. Hypervisor, a middle layer for virtualization which locates under a VM kernel layer, restricts unauthorized actions such as resource access from other VMs, and it is responsible for orchestrating resource allocation among VMs. With VM, resources can be strongly isolated because hypervisor fundamentally limits resource view under kernel. However, performance degradation cannot be ignored due to the duplicated kernels.

To address the performance issues of VM, containers have been proposed. In contrast to VM, each container shares the kernel, so the user space is the only one isolated among container instances. This greatly reduces overhead for kernel-related operations, such as system calls. Due to its performance advantages, many IT vendors adopt container as a virtualization for their cloud [1]–[4]. Despite those benefits, some critical security issues inhere within containers. Unlike VMs, containers share a kernel stack, which is probably vulnerable, and can be a penetration channel to attacks. For example, adversaries are able to invoke system calls to trigger kernel vulnerabilities which affects not only host but also other containers.

Indeed, many vulnerabilities that stem from the (insecure) container architecture have been disclosed: CVE-2016-0728 showed that adversaries can cause memory leak by abusing system call with designed arguments [5]. CVE-2016-5195 showed that adversaries can also intentionally bring about race condition by simultaneously invoke `write` system call [6]. Moreover, privilege escalation can be done by `waitid` system call [7]. Besides, globally accessible information have to also be concerned. Luo et al. [8] proposed a covert channel attack using global information which is not limited by Linux security functions, total memory usage, and kernel logs. ContainerLeaks [9], likewise, showed system-wide host information can be leaked by using globally accessible files. Meanwhile, internal attacks from a compromised container to other benign containers have been reported. For instance, PWN Docker Redis Attack compromise vulnerable server which accept Docker API and it compromise other containers in same network [10]. Therefore, despite of its performance efficiency, it is important to handle security issues on containers.

978-1-6654-4067-7/21/$31.00 © 2021 IEEE

For this, several methods were recently introduced to address the security concerns about container. SCONE [11] utilizes Intel SGX to secure information inside of container. It can securely prevent information leakage from outside even from host, but it contains significant performance issue. SPEAKER [12] separates running phase of container to minimize available capability by using dynamic analysis. Unfortunately, it does not take account of the limitation of dynamic analysis which cannot cover entire logic of container. Cimplifier [13], however, choose debloating method which separate single large container to a number of container. Although separating container reduces attack surface such as vulnerability of container, these containers still threatened by vulnerability. Security Namespace [14] suggests to use Linux Security Module (LSM) with fine-grained policy. Most of container products, such as Docker [15] and Kubernetes [16] are compatible with LSM, it does not automatically provide policy guideline. Confine [17] reduces system call using static analysis. By using static analysis, this work can produce policy which covers a entire set of system calls in applications. However, some system calls might be never invoked while the static analysis can consider it to be called. In case of unoptimized application, Confine might provide a super set of system calls. On the other hand, LSMs such as SELinux, AppArmor, Seccomp [18]–[20] are used to apply security policy to containers, still they do not provide ideal policies to prevent containers from kernel vulnerabilities.

To tackle these challenges, in this paper, we propose a security enforcement framework, `MiniCon`, that confines minimal container capabilities for building a secure container environment. To find out minimal capability set of given container, we first implement eBPF [21] capability probe which collects set of capabilities required by containers. We then build an environment generator that creates realistic environment of running container. Finally, we create Seccomp [20] policy based on a minimal capability set to enforce it.

II. Background

A. Container

To satisfy requirements of cloud systems, containers aim to isolate system resources such as CPU usage, and network interfaces from other users. Not only for physical hardware resources, containers enable to isolate logical resources such as UID, PID, and even file systems. Isolating UID, for example, users in different containers do not have visibility to each others. By doing this, container environments abstract user's view such that a user is the only one who uses this machine.

Containers provide isolation of these resources by implementing a thin layer which uses Linux *namespaces* and *cgroups*. Thin layer resides in host user space as a daemon process and they create, initialize, stop, and delete according to administrators command. Once administrators create and initiate container, Linux namespaces inside of thin layer restrict a view of file system including devices and system file to isolate logical resources. Simultaneously, it applies available capacity of hardware resource by applying cgroups policy.

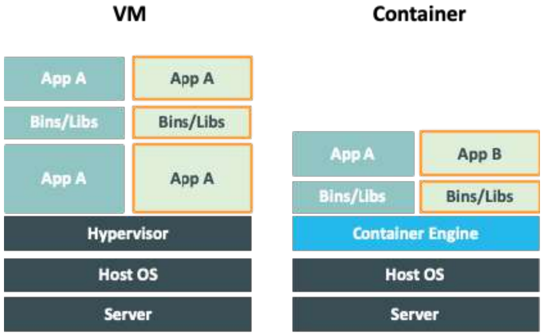

Fig. 1. The conceptual architecture of containers compared to VMs.

Therefore, containers are basically user spaces isolated by Linux namespaces which is allowed to use limited amount of hardware resource enforced by cgroups Policy. Fig. 1 shows conceptual architecture of container by comparing it to Virtual Machine.

B. Linux Capabilities

Linux kernel supports security sensitive, but compulsory operations such as system calls. Although these operations should be able to be invoked by users, triggering them must be controlled very strictly. For this purpose, Linux kernel introduces capabilities which define fine granularity as a key of root permissions. For example, containers which executed without CAP_CHOWN, are not able to change the UIDs and GIDs of files. There are 38 capabilities Linux kernel 4.18, and 15 are set in containers by default as described in Table I [22].

C. Motivating Examples

As a default, containers only allowed 15 capabilities, but adversaries are still able to abuse system calls to accomplish their goal. For example, CVE-2016-0728 [5] is a vulnerability which can cause memory leakage. In this example, adversaries invoke `keyctl` system call which only requires CAP_SETUID and CAP_SYS_ADMIN. From the result of the memory leakage vulnerability, adversaries can escalate privileges and achieve root permission even they have never been granted. Another example about CVE-2016-5195 [6] is a vulnerability of race condition. In the case that adversaries already have privilege to CAP_SYS_ADMIN and CAP_SYS_PTRACE, they can routinely invoke `madvise` or `ptrace` to provoke race condition. Then adversaries can write their arbitrary code on the memory where a race condition occurred even if memory area is read-only.

III. MiniCon Design

A. Overview

As mentioned in Section II-C, assigning capabilities without any verification may critically affect security of container, even though these capabilities are granted by default. Thus, it is important to find out unused capabilities and drop these capabilities. In this paper, we suggest minimal capability enforcement by using eBPF [21] and Seccomp [20] to mitigate chance

TABLE I
CAPABILITIES SUPPORTED BY LINUX KERNEL 4.18

Cap. No.	Capability	Set by default
0	CAP_CHOWN	Y

37	CAP_AUDIT_READ	

of exploit by eliminating unnecessary capabilities. Fig. 2 shows the overall architecture of the work. The architecture mainly categorized to three steps: presenting realistic container execution environment, identifying capabilities required by container, applying security policy.

B. Presenting Container Execution Environment

Container can be executed by various command, configuration network environments. Various environments trigger container to be executed with different program logic path. Network environment, for example, server-client model application continuously invokes `epoll` and `wait` system calls in idle state. When it receives network packets from client, an application moves its state to handler to perform function related to incoming request. This is obviously essential, otherwise policies produced by system may disable functionality of application. To cover enough program logic path, we created execution environments by three methods.

Via Container Execution Command. Container execution commands such as `docker run` provide various arguments. Although these arguments supports users to build their unique and optimized environment, most of them are rarely used. The main reason of it is that these arguments are constructed for user convenience which do not largely affect environment. From this reason, we found that most of execution command guided from container image manual pages only contain a few frequently used options. Therefore, to find out these options out of arguments, we crawled execution command pattern from image hub of container vendor. As a result, we found that networking, volume mounting, attaching and detaching standard in/output, allocating TTY were mostly used option.

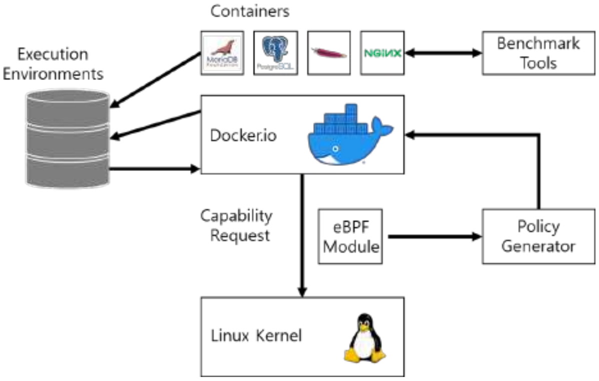

Fig. 2. `MiniCon` architecture overview

Via Application Execution Command. Applications reside in containers takes various arguments same as execution of container. We collect command manual by providing option `--help` to application execution command and formalize it to apply proper arguments to options. For instance, it is possible to describe existence of options by formalizing it to boolean value. Some options takes only integer or string or even a few defined string as a value of option, otherwise it returns error. By formalizing these arguments, we were able to run same containerized application with various environment. This can be similarly applied configuration, since configuration of applications are mostly given by dictionary format such as json.

Via Benchmark Tools. To generate realistic network interaction of container, we utilize benchmark tools for known applications. For example, we use `ab`, an apache benchmark tool, for `httpd` container to create network packets. Since benchmark tools are developed to verify functionality of target application, benchmark tools are appropriate to generate realistic network interaction.

C. Capability Probing

From the number of cases to execute container, we extract capability requirements for each cases and intersect them. This is because we do not know exact argument and configuration that user run, thus we have to produce a capability set which contains every capability possibly required by containers. To identify capability requirements, extended berkeley packet filter (eBPF) is used for fast and reliable monitoring. Our implementation was done by BPF Compiler Collection

(BCC) [23] which is toolkit for creating kernel tracing while using of eBPF. Since capability checking is done by kernel function `int cap_capable(...)`, we implement probing function for `int cap_capable(...)` to identify which process request and what capability was requested. By referring argument `int cap`, we were able to get capability number. For the final step, we filter out unrelated logs such as comparing process tree.

D. Policy Enforcer

From the minimal capability set given by Section III-C, Seccomp [20] policies were created. Our policy generation code separates capabilities to required set which is minimal capability set and unnecessary set, then it convert to Seccomp policy format. We apply policy by using option such as *–security-opt="seccomp=path/to/file"*. There can be randomness issue which cause failure of collecting few required capabilities, it is important to keep checking whether containers fail. If there is no failure regarding operation permission (`EPERM`) error, we finally conclude that `MiniCon` finds out a minimal capability set to run containers. Otherwise, we add capabilities which causes `EPERM` error and repeat capability checking procedure.

IV. Preliminary Evaluation

For the sake of showing our analysis result, we used 15 container images from Docker Hub [24].

Generally Required Capabilities: We classified capabilities into three categories by their functionality. Table II shows the capabilities that were used in namespace category are used to create isolated namespaces by host. When isolating namespaces, CAP_SETUID and CAP_SETGID were requested.

Another capability which always required for most containers was the file access. This is because applications in containers generally access shared files from a host. For example, some applications require configuration files, and they are mostly located in shared mounted volumes. In this case, containers are required to have CAP_FOWNER to read file inside of container.

On the other hand, we found that networking related capabilities are also generally used by containers. The reason is that majority of the applications are aimed to developed to act as a server. To do so, they have to be assigned well known port which is port less than 1024. In this case, containers are required to have CAP_NET_BIND_SERVICE. Moreover, these containerized applications have to send non-TCP/UDP packets such as ARP and ICMP, and they are required to have CAP_NET_RAW capability.

Required Linux Capabilities Fig. 3 shows number of required capabilities for each container images. In this result, we are able to find most of containers are likely to use similar capabilities, and they rarely use other capabilities given by default.

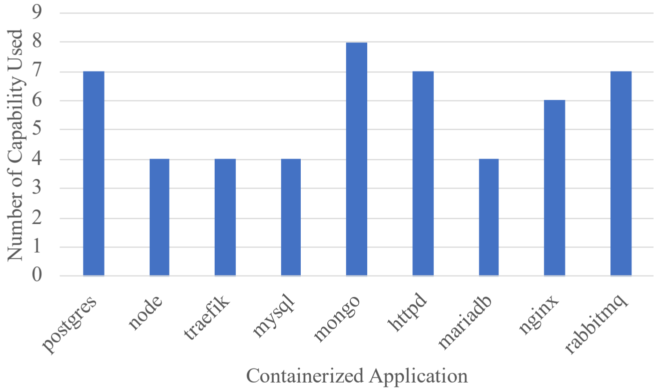

Fig. 3. Number of Linux Capability Usage

V. Conclusion and Future work

Containers have been adopted not only to a number of major cloud vendors, but also for developers. Design of containers dramatically increases performance compared to virtual machines, still security issues remain unsolved. Adversaries are able to abuse system calls to bypass isolation, and may grant root privilege or leak critical information. To handle it, we introduce eBPF base capability enforcement system by using Seccomp Filter. With this system, operators are able to give a minimal capability set which prevents unintentional operation of containers, even adversaries who tries to exploit host and other containers by abusing unnecessary capabilities.

Our preliminary result shows that majority of containers does not required entire default set of capabilities. In other words, default capabilities provides excessive privileges which may chance of exploit. With our work, it is possible to identify a proper capability set to be assigned for containers.

Our first target of future work is increasing coverage. Although we made an effort to cover as many case as we can, still unfounded capability can be remained. To handle this issue, we will extend our work by applying static analysis.

Abstract—**Breast cancer is one of the main reasons that lead to mortality, particularly in females. One of the factors that help in breast cancer detection is the existence of breast phantom with high similarity to the real breast associated with the utilized modality. Currently, the existing breast phantoms are limited in terms of anatomy and breast ionization reactions properties. Thus, the aim of this paper is to design a heterogenous patient-based breast phantom that mimics the real breast tissues properties concerning ionizing imaging modalities. The phantom includes skin tissue, fibroglandular tissue, adipose tissue, pectoral muscles, and insertion of malignant lesion. The process started with real breast MR images from King Fahd Specialist Hospital with BI-RADS I tissue segmentation for molds creation. 3D Slicer software was used for segmentation, and the Meshmixer was used to refine the segmented tissue. The molds are printed using PRUSA 3D printers. The tissue-mimicking materials were tailored in terms of their elemental composition weight fractions and three ionization properties. These are the mass attenuation coefficient (MAC), electron density (n_e) and effective atomic number (Z_{eff}). These characteristics were compared with the corresponding properties of the real breast ICRU reported elemental compositions. The achieved results showed an excellent agreement between the MAC of the tissue-mimicking materials and the ICRU-based breast tissues. The percentage of error in n_e and Z_{eff} amounts to only 2.93% and 5.76%, respectively. That means the phantom can optimize the function of breast ionizing imaging modalities and lead to higher breast cancer detection sensitivity.**

Keywords—breast, phantom, ionization, electron density, mass attenuation coefficient, effective atomic number, tissue-mimicking material.

I. Introduction

Breast cancer is the second most occurring cancer in females and considered as the second reason of mortality [1]. Based on the national breast cancer foundation, an estimation of 276 thousands new cases were diagnosed with breast cancer in 2020 and more than 42 thousands women are expected to die in the United States (US) [2]. However, early-stage cancer detection would increase treatment possibilities and the survival rate [3]. Breast phantoms are significant devices that help in early breast cancer detection. They must mimic the properties of the breast tissues with tissue-equivalent materials having similar response of the breast when it is screened by each imaging modality. Anthropomorphic breast phantoms are utilized to produce images that simulate aspects of clinical breast screening. They are beneficial in characterization and optimization of breast imaging modalities. In the development of imaging screening technologies, technical assessment for modality optimization through phantoms is essential before the modality can be utilized for clinical use. Nowadays, the existing medical imaging phantoms have a lot of limitations including unrealistic uniform background structure that does not mimic real organs and tissues. They are mostly designed with homogenous solutions for the whole aimed organ with no simulation of tumors, masses, or other lesions.

Phantoms are devices that are being used in the field of medical imaging physics and health science [4]. They are considered as artificial models that represent the human body to evaluate, examine and tune the performance of several imaging modalities. Phantoms are designed to help in assessing the optimal radiation that is subjected to the patient especially in new emerging imaging techniques and for quality assurance (QA) purposes. Such advanced phantoms that are patient-based developed can further benefit in hands-on operator training and image-guided interventional procedures. Based on the purpose that the phantom is developed for, the composition and the design process would be established.

A. Mammography Breast Phantoms

In 2015, a group at Duke University developed a breast phantom by matching virtual breast phantoms for mammography projections. The virtual phantoms were made into physical phantoms using additive manufacturing multi-material 3D printing. One design with printed with single additive materials then filled with oil. Second design with double additive printed materials for whole breast. The first phantom design offer a better result in term of breast contrast compared to the first design, but the second presented an undesirable air bubbles [5].

Another physical 3D anthropomorphic breast phantom was developed at the University of Pennsylvania for image quality assessment of 2D and 3D breast x-ray imaging systems. The fabricated phantom consists of 45% dense tissue and

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

already 5cm deformed in thickness for mammography scan. Digital mammographic images with W/Rh at 30 kVp and 104 mAs showed a less than 1% coefficient of variation of the relative attenuation between the two simulated tissues with acceptable appearance with presence of air bubbles [6].

Moreover, another method for fabricating breast phantoms was developed by a research group at the Committee for the defense of human right (CDHR). The aim was to model breast x-ray attenuation properties. The phantom was designed only to match full-field digital mammography (FFDM) and digital breast tomosynthesis (DBT). After projections at 35kVp it was found that both glandular and adipose tissues were acceptable with limitation of masses and lesions insertion to the phantom [7].

B. Computed Tomography Breast Phantoms

A study was published with an aim to construct breast phantom made from polyethylene by segmenting the patient's breast image into adipose and fibro-glandular tissues. To mimic the different tissues, thermoplastic mold was placed as the outer layer of the skin, fibro-glandular tissue represents by filling the air gaps by water, while polyethylene and paraffin wax were used to mimic the adipose tissue. Moreover, calcium carbonate particles were used to represent the macrocalcification. The designed phantom model uncompressible breast with an ability to do measurements [8].

C. Multimodality Breast Phantoms

In 2016, a paper published with an aim to develop a multipurpose gel-based breast phantom consisting of a simulated tumor to function with ultrasound, CT, and MRI. The TMMs was ballistic gelatin powder and Metamusil^{TM} for breast background. Barium sulfate, copper sulfate, water and ballistic gelatin were used for the simulated tumor. The resulted Hounsfield units (HU) of the simulated breast background was 24 HU which was far from the reference value of –100 HU for adipose and 40 HU for fibro-glandular. On MRI, the tumor showed a signal-difference to noise ratio of 3.7. The results indicate a further development should be done [9].

In 2019, a study was conducted to design a 3D-printed breast phantom for multimodal imaging with TMMs based on a 3D printing. The developed phantom was based on polyvinyl chloride (PVC) including a structure of different lesions, adipose, and fibro-glandular tissues. CT and MRI were used to determine the tissue mimicking properties considering the HU and MRI relaxation times. The results showed that the temperature difference between the PVC softener mixture and the breast mold could present bubbles that affects the image quality and cannot be eliminated. Also, lack in heterogeneity present in the tissues reduces the similarity to the real breast tissues [10].

Recently in 2020, a group at Sapienza University published a phantom for multimodality use. The TMMs were based on different properties such as dielectric properties, acoustic properties, and attenuation coefficient. The phantom used TMMs to simulate the skin, fat tissue, glandular tissue, tumor, and muscle. The phantom resulted a good match between the reference and the physical measured values with ±10% for the majority of the TMMs. However, the phantom solid parts were compression irreversible because of the fat layer composition. Also, further investigation should be done in order to have more contrast between the tumor and surrounding tissues [11].

This paper aims to design and develop a heterogenous patient-based breast phantom that mimics the real breast tissues heterogeneous. The anatomy and tissues properties of the breast when screened with ionizing imaging modalities are considered. Three main tissue characteristics are investigated and analyzed to validate the performance of the proposed design. These are the mass attenuation coefficient, electron density and effective atomic number.

II. Materials and Methods

A. Patient data acquistion

Institutional Review Board (IRB) approval was obtained from King Fahd Specialist Hospital (KFSH) in Saudi Arabia, Dammam (RAD0319), in order to use patient data. A Digital Imaging and Communications in Medicine (DICOM) magnetic resonance imaging (MRI) breast images with dynamic contrast-enhancement is used. The criteria of patient data selection were built upon the BI-RADS which was established by American College of Radiology (ACR). The score of the chosen image was I (normal breast) with dense fibro-glandular tissues to be inserted with a malignant lesion.

B. Image segmentation and molds creation

For breast tissue segmentation, the acquired MR breast images were imported into segmentation software. This is to have a realistic separated geometry for the external shape, skin, fibro-glandular tissue and tumor. The patient DICOM images were imported into 3D slicer software with 128 slices for internal tissues segmentation to segment out the skin and fibro-glandular tissue from the surrounding adipose. The purpose was to ensure a complete elimination of all the surrounding structures. Each slice was segmented in different orientations to improve segmentation reliability using the threshold function, which was adjusted manually. Afterwards, the segmented fibro-glandular tissue was converted into 3D model and saved as Standard Triangle Language (STL) file for further processing. Negative and positive molds were created from the segmented skin layer to create a single flask for the skin and adipose tissue. Segmented fibro-glandular was modified to create a base for handling purposes. Segmented fibro-glandular was modified to create a base for handling purposes. Also, a tumor mold of 2 cm diameter was created. The molds of the external breast shape, skin, and fibro-glandular were printed using acrylonitrile butadiene styrene (ABS) plastic to have a high realistic distribution of the interior structure, specifically for the fibro-glandular mold [12].

C. Tissue-mimicking materials (TMMs)

The proposed components for the TMMs in Table 1 was based on choosing specific materials [11], [13]-[18] that have been modified and validated using the ionizing characteristic parameters. This is to provide realism to mimics the representation of the real breast tissues with an improved anthropomorphic nature as well as meeting the response of the breast ionization reactions. Deionized water and safflower were introduced to all TMMs to simulate the water and oil concentrations in the tissues, respectively. Additionally, Sodium chloride, Aluminum oxide and Potassium chloride were used as scattering particles when the tissue is introduced to the X-rays and to affect the attenuation with a linear dependence as a function of frequency.

TABLE 1: FORMULA FOR THE SKIN, ADIPOSE, FIBRO-GLANDULAR, CARCINOMA AND PECTORAL MUSCLES TISSUES.

Layer	Component	Weight (g)
Skin	NaCl	15
	Deionized water	620
	X-100 surfactant	30
	PVA	50
	Agar	5
	Benzalkonium chloride	4
	Sugar	300
Adipose Tissue	NaCl	2
	Deionized water	110
	X-100 surfactant	100
	Safflower oil	315
	Beeswax	400

	Sugar	220
	Deionized water	700
	Benzalkonium chloride	3.5
	KCl	1.9
Pectoral muscles Tissue	Agar	20
	Sugar	360
	Deionized water	900
	Benzalkonium chloride	4.14
	X-100 surfactant	20
	White egg	50
	Safflower oil	40

D. *Tissue-mimicking materials characterization*

The tissue-mimicking materials would be characterized for modalities utilize ionizing radiation such as computed tomography and mammography. The TMMs of the proposed phantoms are characterized analytically by using three important parameters which are mass attenuation coefficient, electron density (n_e) and effective atomic number (Z_{eff}). Mass attenuation coefficient describes how simply it can be penetrated by a beam of light, sound, particles, or other energy or matter [19]. While the electron density measures the electron probability of being exist in a unit volume of an element [20], and for the Z_{eff} it is an element atomic number in which photon interact similar to a given composite material. It would be found numerically by using National Institute of Standards and Technology (NIST) XCOM. The energies will be specified according to the range used in each imaging modality after having the weight fractions for each tissue compounds.

From the mass density (ρ_m) and atomic composition ($\frac{Z}{A}$), the electron density of a material can be calculated according to the formula:

$$n_e = \rho_m . N_A . \left(\frac{Z}{A}\right) \quad (1)$$

$$where: \ \frac{Z}{A} = \sum_i a_i . \left(\frac{Z_i}{Ai}\right) \quad (2)$$

N_A is Avogadro's number and a_i is the fraction by weight of the ith element of atomic number Z_i and atomic weight A_i ranging from 0 to 8 depending on the elemental composition.

Z_{eff} can be obtained from:

$$Z_{eff} = \Big(\sum_{\substack{all\ tissue \\ components\ (n)}} a_n Z_n^{2.94}\Big)^{\frac{1}{2.94}} \quad (3)$$

Where a_n represent the fractional contribution of each element to the total number of electrons in mixture.

Based on the International Commission on Radiation Units (ICRU), reference values elemental compositions weight fractions of the real tissues would be compared and validated with the above calculations.

III. RESULTS AND DISCUSSION

A. *Image segmentation*

For the patient DICOM images segmentation to extract the region of interest (ROI) through detection of boundaries, breast outer shape and fibro-glandular tissue was separated from other surrounding tissues using 3D Slicer software to have a realistic separated geometry for the external shape, skin and fibro-glandular tissue. The resulted 3D fibro-glandular volume model comparable to the axial and coronal images slices with high anatomical precision shown in Figure 1 from different perspectives. The segmented model presented a need for further smoothing and processing to be able for 3D printing without defects.

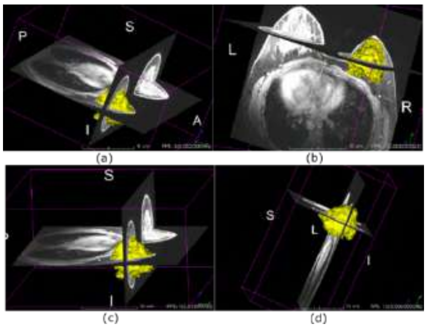

Figure 1: 3D segmented model comparable to the MRI image slices from different perspectives. 3D Slicer is used.

B. *3D mold fabrication*

Free-floating and deformities were removed, and model hollows were edited during this process. The skin was converted into a negative mold to represent the outer shape of the phantom. In this outer shape mold, a 3 mm thickness was added at the rounded corners to create the skin tissue thickness. The fibro-glandular STL file was edited to have an applicable adipose to fibro-glandular interface surface for printing. Figure 2 presents all processed molds.

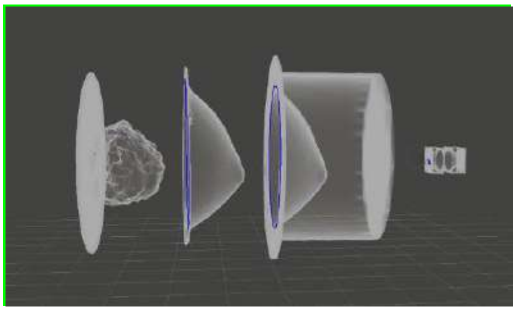

Figure 2: 3D phantom molds design.

The 3D models of the phantom were printed in Namthaja 3D printing manufacturing solutions, Saudi Arabia, Dammam. The printed external shape, skin, fibro-glandular, tumor molds are shown in Figure 3.

C. *TMMs characterization*

The weight fractions of the proposed TMMs elements were calculated for each breast tissue of skin, fibro-glandular, adipose, pectoral muscle, and malignant carcinoma. Table 2 presents the resulted weight fractions of TMMs comparable to the real breast tissue elemental compositions weight fractions found from ICRU reports. The values where close to the real especially when focusing on the main tissue elements which are C, H and O for all tissues. Table 3 was develop based on Equations (1) and (2) which present the specific tissue electron density and effective atomic number. Low errors were observed with maximum of 5.76% for fibroglandular Zeff and minimum of 0.00415% for pectoral muscle ne. That means the proposed materials and quantities can produce similar real breast tissue interactions when exposed to ionizing radiations with energies in the range 10-150 KeV.

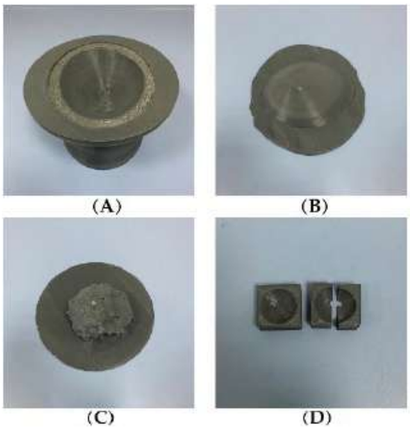

Figure 3: Breast phantom molds: (A) Outer skin, (B) skin, (C) fibro-glandular and (D) carcinoma mold.

Additionally, the mass attenuation coefficients in cm^2/g of the proposed phantom tissues were found and plotted against the real breast tissues mass attenuation coefficients in the energy range of 10 KeV to 150 KeV, as clinically used in mammography and CT machines.

Figures 4, 5, 6, 7 and 8 show the mass attenuation coefficient against the applied photonic energy for the skin, adipose tissue, fibroglandular tissue, malignant carcinoma, and pectoral muscles tissues, respectively for both real ICRU elemental compositions and the phantom calculated elemental compositions. All the introduced tissue-mimicking materials of the proposed phantom revealed a good agreement in all the energy range of energy with insignificant differences in the range of small applied photonic energy. The mass attenuation coefficient for the skin and adipose tissue real and calculated results showed a great overlapped graph for all points with high similarity.

IV. CONCLUSION

The purpose of this study was to develop a patient-based heterogenous breast phantom that mimics various breast tissues when screened using ionizing imaging modalities. The chosen phantom TMMs were validated using three main radiation characteristics which are the mass attenuation coefficient, electron density, and effective atomic number. The process of developing the phantom started with IRB that was requested and approved from KFSH, for data acquisition. Then it was followed by segmentation using 3D Slicer and refinement process using Solid work software. The designed molds are then printed using PRUSA 3D printers. For each tissue mimicking process, a combination of different materials with different weights were used. The weight fractions of the elements used in these materials are calculated numerically and compared with the real values from the ICRU reports. The mass attenuation coefficient, electron density and the effective atomic number for each TMMs are each the results showed a good agreement between them.

***Abstract*—Wicked problems are a specific class of complex problems that emerge from complex adaptive systems (CAS) and stakeholder disagreements on the definition and character of these problems and their possible resolution. Attempts at resolving wicked problems through integration and use of formal methods such as ontologies, Bayesian networks (BN), and complex systems dynamic (CSD) models have been attempted recently but wicked problems continue to defy resolution. This paper argues that this is the result of a lack of ontologically precise causal Bayesian models that adequately represent the hierarchical, dynamic, emergent characteristics and multiple perceptions of CAS and their emergent wicked problems. This paper's contribution is the incorporation of complexity systems theory concepts, namely: perspective, granularity and context, as explicit ontological constructs in a high precision ontological causal BN model, the Granular Contextual Perspectives (GCP) causal Bayesian Network model, using Hidden Markov Model (HMM) formalism to address this shortcoming. Using an illustrative example this conceptual paper shows that the (GCP) causal Bayesian Network model performs better than baseline Bayesian Network models at the visual representation, compact and retractable inference, and machine learning of CAS and their emergent wicked problems. The model is useful at supporting the exploration of possible effects of proposed alternative interventions or prototypical design strategies for resolving a given wicked problem.**

***Index Terms*—Hidden Markov Models, Causal Hierarchical Dynamic Bayesian Networks , Ontology engineering, Wicked problems, Complex Adaptive Systems, Design Science strategies**

I. Introduction

Wicked problems, which have been described as specific class of ill-defined complex problems that emerge from complex adaptive systems (CAS) and stakeholder disagreements on the definition and character of these problems have, and continue to be difficult to resolve [1]–[4].

Wicked problems include ill-defined problems like pandemics, climate change effects, traffic jams, rapidly changing business environments, and financial market crashes. While these problems have not always been recognised or defined explicitly as wicked problems, attempts at resolving this class of complex problems has been receiving a lot of attention recently [2], [3], [5]–[7].

Resolving wicked problems has proved to be elusive primarily because of their complex and dynamic nature, the difficulty faced in defining them and disagreements on how to resolve them, especially where multiple stakeholders with divergent perspectives of a given problem are involved. The lack of recognition of these complex problems as "wicked", is in itself part of the problem as inappropriate tools suitable for resolving "tame", well defined static problems as puzzles are then applied incorrectly to resolve these non linear wicked problems [8].

Complex Systems Dynamic (CSD) models [9], Ontologies [10], [11], Hierarchical Bayesian Networks (HBN) [12], Hidden Markov Model (HMM) [13] and combinations of these have increasingly been used to try and solve wicked problems. The promise of these various efforts lies in the integration of the advantages provided for by each of these approaches into an integrated modeling framework.

While some effort at such integration has indeed been attempted in the recent past, [14]–[17], challenges still remain. This paper argues that this is the result of a lack of ontologically precise causal Bayesian Network (BN) models that adequately represent the hierarchical, dynamic, emergent characteristics, and multiple perceptions of CAS and their emergent wicked problems. This paper proposes a novel ontologically precise casual Bayesian model to address this shortcoming.

The paper's contribution is the incorporation of complexity systems theory concepts, namely: perspective; granularity; and context, as explicit BN model ontological constructs to develop a high precision ontological causal BN model, the Granular Contextual Perspectives Bayesian (GCP) causal Bayesian model. The model uses Hidden Markov Model (HMM) formalism to: i) enhance the visualisation of the character of CAS and their emergent wicked problems; ii) extend the scope of Bayesian inference to answer wicked problems' specific queries; iii) refine Bayesian machine learning of the structure and parameters of given wicked problems.

The rest of the paper is structured as follows. Section II gives an account of related work. Section III provides a broad overview of the character of wicked problems. In section IV the key complexity theory kernel concepts (granularity, context, and perspectives) incorporated in the GCP causal

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Bayesian model as modeling constructs are introduced and defined. In section V, using the COVID19 pandemic as an illustrative example, a further exploration of the character of wicked problems is carried out through the lens of the systems theory kernel concepts identified as useful in modeling the character of wicked problems.

Section VI provides the formal definition of the GCP causal BN model and details of the model architecture. In section VII the superiority of the (GCP) causal BN model to baseline Bayesian models in addressing wicked problems is demonstrated using the COVID19 pandemic as an illustrative example. In section VIII a discussion of the implications of the (GCP) causal BN model and its utility claims on modeling wicked problems is carried out. Section IX provides a conclusion and the way forward with respect to empirical experimentation using the GCP causal BN model.

II. Related work

The character of wicked problems as viewed through a systems paradigm lens appears in [1], [7], [18], [19]. Work on modeling CAS using CSD models from which wicked problems emerge is detailed in [9]. Systems thinking and design thinking disciplines having contributed to a better understanding of the systemic character of wicked problems and ways to address such problems [19]–[22].

[23] define an ontology as "a formal, explicit specification of a shared conceptualization". The application of ontology engineering to model the structure of complex phenomena to generate formal human and machine readable artifacts called domain ontologies is found in [11], [24]–[26]. The utility of ontologies as representing the structure of domain knowledge is well documented in [24], [26]–[28]. The application of ontological theory based on logical and philosophical principles to enhance clarity and precision in abstracting complex reality has been proposed in [11], [24], [26].

Bayesian networks, as graphical probabilistic models have been developed to compactly represent and reason over linked complex phenomena using computation techniques [29], [30]. Various attempts to integrate dynamic systems models, ontology engineering methods and Bayesian networks to model CAS are detailed in [16], [31], [32].

While these various disciplines have contributed to a better understanding of complexity and how to handle complexity through visualization and computation, attention to their integration for the purpose of addressing wicked problems emerging from CAS and multiple stakeholder perspectives of such problems has been fragmented and inadequate.

As highlighted in [33] Causal Bayesian Models CBMs need sound knowledge of causal big data generating processes to effectively support useful prediction, inference, and structure, parameter learning applications. CSD models provide insights into CAS dynamic and delayed feedback processes, their causes and effects. CBMs and their formalism in particular, as articulated in [34] hold much promise as the basis for integrating CAS' ontological constructs and processes to adequately represent and provide the computational mechanism to reason about, and resolve wicked problems.

Recent accounts in literature point to the inadequacy of ontological constructs in existing conceptual models to support the conceptual modeling of CAS to resolve wicked problems [35], [36]. Incorporation of highly precise ontological structures as Causal Bayesian Models (CBM) constructs representing CAS and emergent wicked problems' knowledge are thus necessary for such purposes. The GCP causal BN model provides a novel way to addresses these inadequacies.

III. The character of Wicked problems

The term "wicked problem" attributed to Churchman [37], was popularised by [38], and has been used to describe ill-defined, very difficult problems to solve [39]. A summary of the original ten characteristics of wicked problems as outlined in [38] are summarised in [40] as follows: i) non-solubility, i.e., inability to break the problem into parts; ii) non-definitiveness in problem resolution i.e., that there is "no single or definite computational formulation or a set of valid solutions or right answers, but only answers that are better or worse from different angles" [41]; iii) indeterminacy, i.e., conflicting perspectives of the problem and possible solutions emanating from different experiences, knowledge, goals; iv) irreversible consequentiality, i.e., trial and error strategies do not work [40]. Wicked problems include pandemics, inequality, poverty, traffic jams, rapidly changing business environments, and financial market crashes. Recent literature refers to super wicked problems which not only exhibit the characteristics of wicked problems but an added dimension of urgency in resolving them because time to resolve their irreversible effects is running out [42]. Global climate change effects fit into this category [6].

Wicked problems have been closely linked to CAS that are characterised by: non-linearity; positive and negative feedback loops between multiple interacting entities and across multiple dimensions [43]. These characteristics need to be grasped to fully appreciate the complexity of the interacting variables and the pathological emergent structures and behavioural patterns which are refereed to as wicked problems [3], [5], [43], [44].

Wicked problems can thus be viewed as a class of pathological effects that emerge from complex interactions between agents in bounded, albeit open, natural or artificial CAS manifest at varying granular levels of observation or engagement, whose definition for a given context / sub-context is contested by stakeholders with multi-dimensional perspectives of the problem [43]. Emergence is central to the characterisation of wicked problems. [45] provide a useful formal framework for defining emergence:

> Let $\{S_i\}_{i\in I}$ be a family of general systems or "agents". Let Obs^1 be "observation" mechanisms and Int^1 be interactions between agents.
> The observation mechanisms measure the properties of the agents to be used in the interactions. The interactions then generate a new kind of structure $S^2 = R\left(S_i^1, \mathrm{Obs}^1, \mathrm{Int}^1\right)$ which is the result of

> the interactions. This could be a stable pattern or a dynamically interacting system. We call S^2 an emergent structure which may be subject to new observational mechanisms Obs^2 [45].

A wicked problem is thus where S^2 is a pathological emergent structure with related behavioural patterns arising from the numerous dynamic interactions of related entities within natural or artificially defined bounded CAS, and observed at Obs^2.

Wicked problems manifest at two levels. The first level, which in this paper shall be referred to as level I, is about the ontological aspects of the problem, that is, what the problem is, what relationships characterize the problem, and where and how it manifests. The second level, level II, is about the epistemological aspects of wicked problems, that is, how and at which granular level wicked problems are perceived, explored, known, and understood, at say Obs^2, and how candidate solutions are conceptualised. At level II multiple divergent stakeholder contextual perspectives from varying granular levels of observation or abstraction of a level I wicked problem are explored.

[46] identify dynamic complexity, finitude, and normativity as the summary key factors that cause wicked problems. Complexity, they define as a feature that arises from interactions between system variables and feedback loops which make natural and engineered systems unpredictable. Finitude refers to cognitive ability limitations, experience and knowledge. Normativity is about different norms and values held dear by different stakeholders, the major source of conflict that makes consensus difficult to reach [46]. Complexity factors belong to level I, while finitude and normativity belong to level II.

The numerous interactions among variables, (the causes), and the unpredictable patterns of change, (the effects), make it difficult to make effective interventions to resolve wicked problems. Interventions can easily become the source of other problems. As a result these problems are notoriously difficult to abstract, represent in conceptual models and solve using existing computational models in information systems.

Systems theory and systems thinking as a practice have been applied to identify prototypical pathological patterns that emerge from such interactions and unintended consequences that arise from the inappropriate of use of deterministic [20], [47], [48].

IV. Granularity, Context, and Perspective

For any given context or sub-context complex phenomena is abstracted cognitively and described at different levels of granularity and from a specific perspective. [35] captured this phenomena thus:

> "There is only one Herbert (the frog) that we and the molecular biologist apprehend, but, depending upon our interests and our focus, we may each apprehend him from different granular perspectives" [35].

Granularity is a concept relating to the cognitive, spatial, or temporal level of abstraction of a phenomena from an observer's point of view [36], [49], [50]. It is also used to define the coarseness of an observation or an investigation [51].

The important factor about granularity with respect to complex phenomena is that the observer's interest and hence level of abstraction is a key determinant in what is defined, 'seen' and investigated [26]. [52] argues that to study and understand complex phenomena fully "we need to be able to keep an eye both the tree and the forest", that is, atomic elements, micro sub-systems that emerge from their interactions, and the macro system that result from the linkages between sub-systems.

Context in modeling systems is important. Natural and artificial systems are said to have a translucent boundary which defines what is inside of a system and what is outside, determined by the focus of interest [53]. [34] demonstrates the importance of context in deciding what is considered endogenous and exogenous to the system under review, and the impact this has on the modeling process.

Perspective refers to enduring beliefs by a person or a group of people with similar mental models of the world, a product of our knowledge, past experience, uncertainty, incomplete information and societal norms. Perspectives influence the definition, and proposed solution spaces for wicked problems and are a source of bounded rationality, that is, restricted understanding and explanation of the state of the world we live in and its problems [54].

Different perspectives of a given problem are the source of disagreements between stakeholders about the definition of a given common problem. The divergence in belief systems is typically driven by one or more of the following: local context; various scientific philosophical standpoints about complex phenomena; the related methods of studying them; experiences; culture; divergent stakeholder interests and biases [3], [6], [40].

Veridical partitioning is the essence of representation of some aspect of reality in a model for a given purpose [35]. [35] advocate embracing realist perspectivalism, a view that knowledge can be obtained by means of veridical granular partition integration. The GCP casual BN model is about exploring veridical partitions and promoting veridical integration as a way of promoting ontological commitment to a common view of a given wicked problem and its solution. It is thus important, given this objective, to explicitly represent multiple perspectives in ontologies and BNs to support the sharing of knowledge and gain wider understanding of a given wicked problem.

V. The COVID19 Pandemic as a Wicked Problem

In this section the Coronavirus Disease 2019 (COVID19) pandemic is used as an illustrative prototypical wicked problem example to further explore the character of wicked problems applying the key identified key systems theory modeling concepts: granularity; context; and perspective.

At the micro granular contextual sub-system level interactions between the Severe Acute Respiratory Syndrome

Coronavirus 2 (SARS-CoV-2), the lung cells and the human immune system take place. At the individual human granular contextual level, the COVID19 disease manifests (observed) as a complex clinical ailment that emerges from micro granular level interactions.

The problem is wicked for the following reasons. The problem is non-soluble, that is, it cannot be easily broken into parts that can be analysed and dealt with separately. The ailment is an emergent phenomenon from a wide range of interacting variables at the micro granular contextual sub-system level, i.e., the SARS-CoV-2, the lung cells, the human immune system, and pre-existing health conditions, which interact in both known (deterministic) and uncertain (unknown) ways. The solution to the ailment is non definitive. While development of specific vaccines provide a solution, such a solution is likely to be temporary. The coronavirus is subject to mutations, a result of the virus adapting to its dynamic ever changing environment, thus making it difficult to find a singular clinical solution to its eradication. At coarser granular contextual level, say the community level, large gatherings, the so called "super spreading events" lead to exponential spread of the coronavirus through close contact between those infected and those not yet infected, leading to surges or "waves" of community level infections. This phenomenon, as systemic pattern, is typical of pandemics, the 1918 H1N1 influenza 'Spanish flu' pandemic being a case in point. Here, consequences of inappropriate actions or behaviours are irreversible.

While the pandemic is broadly understood to be a health problem of level I 'wickedness' more complexity, level II complexity, is brought on by conflicting perspectives on the nature of the broader economic and social impacts of the level I health problem, and how these should be defined and resolved, a case of indeterminacy of the wicked problem. Non clinical solutions implemented in different countries like 'lock-downs' to limit the movement of people as a measure to stop the spread of the coronavirus have been contested by stakeholders with varying perspectives of the problem and with different specific interests.

Stakeholders with an interest in preserving economic activity argue that lock-down impositions threaten jobs and livelihoods. Travel restrictions have resulted in the collapse of businesses in the airline, hospitality and tourism sectors across the world, highlighting another characteristic of wicked problem, irreversible consequentiality, where decisions and their consequences cannot be reversed. Other interest groups argue that restrictions on movement impinge on their rights of freedom of movement, and this has led to riots in some countries. This is a classic character of wicked problems, where a solution to a given problem becomes the cause of another problem [38]. The divergent perspectives represent level II characteristics to do with finitude and normativity [46].

The foregoing represents a wide range of complex interactions between CAS at different levels that make the problem non-soluble, non-definitive, non-determinate, and subject to irreversible consequentiality [40]. CAS exhibit dynamism, emergence, counter-intuitiveness, inter-connectedness between interacting agents within systems at various granular contextual levels, which lead to non-linear, unexpected outcomes. These outcomes or impacts are emergent at at various granular levels of observation for given contexts and perspectives.

It has been argued in [55] that the hierarchical dynamic complexity of complex adaptive systems means that wicked problems cannot be solved in a deterministic kind of way, that is, by analysing the character and behaviour of the problem, and developing interventions at the same level of the problem observation. Interacting variables are different for each granularity, context, and perspective delineated sub-system, and thus have to be represented in models as such. Further, the inter-connectedness of these sub-systems, driven by the fact that they represent multiple perspectives of the same wicked problem have to be represented as such in ontologies to support the sharing of knowledge and perspectives.

It has been suggested in [43] that there is "an engaging symmetry between complexity and wicked problems, where complexity is both the source of intractable wicked problems, and a way to trace the pathway out". This is the approach taken in this paper in building a high ontologically precise casual hierarchical and dynamic Bayesian Network model to represent and support the resolution of wicked problems through Bayesian inference, structure, and parameter learning.

VI. The Granular Contextual Perspectives Causal Bayesian network model

Figure 1 shows a high level architecture of the GCP causal BN model depicted as a 2 time step unrolled dynamic HMM representation of two separate Granular Contextual Perspectives (GCP) systems and sub-systems A and B and an integrating GCP system C.

Each GCP system is modeled as a template, where the key ontological notions of granularity, context, and perspective are incorporated as template variables, see [56] for a detailed definition of templates as representational model frameworks.

Within each GCP sub-system entities and their attributes are modelled as observable, semi-observable and latent random variables and values, after [57]. Observable variables are colored grey. The relationships between the variables represent causal links between world entities concepts and their conditional probabilities.

The major difference between typical dynamic HMMs, and the GCP causal BN model, wherein lies the novelty of the GCP causal BN model, is that while the variables propagated and observed over time are the same for dynamic HMMs, represented by a single GCP sub-system, say GCP A in the GCP causal BN model model, each GCP template contains a set of interacting random variables which are either different for each GCP or interact in a unique way as their existence and behaviour is determined or influenced by the parent sub-system meta-properties: granularity, context, and perspective. Each variable in a GCP subsystem is essentially an entity playing a role defined by the GCP sub-system.

Further, intra - GCP sub-system variable interactions produce emergent patterns and properties at the sub-system level

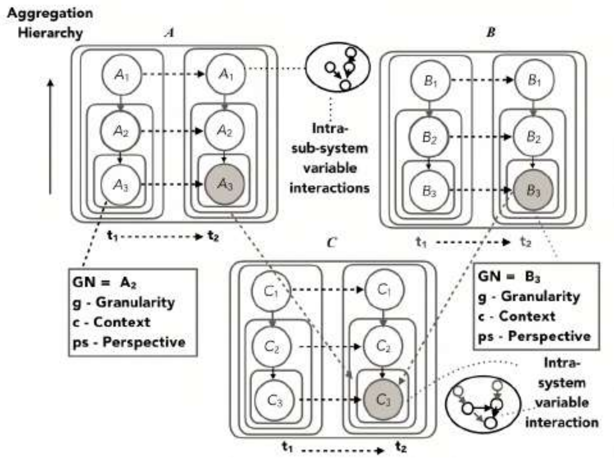

Fig. 1. Granular Contextual Perspectives Architecture

which are greater or smaller than the sum of their parts. In the COVID19 example provided this could be the disease, an emergent outcome of the interactions of the coronavirus and the lung cells and immune system of the individual.

The formal definition of the GCP system ontological architecture, which adapts and extends the definition of granular niches in [58] follows.

Definition 1:

A GCP is defined as an 9-tuple (S,T,M,N,Gl,C,Ps,A,E) where:

- (S) is a spatial or virtual location occupied by this GCP;
- (T) is a time interval granularity;
- (M) is a non-empty set of member entities, present at location S for part of time interval *T*, each representing a role;
- (N) is a non-empty set of interactions between entity roles, the normal behaviour in that gcp;
- (Gl) is a hierarchical structuring of the entities, *M* based on relative granularity of abstraction /
- observation/ manifestation i.e. *Gl* is a function mapping every *m* in *M* onto a granular level*gl* i.e. *Gl(m)* = *gl*;
- (C) is a description of contextual character for a given granular niche;
- (Ps) is a description of the world view that holds for a given GCP, a product of stakeholder belief system, knowledge, experience and culture;
- (A) is a set of emergent attributes of the GCP sub-system which are not direct attributes of its members *M*;
- (E) is a possibly empty set of environmental parameters that hold at location *S* during time *T*

The following constraints are applicable for GCP sub-systems:

- If *m* ∈ *M* then $Gl(m)$ *is unique i.e. every entity playing a specific role has exactly one granular level in a GCP.*
- *If* $m_1 \in M$ *and* $m_2 \in M$ *and* m_1 *is-part-of* m_2 *then* $Gl(m_1) \leq Gl(m_2)$
- *If* $m_1 \in$ *M,* $m_2 \in$ *M,Gl* ∈ *N and Gl* (m_1, m_2)*) then* ∃*t* ∈ *T s.t. In*(s, t, m_1) *and In*(s, t, m_2) *i.e. for two entities to interact in a GCP sub-system they must exist in that sub-system at the same time.*
- *For all m* ∈ *M,* ∃ *t* ∈ *T s.t. In(s,t,m) = false i.e. an entity does not have to remain in a GCP sub-system throughout its existence.*

The GCP causal BN model is defined formally as as a plate model, after [56] as follows:

Definition 2: A Plate model M_Plate defines, for each template attribute $A \in \aleph$ with argument signature $U_1, ..., U_k$:

- *A set of* template parents $Pa_A = \{(B_1(U_1)..., B_l(U_l)\ \}$, such that for each $B_i(U_i)$ we have that $U_i \subseteq \{U_1.., U_k\ \}$. The variables U_i are the argument signature of the parent B_i.
- A template CPD P$(A|Pa_A)$

The set of template parents B_i, $A_{1\cdot\cdot n}, B_{1\cdot\cdot n}, C_{1\cdot\cdot n}$, the template parents, in GCP causal BN model, and $\{granularity, context, perspective\}$, being instances of the argument signature, U_i.

The proposed GCP causal BN model artifacts are intended, on the one hand to specifically abstract an 'objective' ontological structure and stochastic processes character of a complex world, while on the other hand, surface, and lay bare, the various granular contextual perspectives and assumptions held by stakeholders about a given wicked problem. The GCP causal BN model is expected to support the design of model artifacts that more precisely represent complex reality and provide richer probabilistic reasoning and learning capabilities with respect to CAS and their emergent wicked problems than baseline Bayesian modeling frameworks.

A, for instance, using our illustrative example could represent the health services' perspective within the context of the COVID pandemic at different granular levels. A_3 then represents the micro granular contextual sub-system level. Here the variables of interest include the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), the lung cells, the human immune system, and pre-existing health condition present. A_2 then represents the individual person granular contextual perspective sub-system level. Variables of interest at this level include COVID19 status, access to quality health care, severity of symptoms if present, and levels of anxiety.

The GCP system B could represent the economic perspective within the context of the Covid19 pandemic at different granular levels. C represents an integrative architecture to visually explore the linked sub-systems and Bayesian graphical pathways to enable the exploration of the likely effects of an intervention, within a GCP system (e.g., A), at a GCP subsystem level (e.g., A_3), across GCP systems and sub-systems (e.g., B_3). GCP C represents multi-stakeholder ontological commitment to a wicked problem definition and a candidate design solution/s, arrived at through consensus using the model.

VII. Utility of the GCP causal BN model

Figure 2 shows the application of causal diagrams, after [33] to inspect the precision of causal representation and the effects of interventions using the GCP causal BN model.

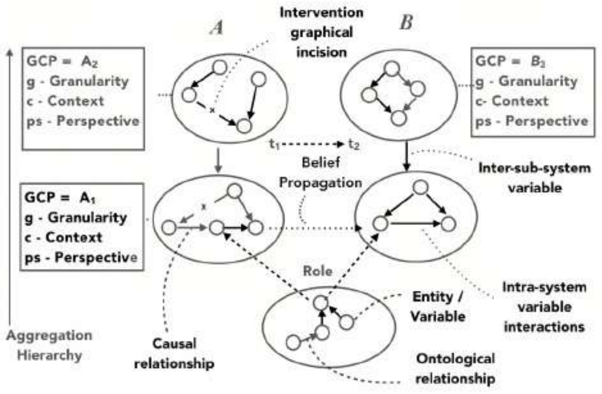

Fig. 2. Granular Contextual Perspectives causal graph showing an intervention

The X in the edges between the variables indicate an intervention, an incision of an edge to control the pathways between interacting variables. For example, wearing a mask "deletes" the pathway through which the coronavirus is transferred from person to person.

A comprehensive account of how to identify causal inconsistencies, such as spurious non-causal confounding variables, and the problems brought about by conditioning on collider nodes, i.e., nodes in a causal graph representing a variable causally influenced by two or more variables is provided in [33]. [33] also outlines techniques applied to handle such issues in causal graphs, such as the back door criterion.

Causal diagrams provide the means to visually inspect cause and effects to: i) handle any conceptual inconsistencies; and ii) illuminate likely effects of proposed interventions [34]. The *do* calculus, after [34] is applied to determine causal inference of the form:

$$P(y|do(x), z) \tag{1}$$

which describes the conditional probability of y if an intervention on x, given knowledge of z, where z represents existing knowledge of the causal influence of the triple factors: granularity; perspective; and context.

By explicitly incorporating granularity, perspective, and context as top level ontological knowledge structuring constructs in a plate model representing GCP causal BN subsystems, the Markov conditioning assumption [56] can be utilised to extend the range of queries answerable by the model to address wicked problems.

The Markov conditioning assumption links graph and probability functions where each variable is probabilistically independent of its non-descendants, conditional on its parents, and is defined more formally after [56] as:

$$P(x_j|pa_j) = P(x_1, ...x_j - 1) \tag{2}$$

Conditional probability x_j is sensitive only to a small subset of predecessors PA_j., the ontological meta-properties, the argument signature U_i of the plate model representing a GCP sub-system, which considerably simplifies and reduces input information required [34]. Thus the application of the GCP causal BN model leads to reduction in computational complexity, given that Bayesian inference is NP Hard. NP hardness refers to computational complexity that increases exponentially with the size of the network making a problem unsolvable in non-deterministic polynomial time [59].

The possible effects of an intervention on inter-linked variables, given pre-existing knowledge of granular contextual perspectives encoded as conditional probability distributions, can be computationally simulated. Using the Covid19 pandemic example, this facilitates decision making on important questions such as, which granular hierarchical level to target with an intervention for a given Covid19 context (e.g., health, economic, and human rights contexts), to obtain the most desirable outcomes, with the least negative effects.

Queries of the following kind are enabled: "What is the likely effect of a statutory requirement for everyone to stay at home for 3 weeks on hospital *x* , located at location *l*, and the likely effect on employee *y*, an airline pilot who works for airline *z*, given the different perspectives and belief systems of the affected stakeholders?"

The GCP causal BN model also supports counterfactual queries by applying the following calculus, after [33]

$$P(y_x|x', y') \tag{3}$$

which describes a hypothetical situation that says, "was it *x* that caused *y*, and, what if I acted differently". The calculus extends the query space to address complex scenario planning queries of the kind:

"Imagine today is date *d*, 30 September 2022, *(representing temporal granularity in the GCP causal BN model)*, the pandemic has been brought under control through wide spread vaccination, and people are free to travel to *l* locations *(representing sub-context in our model)*. Airline company *x* finds out that its most lucrative market segment *b* of business travellers *(representing a granular sub-context in the model)* has adapted to doing business online *o*, and business people do not travel as much as during *bc*, the pre-COVID19 era, *(representing a sub-context, and temporal granularity in the model)*.

What could company *x* have done to prepare for such an eventuality *e a*ffected by multiple perspectives *ps* in the model, given evolving knowledge *k* of changes in business cultural practices, such knowledge being fragmented and subject to divergent beliefs *db* of company executives of how the future could pan out?".

The foregoing inferential and counterfactual queries are essential for the exploration of possible effects of proposed alternative interventions or prototypical design strategies for resolving a given wicked problem, and it is argued in this paper, that such queries cannot be handled efficiently and effectively through existing baseline Bayesian models as they do not have the systemic meta-properties as modeling constructs.

VIII. Discussion

Wicked problems are emergent features of CAS and while modeling of emergence in CAS is provided for in some research work such as [60] the specific modeling of the epistemological elements of CAS and wicked problems from an observers view point, level II of wicked problems in this paper, is not represented in such models. By incorporating granularity, context, and perspective as constructs delineating CAS subsystems the GCP causal BN model, using HHM conditioning, the model provides the mechanism to compactly represent both levels, I and II of wicked problems to support tractable inference computation. While some baseline Bayesian models do utilise HHMs to compactly model hierarchy and systems nestedness as elaborated in [12] such Bayesian models are not able to simulate the effects of interventions across granular contextual perspective sub-systems through Bayesian belief propagation.

The use of a common formal ontological modeling language promotes semantic inter-operation between collaborating stakeholders and helps eliminate bounded rationality between divergent perspectives about a given wicked problem. The model can thus be used to support multi-stakeholder group learning and understanding of the ontological and stochastic character of a given wicked problem, paving the way for improved collaborative exploration, and solution design.

The GCP casual BN model further refines machine learning capabilities with respect to learning the structure of wicked problems. The argument is that the incorporating of granular contextual perspectives as ontological knowledge constructs in the model provides a causal model that supports an estimand that refines statistical classification of data to more precisely recover the structure, and learn about parameters of a given wicked problem than baseline Bayesian models. The need for such high precision estimands is well articulated in [33]. The constructs provide the means to model data generating structures and processes missing from models without the representational complex systems constructs.

IX. Conclusion and the way forward

The GCP causal BN model outlined in this paper provides a novel high precision ontological representation of wicked problems in dynamic, hierarchical, Bayesian networks, problems that emerge from complex adaptive systems, and stakeholder context, perspectives and granular level of observation.

The incorporation of granularity, context, and perspective of kernel complexity theory notions as Hidden Markov Model modeling constructs in the GCP causal BN model architecture extends the scope of queries answerable using baseline Bayesian models to specifically handle inference and counterfactual queries that support the understanding and resolution of wicked problems. The constructs further serve to refine machine learning of a given wicked problem structure and its parameters. To the best of our knowledge no such model has yet been developed to enhance understanding of wicked problems and their resolution through Bayesian reasoning and causal graphical logic.

By providing a modeling architecture that links sub-systems as multi-domain ontology / perspectives of bounded linked sub-systems the proposed GCP causal BN model architecture reduces computational complexity. The model also simplifies representation of the complex relational interactions for a given wicked problem for visual inspection and discussion by stakeholders with different perspectives and beliefs about the status of the wicked problem, and to arrive at informed consensus based solutions.

While a single prototypical example was used to illustrate the utility and novelty of the model, the model is equally applicable in resolving other wicked problems exhibiting similar challenges of dynamic complexity, finitude and normativity, which include market crashes, urban development, and negative climate change effects.

The intention, as a way forward, is to carry out empirical experiments to benchmark the GCP causal BN model against baseline Bayesian models to further validate the veracity of the model for Bayesian inference reasoning and machine learning of wicked problems. This is to be carried out using synthetic ground truth data, applying the Kullback–Leibler KL divergence method as applied in [13] for structure and parameter learning in dynamic environments.

***Abstract*— This paper presents a simulation and lab-based experimental study of detecting oil spills in the oceans using drones. The proposed simulation process is the first phase of long-term research that is targeting to limit the oil spill contaminations in Omani coastline. This study presents some methods and tools to detect an oil spill in a prearranged scenario. The methods and tools are tested in simulation and verified in lab-based experiments. Footage of oil spill cases is used to illustrate the process of oil spill detection. In addition, image processing techniques are applied to provide an accurate outline of the spill's perimeter. The results exhibit the effectiveness of using the proposed methods and tools in detecting oil spills.**

Keywords—simulation, lab-based experiment, oil spill, contamination, detection, image processing

I. Introduction

The last few decades have witnessed major oil spill incidents around the globe. It is a challenge to overcome these ecological problems and the pollutions caused by the accidental leaks of oil [1-3]. It has been recorded that around 750,000 m^3 of crude oil were spilled into the Gulf of Mexico in 2010 [4]. Such a leak in the oilfield can cause pollution on the coastline thousands of miles away. The most obvious sign of the leak is a film of oil spreading on the surface of the ocean, which can easily be noticed. Then, the nearby beaches and shorelines are polluted by oil stains. However, the most critical impact of the oil spill occurs long after the initial spill. Oil consists of at least 300 types of chemicals, most of which can negatively harm the living marine organisms. Once these hazardous chemicals are introduced to the food chain, they can cause serious health issues to sea life and humans alike.

Very few leaks are naturally caused by the infiltration of the oil deposits underneath the ocean floor. However, most of the oil leaks are caused by human errors due to a damaged tanker or a leaking oil rig. An example of the largest oil spills, caused by humans, is the leak near Alaska in 1989 when the oil tanker Exxon Valdes accidentally released millions of liters into the sea. Years of efforts have been spent to clean up the polluted area.

Containing oil spills and cleaning the seawater and shores are enormous tasks, and therefore several studies have investigated effective oil spill remediation techniques [5-8]. These techniques aim to either remove or separate the oil from the seawater. Such techniques include:

- Chemical cleanup by using chemical dispersants and emulsifiers [9, 10],
- Mechanical tools that showed high efficiency in recovering the oil such as booms, sorbents and skimmers [11- 14], and
- Bioremediation by using oil-eating bacteria, which can break down the oil into sub composites that can be consumed by marine life [15].

However, several challenges face the use of these techniques, which can be applied only under certain conditions. For example, adding chemical dispersants into the seawater can be harmful [11]. On the other hand, cleaning the oil spills using mechanical tools is expensive and requires a large number of tools and equipment [16]. For instance, Exxon has spent over 2 million dollars on the Valdez cleanup operations [17].

The cleaning process of the oil spill becomes more challenging when the oil spreads widely in the ocean. Therefore, it is important to detect oil spills immediately. Various studies have been focused on achieving rapid and accurate detection of oil spills in the sea and the ocean. During the last 15 years, the operational use of satellites in detecting oil spills has bloomed, especially when satellite images became available for researchers. Alternatively, Synthetic-Aperture Radar (SAR) imagery is used by many organizations (e.g. European Maritime Safety Agency) to monitor the oil spills in the ocean. SAR imagery has the capability of providing usable images under all weather conditions day and night [18-21]. On

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

the other hand, various studies have been performed to examine the capabilities of thermal infrared cameras in detecting oil spills in water [22].

Robotics, artificial intelligence, and computer vision are fields that can be integrated to provide solutions that would automate many processes. One of which is the detection and reporting of oil leakage. In recent years, remote sensing technologies were widely applied to investigate and monitor various environmental issues related to oil spills and red tides. Common techniques use cameras in the visible spectra. However, using standard cameras to inspect particular spectral regions in the visible spectrum cannot easily discriminate such ecological issues in water environments [23]. Many studies proposed modifications to standard cameras to unlock the major obstacles that interfere with the use of visible light [24-26]. Unmanned Aerial Vehicle (UAV) equipped with remote sensing is a very promising approach for oil spills and red tide investigations. It enables for higher accuracy, lower costs, and revisit times determined by the operator as opposed to fixed satellite revisit times [27]. All of these remote sensing methods are regularly applied. For example, a pollution control aircraft is operated by the German Navy is mainly used for oil spill detection [28]. UAVs equipped with multispectral or hyperspectral imagers are used in many studies to accurately map multiple types of water pollution [29].

II. Problem Statement

Oil spills in the oceans pose a threat to coastal countries such as the Sultanate of Oman. The Sultanate is blessed with a unique geographical location, with a long shoreline filled with diversified marine life forms. In particular, the peninsula of Musandam overlooks the Strait of Hormuz; a strategic location for maritime trade and a passage to 35% of the world's seaborne oil shipments. Also, the Arabian Gulf is a busy route for cargo ships and marine trading. Therefore, incidents of oil spills leaking from ships and tankers could happen. The government’s mandate is to watch for any spillage around the clock to protect the environment. In the occurrence of spillage, current, winds, and waves carry the spilled oil toward the coast. Therefore, before reaching the coast, the oil is subject to physical and chemical transformations, primarily due to the prevailing weather conditions [30]. As it reaches the shoreline, the oil is most likely to penetrate deeply in the sandy beaches or to be retained by rocky coastal tracts. Given the dangerous chemical composition of the crude oil (a mixture of thousands of hydrocarbons [31]), its primary environmental impact is on the atmosphere, on the surface of the sea, in the water column, onshore, as well as on the humans and marine life [32, 33]. Fig. 1 shows some examples of such leakage in the Musandam shoreline that would threaten the environment and marine life.

The current approach for detecting oil spills is both costly and time-consuming as it involves coordination between several parties. Drones’ applications have been spread widely in many fields [34] due to the drones’ flexibility. Therefore, as an alternative solution, we propose a UAV-based solution capable of detecting oil spills using remote sensing and machine vision techniques. The proposed alternative employs drones that are performing real-time, low-end imaging analysis on the target areas. Additionally, the system is capable of accurately locate the spill and measure weather parameters such as wind speed and direction. The latter is needed to predict the direction and speed at which the spill will extend.

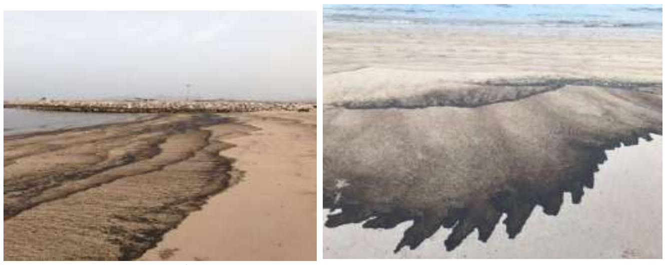

Fig. 1. Examples of oil leakage in Musandam shoreline threatening the environment and marine life [Courtesy: Environment Authority, Sultanate of Oman]

The proposed solution is a comprehensive one that entails many subsystems. As such the research project is conducted over several phases. This paper discusses the work done in the first phase, where both simulation and emulation environments were developed to experiment with the proposed solution. This provides the authors with a lab-based experimental study to test several remote sensing and machine vision techniques for oil detection before conducting field tests in the Gulf of Oman. The authors believe that these lab-based experiments should cut the development cost and time. Furthermore, the experiments will facilitate diversifying the circumstances in which the oil spill has occurred.

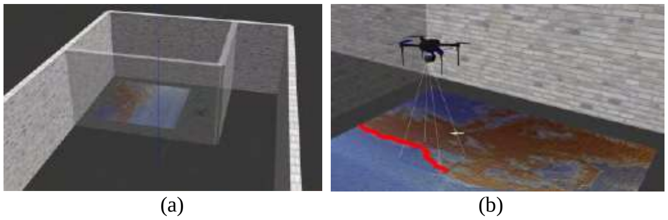
III. Development of Simulation Environment

Robot Operating System (ROS) and Gazebo are used to simulate UAV flight workspace, with the dimensions of 5×4×2.8 meters. These dimensions are based on the EIVS laboratory [35] as shown in Fig. 2 (a).

The simulation environment models a UAV that hovers over the seawater. The water includes an oil spill as shown in Fig. 2 (b). This simulation environment mimics the incident at the Gulf of Mexico, which took place in April 2010 [4].

During the simulation run, the modeled UAV flies over the oil spill a shown in Fig. 2 (b). The UAV surveys the region while capturing images simultaneously. The route taken by the UAV during the survey is determined by several factors such as mission time. It is worth mentioning that the UAV plans its missions based on two different modes. The first mode is when the oil spill location is known. In this mode, the task will be to survey the area and give exact locations for the oil spill area without the need to search for the ship that caused this spill. In contrast, the second mode entails patrolling the shores looking for potential oil spills. if a spill is detected, the UAV will undergo the search mode, looking for nearby ships that might have caused the spill.

A connection has been made between the simulated drone and ArduPilot. Using this software it is possible to locate the simulated drone at any point in Google map and give the drones point-locations or routes to follow. As an example, the starting location of the UAV is at Ras Al-Hadd in Oman, where the UAV was given a specific area to survey. This tool can be useful to simulate the task, which will be given to the actual UAVs; providing an estimate of the time and the battery life required to accomplish the task.



(a) (b)

Fig. 2. (a) Gazebo simulation of the lab room, and (b) a drone detecting the area of the oil spill in simulation

As mentioned earlier, the UAV is equipped with a thermal camera. The captured thermal images provide a means to segregate water from oil given the disparity in the measured temperatures. The thermal images were processed using several image processing techniques to automatically determine the outline of an oil spill by analyzing the temperature profile of the images.

IV. Emulation Environment

An indoor UAV emulation environment is used to experiment with the proposed oil spill detection system. Experimenting with the system in an indoor and controlled environment leads to a significant reduction in cost and time. Additionally, the emulation environment offers us the ability to test the system with several cases of oil spills under various conditions. It should be noted that the occurrence of an oil spill in oceans infrequent, which makes it very challenging to test the system. Therefore, the indoor emulation environment allows the team to experiment with different techniques and strategies to detect oil spills and be prepared for any unexpected scenarios. Fig. 3 shows the emulation environment that was constructed at the EIVS lab. The figure also shows the equipment used in the experiments.

The floor of the area is furnished with a printed poster that shows seawater contaminated with an oil spill (see Fig. 4). The poster size is 3×4 m. Indoor drones from Quanser are used in these experiments. These drones are equipped with downward-facing cameras, which capture images in grayscale color space. This camera is selected to resemble the output of thermal images similar to the ones captured by the FLIR Zenmume X2 camera that are mounted on Matrice 200 V2 (to be used in the 2nd phase of the proposed system development).

Given that indoor drones are unable to receive GPS signals, it is not possible to rely on GPS service for positing and localization. Instead, the emulation environment uses the OptiTrack camera system to localize the drones.

The indoor drones are equipped with fixed focal-length cameras. Therefore, the drones are maintained at a fixed altitude. Capturing images at the predetermined altitude mimics that the same images that would have been captured in actual field tests.

Then, a suitable flying trajectory in the x- and y- plane (the horizontal plane) is set in such a way that the field of view (FoV) of the cameras is adequate with the arena. This is depicted in Fig. 4. For this reason, the desired x- and y-trajectory in Fig. 5 was designed so that the drone flies in the boundary of ±0.8 m in the y-axis, while the x-axis location is incrementing by 0.45 m every time the drone makes a turn.

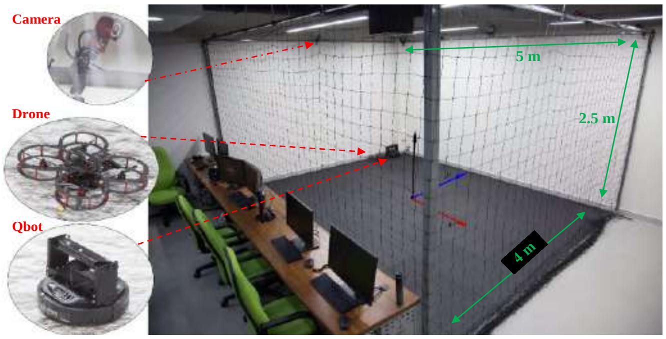


Fig. 3. The emulation environment constructed at the EIVS lab

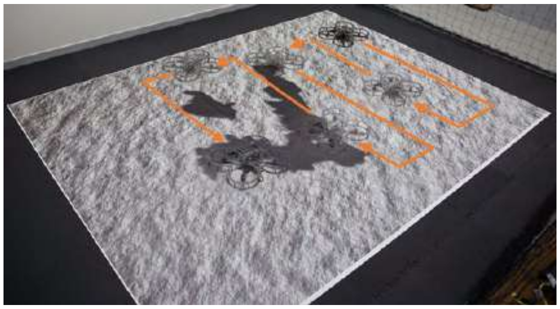

Fig. 4. The drone is flying above an image of an oil spill case in the ocean

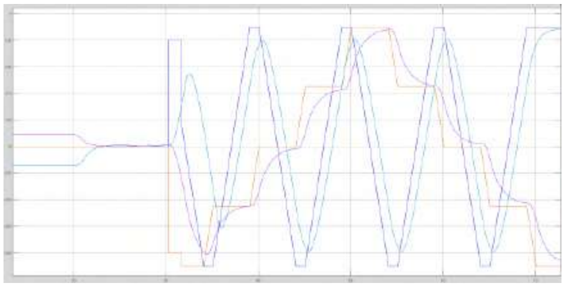

Fig. 5. Monitoring of the drone's location during the experiment

V. Image Processing Techniques

To perform the image processing method, the following steps are followed:

A. Image acquisition: During the flight of the drone with the designed trajectory, the drone was capturing an image every 0.3 seconds. This small period is enough for the drone to capture all 49 mini-images that represent the whole workspace area, as exhibited in Fig. 6.

B. Image stitching: The images that were captured in the previous step are stitched to one another. This yields an image that encompasses that the whole poster. This process was automated using a MATLAB script that was developed for this purpose. An example of stitching three images is shown in Fig. 7.

It is worth mentioning that in actual field tests, the image stitching process is not required. Image stitching was performed in this experiment to provide coordinates for all points in the stitched image since the location of the starting point is known by the OptiTracking cameras (the coordinates of the first mini-image taken by the drone).

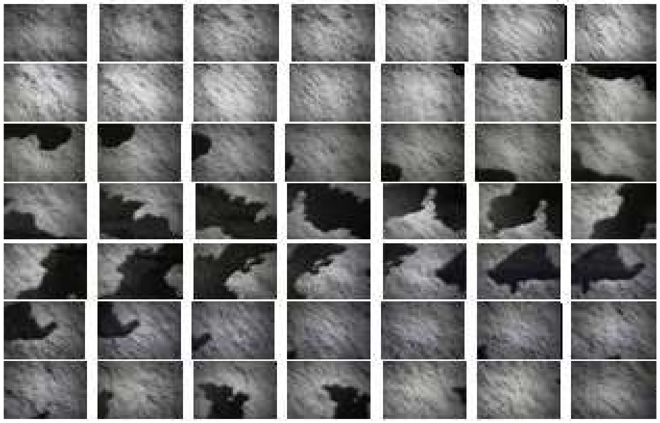

Fig. 6. 49 images captured by the drone while flying above the workspace area

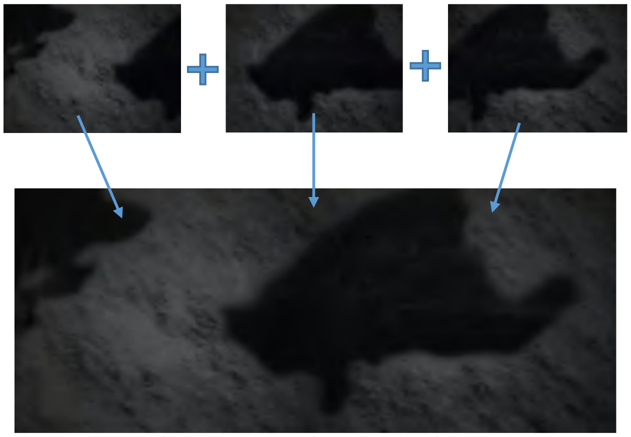

Fig. 7. An example of image stitching for a portion of the study case image

C. Image Analysis: the next step is to identify the region of the oil spill. Image processing techniques are used to detect the outline of a spill (contour). The input images are in grayscale color space. The images are first converted to HSV color space, as it gives better segregation between the seawater and oil spill regions. Fig. 8 shows the oil spill as represented in the HSV color space. It is noted that the spill is not distinguishable from the background when in the Hue and Saturation channels. This is because they both describe the color (for Hue) and the intensity of the color (for Saturation). On the other hand, the oil spill is much more visible in the Value channel. The Value channel represents the brightness of the area. Some adjustments in the HSV threshold for three channels can affect the detection of the oil spill. This overall process is used to identify the location of the oil spill area with respect to the room reference frame of the room.

Based on the outcome of the previous steps, the system outline the region where the oil spill is located (see Fig. 9). The spotted difference between oil and water in the V channel of the HSV color space was noticeable, where the black color was indicating the water and the white color was indicating the oil. However, in the current stage of this research the accurate calculation of the region was not implemented. Therefore, the detected region was presented as a rectangular shape that is bounded by the maximum and the minimum distance in x- and y- directions. Then, the system reports location of the contour around the oil spill.

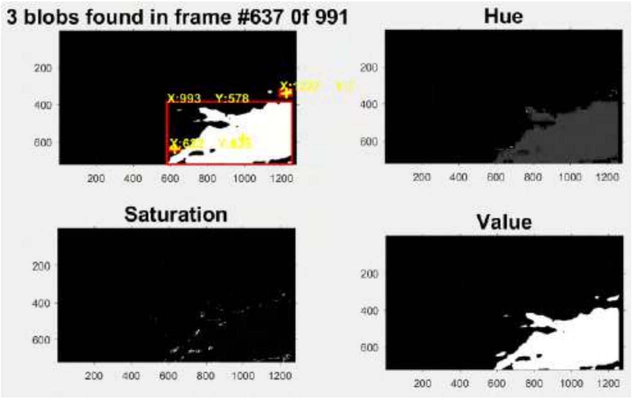

Fig. 8. Captured images are represented in HSV color space. Notice how the oil spill is more visible in the V channel.

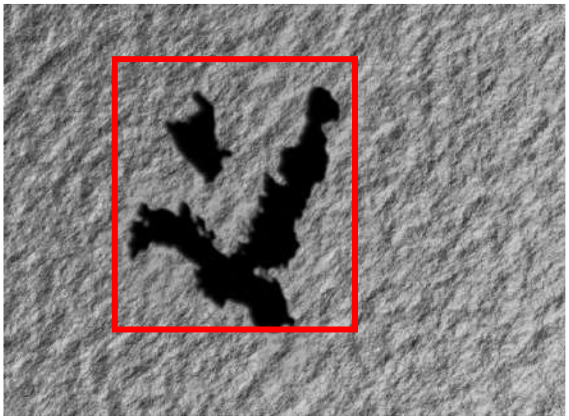

Fig. 9. The detected area of the total oil spill and contour location is reported

VI. Conclusion

This paper described a simulation and lab-based experimental study of a proposed UAV-based system for detecting oil spills in the oceans. Oil spill detection has always been an issue since it is infrequent to detect oil spills in real life and monitor the wide ocean all the time. Therefore, this study is conducted, using a cost-effective solution than the existing ones, to provide a training environment to deal with oil spill cases. The drone-based system can provide the required information for the detection process. This research has gone through two stages to implement the oil detection process. The first stage of the project was to simulate the environment, for which oil detection can be made possible for study and analysis. The second stage was a laboratory-based, emulation test to demonstrate the effectiveness of the proposed algorithms. Since the proposed system was successfully tested in simulation and emulation, the real drone will be used to implement the proposed solution and will be tested on real oil spill scenarios.

In the future, the proposed system presented in this paper as simulated and lab-based procedures will be carried out for real-life cases, where drones that are more sophisticated will be used. Moreover, the contour around the detected oil will be improved to detect exactly the area of the oil spill.

Acknowledgment

This work was funded in parts by research grants from BP Oman (EG/ENG/ECED/18/01), Smart City Platform (TRC/SRG/SC/IMCO/01/2019), His Majesty Trust Fund

(SR/ENG/ECED/19/01), and the Ministry of Higher Education, Research and Innovation's Block Fund (RC/RG-ENG/ECED/18/02). The authors would like to thanks Sultan Qaboos University for providing a conducive research environment. Additionally, the authors thank Mr. Abdul Hakim Alharthy for his support to the research efforts. Special thanks to Environment Authority for providing data and information related to oil leak incidents.

***Abstract*—This article presents a new control scheme for an aircraft that has suffered from actuator failure due to severe damage to its vertical tail. The damaged degree of the vertical tail is treated as uncertainty. Firstly an output feedback controller is designed for the nominal lateral dynamic model of aircraft. However, when the actuator's fault/failure occurs, the idea of generalized virtual actuators is adopted. In this way, the same baseline controller is used even in the presence of fault/failure. Linear matrix inequality is used to compute the controller and virtual actuator's gains. The simulation results show good tracking performance and fault-tolerant competency.**

***Index Terms*—linear matrix inequality, control reconfiguration, virtual actuator, linear quadratic regulator**

I. Introduction

An escalation in the safety and reliability requirements in civil aviation requires a tremendous amount of toil in aircraft protection and reducing the possibility of a significant failure. In an aircraft, most of the structural damage occurred due to control surface malfunctioning or vertical-tail loss that often causes a significant chore for the pilot to control the craft [1], [2]. The misfortune disaster in 1985 with Boeing 747 is one of the examples of vertical-tail damage, which lead to a plane crash. One more similar site surfaced in which airbus A-300 in 2001 caused the death of 265 passengers. Reconfiguring the control input immediately after the fault appears in the system can avoid such failures. However, in customary hybrid actuation systems (HAS), adequate measures in dealing with this problem are not present. Due to this reason, the trend of more electrically powered aircraft is increasing nowadays. Recently, the dual redundant actuation systems (DRAS) [3], [4] in modern aircraft has replaced the traditional similar actuation system to make the system more reliable and to solve the actuator failure issues due to common cause. Nowadays, commercial aeroplanes A-350, A-380, and A-400 M use 2H/2E type DRAS. The use of DRAS indicates the potential fault-tolerant control (FTC) capability to meet some extreme situations [5]. For example, when the vertical-tail total loss occurs, hydraulic lines pull apart, resulting in the system's total failure of hydraulic actuators. Therefore, to handle this situation, aircraft with DRAS is more effective than Electro-hydrostatic actuators (EHA) to drive significant control surfaces.

The overall effects of vertical tail loss on directional characteristics are comparable to the pitch axis from stabilizer damage. Much work has been performed studying the damaged aircraft modelling and the fault-tolerant strategy. The calculation of the vertical tail loss of Boeing-747 100/200 data is done by [6], [7]. However, the aircraft can only lose a centralized HAS input channel when exposed to vertical tail loss. Damage-induced aerodynamics in these studies does not characterize the nonlinear association and control derivatives. Passive fault-tolerant control (PFTC) for vertical tail loss of an aircraft is studied in [8], but after the degree of damage increases, the PFTC techniques are no longer valid. An active fault-tolerant control (AFTC) [9]–[11] is a more reasonable response for more extreme losses.

In a recent survey, several researchers have proposed solutions to deal with structural damage scenarios, such as model predictive control (MPC) in [12], model reference adaptive control (MRAC) in [8], [13]–[15], sliding mode control (SMC) in [16], [17] and adaptive control [18]. The authors in [19] proposed adaptive control law to compensate for the vertical-tail loss by utilizing differential thrust because all the actuators would lose their efficiency. In contrast, the vertical tail is significantly damaged with hydraulic loss. Because of the error management ability of more electric aircraft (MEA) fortified through DRAS, [20], [21] proposed a reconfiguration control law in which the nominal controller

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

is designed using a linear quadratic regulator (LQR) and MRAC is used to design reconfiguration controller in case of actuator failure.

This paper presents a different control scheme that utilized virtual actuator configuration to deal with actuator failure due to damage in the vertical-tail of aeroplanes driven by DRAS. In a fault-free situation, attaining tracking control is done by an output feedback controller. Fault-tolerant is achieved by placing a virtual-actuator circuit between the nominal controller and faulty plant for fault or failure conditions within specific actuators. The proposed scheme is dominant over the existing strategies in the following ways.

- The presented method is advantageous because both the nominal and the faulty cases use the same baseline controller. Therefore, the designer can choose the nominal control law according to the tracking performance requirement.
- Since the state feedback controller is not practical; therefore, an output feedback controller is designed based on the nominal system. The controller gains are obtained using an iterative LMI procedure that gives more optimal controller parameters than the simple LMI procedure.

The organization of this paper is: the plane model with a vertical-tail is specified in section II. The reconfiguration problem is discussed in section III, containing the overview of a virtual actuator, problem formulation, and reconfiguration using a virtual actuator. The nominal output feedback controller design is proposed in section IV. Section V contains the design of a virtual actuator. The simulation result is given in section VI. Finally, the conclusion in section VII proposed the effectiveness of the proposed approach.

II. MODELING OF DAMAGED AIRCRAFT

A. Configuration of DRAS

Fig. 1 shows the aircraft layout with the DRAS configuration. The complete elevator, inboard aileron, lower rudder, and spoilers are operational using a hydraulic actuator (HA) and electro-hydraulic actuator (EHA) system.

B. Nominal aircraft modelling

Two dissimilar actuators EHA and HA, derive the aircraft's vertical-tail in nominal condition as vertical-tail fault influences the lateral model constraints, taken into account for the paper. The nominal model of aircraft is taken from [13] and is represented as follows.

$$\begin{aligned} \dot{x}_p &= A_p x_p + B_p u_p \\ y_p &= C_p x_p(t) \end{aligned} \tag{1}$$

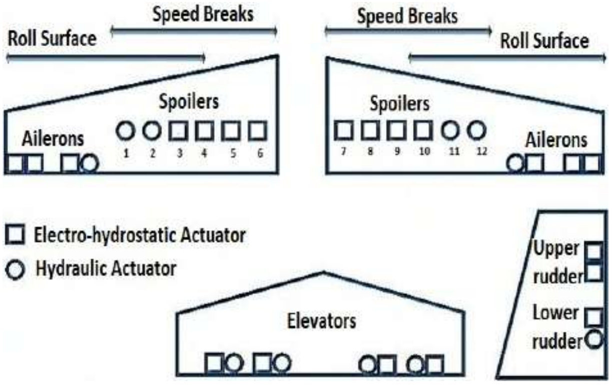

Fig. 1. The aircraft actuation system with DRAS

where the aircraft state vector $x_p = [\beta, p, r, \phi]^T$, and the state variables β denotes the angle of side-slip, r shows yaw angular rate, ϕ and p represents aircraft roll angle and its rate. The state-space matrices of the nominal aircraft model are given as

$$A_p = \begin{bmatrix} \frac{R_\beta}{m} & \frac{R_p}{m} & \frac{R_r}{m} - (u_o) & g_o cos\theta_o \\ \frac{K_\beta}{J_x^{'}} + J_{zx}^{'} Q_\beta & \frac{K_p}{J_x^{'}} + J_{zx}^{'} Q_p & \frac{K_r}{J_x^{'}} + J_{zx}^{'} Q_r & 0 \\ \frac{Q_\beta}{J_z^{'}} + J_{zx}^{'} K_\beta & \frac{Q_p}{J_z^{'}} + J_{zx}^{'} K_p & \frac{Q_r}{J_z^{'}} + J_{zx}^{'} K_r & 0 \\ 0 & 1 & tan\theta_o & 0 \end{bmatrix}$$

$$B_p = \begin{bmatrix} \frac{R_{\delta a}}{m} & \frac{R_{\delta r}}{m} \\ \frac{K_{\delta a}}{J_x^{'}} + J_{zx}^{'} N_{\delta a} & \frac{K_{\delta r}}{J_x^{'}} + J_{zx}^{'} N_{\delta r} \\ \frac{Q_{\delta a}}{J_x^{'}} + J_{zx}^{'} K_{\delta a} & \frac{Q_{\delta r}}{J_x^{'}} + J_{zx}^{'} K_{\delta r} \\ 0 & 0 \end{bmatrix}$$

$$C = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

where $J_x^{'} = \frac{J_x J_z - J_{zx}^2}{J_z}$, $J_z^{'} = \frac{J_x J_z - J_{zx}^2}{J_x}$, $J_{zx}^{'} = \frac{J_{zx}}{J_x J_z - J_{zx}^2}$,J_x and J_z denote moments along x and z axes; J_{zx} represents coupling moments along (z, x) axes. R_p, R_β, and R_r shows aerodynamics in 3-axes; K_β, K_p and K_r defines rolling moments; Q_β, Q_p and Q_r represent the yawing moments; $R_{\delta a}$ and $R_{\delta r}$ represent the side aerodynamics; $Q_{\delta r}$ and $Q_{\delta a}$ are the rolling moments provide by rudder and aileron; m is the total airplane mass; u_o denotes reference flight speed and θ_o represents reference angle of climb. Furthermore, $u_p = [\delta_a \quad \delta_r]^T$ represents the control input vector where δ_a and δ_r are the control surfaces inputs delivered via aileron and rudder. The outputs are β and ϕ.

III. THE RECONFIGURATION PROBLEM

A. An overview of the virtual actuator

The basic concept here is to avoid the whole system's failure after the fault is induced in one component. Without the proper control reconfiguration, the actuator fault deviates the system from its normal behaviour and even causes physical damage. The approach adopted in this paper aims for output to be free from fault. Possible means to deal with such faults are placing a reconfiguration block in the middle of all the actuator vector and controller output. The purpose is to reconfigure the control input signal to the faulty plant such that it produces the same effect as nominal. That block is named the virtual actuator [22].

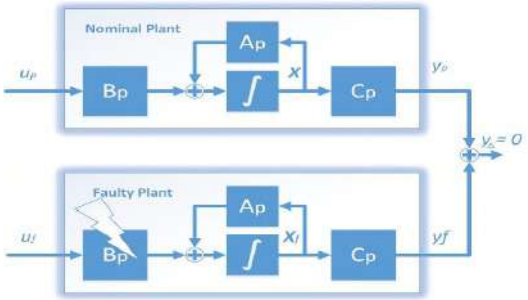

Fig. 2. The reconfiguration goal

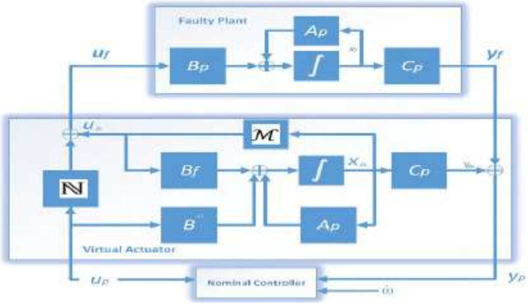

Fig. 3. The closed-loop configuration of a generalized virtual actuator

With the proper virtual actuator, a faulty plant and the virtual actuator behaviour match the nominal. Hence the nominal controller can be used for the defective plant, which is a significant benefit for the reforming controller because of its prolonged procedure and several closed-loop stability tests.

B. Nominal plant and faulty plant Modeling

The nominal plant $\Sigma_p(A_p, B_p, C_p, x_{p_0})$ is modeled in state-space form

$$\Sigma_p \begin{cases} \dot{x}_p = & A_p x_p + B_p u_p \\ & y_p = C_p x_p \qquad : x_p(0) = x_{p_0} \end{cases} \tag{2}$$

where $x_p \in \Re^{n_x}$, $y_p \in \Re^{n_y}$ and $u_p \in \Re^{n_u}$ the system's states, output and input vectors. $A_p \in \Re^{n_x \times n_x}$, $B_p \in \Re^{n_x \times n_p}$, $C_p \in \Re^{n_y \times n_y}$ is the system matrices. The nominal controller is an output feedback controller with an input y_p and reference input $\omega(t)$ is represented as

$$u_p(t) = -\mathcal{F} y_p(t) + \mathbb{N}\omega(t) \tag{3}$$

Where $\mathcal{F} \in \Re^{n_u \times n_y}$is the output feedback gain and $\mathbb{N}$ is the outer loop term to facilitate tracking. Since the actuator failure is considered in this paper, so the difference between the faulty and the nominal plant is in its input matrix B_p that is $B_p \neq B_f$. The model of the faulty actuator under the actuator failure is obtained as

$$\Sigma_f \begin{cases} \dot{x}_f = A_p x_f + B_f u_f \\ y_f = C_p x_f \qquad : x_f(o) = x_{f_o} \end{cases} \tag{4}$$

The initial state x_{f_o} is assumed to be the same as the plant's initial state. We assumed that actuators' failure information is known in prior; therefore, the model of faulty plant $\Sigma_f(A_p, B_f, C, x_{f_o})$ is known.

C. Reconfiguration Goal

A plant is configured successfully if the system contain a virtual actuator and the faulty plant, as shown in Fig. 2. That is, the reconfigured and nominal plant has the same input-output behaviour $(y_f(t) = y_p(t))$ and also the reconfigured plant is stabilizable.

D. Reconfiguration using the virtual actuator

Considering (4), the generalized virtual actuator is clear as

$$\begin{aligned} \dot{x}_\Delta &= A_\Delta x_\Delta + B_\Delta u_p \qquad : x_\Delta(o) = x_{\Delta_o} \\ u_f &= C_\Delta x_\Delta + D_\Delta u_c \\ y_p &= C_p x_\Delta + y_f \end{aligned} \tag{5}$$

where the state $x_\Delta \in \Re^{n_x}$ and the matrices

$$\begin{aligned} A_\Delta &= A_p - B_f \mathcal{M} \\ B_\Delta &= B - B_f \mathbb{N} \\ C_\Delta &= \mathcal{M} \\ D_\Delta &= \mathbb{N} \end{aligned} \tag{6}$$

where the matrices $\mathcal{M}$ and $\mathbb{N}$ are selected at liberty.

E. Analysis of Reconfigured Closed Loop System

For analyzing the closed-loop system, the combination of the model of plant (2) and virtual actuator (5)-(6) along with the nominal controller (3), gives the model of reconfiguration plant,

$$\begin{pmatrix} \dot{x}_p \\ \dot{x}_\Delta \end{pmatrix} = \begin{pmatrix} A_p - B_p \mathcal{F} C_p & 0 \\ -B_\Delta \mathcal{F} C_p & A_p - b_p \mathcal{M} \end{pmatrix} \begin{pmatrix} x_p \\ x_\Delta \end{pmatrix} + \begin{pmatrix} B_p \mathbb{N} \\ B_\Delta \mathbb{N} \end{pmatrix} \omega$$
$$\begin{pmatrix} x(0) \\ x_\Delta(0) \end{pmatrix} = \begin{pmatrix} x_0 - x_{\Delta_0} \\ x_{\Delta_0} \end{pmatrix} \tag{7}$$

$$y_c = \begin{pmatrix} C_p & 0 \end{pmatrix} \begin{pmatrix} x_p \\ x_\Delta \end{pmatrix} \tag{8}$$

$$y_p = \begin{pmatrix} C_p & -C_p \end{pmatrix} \begin{pmatrix} x_p \\ x_\Delta \end{pmatrix} \tag{9}$$

It can be seen from (7-9), the closed-loop system contain the eigenvalue of the nominal plant (2) with output feedback controller (3) and set of virtual actuator eigenvalues (5-6).

IV. DESIGN OF NOMINAL OUTPUT FEEDBACK CONTROLLER

This section will design the output feedback control to stabilize the plant (2) with the state feedback control law (3). The methodology followed in this paper is adopted from [23] and extended to the given plant. ILMI algorithm helps to calculate the controller gain. For a plant (2) and output feedback controller (3), the control task is to find output feedback gain, the closed-loop system Σ_c as

$$\Sigma_c : \dot{x}_p = (A_p - B_p \mathcal{F} C_p) x_p \tag{10}$$

is stable.

Theorem 1: The system Σ_c is stabilizable through output feedback control if $\mathcal{P} > 0, \mathcal{X} > 0$ and $\mathcal{F}$ satisfying

$$\begin{aligned} A_p^T \mathcal{P} + \mathcal{P} A_p - \mathcal{X} B_p B_p^T \mathcal{P} - \mathcal{P} B_p B_p^T \mathcal{X} + \mathcal{X} B B^T \mathcal{X} + \\ (B_p^T \mathcal{P} + \mathcal{F} C_p)^T (B_p^T \mathcal{P} + \mathcal{F} C_p) < 0 \end{aligned} \tag{11}$$

Apply Schur complement to the inequality (11), the following quadratic matrix inequality (QMI) is formed as:

$$\begin{bmatrix} \begin{matrix} (A_p^T \mathcal{P} + \mathcal{P} A_p - \mathcal{X} B_p B_p^T \mathcal{P} - \\ \mathcal{P} B_p B_p^T \mathcal{X} + \mathcal{X} B B^T \mathcal{X}) \end{matrix} & (B_p^T \mathcal{P} + \mathcal{F} C_p)^T \\ (B_p^T \mathcal{P} + \mathcal{F} C_p) & -I \end{bmatrix} < 0 \tag{12}$$

For a fixed value of X, (7) is reduced to the LMI problem with the unknown value of $\mathcal{F}$ and $\mathcal{P}$. To obtain the necessary condition of the feasibility of (11) perturb A_p to $A_p - (\alpha/2)I$ for some $\alpha \geq 0$ such that

$$\begin{aligned} A_p^T \mathcal{P} + \mathcal{P} A_p - \alpha \mathcal{P} - \mathcal{X} B_p B_p^T \mathcal{P} - \mathcal{P} B_p B_p^T \mathcal{X} + \mathcal{X} B B^T \mathcal{X} \\ + (B_p^T \mathcal{P} + \mathcal{F} C_p)^T (B_p^T \mathcal{P} + \mathcal{F} C_p) < 0 \end{aligned} \tag{13}$$

Based on this equation, the eigenvalue of Σ_c shifted to the left half-plane depend on the reduction of α. A step-wise procedure to choose the optimal value of α is proposed in [23] and is given below.

A. Iterative linear matrix inequality

For a given plant Σ_p (with realization A_p, B_p, C_p) is stabilizable via output feedback controller given in (3). The following step-wise procedure is adopted to obtain optimal α

- Step 1: Select $\mathcal{Q} > 0$ and resolve $\mathcal{P}$ from $A_p^T \mathcal{P} + \mathcal{P} A_p - \mathcal{P} B_p B_p^T + \mathcal{Q} = 0$ Set $i = 1$ and $\mathcal{X}_i = \mathcal{P}$
- Step 2: For $\mathcal{P}_i$, $\mathcal{F}$ and α_i. Lessen α_i focus on succeeding LMI constraints

$$\begin{bmatrix} \begin{matrix} (A_p^T \mathcal{P} + \mathcal{P} A_p - \mathcal{X} B_p B_p^T \mathcal{P} - \\ \mathcal{P} B_p B_p^T \mathcal{X} + \mathcal{X} B B^T \mathcal{X} - \alpha_i \mathcal{P}) \end{matrix} & (B_p^T \mathcal{P} + \mathcal{F} C_p)^T \\ (B_p^T \mathcal{P} + \mathcal{F} C_p) & -I \end{bmatrix} < 0 \tag{14}$$

$$\mathcal{P}_i = \mathcal{P}_i^T > 0 \tag{15}$$

Denote α_i^* as the minimum value of α_i

- Step 3: If $\alpha_i^* \geq 0$, then $\mathcal{F}$ is a stabilizable output feedback gain.
  Stop
- Step 4: Minimize trace $(\mathcal{P}_i)$ subject to LMI constraints (14)-(15) with $\alpha_i = \alpha_i^*$. Denote $\mathcal{P}_i^*$ as the $\mathcal{P}_i$, that minimize trace $\mathcal{P}_i$
- Step 5: If $||\mathcal{X}_i - \mathcal{P}_i^*|| < \delta$, go to step 6 else set $i = i + 1$ and $\mathcal{X}_i = \mathcal{P}_{i-1}^*$, then go to step 2
- Step 6: The system may not be stabilizable via output feedback gain.
  Stop

V. VIRTUAL ACTUATOR DESIGN

The design procedure to select the value of the virtual actuator gains $\mathcal{M}$ and $\mathbb{N}$ and to have little change among the behaviour of nominal and reconfigured systems is discussed in this section. It can be seen from generalizing virtual actuator equations (5)-(6) and reconfigured close-loop system given in (7)-(9), the stability depends on the proper choice of $\mathcal{M}$ such the σ_{min} $(A_p - B_f \mathcal{M})$ lies in the left half-plane. In this paper, the LQR approach is adopted to compute the value of $\mathcal{M}$ that satisfies the Algebraic Riccati Equation (ARE) given as

$$A_p^{'} \mathbb{P} - \mathbb{P} A + \mathbb{Q} + \mathbb{P} B_f \mathbb{R}^{-1} B_f^{'} \mathbb{P} = 0 \tag{16}$$

The optimal controller gain is evaluated using

$$\mathcal{M} = \mathbb{R}^{-1} B_f^{'} \mathbb{P} \tag{17}$$

where $\mathbb{P}$ is the symmetric positive definite matrix obtained using ARE.

To match the behaviour of the reconfigured system with that of the nominal system under the commanded input ω, $\mathbb{N}$ is selected so as

$$B_\Delta = B_p - B_f \mathbb{N} = 0 \tag{18}$$

holds.

In this paper, the matrix $\mathbb{N}$ is chosen through a zero-pole placement technique [24]. The goal is to have y_f become equal to y_p that is y_Δ converges to zero. According to (5) the equilibrium of output deviation is

$$y_\Delta = C_p (sI - A_p + B_f \mathcal{M})^{-1} (B_p - B_f) \mathbb{N} u_p \tag{19}$$

The goal is to vanish steady-state output deviation y_Δ for all constant input; it requires

$$0 = C_p (sI - A_p + B_f \mathcal{M})^{-1} (B_p - B_f) \tag{20}$$

Since (20) is the same as the transfer function at $s = 0$, it corresponds to the placement of input-decoupling zeros at zero. Eq. (20) has a solution in $\mathbb{N}$ if

$$\begin{aligned} rank(C_p (A_p + B_f \mathcal{M})^{-1} B_p) = \\ rank(C_p (A_p + B_f \mathcal{M})^{-1} (B_p, B_f)) \end{aligned} \tag{21}$$

If the solvability is confirmed, then the matrix $\mathbb{N}$ can be found by inverting (17) such that

$$\mathbb{N} = \mathcal{H}^{+} C_P (A_p - B_f \mathcal{M})^{-1} B_p \tag{22}$$

where $\mathcal{H} = C_P(A_p - B_f\mathcal{M})^{-1}B_p$ and right pseudo inverse $\mathcal{H}^{+}$ is constructed such that $\mathcal{H}\mathcal{H}^{+}\mathcal{H} = \mathcal{H}$.

VI. Simulation Results

This section presents the simulation results to control β and ϕ of aircraft that suffer from actuator failure due to damage that occurs in its vertical-tail. The information of the failed actuator is expected to be known. The expression of state coefficients of the plant is obtained from [13] and given as

$$A_p = \begin{bmatrix} -0.11 & 0 & -673 & 32.20 \\ -3.53 & -0.84 & 0.31 & 0 \\ 3.65 & -0.04 & -0.25 & 0 \\ 0 & 1 & 0.03 & 0 \end{bmatrix}$$

$$B_p = \begin{bmatrix} 0 & 0 & 0.0041 & 0.0032 \\ 0.22 & 0.35 & 0.126 & 0.027 \\ 0.02 & 0.02 & -0.275 & -0.2 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$C_p = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

Where $u_p = [\delta_{a_o}, \delta_{a_{in}}, \delta_{r_u}, \delta_{r_l}]'$ is the control input vector that is considered in the simulation.

The nominal controller is designed based on ILMI using the CVX toolbox in MATLAB. To achieve output tracking, $\mathbb{N}$ is calculated to guarantee zero steady-state error at step input that is

$$\mathbb{N} = -\frac{1}{C_p(A_p - B_p\mathcal{F}C_p)B_p}$$

The nominal controller gain is computed as

$$\mathcal{F} = \begin{bmatrix} 9.31 & 1.04 \\ 1.04 & 1.57 \\ 2.15 & 0.20 \\ 4.22 & 0.94 \end{bmatrix}$$

A. Tracking performance under the nominal condition

Testing controller enactment under normal condition (without actuator failure), a 12^o and 0^o amplitude signal is smeared to the roll slip and side slip, respectively. The simulation result in Fig. 4 shows the defined tracking of the roll slip angle. The roll angle trajectory commanded input thru satisfactory delay while variation for side-slip angle is within the limit of ± 0.1 which is observed as zero steady-state error.

B. Simulation results under actuator failure

In this simulation, the vertical-tail damage occurs, and there is no upper rudder control surface, and all the hydraulic lines pull apart. Therefore, the control surfaces associated with HA fails to activate. Since the inboard aileron and lower rudders remain fortified by DRAS. So, the switching device takes EHA into the loop, and the two control surfaces equipped with EHA can still be operational. Therefore, the input distribution matrix B_p changes to B_f as

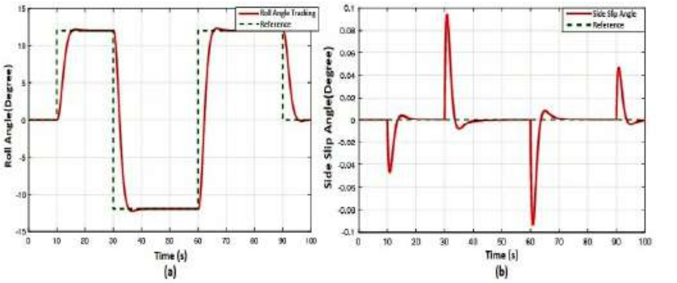

Fig. 4. System dynamical performance under the normal condition at square input

$$B_f = \begin{bmatrix} 0 & 0 & 0 & 0.0032 \\ 0 & 0.35 & 0 & 0.027 \\ 0 & 0.02 & 0 & -0.2 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

Due to a faulty actuator, Fig. 5 shows the degradation in system performance. As grasped by Fig. 5(a), the roll slip angle cannot trail input and leads to sizable steady-state error. Also, in Fig. 5(b), the fluctuation in the side-slip angle's output reaches over the prescribed level of tolerance.

C. Simulation results of control reconfiguration after actuator failure

To reconfigure the controller structure after the occurrence of the fault to the system, only EHA provides the required control input and brings the system to the nominal condition. To overcome the slower dynamics of EHA, a first-order delay system $u_{EHA} = e^{-0.1t} u_{HA}$ is announced, whereas, u_{EHA} is the input to EHA and u_{HA} is the current input to HA. To provide tolerance against this severe failure condition, a virtual actuator is brought into operation. Choosing the parameter of the virtual actuator as

$$\mathcal{M} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1.27 & -1.31 & -13.61 & -0.95 \\ 0 & 0 & 0 & 0 \\ 5.2 & 0 & -0.24 & 0.30 \end{bmatrix}$$

Such that $\sigma_{min}(A_p - B_f\mathcal{M})$ is stable whereas $\mathbb{N}$ can be chosen using (22). The roll angle and side-slip angle are recovered from the simulation plots to their nominal position (see Fig. 6) with a virtual actuator inserted in the middle of the faulty plant and the nominal controller.

VII. Conclusion

The paper presents the fault-tolerant control strategy subject caused by vertical-tail damaged aircraft driven by dissimilar redundant actuation system. First, designing the nominal output feedback controller using iterative linear matrix inequality. A virtual actuator circuit is induced between the faulty plant and the nominal controller to facilitate fault-tolerant control

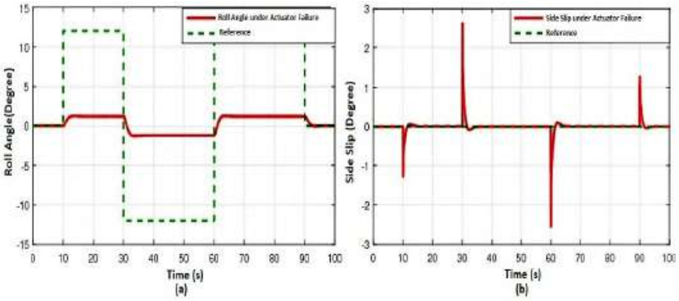

Fig. 5. Degradation of dynamical performance under actuator failure

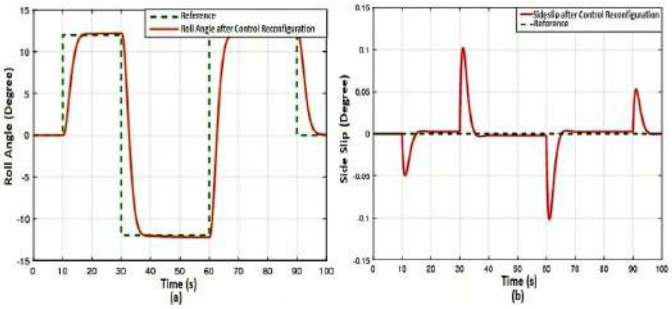

Fig. 6. Dynamical system performance after control reconfiguration

capability. The simulations are performed subject to HA failure due to severe damage. Due to dissimilar redundancy, the control surfaces associated with EHA provides the desired flight path in severe failure condition.

***Abstract*— Maintaining a customer base at a feasible rate is considered important in most business organizations since customers are the precious asset of the business sector. It is a vital task to retain the customers at a steady level in any business enterprise for the overall stability of its business activities. Sufficient pieces of evidence in this connection have been gathered to prove that the telecommunication industry is the most affected field of business by the tendency of the customers to shift towards alternative service providers. Therefore, a distinctive effort has been made to design this specific forecasting method is carried out utilizing a combination of a properly approachable method aiming at clarifying the probability of the above-mentioned tendency of the clients seeking an alternative service provider in the industry. In this attempt, a data set that included 10, 000 postpaid consumer particulars including 20 attributes were taken for this research for a thorough analysis of this aggravating issue in the telecommunication industry. In the end, a satisfying outcome was witnessed and certain clarification was made out of the 10,000 subscribers 4888 showed positive attitudes and 5112 indicated negative to the churning behavior. Besides, this specific data set was subjected to complete verification in comparison to certain supervised machine learning algorithms such as Decision tree, Logistic Regression, Support Vector Machine (SVM), and Artificial Neural Networks (ANN). Along with this, ensemble techniques such as Random Forest, Extreme Gradient Boosting (XGBoost), and Adaptive Boosting (AdaBoost) also have been considered. Subsequently, an assurance was made that XGBoost possessed the ability to bring out the maximum and précised accuracy of 82.90%. Eventually, a hyperparameter tuning had been performed with XGBoost. As a result, an assurance was acquired that XGBoost showed an upsurge in the previously obtained accuracy from 82.90% to 83.13%.**

I. INTRODUCTION

The customers of any business enterprise are the major component of its progress and success. They are the ones who contribute immense boost for the continuous development and reputation of these companies. So, it is obvious that these enterprises largely rely on their customers. Therefore, it is essential for them to preserve their customer base and to uphold their reputation in the competitive business background. Otherwise, there are chances for the regular clients to churn from the existing company or their service providers. As a consequence of this, the productivity and the valuable status of the company may severely be damaged. Here, the word "Customer Churn" means the termination of the relationship of a particular client or clients with the organization. For example, the individual who is a usual customer of a business establishment "A" could perhaps discontinue having the services and select another establishment named "B" [1] [2]. Depending on the contemporary condition of the organization, numerous reasons may be cited for the above feature. Customer churn often occurs in most organizations anywhere in the world. They may be industries like banking, finance companies, insurance companies, or telecommunication services. It is risky and unreliable to identify the reasons for such churning behaviors of the customers and to avoid these situations because the consistency and the progress of the company are straightly influenced by this attempt. So, it is inevitable for the company to have a practical "Churn Prediction" method for safeguarding the company from being suffered by the behavior of customer churning. A properly planned churn prediction does have an important part and makes a significant impact on handling customer churn.

To provide satisfactory communication, the telecommunication industry has various service providers in its possession. Almost all the people in the world have subscriptions to telecommunication and at the same time, they opt to use multiple systems. As the subscribers tend to switch on to an alternative service provider due to dissatisfaction, customer churn is very common to see in this industry. The reasons for this tendency may be poor customer service, high usage of service, and very low switching cost [3]. What has been mentioned above are the traditional causes. However, this particular attrition behavior is also caused by some personal intentions that have been recognized recently in this field. If an attempt has to be made to find out the reasons for the above, the following features stand as proof. They are namely "Disappointment based on facilities provided by the service provider at the primary on entering the firm for their needs" and "The failure of the enterprise in supplying the expected service to their clients", though they might be somewhat impractical on a particular situation. Besides, another noticeable destructive feature in the telecommunication industry is that it faces an inevitable customer churn of 40% every year [4]. In consequence of these harmful circumstances, this industry employs various unique methods to survive in the competitive market. These attempts may aim to sustain the continuous presence of the customers at a steady level. It is usually presumed that retaining the subscribers who are already present in the industry is more advisable than seeking new ones because the latter burden the company with unbearable spending. The

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

expenditure to attract new subscribers forces the company to bear nearly 5 times higher expenses [5][6].

Since it is very costly to attract fresh customers into the company, it is truly advisable to keep the ones who are already there in the business. Further, it is said that the existing long-term customers are the cash – cow of the company, the entrepreneurs ought to make sure about their continuous existence there. It should not be forgotten that to retain the existing customers most companies use a huge amount of their annual budget for “Customer Churn Prediction”. A properly planned research in this connection could help the organization detect the most apparent churners so that the organization concerned can resist the issue of churning and would be able to retain the existing clients. If this happens, the precious manpower would not be wasted.

Besides, a few more models of this nature came into being previously that were very similar to the churn prediction within the companies of telecommunication services. Here too, the following models of algorithms were taken into consideration. They are namely – ANN, Decision tree, Logistic regression, SVM, and Bayesian models (Naïve Bayes). In most of the previous efforts of developing “Churn Prediction”, a contrasting and comparing approach was carried out making use of the basic algorithms that are accustomed in the field. In this effort, the ensemble algorithms were not considered (XGBoost, AdaBoost). Besides, in the greater number of such cases, it has been noted that only a last and ultimate suggestion was shown in creating prediction models using techniques of greater accuracy devoid of the implementation of the graphical user interface.

The sole purpose of this prediction effort was to foresee the number of clients who tend to shift to another service provider with the use of some unverified machine learning algorithms. This effort also aimed at creating an effective churn prediction model to manage the deliberate churning behavior of the customers. To proceed with this research, exactly 10,000 post-paid customer records were collected from a telecommunication company in Sri Lanka. Identifying such churners in a telecommunication company is indeed a difficult challenge using the data of prepaid customers who have many options for their services. This is because there is no reliable source or agreement available for such identification. In the process of this study, 20 attributes were made available. Some of them are “Statistics of Billing”, “Complaint Details”, “Call Duration Details and so on. Further, a user-easing way was made use of in the effort of identifying churners and consequently, a Graphical User Interface (GUI) was established for this purpose. Accordingly, all the above-mentioned “Supervised Algorithms” such as Decision tree, Logistic Regression, Random Forest, SVM, XGBoost, AdaBoost, ANN were properly subjected to proper contrasting and comparison. Consequently, a highly accurate technique was used to make an effective churners’ prediction model. For this endeavor, the cross-validation was purposefully and thoroughly done with all the aforementioned techniques.

II. Literature Review and Related Works

Keramati et al. have accomplished research using the binomial logistic regression algorithm to pinpoint the features that mostly influence customer churn. These features are namely number of service failures, number of complaints, amount of service usage switching cost, and some other customer demographic factors. Further, the results showed that client/customer status (active or non-active) facilitates the connection between the attrition behavior of customers and the reason for attrition. The non-appearance of greatly influencing factors and pressurization between various operators are the major limitations found in this study. For example, the service cost is a powerful factor of customer churn because of the limitation of pressure. Also, the service cost lies between multiple operators [1].

Sharma et al. have carried out research using the Neural Network method to predict the churning customers in prepaid telecommunication services. This research has identified the factors that are necessary to be considered to improve an accurate and consistent churn prediction model. There are 20 factors taken into consideration and the model was developed by examining 2,427 customers. Some of these features include state, account length, area code, and overall day minutes, etc. To evade the overtraining of the model, a randomly chosen ratio of the data set was trained. The model has produced results with 92.35% accuracy in the prediction of churn behavior. But, there was a restriction in poor performance and it took some extra time to give out the expected results [2].

Keramati et al. have made a hybrid model consisting of Decision Tree, SVM, ANN, and K-Nearest Neighbor (KNN). 95% accuracy in churn prediction was obtained from this recommended model. The accuracy value is efficiently achievable here. As an added feature of this method, a novel approach has been suggested to pinpoint the main factors that need to be adjusted in the churn prediction model. The outcomes of the research have revealed that the hybrid methodology which is comprised of four methodologies depicted above produced higher accuracy when in comparison with isolated algorithms performed in this process. Finally, a completely new approach has been suggested for dimensionality reduction [5].

A hybrid churn prediction model using bagging and boosting methods has been prepared by Fathian et al. During this research, a technique incorporated with specific predictive modeling was taken into consideration. To name them would be ANN, Self-Organizing Maps (for clustering), SVM, the algorithm named KNN, and Decision Tree. In this process, the PCA (Principal Component Analysis]) was utilized, aiming at the total elimination of the unnecessary features. The comparison between the existing models was performed, based on the following 5 factors namely specification, accuracy, sensitivity, F-measure, and AUC. The results of the research have shown that merging the clustering techniques depicted above with bagging and boosting has created better results concerning accuracy. This attempt had some difficult experiences while trying to obtain a better classification [8].

During yet another research, Olle et al. have made a hybrid churn prediction model with the amalgamation of Logistic regression, Voted Perceptron, and clustering techniques. The model had achieved a little more leap forward to produce very high accuracy results compared to the results obtained by the previously mentioned isolated algorithms. The accuracy of this model is approximately 99%. 23 variables had been taken to analyze and 2,000 subscriber details were assembled from Asian telecommunication. The model had undergone training and testing against a relatively smaller number of subscriber data. Therefore, it is suggested that this particular model has feasible to be enhanced in the future in dealing with larger data sets [9].

Preeti et al. researched a customer churn prediction with the adaption of Logistic regression and Decision tree techniques. This study evidenced that choosing the relevant and correct set of attributes would produce high accuracy results. Hence, they have ascertained that how Logistic regression has identified the factors that affect the defection rate of customers. A model with higher précised accuracy is not needed if it is incapable of describing the causes for the attrition behavior. Besides, the study provides some strategic pathways (comparative analysis) to select the finest algorithm to recommend the prediction model [10].

Umayaparvathi et al. have developed a churn prediction for the telecommunication industry. During this study, an easy interpretation of churn prediction methodology was proposed. Further, the efficiency of some predictive modeling methods corresponding to the subject was subjected to the analysis here. They are Gradient Boosting, KNN, Decision Tree, Ridge Regression Classifier, SVM, Random Forest, and Logistic Regression. In order to increase the accuracy of the prediction model, each attribute in the data set was assessed to find its significance in churn behavior. Openly adaptable churn data set from two telecommunication companies were taken to validate the performance of this model. The outcome of the research indicated that Gradient Boosting is the best classifier in the churn prediction [11].

A novel churn prediction was modeled by Gregory using a prevailing algorithm named as XGBoost. This model was prepared to take part in the “WSDM Cup Churn Challenge competition” in 2018. Music streaming data given by KKBOX (One of the foremost music streaming services in ASIA) have been used in this study. These data comprise user log details, transactions, and statistics about members. Log loss is the utility used in this research to assess the performance of the prediction model. The model developed with XGBoost outperformed all the models exhibited during this competition. In order to increase the accuracy of the model, the Light GBM (Light Gradient Boosting Machine) library and XGBoost primary based model were integrated. The final results of the research have ascertained that feature engineering is a significant part of boosting the accuracy of the model [12].

Umayaparvathi et al. have completed yet another survey concerning churn prediction for the telecommunication industry. This study was mostly focused on the analysis of freely and commonly available telecommunication data sets, methods used in emerging the prediction models, and the metrics used to assess the performance of the model. In addition to the previous researchers, this study conveyed the features of the considered data sets and classified the most noticeable features. Further, the performance metrics analyzed in this attempted study were Confusion matrix, Accuracy, Precision, Recall, F1-score, AUC curve, and Lift curve [13].

J. Vijaya et al. also designed a model of hybrid churn prediction by mingling both supervised and unsupervised learning techniques. K-Means clustering, Decision tree, SVM, Linear discriminant analysis, Naive Bayes, and KNN have been adapted to carry out this study. 50,000 subscriber details with 230 features were subjected to this particular analysis. This analysis contains 190 numerical features and 40 nominal features. The results of this study depicted that the model developed with the mixture of SVM and K-means algorithm has brought out a better outcome in accuracy, sensitivity, and consistency [14].

Sabbeh attempted to predict the churn behavior of customers by associating ten varieties of predictive modeling methods. They are Discriminant Analysis, SVM, Decision Trees (CART), Ada boost, Random Forest, Stochastic Gradient Boosting, KNN, Multi-Layer perceptron, Naïve Bayesian, and Logistic regression. 3,333 subscriber details were taken for analysis throughout this study. Finally, the following outcomes were noticeably acquired. They are as follows. Both the AdaBoost and Random Forest (Ensemble techniques) nearly produced similar outcomes with 96% of accuracy, Multi-Layer perceptron and Support Vector Machine produced results with 94% accuracy in churn behavior, Linear Discriminant Analysis, and Logistic Regression revealed the accuracy of 86.7% and at last 90%, 88% accuracy level was obtained by the Decision Tree and Naïve Bayes respectively. Only the comparison between single predictive modeling techniques was taken into consideration. This is the main shortcoming of this study [15].

Özer Çelik et al. have researched “Comparing Techniques Used in Customer Churn Analysis” by associating XGBoost, Random Forest, SVM, Logistic Regression, ANN, Naive Bayes, KNN, and Weibull Time To Event Recurrent Neural Network (WTTE-RNN). During this research, the following observations were made. Firstly, the deep learning technique can be utilized for a large amount of data, and secondly, the ensemble machine learning techniques can be used for a small portion of data. In order to produce prominent results in prediction. Besides, with the help of the Cox Regression technique, highly distributed independent features towards the dataset can be easily identified. The main shortcoming found in this study was the way of adapting the dataset. For instance, the separate dataset is used for machine learning techniques and deep learning techniques. In other words, a unique dataset could have been used for the machine learning technique and another dataset for the deep learning technique separately [16].

On the basis of related works mentioned above, several techniques have been employed in the development of the churn prediction model so far. Rather than using basic techniques in this regard, the use of ensemble techniques gives better accuracy in most instances. Besides, it can be a strong foundation to develop a churn prediction model using the “Ensemble Techniques” favoring the researchers in the future on the Sri Lankan context as well as international level.

III. Methodology

Fig. 1 shows the overall methodological framework used during this research to develop the final prediction model. Each step has been explained in detail below.

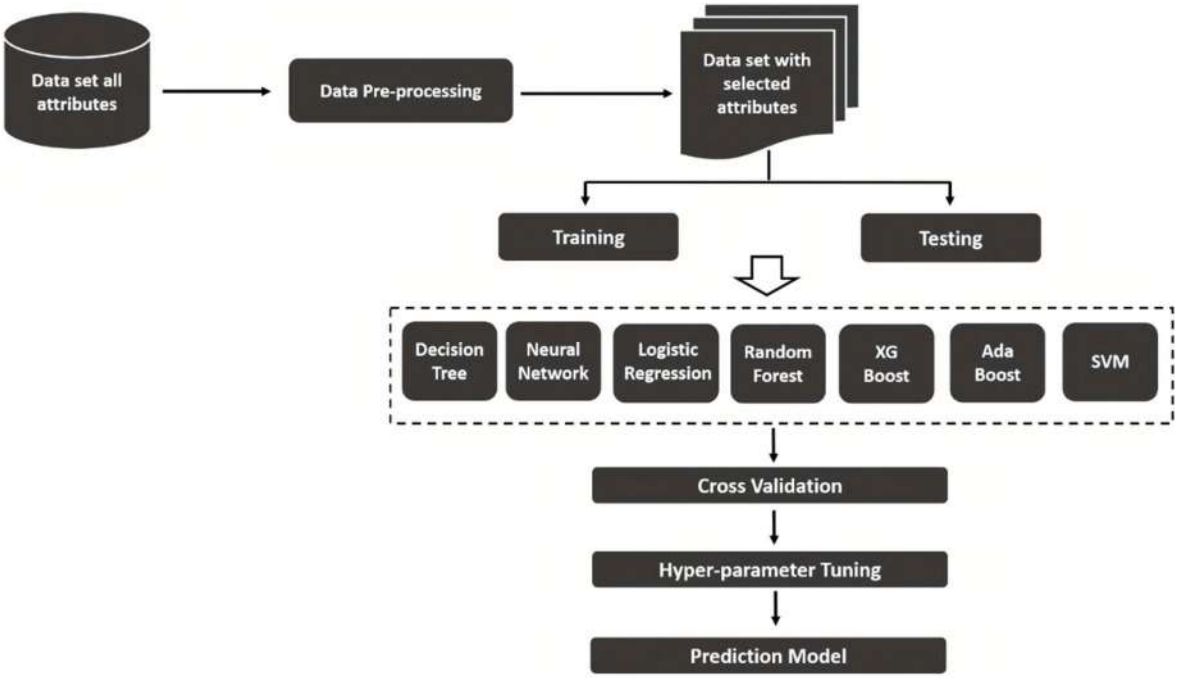

Fig. 1. Overall methodological framework

A. Data set and Requirement analysis

Requirement analysis or the prerequisite analysis would be certainly a leap ahead for examining anticipations of the consumers for a new or modified creation. Pinpointing exactly the major necessities of the particular analysis very correctly is indispensable before the making of any software project or model. Being inclined in this endeavor, many approaches can be made to find more evidence in this regard. To name a few are 'Face to Face Meetings', 'Brainstorming, 'Surveys', 'Web Scraping', and 'Data Collection' from a Web API.

In the course of the above-mentioned effort, a due consultation was made with the reputed telecommunication industry. During this survey, subscriber particulars from exactly 10,000 post-paid subscribers for the year 2019 were collected and systematically studied. The content of 20 attributes along with the target attribute of the dataset and their descriptions are represented by the Table I have given here.

B. Data Pre-processing

This is a task that is aimed at carrying out "Data Pre-Processing" and removing the unfinished, noise-producing, or unreliable data from the system. This process is considered to be the most essential phase in originating such a forecasting structure to find out the churn behavior among the customers. In the course of this strategy, the "Python Pandas Library" was made use of, as an aid to achieve the above-stipulated target. The following tasks were executed under the above function.

a) Storing the raw data into a Comma Separated Values format (CSV) file.

Initially, the required dataset has been obtained in an excel sheet format. To Perform the rest of the processes conveniently the dataset has been converted into a CSV file format.

b) Loading the CSV with pandas.

c) Checking for number of columns and rows

d) Removing unnecessary columns

The data set contained a column named "National Identity Card Number" (NIC) which helps to identify each customer uniquely. It has been removed from the data set because it is not useful for the prediction purpose.

e) Checking for null and duplicate values

The null and duplicate values make the final prediction model to be overfitted. To overcome this issue the null and duplicate values have been replaced with the mean value of the corresponding column.

f) Converting all variables to a common type

For instance, the total number of complaints and the number of negative feedbacks sent by the customers have been presented in the integer data type. Meanwhile, download bandwidth, monthly bill, and most of the other features have been presented in the double format with decimal points. To conclude, the integer datatype features have been converted into the double data type.

g) Outlier detection and replacement

i. Initially, outlier values for each column have been identified. (First Quartile (Q1), Third Quartile (Q3), and Inter Quartile range (IQR) values of all columns have been used in this regard.)

ii. Replacement of random values within quartile range for outlier detected cells.

iii. Validation of each column value is within the quartile range limit.

iv. Creation of new CSV without the outlier values.

h) Normalizing the data set between the fixed ranges.

i. Min Max Scaling technique has been adopted in this regard.

ii. Normalized Value = (Actual Value – Minimum Value) / (Maximum Value – Minimum Value)

b) Names of the Attributes & Their Descriptions

No	Attribute	Description	Repre-sentation
1	Monthly Bill	The average amount of payment done by the customers	Sri Lankan Rupees
2	Billing complaint resolve time	The time duration used to resolve billing complaint	Minutes
3	Billing complaint count	Number of complaints concerning bills	Numeric
4	Promotions	The Short Message Services provided by the company to the customers about their products, services, and so on	Numeric
5	Hotline call time	Total number of minutes taken for hotline call duration in a specified period	Minutes
6	Hotline call count	Total number of hotline calls in a specified period	Numeric
7	Arcade visit time	Total number of minutes visit taken to visit the arcade	Minutes
8	Arcade visit time waiting time	Total number of minutes taken to wait at the arcade	Minutes
9	Arcade visit count	Total number of visits made to the arcade	Numeric
10	Negative feedbacks customer sent	The count of negative feedbacks given by a customer	Numeric
11	Positive feedbacks customer sent	The count of positive feedbacks given by a customer	Numeric
12	Complaint resolve duration	Amount of time used to resolve complaints	Minutes
13	Total complaints	Number of complaints made by a customer	Numeric
14	Complaint breach count	Count of complaints not resolved within a given time	Numeric
15	Coverage related complaint duration	Amount of time taken for complaints regarding coverage made by a customer	Minutes
16	Coverage related complaint count	Complaints made regarding coverage	Numeric
17	Adjustment charges	Alternative charges for additional packages	Sri Lankan Rupees
18	Download bandwidth	Average Bandwidth	Megabytes per second
19	Data used for download	The total amount of data used	Megabytes per second
20	Data Charges	Total payment for data usage	Sri Lankan Rupees
21	Churn [Target]	Churn represents by – 0, Non-churn represent by - 1	Boolean

C. Feature Engineering and Model Generation

After completing the data abstraction and enhancement segment, the dataset with all the attributes has been fed into the selected supervised machine learning algorithms and encountered a problem of model overfitting. After a certain amount of analysis, the subsequent phase would be pinpointing the finest set of attributes that could offer a significant contribution to the data set. The Pearson correlation analysis technique was followed for the above purpose. By the utilization of the aforementioned technique, highly correlated attributes towards the target variable were removed. This was done because the highly correlated variables would not help improve the model score further. Then the dataset has been reshaped according to the significant attributes and fed into the selected supervised algorithms.

As the next step of identifying the most suitable algorithm consisting of better accuracy, this procedure comes to an end with the preparation of the final or last forecasting model. Besides, to identity the churners and non-churners a user-friendly GUI has been developed by adapting the algorithm which provides the highest accuracy.

IV. Results and Discussion

A. Results of detecting the extremely co-related features

During this process, a thorough analysis was carried out to find out the relationship between the prevailing attributes and the target attribute. Pearson correlation analysis was used for this purpose.Fig.2 shows the numerals and the complete score obtained by comparing and contrasting the relationship between each variable with the target variable [‘churn’]. As Fig.2 shows, the highly correlated features that contain an absolute score of 0.5 and more were identified.

With the results obtained from above, further analysis also was done to recognize 17 out of 20 attributes provide a certain amount of correlation with the target variable. Consequently, the removal of the rest of the highly correlated attributes from the data set was successfully carried out.

After finding out only the important attributes, the whole dataset was classified into two non-equivalent sections. These two sections are namely training and testing. Then, it is fed into the particular supervised machine learning techniques (Random Forest, XGBoost, AdaBoost, Logistic Regression, SVM, ANN, and Decision Tree) to identify the best one to originate the final forecasting model.

The possible results of the performances during the forecasting task were duly evaluated. For this purpose, several methods such as Accuracy, Mean Squared Error (MSE), Confusion Matrix, Mean Absolute Error (MAE), Precision, Recall, and F1-Score were used. The main procedure taken into consideration here was the K-fold cross-validation. [1][2].

B. Comparison of performance

The discussion below is based on the results got during the comparison of performances concerning several algorithms in forecasting the churners and non-churners in the industry of telecommunication. This type of discussion has paved a dependable way to follow a feasible approach towards a “Supervised Learning Technique” in machine learning because the target variable and the highly connected variables were tested in this lengthy investigation. Numerous algorithms were adapted and compared against certain evaluation metrics in the course of this prediction process. Shown below is the additional investigation of this task.

Fig. 2. Correlation between variables of the data set

As depicted before in this research, 10,000 subscriber details with 17 attributes and one target variable were incorporated for deep analysis. With the randomly selected datasets, 70% was included for training and 30% was taken for testing. In Table I and Table II "Evaluation Metric" results and "Confusion Metric" results of various models are presented.

TABLE I. PERFORMANCE OF CLASSIFIERS AGAINST CERTAIN EVALUATION METRICS

Models	Accuracy (%)	MSE (%)	ASE (%)	Precision (%)	Recall (%)	F-1 (%)
Decision Tree	75.00	25.00	25.00	74.87	73.75	74.31
Neural Network	82.40	17.60	17.60	75.45	96.14	84.55
Logistic Regression	77.36	22.63	22.63	73.23	84.84	78.61
Random Forest	78.50	21.50	21.50	74.49	85.38	79.56
XGBoost	82.90	17.10	17.10	74.48	99.04	85.03
AdaBoost	82.03	17.96	17.96	74.34	96.73	84.07
SVM	79.76	20.23	20.23	72.61	94.28	82.04

TABLE II. CONFUSION METRICS OF THE CLASSIFIERS

Models	Confusion Matrix			
	TN	FP	FN	TP
Decision Tree	1165	364	386	1085
Neural Network	1027	470	58	1445
Logistic Regression	1073	456	223	1248
Random Forest	1099	430	215	1256
XGBoost	**1030**	**499**	**14**	**1457**
AdaBoost	1038	491	48	1423
SVM	1006	523	84	1387

In addition to the results obtained from the aforementioned tables, the K-fold cross-validation technique was performed with 5 folds to find the best technique to deal with any proportion of testing and training data. (Fig 3)

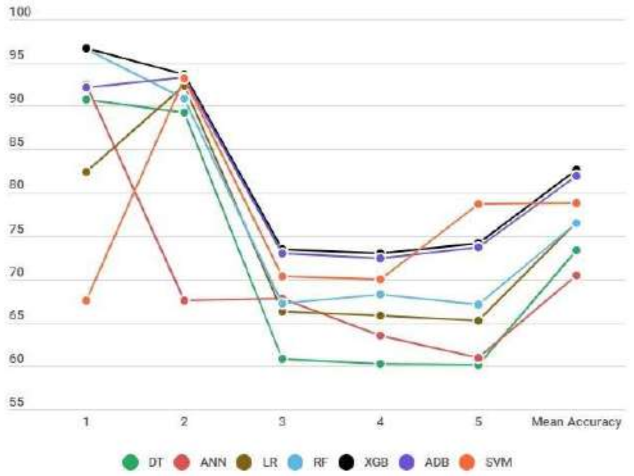

Fig. 3. Five-Fold cross-validation accuracies of selected algorithms

The aforementioned graph shows the accuracies obtained by the algorithms for each fold along with mean accuracy. All in all, the accuracy declines after the 2nd fold over the period up to the 3rd fold, whereas the accuracy shows some optimum level with ensemble techniques. Even though there is a slight increase in accuracy shown by SVM at the 5th fold, the highest mean accuracy is obtained only by XGBoost.

As a final attempt, it was noted and ensured that with all sorts of analyses completed so far, XGBoost has surpassed all other techniques with higher and better accuracy which is 82.90 % showing a low error rate of 17.1 %. Therefore, a more confirmed assumption can be made that the XGBoost is the most suitable algorithm in the course of attaining the final and ultimate model of prediction. Furthermore, to obtain an even better accuracy out of what already received, Grid Search CV hyper-parameter tuning was done with XGBoost and this effort has brought about 83.13% of accuracy in the forecasting of churning behavior. It is also well noted that during the process of tuning, “Learning Rate”, “Max Depth”, “Min_Child_Weight”, “Gamma” and “Colsample By Tree” were taken into attention because hyper-parameters and tuning had been carried out with optimum values.

It can be concluded that the ultimate prediction model was designed with the use of XGBoost along with a GUI implementation and it is sufficiently efficient to forecast the churners and non-churners relatively earlier.

V. Conclusion and Future Works

It can be thus concluded that forecasting the attrition behavior on the part of the clients is compulsory for almost all the manufacturing or service sectors. Start-ups too can be included in this importance. As an experimental procedure, the management of the churning attitude of the clients in the telecommunication industry has been effectively assessed in the process of this research. As it has become severely competitive, there is a tendency on the part of the users of the communication facilities to leave certain service providers and opt for another one. Therefore, as mentioned above, this model will enable an organization to identify the possibility of the churning and the reasons for such behavior on time and in advance. Further in this investigation, an attempt had been made to employ several supervised machine learning techniques. As a result of this effort, evaluation has been successfully carried out in connection with various performance metrics.

Besides, this study has made an effort to adapt several supervised machine learning techniques here and so, the evaluation was easily done concerning different performance metrics. Besides, a thorough comparison incorporating the algorithms such as Decision tree, Neutral Networks, Logistic Regression, Random Forest, SVM, XGBoost, and AdaBoost, has duly been done. Subsequently, correct cross-validation on these algorithms was also performed by utilizing a very suitable method to develop the most expected final prediction model in this field. As a reward, a relatively increased accuracy of 82.90% was produced by XGBoost, and at the same time, the least error rate of 17.10 % was gained by the XGBoost. As the last effort, a most practical prediction model was successfully created. The above effort has brought about the advantage of having the capability to predict the probability of the churners and non-churners very correctly. A further expansion of this model can be made available through the development of a combined model of churn prediction in the telecommunication industry. So, this particular model can be considered as the most appropriate prediction model which could be used in several other companies free of charge. Further, it was felt that when the hyper-parameter tuning was used before executing cross-validation, the accuracy shown by the prediction done in the supervised learning techniques would be greater. So, it is certain that anyone willing to carry out similar research in the future can depend on this effective churn prediction model when they attempt to combine or associate the supervised machine learning method and the unsupervised machine learning technique.

***Abstract*— The emergence of electrical energy in the field of vehicle traction remains a major preoccupation of electro technicians today after a long absence, owing to the collective commitments and responsibilities of the states and automobile manufacturers as well as the advances made in various technological and scientific fields and more precisely the optimization of the electrical energy consumed by the motor. In this paper, we present a method of control of a Brushless Direct Current Motor (BLDCM) during the traction of an autonomous robot. This is done by optimizing the power consumed by the motor to find the optimal current and then find the optimal torque to function the machine. Then we optimize the energy of the traction to find the optimal slip ratio and the optimal linear velocity for an optimal operation that allows us to reuse the lost energy.**

***Keywords*— autonomous robot, BLDCM, optimization, optimal current, optimal slip ratio, power consumed, traction.**

I. Introduction

With a strong increase in demand for the use of electrical vehicles, the consumption of electrical energy has remained higher in recent years. Energy savings not only make it possible to quickly recover the additional cost of investing in electrical equipment (e.g. reactive energy compensation, electricity consumption monitoring devices or the use of a high-efficiency motor), but also to ensure the competitiveness of a company [1].

In this context, the problem of optimization comes to solve this challenge [2, 3]. Optimization problems in electrical engineering present several difficulties related to the user's needs [4, 5] (search for a global solution, reliability and precision of the solution, diversity of the problems treated, available calculation time, ...), as well as to the characteristics of the optimization problem [6, 7] (non-linear, derivatives not easily accessible, ...), and to the important calculation time. The resolution of such difficulties has been subject of numerous works using several optimization methods [8, 9]. In order to determine the most appropriate way to solve the problem of optimization of the energy consumed by the engine, it is necessary to inspect all the optimization methods to determine which ones are the most appropriate for the problems that the authors consider. the choice of the optimization method is made according to several criteria: the type of variables related to the problem, the knowledge of the mathematical model that describe the problem, the knowledge of the evolution of the objective function on the solution spaces, or the possibility of using a population of solutions to perform the optmal solution. Several optimization methods and algorithms are descussed in literature [10, 11]. Some authors use combinatorial optimization to solve the desired objective using either the exact method [12, 13] or the approximate method [14]. This last, uses either the heuristic method [15] or the metaheuristic method [16]. Other authors use continuous optimization [17] to solve the problem either through the linear method [18] or the nonlinear method which is based on the local gradient method [19] or the local gradient free method [20] or also the classical global gradient method [21] which brings us to the neighborhood or distributed methaheuristic method. Others use the evolutionary algorithm to solve the optimization problem using the genetic algorithm [22], also others use the swarm intelligence algorithm [23], and finally some authors use the hybrid optimization methods to solve a given problem [24], either using serial hybrid method, pararallel hybrid method or insertion hybrid method.

The objective of this paper is to optimize the energetic consumption of Brushless Direct Current Motor (BLDCM) using a cascading optimization. The first is relative to the optimization of the power used to generate the mechanical energy and the other is the optimization of the traction power used to navigate the agriculture robot « Agri Eco robot » [25, 26] in a rough environment, in order to gain the energy, and reuse it to aliment other equipment. In this perspective, we will present in the second paragraph the motor modeling, the power efficiency of the motor, and the traction efficiency of the wheel. The obtained relations in terms of power efficiency and traction efficiency are optimized in order to find the optimal current and optimal slip ratio that held to the optimal linear velocity for an optimal function of the robot, this will be discussed in the third part. The last paragraphe is dedicated to the result of this approach that will be implimented and validated using Matlab Simulink Software. At the end of this paper, we will summarize the results that we have reached, to be then reused in the next papers.

II. Description of the model

A. The motor modeling

The main objective of this paragraph is to develop a continuous model of the BLDCM [27]. The motor connection devices is given in the schematic as follows:

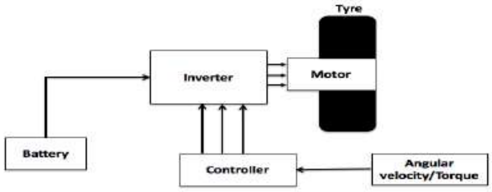

Fig. 1 Motor connection devices

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

It is assumed that the motor is governed by the following conditions:

- The three-phases stator are symmetric, this means that their resistances R and inductances L, are equal in the three phases;
- The induction field distribution created by the magnet is purely trapezoidal;
- The Electromotive Forces (EMFs) in the gap are trapezoidal distributed;
- The Magnetic Circuit is assumed to be unsaturated, which allows flux to be expressed as a linear current function;
- The Magnetic circuit is assumed to be perfecty laminated; this means that the hysteresis effect and the Foucault currents are neglected;
- Skin effect and temperature effect are all neglected.

The Electrical Equations that govern the operation of the BLDCM [28]. If the motor is without salience, the voltages at the terminals of the three stator phases are written according to Ohm's law:

$$\begin{bmatrix} V_a = Ri_a + L\frac{di_a}{dt} + e_a \\ V_b = Ri_b + L\frac{di_b}{dt} + e_b \\ V_c = Ri_c + L\frac{di_c}{dt} + e_c \end{bmatrix} \quad (1)$$

In which,

$$\begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} = p\Phi_m\omega \begin{bmatrix} tra(\Theta_e) \\ tra(\Theta_e - \frac{2\pi}{3}) \\ tra(\Theta_e + \frac{2\pi}{3}) \end{bmatrix}$$

$$tra(\Theta_e) = \begin{bmatrix} 1 & si\ 0 < \Theta_e < \frac{2\pi}{3} \\ 1 - \frac{6}{\pi}(\Theta_e - \frac{2\pi}{3})\ si & \frac{2\pi}{3} < \Theta_e < \pi \\ -1 & si\ \pi < \Theta_e < \frac{5\pi}{3} \\ -1 + \frac{6}{\pi}(\Theta_e - \frac{5\pi}{3})\ \ si & \frac{5\pi}{3} < \Theta_e < 2\pi \end{bmatrix}$$

where,

V_a, V_b, V_c : Voltages between the end of the phase winding and the middle of the Direct Current voltage source.

i_a, i_b, i_c: The stator phase currents.

e_a, e_b, e_c: The back-electromotive forces (back-EMF) in the stator phases.

Φ_m: The maximum flux produced at the stator.

p: The number of pole pairs.

Θ_e : The electrical position of the rotor that relate the mechanical position by the equation.

$$\Theta_e = p\Theta \quad (2)$$

The conversion of electrical energy into mechanical energy in the brushless direct current motor (BLDCM) is governed by the following relationship derived from the Theorem of Momentum:

$$C_{em} - C_r = f_v\omega + J\frac{d\omega}{dt} \quad (3)$$

where,

$$C_{em} = \frac{1}{\omega}(e_a i_a + e_b e_b + e_c e_c) \quad (4)$$

where,

J is the inertia of the rotor, the mechanical speed of rotation of the rotor,

C_{em} the motor torque provided by the stator,

C_r the load resisting torque,

f_v the viscous friction coefficient.

The projection of this equation into the two-phase frame is obtained using the projection into the Park frame whose equations is given by:

$$P(\Theta) = \frac{2}{3}\begin{pmatrix} \cos(p\Theta) & \cos(p\Theta - \frac{2\pi}{3}) & \cos(p\Theta + \frac{2\pi}{3}) \\ -\sin(p\Theta) & -\sin(p\Theta - \frac{2\pi}{3}) & -\sin(p\Theta + \frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{pmatrix} \quad (5)$$

The magnetic equation is defined as follows:

$$\Phi_d = L_d i_d + \Phi_m \quad (6)$$

$$\Phi_q = L_q i_q \quad (8)$$

Thus, the electrical equation is defined as follows:

$$V_d = Ri_d + L_d\frac{di_d}{dt} - p\ \omega L_q i_q \quad (9)$$

$$V_q = Ri_q + L_q\frac{di_q}{dt} + p\ \omega L_d i_d + p\omega\Phi_m \quad (10)$$

The mechanical equation is defined as follows:

$$C_{em} - C_r = f_v\omega + J\frac{d\omega}{dt} \quad (11)$$

In which,

$$C_{em} = \frac{3}{2}p\ i_q\Phi_m \quad (12)$$

where,

V_d,V_q: Voltages projected at Park's reference frame.

(d, q): Symbols refers to the direct and quadratic axis.

L_d , L_q: Direct inductance and quadratic inductance.

For the control of this type of motor, we apply the principle of vector control, which is identical to the control of a Direct Current motor with separate excitation. However, the Park reference frame mark must be used.

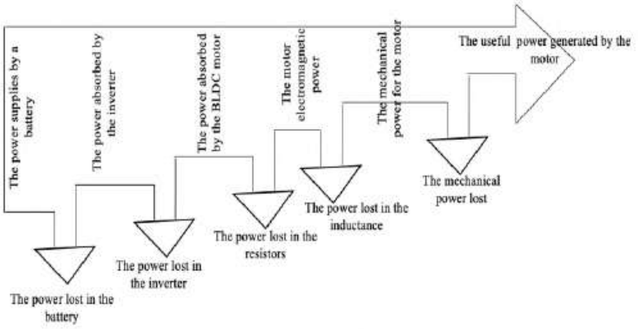
The d-axis component of the stator current acts as the excitation and allows the flux value in the machine to be adjusted. The q-axis component acts as the armature current and controls the torque.

Thus, the strategy consists in imposing the current i_q at a value corresponding to the desired torque C_{em} while maintaining zero current i_d, in order to work at maximum torque. The speed regulation is done in cascade by imposing the desired value of the speed on channel q.

In the following we will consider that L_d= L_q= L

B. The energitic efficiency of the motor

Let the energy distribution chain of the motor be defined as follows:



The power supplies by a battery
The power absorbed by the inverter
The power absorbed by the BLDC motor
The motor electromagnetic power
The mechanical power for the motor
The useful power generated by the motor
The power lost in the battery
The power lost in the inverter
The power lost in the resistors
The power lost in the inductance
The mechanical power lost

Fig. 2 The energy distribution chain obtained from the battery to run the engine

By neglecting the ohmic and inductive voltage across the stator windings, the following expressions are obtained:

$$P_c = i_s V_s \qquad (13)$$

Where,

$$i_s = \sqrt{i_d^2 + i_q^2} \leq i_n$$

$$V_s = \sqrt{(p\omega L i_q)^2 + (p\omega)^2(\Phi_m + L i_d)^2} \leq V_n$$

i_n: Maximum value of the current that can be absorbed by the BLDCM.

V_n: Maximum output voltage of the inverter depends on the DC bus voltage at its input.

Hence, the power consumed by the motor is defined as follows.

$$P_c = \sqrt{i_d^2 + i_q^2}\sqrt{(p\omega L i_q)^2 + (p\omega)^2(\Phi_m + L i_d)^2} \leq i_n V_n (14)$$

While regulating direct and quadratic current to work at maximum torque, we obtain i_d=0.

$$P_c = p\omega i_q \sqrt{(L i_q)^2 + (\Phi_m)^2} \leq i_n V_n = P_n \qquad (15)$$

In which, $\boldsymbol{P_n}$ is the nominal power of the motor.

The effective power required to function the motor is defined as follows:

$$P_u = C_{em}\omega \qquad (16)$$

Hence,

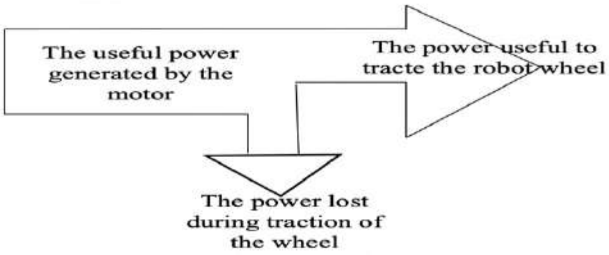
$$P_u = \frac{3}{4} p\, i_q \Phi_m \omega \qquad (17)$$

The energetic efficiency of the motor is defined in equation as follows.

$$\eta = \frac{P_u}{P_c} = \frac{1}{2} * \frac{\frac{3}{2}\Phi_m}{\sqrt{(L i_q)^2 + (\Phi_m)^2}} \qquad (18)$$

C. The traction efficiency of the wheel

Let the energy distribution chain of the wheel of the robot be defined as follows:



The useful power generated by the motor
The power useful to tracte the robot wheel
The power lost during traction of the wheel

Fig. 3 The energy distribution chain obtained from the rotation of the motor to move the wheel

We assume that the robot is towed by a single wheel defined as follows

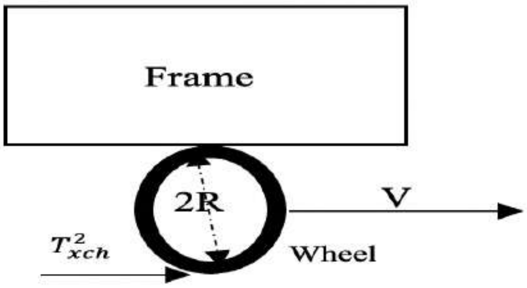


Fig. 4 The frame of the robot under one wheel

The power provided by the motor is defined as follows:

$$P_u = \frac{3}{4} p\, i_q \Phi_m \omega \qquad (19)$$

The power required for the traction of the vehicle:

$$P_t = T_{xch}^2 \times V \qquad (20)$$

With T_{xchi}^2 is the longitudinal tractive force [29], [30], [31]:

$$T_{xch}^2 \approx R w \tau_{m,t} \theta_f \qquad (21)$$

Where:

$$\tau_{m,t} = (C + (\left(\frac{k_c}{w} + k_\emptyset\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q \left(R\omega\theta_f\right)^q) \tan(\emptyset))(1 - \exp\left(\frac{R\,\theta_f s)}{K}\right) \qquad (22)$$

And:

$$\theta_f = \left(\frac{2^n m_t g}{R^n w\left(\frac{k_c}{w} + k_\emptyset\right)}\right)^{1/(2n+1)} \qquad (23)$$

V is the linear velocity of the wheel:

$$V = R\omega(1 - s) \qquad (24)$$

Where:

w is the width of the wheel

k_c is the cohesion module;

$k_\emptyset$ is the friction module;

n is the sinkage exponent;

K_q is the sinkage speed constant;

q is the soil propriety constant;

$\tau_{m,t}$ is the maximum of tangential shear stress.

C is cohesion;

ϕ is the angle of internal friction;

K is shear deformation modulus;

s is the slip ratio of the wheel.

Hence

$$\eta_t = \frac{P_t}{P_u} = \frac{4}{3} * \frac{R^2 w \tau_{m,t} \theta_f (1-s)}{p\, i_q \Phi_m} \qquad (25)$$

III. Optimization using metaheuristic

A. The optimal current and torque to optimize the energy consumed by the machine

Mathematically, the optimal problem is to maximize the machine's output for better machine efficiency

The objective function is mention as follows:

Maximize ($\eta = \frac{1}{2} * \frac{\frac{3}{2}\Phi_m}{\sqrt{(L i_q)^2 + (\Phi_m)^2}}$) involves minimizing $(f(i_q) = \sqrt{\left(L i_q\right)^2 + (\Phi_m)^2}\ )$

Hence, the heuristic function under study is defined as follows:

minimize $(f(i_q) = \sqrt{\left(L i_q\right)^2 + (\Phi_m)^2}\ )$

Subject to:

$$0 < i_q < i_n$$

$$V_s = p\omega\sqrt{\left(L i_q\right)^2 + (\Phi_m)^2} \leq V_n$$

Given variables:

$$\omega, i_q, V_n, i_n, L, \Phi_m$$

Once set all variables except i_q

There we find:

$$i_q < i_{qopt}$$

where,

$$i_{qopt} = \frac{1}{\sqrt{2}}\frac{\Phi_m}{L} \qquad (26)$$

B. The optimal slip ratio for an optimal control of the energy consumed by the motor

Mathematically, the optimal problem is to maximize the traction efficiency of the Brushless Direct Current motor inserted in the wheel for a better energetic efficiency of the wheel consumption.

Hence,

Maximize $\left(\eta_t = \frac{4}{3} * \frac{R^2 w \tau_{m,t} \theta_f (1-s)}{p\, i_q \Phi_m} \right)$ involves maximizing $(g(\mathrm{s}) = \tau_{m,t}(1-s))$

Hence, the heuristic function under study is defined as follows:

Maximize $(g(\mathrm{s}) = \tau_{m,t}(1-s))$

Subject to:

0< s < 1 While acceleration

Given variables:

$$C, k_c, k_\emptyset, \theta_f, \emptyset, K, \omega, K_q, \mathrm{R}, \mathrm{s}$$

Once set all variables except s

Hence, we find:

$$s_{opt} = {(K + (LambertW(0, \exp\left(\frac{R\,\theta_f}{K}\right)) + \frac{R\,\theta_f}{K} - 1))} \Big/ {R\,\theta_f} \quad (27)$$

From the point of view, the slip ratio of the wheel is defined as follows:

$$s_{opt} = \frac{R\omega - V_{opt}}{R\omega} \quad (28)$$

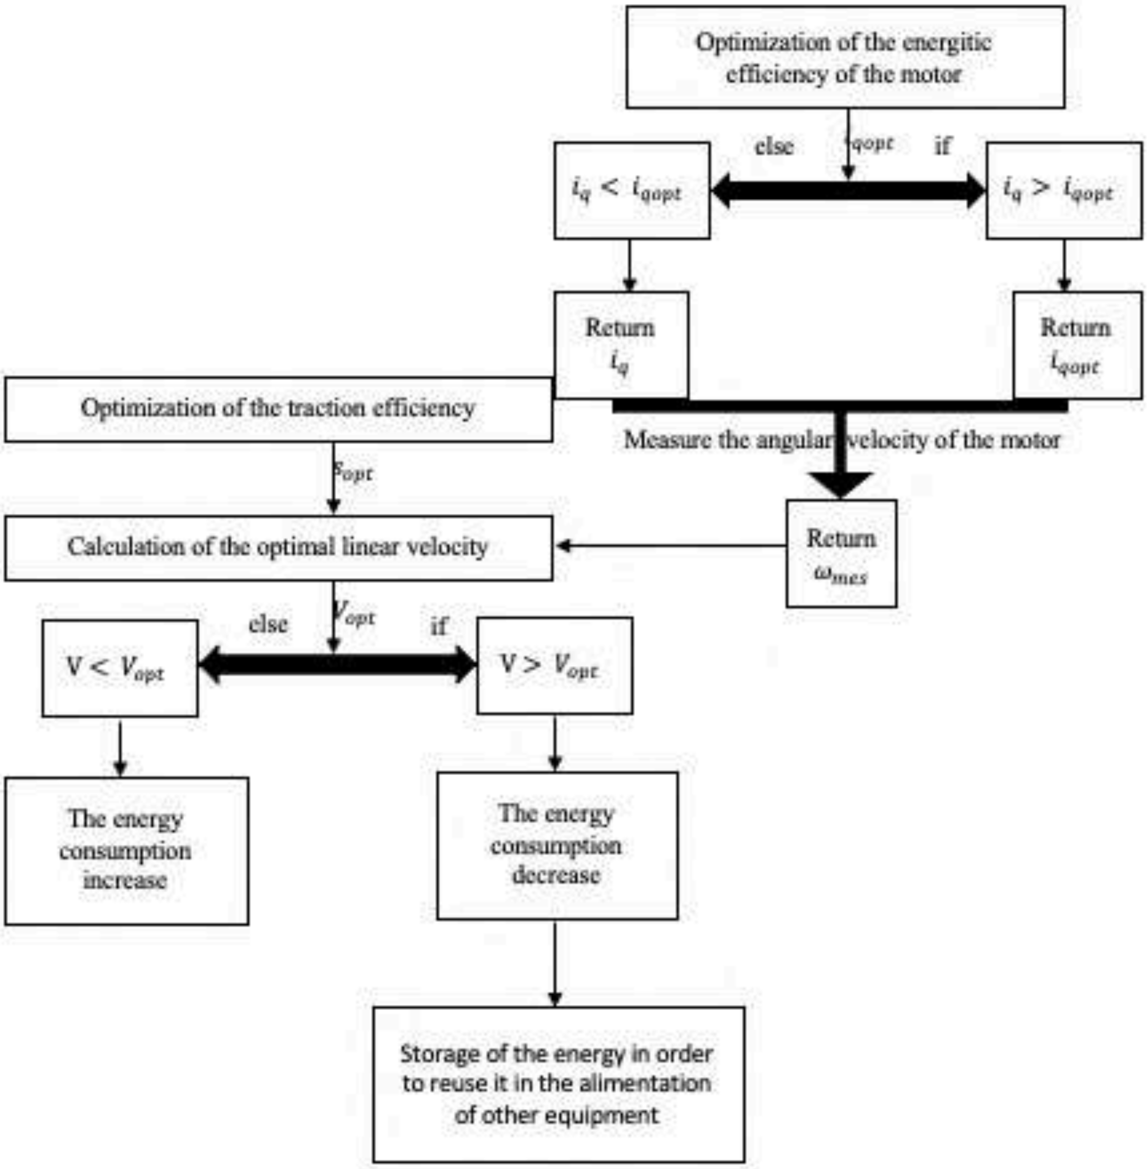
Hence, the linear velocity of the wheel is:

$$V_{opt} = R\omega(1 - s_{opt}) \quad (29)$$

IV. Result of the optimization design

A. Overal optimization design

The algorithm elaborated to optimize the energy consumption of the motor is illustrated in the flowchart as follows:



Optimization of the energitic efficiency of the motor
i_{qopt}
else
if
$i_q < i_{qopt}$
$i_q > i_{qopt}$
Return i_q
Return i_{qopt}
Optimization of the traction efficiency
Measure the angular velocity of the motor
s_{opt}
Calculation of the optimal linear velocity
Return ω_{mes}
V_{opt}
else
if
V < V_{opt}
V > V_{opt}
The energy consumption increase
The energy consumption decrease
Storage of the energy in order to reuse it in the alimentation of other equipment

Fig. 5 Flowchart of the optimization algorithm

B. *Result of the modeling system*

The mathematical modelling of the motor is validated under Matlab Simulink Software as shown as follows:

In which,

$$i_{qref} = \begin{Bmatrix} i_q & if\ i_{qref} < i_{qopt} \\ i_{qopt} & if\ \ i_{qref} > i_{qopt} \end{Bmatrix} \quad \text{and} \quad i_{dref} = 0 \quad /$$

To maximize the torque generated by the motor.

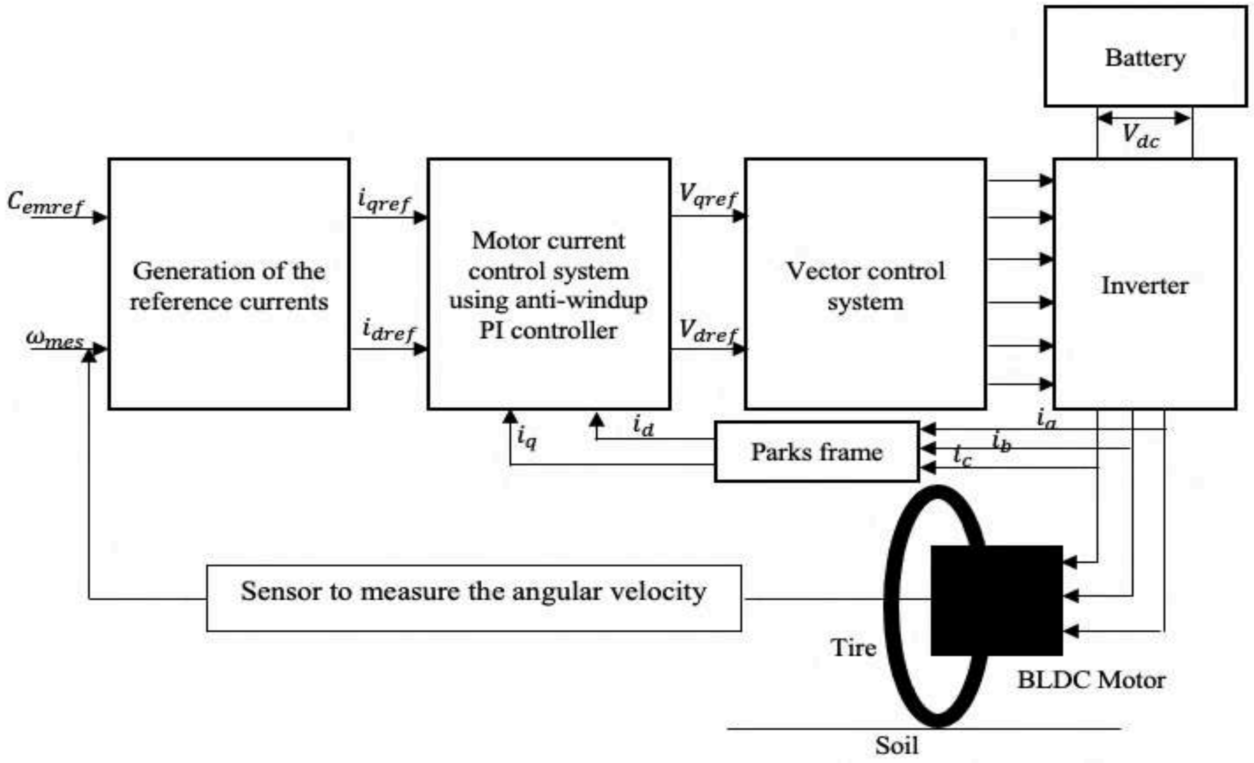


Fig. 6 The closed loop torque regulation of the BLDCM

The characteristics of the motor is defined in the table as follows:

TABLE I. BLDC MOTOR PARAMETERS

Nominal power (W)	250
Dc link voltage (V)	36
Maximum rotor-flux (Wb)	1.255 e-2
Viscous friction coefficient (N$mrad^{-1}s^{-1}$)	1.6e -3
Phase resistance (mΩ)	500
Phase inductance (mH)	0.68
Maximum speed (rpm)	3000
Pairs of poles	4
Moment of inertia (Kgm^2)	0.06

The soil parameters are defined as follows:

TABLE II. SOIL PARAMETERS

The cohesion module (KN/m^{n+1})	14.5
The friction module (KN/m^{n+2})	705.22
The sinkage exponent	0.36
The viscous friction coefficient (KPa)	4.76
The sinkage speed constant	0
The soil propriety constant	0.1
The angle of internal friction (Degree)	31.5
The shear deformation modulus (Cm)	1,2

The geometrical parameters of the robot wheel are defined in the table as follows:

TABLE III. WHEEL AND VEHICLE PARAMETERS

The mass of the vehicle (Kg)	84
The gravitational acceleration (m/s^2)	9.8
The wheel radius (m)	0.20
The wheel width (m)	0.05

Hence, the figures as follows gives us the result of the approach elaborated previously:

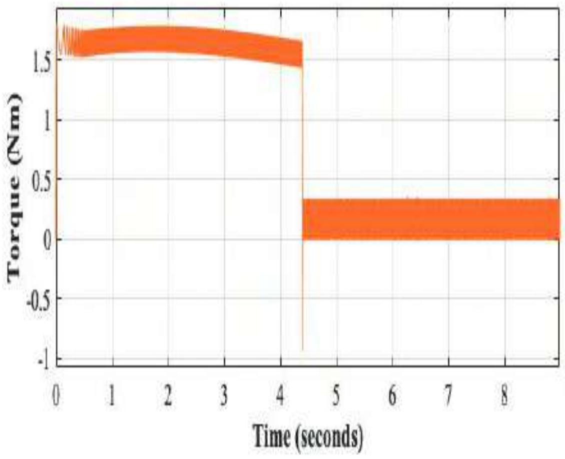

Fig. 7 *The torque imposed* during regulation

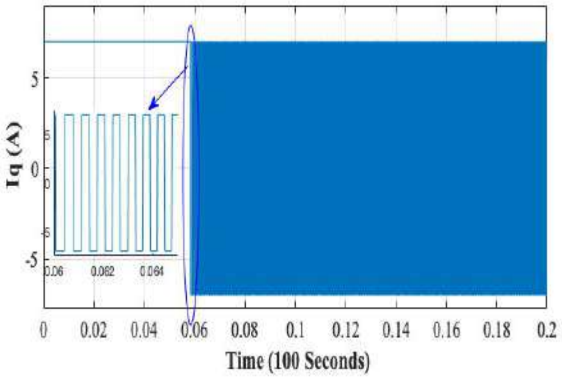

Fig. 8 The quadratic current response as a function of time

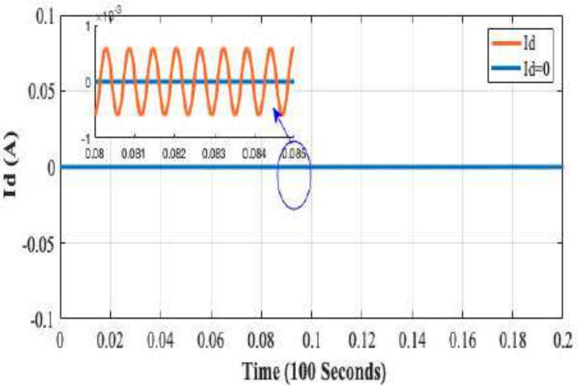

Fig. 9 The direct current during regulation to have maximum torque

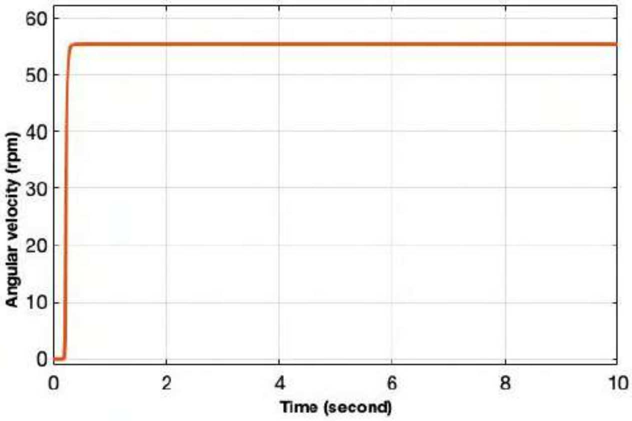

Fig. 10 The measured angular velocity of the wheel while controlling the torque

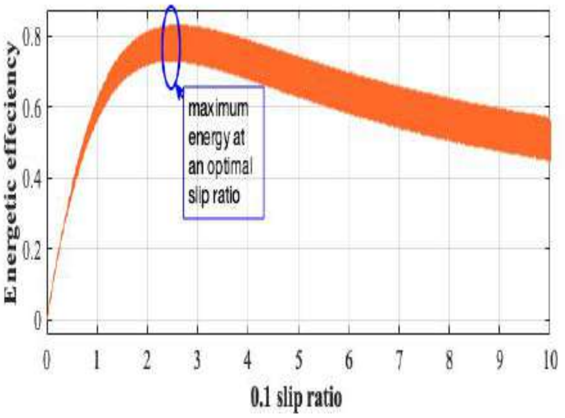

Fig. 11 The energetic efficiency of the motor as a function of slip ratio

From the figure 11, the optimal slip ratio is about 0.27, and the measured angular velocity in steady state is about 55 rpm, hence we obtain a linear velocity equal to 0.84 m/s. We can conclude that if we exceed a velocity equal to 0.84 m/s, the energy consumption decrease. Hence, we can storage the energy and reuse it to aliment other robot equipment.

To have a maximum torque we have regulate the direct current to be zero and the result of the regulation is appropriate.

V. CONCLUSION

In this paper, we propose an algorithm to optimize the energy consumption of the vehicle using a cascading optimization, once use the optimization of the current to control the torque generated by the motor, and the other use the optimization of the slip ratio to obtain an optimal velocity achieved with minimal energy consumed under different driving profiles. In this perspective, we have modelized the Brushless Direct Current Motor (BLDCM) with Trapezoidal Back-Electromotive Force (back-EMF) and its mathematical model, as well as the control of this kind of machine, using the park transformation to apply the algorithm proposed for the optimization. This assumption is validated using Matlab Simulink Software.

Optimizing the energy consumed while controlling the torque generated by the driven wheel of the robot navigating a deformable soil (while sliding) in real time, will be the subject of further works.

ACKNOWLEDGMENT

The authors of this paper are thankful to the Ministry of Higher Education and Scientific Research of Morocco (MESRSFC), and the National Center for Scientific and Technical Research of Morocco (CNRST) for financing this project.

***Abstract*—Metered dose inhalers (MDI) are used to manage or to provide quick relief to asthmatics. The improper use of an inhaler can result in the administration of an incorrect medication dosage, reducing the effectiveness of the device and resulting in higher treatment costs for the patient. The design process of an inhaler sleeve is outlined, intended to assist in the use of a standard MDI.**

The purpose of the sleeve is to monitor the user's technique during the four most critical steps of their inhaler use. These steps include shaking the device before use, coordinating the canister actuation with their inhalation, inhaling at the correct rate, and holding their breathing for the correct amount of time.

The final design consists of a 3-D printed sleeve and a mobile application that guide the patient through the process. Lights are integrated into the sleeve indicating to the user which step they are on and for how long. Sensors are able to monitor the inhaler throughout its use and provide feedback by sharing the data collected to a mobile app. From there, users are shown what steps they are preforming correctly, and which ones need further improvement.

A prototype printed in polylactic acid (PLA) acts as a reference for the accuracy of the 3-D model created. A finite element analysis conducted on the model indicates that the PLA material has sufficient strength for the product; however, opting to print in polyethylene terephthalate glycol (PETG) will allow the inhaler to fit into the sleeve more easily and will reduce the concentrated stresses and deformations seen on the sleeve.

Keywords*— *3-D printing, asthma, inhalation, inhaler, mechatronics, medicine, monitor, puffer, respiration.

I. INTRODUCTION

Asthma is a chronic disease that impacts the airways in the lungs, causing inflammation and constricting the bronchial tubes which restricts the amount of air that can reach the lungs. It affects 1 in 13 people worldwide and is the leading chronic disease in children [1]. Asthma can have several triggers such as exercise, strong scents, or allergic triggers including pollen or pet dander [2]. An asthmatic encountering these triggers can experience asthma symptoms such as wheezing, shortness of breath and chest tightness [3].

The symptoms can be managed using long-term control and quick-relief asthma medications. The medications are dispensed using one of two types of inhalers: the metered dose inhaler (MDI), or the dry powder inhaler (DPI). The most commonly used inhaler is the MDI which is illustrated in Fig. 1 along with its corresponding components [4]. When the user presses on the canister, the medicine is dispensed out of the MDI as a measured puff of fine mist that is then inhaled [5].

Research reveals that up to 94% of asthmatics demonstrate incorrect techniques when using their MDI [6]. Improper inhaler techniques can lead to the administration of an incorrect medication dosage, reducing the benefits of the inhaler. Further, this creates an economic loss due to wasted medication and increased emergency hospital visits for higher cost treatments. The estimated annual losses in Ontario, Canada alone are approximately $141 million [7].

The purpose of this paper is to present a device capable of monitoring the four most common mistakes practiced by asthmatics when using and MDI. These mistakes are as follows [8]:

- Inadequate shaking and mixing of inhaler before use.
- Failure to coordinate actuation of the MDI or canister press on inhalation.
- Incorrect inspiratory flow rates.
- Too short a period of breath holing after inhalation.

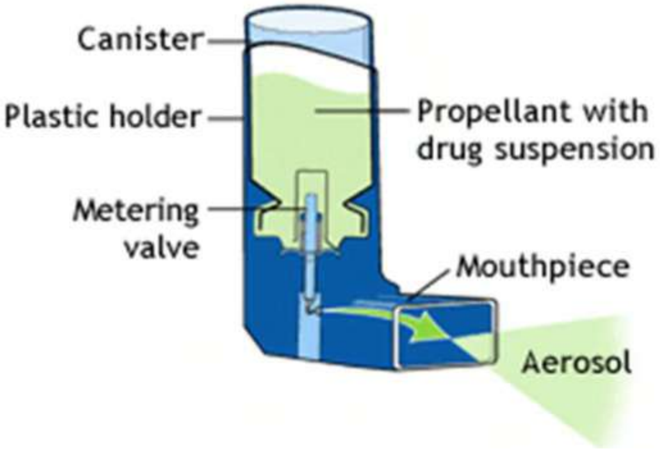

Figure 1. Labelled components of a metered dose inhaler (MDI) [4]

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

The main cause for improper inhaler use technique is the ineffective education practices currently in place. Patients learn how to use an MDI through diagrams, instructions and demonstrations by their healthcare provider. After receiving the demonstration, it is up to the patient to continue to practice proper inhaler techniques.

Consequently, a need exists to provide a solution that helps asthma patients practice consistently proper inhaler techniques on their own to increase the effectiveness of asthma medications.

The developed design is able to monitor the four mistakes mentioned previously and further provide feedback to the user. The feedback on the inhaler use technique is provided to the user both through real-time feedback and after their MDI use. The main goal of the sleeve is to provide a more satisfactory user experience and to reduce the wasted medication.

II. Proposed Solution

A. Constraints and Criteria

The main constraints for the designed device are outlined in Table I and are related to the ability to monitor the inhaler use mistakes and the ergonomics of the design. In addition to the constraints, several criteria are also considered. The product usability determines the chances that a patient will adopt the device. Creating a design that is simple and straightforward to use motivates an asthmatic to frequently use the product and develop the proper inhaler techniques.

The discreetness of the device further encourages its use by the user. The patient should feel comfortable using the product when needed despite their environment. This consideration lends to avoiding designs that are loud and obtrusive which may draw the attention of people nearby.

Implementation and the environmental impact of the proposed design will determine the success of the final product. A device that is easily adapted to current MDIs is more accepted by patients and will result in less environmental waste than developing a unique inhaler. Developing a reusable design will further minimize the environmental impact of the product.

To determine the optimal design for the problem presented, various solutions are compared using decision matrices, and one is selected to meet the constraints and criteria outlined. Each matrix lists the options in the left-hand column and the criteria in the top row. Each criterion is associated with a weight depending on its importance. The options are scored in terms of the criteria with a high score indicating a good option. The option with the highest total after scoring all the criterion is determined to the optimal choice.

TABLE I. Constraints in consideration for the device

Characteristic	*Value*	*Comments*
Product cost	≤ $150 CAD	Based on similar products currently on the market
Device mass with inhaler	≤ 250 gr	Inhaler accounts for 30 gr
Device Dimensions	≤ 10x10x10 cm	Maximum device volume is 1000 cm^3
Battery life	≥24 hrs	
Shaking acceleration detection	≤ 80 m/s^2	Required values to provide the user with valuable feedback
Inhalation speed detection	≤ 100 L/min	
Actuation force detection	≤ 50 N	

B. Design Options

For the overall design, three possible options are considered. The first option is a full inhaler redesign, replacing the current MDI, where the medication canister alone is inserted into. The second is a sleeve attachment that is designed around the standard MDI. Finally, a cap attachment is considered that connects to the top of the standard MDI. Comparing the three designs using the decision matrix shown in Table II, results in the sleeve attachment as the optimal option. This design is compatible with existing MDIs and more compact than the cap, providing additional space for sensors.

C. User Feedback

Four possible feedback methods are considered to provide the patient with real-time feedback. Visual feedback is achievable through the use of lights or a display screen, auditory feedback is limited to a speaker, and haptic feedback is provided through a vibration motor. The optimal user feedback method is determined from the decision matrix in Table III and results in the visual feedback method. This method is more compact and provides minimal public disturbances.

D. Shake Detection

Proper inhaler shaking technique verification is determined through the use of an accelerometer and gyroscope to measure the acceleration of the device. The benefits of this detection method is its accuracy, compact size, and its availability in premade development boards.

E. Inhalation Detection

A method to detect inhalation is necessary to ensure that the user is inhaling at the appropriate rate and for the correct duration. Two options are compared to detect inhalation: an air flow sensor, and a differential pressure sensor. Both options make use of the hollow MDI body by attaching to the top of the sleeve and allowing air to flow through the inhaler body to the sensor. The differential pressure sensor is selected by using the decision matrix in Table IV due to the size and expected cost.

F. Canister Actuation

Three options are compared to ensure proper canister actuation and coordination, each are further categorized as automatic or manual actuation. The automatic options actuate the canister for the patient when inhalation is detected to ensure correct actuation timing. This method is completed by using a motor or a spring to press down the canister. The manual option indicates to the user when to actuate using the selected feedback method. Actuation is detected through the use of a thin-film pressure sensor located in the bottom of the device which reads the actuation force. The optimal actuation method is determined by using the decision matrix seen in Table V. The manual option, using an indicator and feedback, resulted in the optimal choice due to the size, cost, and ease of implementation.

III. Detailed Design

The final design integrates the selected sensors into a sleeve to monitor the user's inhaler technique and to provide feedback during and after its use.

A. *Detection of Common User Mistakes*

Before using the MDI, the patient must properly shake the device to mix the medication in the canister. Failure to properly complete this step can result in the inaccurate administration of the medication and reduce the effectiveness of the MDI. To validate proper inhaler shaking technique, an accelerometer and gyroscope are integrated into the design. This sensor combination is used to recognize that the inhaler is being shaken with an appropriate amount of force and with the correct orientation. Experimental tests consisting of shaking an MDI are completed to determine the threshold of force that indicates that the inhaler is properly being shaken. An accelerometer and gyroscope are attached to an MDI before being shaken by hand to collect the results summarized in Fig. 2. The test is repeated multiple times with little deviation from the data presented. It can be seen that a reading of ± 60 m/s^2 indicates that the inhaler is shaken correctly with peaks of ± 8 m/s^2. The sensors must be calibrated to indicate that the user is shaking the inhaler at the correct acceleration by utilizing an accelerometer that can measure an acceleration of at least 8 m/s^2.

Following the shaking of the MDI, the user is required to simultaneously actuate the inhaler and breathe in the medication. Two common mistakes occur at this step: failure to coordinate the actuation of the canister and inhalation, and failure to inhale at the correct speed. These errors can result in the incorrect dose administration and in the incorrect speed at which the medication reaches a user's lungs. To prevent these common mistakes, two additional sensors are implemented. The first is a thin film pressure sensor which recognizes when and for how long the canister is actuated. Reasearch has identified that the force required to actuate the canister to be around 40N [9]. The thin film pressure sensor is integrated into the sleeve design to measure a force between 30N to 40N indicating that the patient is administering the medication.

During the actuation of the canister, the user is required to breath in the medication slowly for 5 seconds. The optimal rate of inhalation is between 20-30L/min [10] and needs to be monitored by the differential pressure sensor. Due to the small pressure difference, an orifice plate is designed to generate a more dramatic pressure difference that is then detectable by the differential pressure sensor. The sensor should be able to detect a flow rate of 0-100L/min. Bernoulli's equation combined with information provided by [11] are referenced to determine the dimensions of the orifice plate required for the corresponding pressure difference. Once integrated into the sleeve, the orifice plate combined with the differential pressure sensor are able to detect the user's inhalation rate.

Following the inhalation of the medication, the patient is required to hold their breath for 10 seconds to ensure the medication reaches their lungs and is given time to work. A simple timer integrated into the design is able to indicate to the user when the time has been reached.

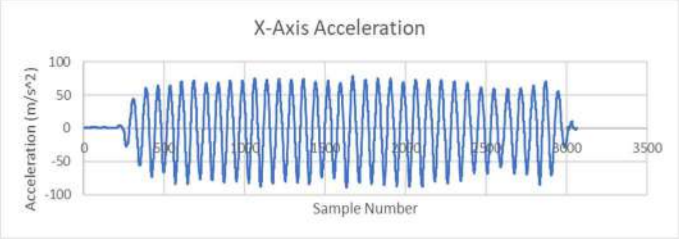

Figure 2. Summary of results gathered from threshold force experiments. The x-axis represents time over which samples are collected

B. *Power*

To power the electronic circuit, a 3.7V, 30mAh rechargeable battery is kept in low power mode until the user starts the device by pressing a button. Setting the standby mode to low power will allow the device to be ready for more than 70 days. Assuming that the product is used for 30 seconds every day, the battery will last for approximately 20 days before requiring to be recharged.

C. Providing Real Time User Feedback

Reinforcing proper inhaler techniques through real-time feedback is achieved by the use of 4 LED lights configured similar to that shown in Fig. 3. The first LED, shown in blue, indicates the step that the patient is on. Each step: shaking the inhaler, actuating the canister, breathing in, and holding the breath are represented by a different colour. This LED indicates to the user the amount of time that they should be spending on each step.

The remaining three LEDs indicate to the patient how well they are preforming the task. If the inhaler is being shaken too gently or the inhalation rate is too slow, the far left LED will turn on. Conversely, if the inhaler is being shaken too aggressively or the inhalation rate is too rapid, the far right LED will turn on. Ideally, the middle green LED will be turned on throughout the use of the device to indicate that the user is following proper MDI techniques.

D. Providing Post Inhaler Usage Feedback

Further improvement of inhaler use techniques is provided to the patient after each use of the product. This is achieved through the connected mobile application which has an appearance and user flow similar to that displayed in Fig. 4. Patients are able to connect their sleeve to the app on their phone which then provides an overview of how to correctly apply inhaler techniques. Also, an explanation of the sleeve is provided so that patients can confidently use the device. The data collected by the sensors on the sleeve design is shared to the app via a Bluetooth module. Patients can access the data of their recent uses to see how well they are applying the inhaler techniques. Additionally, when initially connecting the sleeve to the app, patients will be asked if the canister is new or not. If it is not new, the approximate dosage remaining can be entered so that the app can monitor when the canister is close to being empty and will need to be replaced.

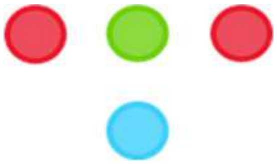

Figure 3. LED light configuration for real-time user feedback

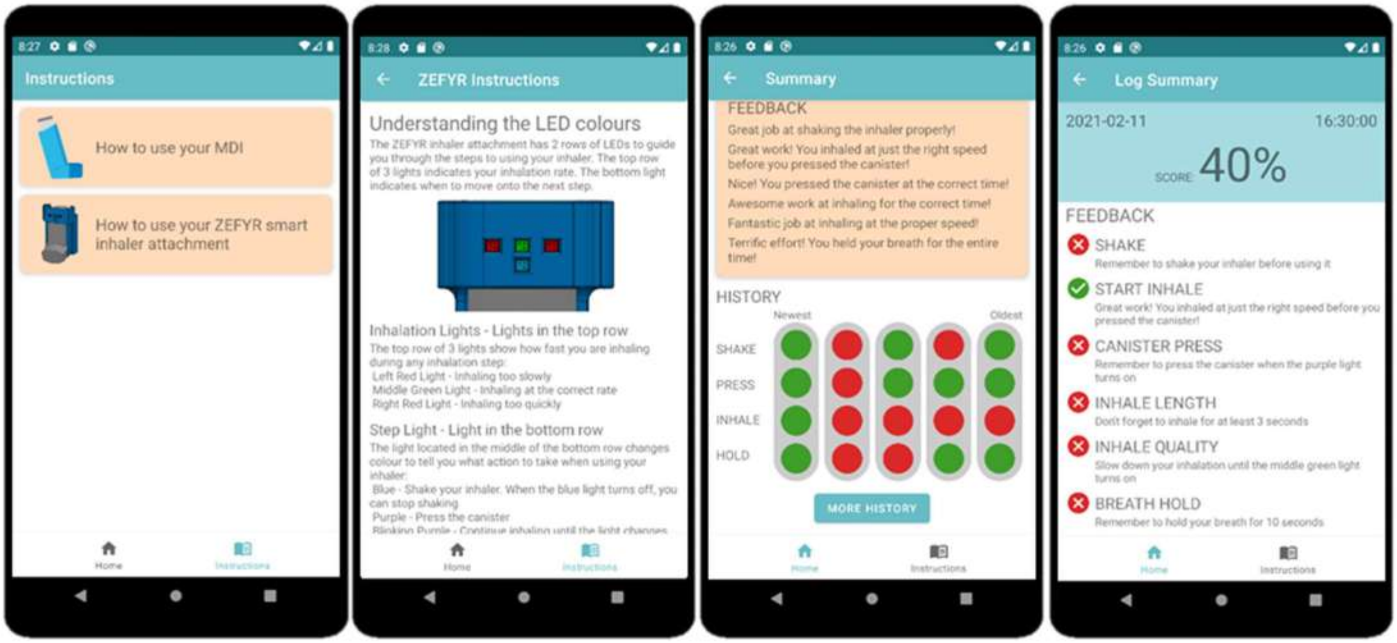
E. Prototype

The final design that is able to integrate all the components necessary to meet the objectives and constraints outlined, is shown in Fig. 5 (a). The sleeve, shown in teal, is designed to fit onto the back, sides, and bottom of a standard MDI. The dimensions accommodate a fixed transition fit, allowing the patient to press the MDI into the sleeve without the possibility of the inhaler falling out. The shape is optimized for a comfortable use and to prevent the inhaler from being excessively bulky. The back of the sleeve is dropped below the top of the canister to allow the user to easily access the canister for actuation.

The approximate location of each sensor and component are identified in Fig. 5 (b) and (c). The development board with integrated Bluetooth module, accelerometer, and gyroscope, and the battery are placed on the back of the sleeve to prevent interference with the use of the inhaler. The touch pressure sensor is located between the sleeve and the MDI body under the inhaler. This is the optimal location as the force applied to the canister by the user is fully transferred onto the sensor. The differential pressure sensor and corresponding orifice plate are placed close to the top of the MDI body to detect the flow rate of the air flowing from the mouthpiece through the hollow MDI body and to the sensor. This location capitalizes on the hollow MDI body and allows the design to be more compact and not as bulky. The indication LEDs are implemented into the front of the sleeve to be visible for the patient during use.



Understanding the LED colours

The ZEFYR inhaler attachment has 2 rows of LEDs to guide you through the steps to using your inhaler. The top row of 3 lights indicates your inhalation rate. The bottom light indicates when to move onto the next step.

Inhalation Lights - Lights in the top row

The top row of 3 lights show how fast you are inhaling during any inhalation step:
Left Red Light - Inhaling too slowly
Middle Green Light - Inhaling at the correct rate
Right Red Light - Inhaling too quickly

Step Light - Light in the bottom row

The light located in the middle of the bottom row changes colour to tell you what action to take when using your inhaler:
Blue - Shake your inhaler. When the blue light turns off, you can stop shaking
Purple - Press the canister
Blinking Purple - Continue inhaling until the light changes

FEEDBACK

Great job at shaking the inhaler properly!
Great work! You inhaled at just the right speed before you pressed the canister!
Nice! You pressed the canister at the correct time!
Awesome work at inhaling for the correct time!
Fantastic job at inhaling at the proper speed!
Terrific effort! You held your breath for the entire time!

Figure 4. Mobile application user flow available to patients after use

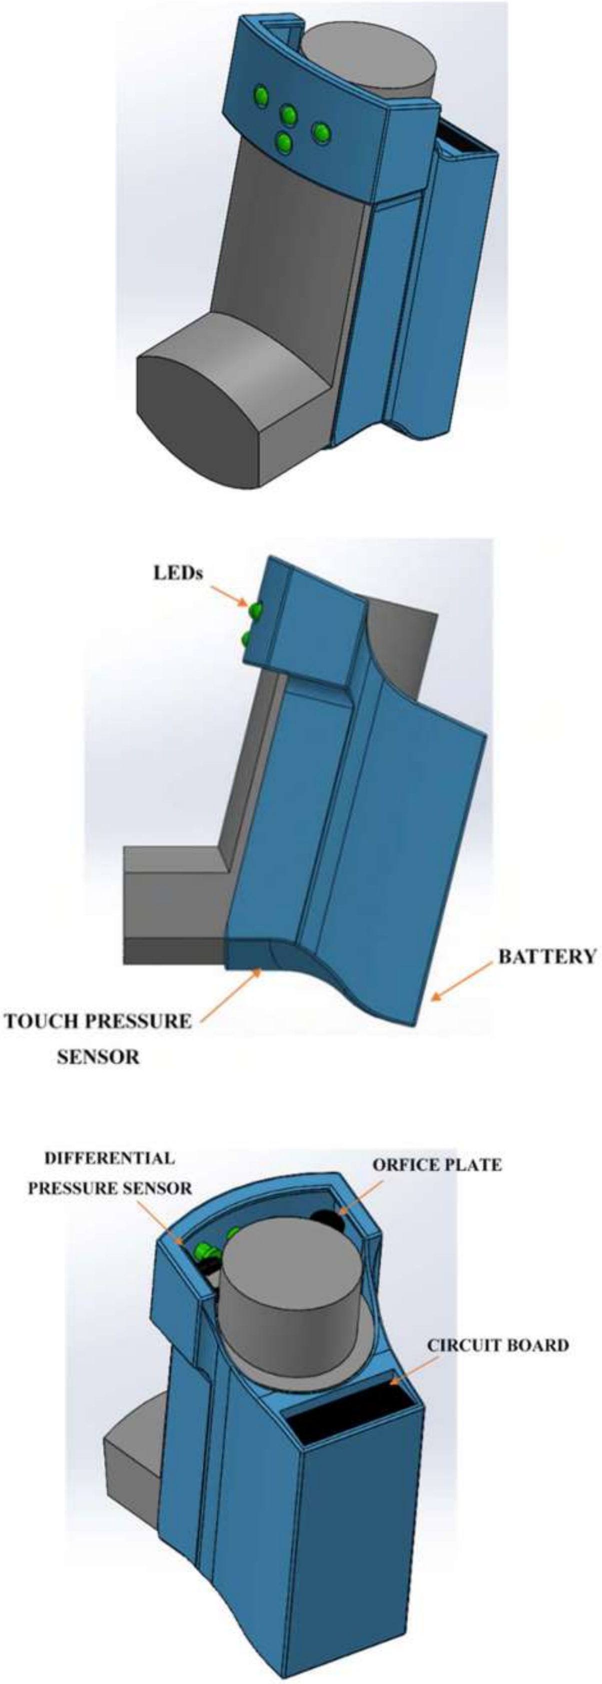

Figure 5. The final sleeve design; (a) final sleeve, (b) and (c) sensor and circuit board locations

A prototype of the sleeve is 3-D printed using PLA and can be seen in Fig. 6. The weight of the prototype with the MDI meets the constraint by falling below 250g. The sleeve fits the MDI properly and indicates appropriate sizing of the model. For future iterations, modifications will be made to increase the ergonomics of the design while maintaining the aesthetic and functionality. Further adjustments to the sensor locations will be made to optimize the sleeve space and to keep the design as compact as possible. Ideally, the final product will be 3-D printed using PETG to allow for more flexibility in the device.

IV. Experimental Results

To perform an analysis on the sleeve design, the model is imported into Abaqus CAE 2020 and the material properties of the product are applied. The original design is 3-D printed in standard PLA filament. This material has a Young's modulus of 4.0 GPA, a Poisson's ratio of 0.3, and a density of 1.3g/cm^3 [12].

The analysis is performed in two steps: the initial step and the loading step. The initial step applies the boundary conditions of the sleeve. The product is designed for the user to place their thumb in the curved profile at the bottom. An average thumb is able to cover the entire curvature allowing that surface to act as a fixed boundary condition. The rest of the sleeve is able to deform freely when the force is applied.

The second step entails applying the loads and forces to the model that will cause the deformations and stress concentrations. The canister that is actuated by the user contacts the MDI through a narrow nozzle. This allows the actuation force to be modelled by a concentrated force vector on the sleeve. To properly orient the force vector parallel to the sleeve walls, the base is partitioned into sections and a new datum is created. A visual representation of the applied force vector and boundary conditions can be seen in Fig. 7.

After defining the boundary conditions and the concentrated force, a mesh is able to be defined for the design. Due to the irregular shape of the sleeve, a tetrahedral element shape is used for the mesh. The fine meshed design is shown in Fig. 8 with a total of 2686 elements.

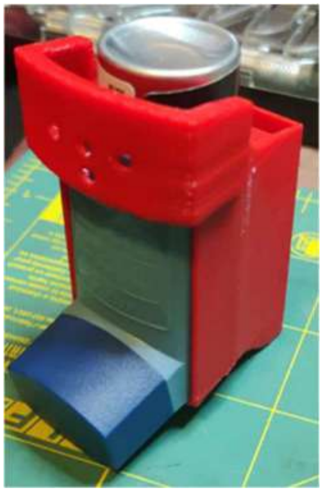

Figure 6. 3-D printed prototype of the final sleeve design model

To determine the effect of the material type on the deformation and stress concentration of the sleeve, a second model is generated. The set-up is identical except that the material properties applied correspond to PETG which has a Young's modulus of 2.0 GPA, a Poisson's ratio of 0.4, and a density of 1.27g/cm^3 [13].

The analysis conducted on the models made from PLA and PETG demonstrates a large deformation and stress concentration at the location where the concentrated force is applied. The values for the maximum stress and deformation in the sleeve depend on the type of mesh used for the analysis. In both cases, a coarse mesh and a fine mesh were used for comparison. The results of the analysis are summarized in Table VI. Since the design that the mesh is applied to remains the same for both models, the elements created for the fine and coarse meshes are the same. The elements in the coarse mesh analysis is 1075 and the elements in the fine mesh analysis is 2686.

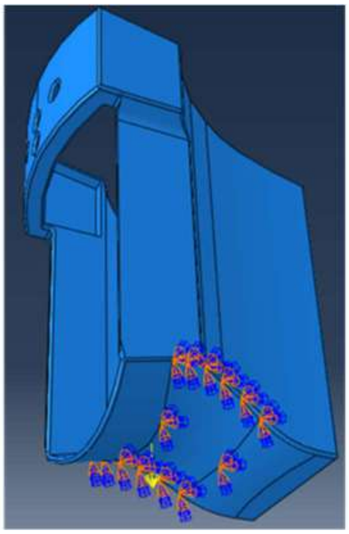

Figure 7. Force vector and boundary conditions applied to sleeve design model

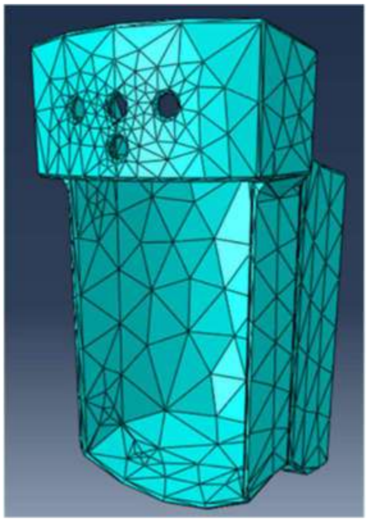

Figure 8. Fine mesh applied to the sleeve design model

TABLE VI. SUMMARY OF FINITE ELEMENT ANALYSIS RESULTS

Model Material: PLA			
Mesh	***Maximum Stress (MPa)***	***Maximum Displacement (mm)***	***Runtime (s)***
Fine	533	0.195	11
Coarse	136	0.0795	9
Model Material: PETG			
Mesh	***Maximum Stress (MPa)***	***Maximum Displacement (mm)***	***Runtime (s)***
Fine	0.375	0.000316	10
Coarse	0.0975	0.000129	9

The deformed model appears the same in both materials with varying magnitudes of stress and deformation. The contour plot for the stress concentration, percentage, and deformation, in millimeters, of the PLA design with a fine mesh is shown in Fig. 9. A deformation scale factor of 47 is applied to visualize the results.

The study conducted demonstrates that the sleeve design made from PETG is best suited to reduce the deformation and stress concentration in the product. To prevent failure from the concentrated force of actuating the MDI canister, the final sleeve should be produced using PETG. This will assist in developing a solution to the improper inhaler use that is durable and effective.

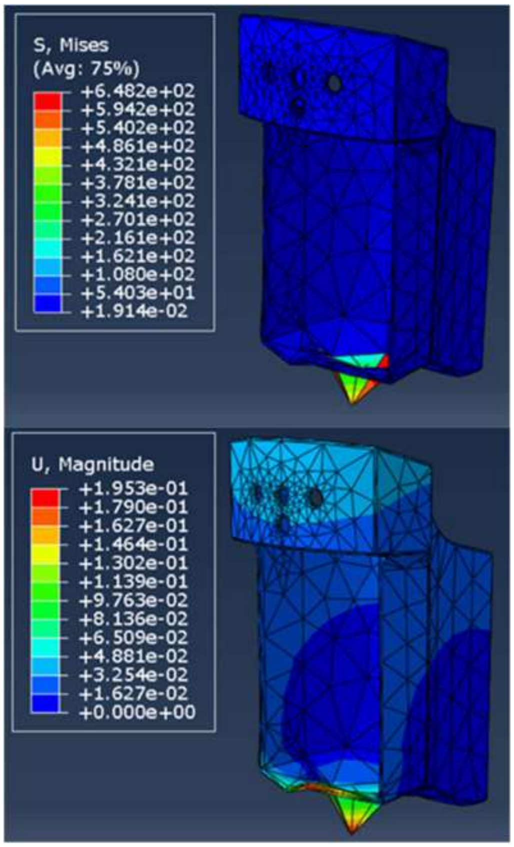

Figure 9. Stress concentration and deformation results (respectively) from the finite element analysis conducted on the final sleeve design model made from PLA

V. Conclusions

A sleeve design described aims to reduce the errors associated with the use of an MDI. Various sensors are implemented into the sleeve to monitor the four most common mistakes of the inhaler use. The patient is able to receive real-time feedback to aid in administering the proper medication dosage and to enforce proper inhaler use techniques. Additionally, a mobile app is developed to provide the user with further information on their technique and the areas in which they require improvement.

A 3-D printed prototype of the sleeve is created and is able to house a development board with an integrated accelerometer and gyroscope to measure the shaking force and orientation of the inhaler. The coordination between the canister actuation and the patient's inhalation is observed with a thin film pressure sensor located at the bottom of the sleeve. A differential pressure sensor is included in the design to monitor the inhalation rate of the patient when administering the medication. LED lights are implemented onto the front of the sleeve to provide the user with real-time feedback.

Conducting a finite element analysis on the sleeve model illustrates that the prototype can benefit from a change in material type from PLA to PETG. This modification allows for a reduction in the maximum deformation and the maximum stress concentration seen by the model. Reducing these values results in a more durable product which requires to be replaced less frequently, reducing maintenance cost and the environmental impact of the device.

In the current stage of development, the smart inhaler has a cost of $135 CAD to account for the sensors, LEDs, and the printing material. The prototype has a weight is 64.2 gr. and a volume of approximately 171 cm^3.

As the sleeve continues to be developed, alternate manufacturing options are being researched to determine an optimal material for the product. Additionally, the opportunities presented by analyzing the data collected by the sleeve is under development. Further advances in the mobile app may result in the ability to predict the likelihood of a patient experiencing the need to use the device given a certain environment.

Acknowledgment

The team would like to thank the Department of Mechanical and Mechatronics Engineering at the University of Waterloo for providing financial support and the resources necessary to develop the smart inhaler prototype.

***Abstract*—In spite of great advances in cell phone technology, the rapid discharge of phone batteries remains a widespread problem. One solution may be recharging phones with movements of the body, such as with energy harvesting shoes. Soft-soled impact-absorbing shoes are best for the feet and for general health. Energy harvesting from shoes have been of interest for decades, but the technology is still in the research phase. Piezoelectric voltage generation at shoes is made more feasible with recent advances in flexible piezoelectric materials. The characteristics of energy conversion at shoes have been studied. Shoes connected through wires on the legs to power electronics can charge a phone at the waist. An extra battery source at the power electronics would be an inconvenience, and a simple full wave rectifier with filter is proposed for initial testing. The resulting large time constant implies the need for a large capacitor. The design considerations in this paper may be the basis of further research and experimentation, and possible commercial implementation.**

Keywords—energy, phone, phone, harvesting, shoe, power electronics, piezoelectric, piezoelectricity, walking, rectifier, filter, capacitor, battery.

I. Introduction

In spite of recent rapid advances in smart phones, there has been relatively slow progress in battery technology, and rapid depletion of phone batteries remains a major problem. Over the last two decades, microprocessors for smart phones have shown exponential growth keeping up with Moore's Law, but Lithium ion batteries have shown slower development.

Electric sockets for recharging may rarely be available in public areas, away from the home. The electric grid may be less available in remote locations and in less-developed countries. Stranded hikers may be calling for help with the last bit of charge on their cell phones. Foot soldiers in remote locations may need additional sources for recharging their portable electronics.

Power banks for charging phones have limited backup charge and require prolonged connection to a power socket. Solar powered phone chargers are likely to be bulky and not portable. These point to the possibility of recharging phones with body movements, such as with energy harvesting shoes.

A. Well-Cushioned Shoes Good for the Feet

From thousands (millions) of years of selective evolution, the feet of Man have mostly evolved for walking on the soft grass of grasslands, or the soft decaying plant matter on the forest floor. The human foot is not well adapted to the hard, smooth and uniform pavements of today.

Soft-cushioned shoes are comfortable, and good for the feet and for general health [1, 2]. Much or most of the energy of walking or running is dissipated in these shoe soles. The absorption of impact means that the mechanical energy of running is being largely converted to heat energy at the soles. At least some of this mechanical energy may instead be converted to electrical energy for charging electronic devices such as the phone.

B. Harvesting Energy at Shoes

Harvesting the energy of body movement for charging mobile and wireless electronics has been proposed for long [3]. The build-up of static electricity at devices at shoe soles has been suggested for harvesting energy [4]. Another possibility is electromagnetic voltage generation at the shoe sole, such as with an armature and field [5, 6]. But the electromagnetics may be cumbersome and not durable enough to be placed at a shoe sole.

Shoe outputs of many volts have been reported in the literature. A relatively high one watt of power has been reported from electromagnetic energy harvesters.

II. Piezoelectricity in Shoes

Of all the proposed methods for energy harvesting in shoes, piezoelectricity is the most common [7, 8, 9, 10]. One option is to use piezoelectric bending beams as shoe inserts [11].

Piezoelectric ceramics for a 90 kg person showed 0.4% or 1.43 mW of walking energy can be harvested [12].

Experimental results from 2009, report a "6-layer heel footwear harvesters have an average power output of 9 mW/shoe at walking speed of 4.8 km/h." Another study reports 55.6 µJ of energy, and peak power of 1.6 mW generated with each footstep.

One study reported walking or running generating 10-20 µJoules per step [13].

Piezoelectricity at the shoe is further supported by recent developments in flexible piezoelectric materials [14]. Piezoelectric powered shoes have been proposed to power a GPS device [15].

A. Power Electronics Interface

With a piezoelectric shoe energy harvester, what type of power electronics is to be used? The piezoelectricity has special voltage and current outputs requiring specific design to interface with the phone [16, 17].

It has been proposed the power electronics and a battery be kept inside the shoe sole [5]. But this would be problematic as it would increase complexity of the shoe and

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

would not be rugged and durable. Also, different phones may require different power electronics.

A piezoelectric cantilever device was implemented and tested together with its electronics [18]. This required a microprocessor, which would be difficult without an extra battery. A Buck converter has been proposed [19], but this too has the requirement of having an independent, separate, battery supply.

This paper proposes keeping the power electronics away from the shoe at the waist (or pocket) level, and to not require any separate intermediate battery.

A separate independent battery may be an added inconvenience and has been avoided in the design. The simple full-wave diode rectifier with filter configuration is proposed here for initial testing and for proof-of-principle.

III. Charging and Battery specifications

The charging requirements and the battery specifications of phones will determine the design of power electronics interface with the piezoelectric shoe.

Lithium Ion batteries for phones are mostly rated at 3.8 V, and may start working at 3.6 - 3.7 V. Other charger voltages are in the region of 5 V,

Two safety precautions include that a battery with less than 1.8 V should never be recharged. Secondly, the charger voltage should not exceed 4.25 V. A battery below 3.0 V needs a trickle current, before its voltage rises to 3.4 V.

A phone with a 4 inch screen may consume 0.75 w power from a battery of 5-6 watt hours capacity. Under practical usage, a battery may last for no more than 5-6 hours of usage.

Mobile phone batteries range from about 700 mA-hrs to 1200 mA-hrs, whereas smart phone batteries are in the range of 1000 - 1300 mA-hrs. The internal resistance of the battery may be about 0.15 ohms. After 300-400 charging-discharging cycles, the internal resistance may double to 0.3 ohms.

IV. Energy Absorbing Characteristics

The energy absorbed by the soles will be the sum of the energy absorbed by the rubber, and the energy converted by the piezoelectric material. The energy absorbed by the rubber will depend on the material and its energy absorbing characteristics.

If the shoe sole acts like a perfect spring, and no energy is converted to piezoelectricity, the energy absorbed during the down step would be completely released during the upstep (figure below).

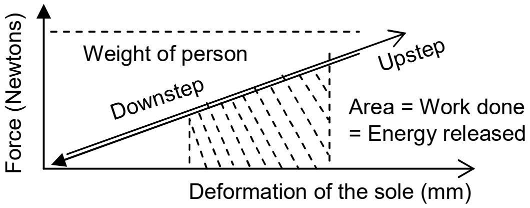

Fig 1. If the shoe acts like a perfect spring, the energy absorbed during down step would be completely released during the up step. Harvested energy will be zero.

The mechanical energy during downstep and during upstep will be about half the force multiplied by distance: We consider a person of 70 kg, deforming a sole by 1 cm at every step.

$$\textit{Work during Downstep} = \textit{Work during Upstep}$$

$$= \frac{1}{2}\ \textit{Weight}\ \text{x}\ \textit{Deformation of sole}$$

$$\textit{Work done} = 0.5 \text{ x } 70 \text{ kg x } 9.8 \text{ x } 0.1 = 3.43 \text{ Joules}$$

In comparison to the spring above, a rubber band, shows some mechanical hysteresis (figure below). The energy lost to hysteresis, or converted to heat, is the difference in the energy used for stretching and the energy released from contraction.

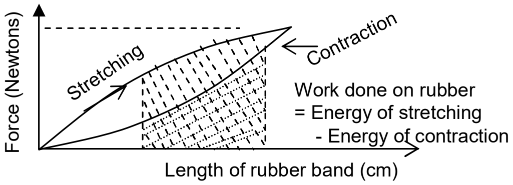

Fig 2. The stretching and contraction of a rubber band shows energy lost to hysteresis (converted to heat) as the work done during stretching minus the work released during contraction.

The energy absorbed or released equals the area under the curve above.

$$\textit{Energy absorbed or released} = \int F(x) \text{ x } dx$$

If the material of the sole has a hysteresis effect such as above, the work done during downstep will be greater than the energy during upstep. The shoe sole may recover slowly from deformation, meaning the force during downstep would be greater than during upstep.

The energy of hysteresis would be the area within the curve (figure below).

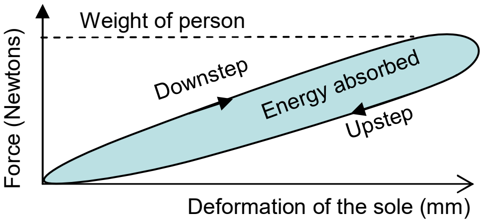

Fig 3. The area in the hysteresis curve will be the work done in the shoe sole.

If very little energy from the sole is returned during upstep, the total energy converted in the shoe is almost half of the energy in the rectangle (figure below).

$$\textit{Energy available} = \frac{1}{2} \text{ x } \textit{Weight} \text{ x } \textit{Deformation of sole}$$

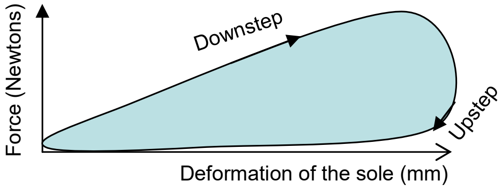

Fig. 4 . If due the hysteresis, the sole exerts little force during upstep, the energy converted would be 0.5 x weight x deformation of sole.

In case the hysteresis effect is very strong during downstep and upstep (from shoe material and energy harvesting), the energy conversion per cycle will be the close to the full area of the rectangle below

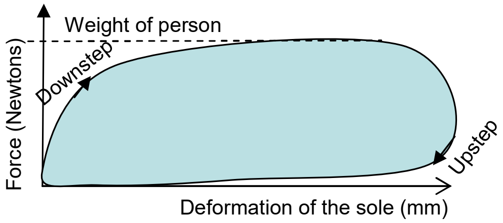

Fig 5 . In the extreme case, the force-deformation curve (hysteresis effect) will take up almost the full rectangular area (maximum energy harvesting).

Assuming maximum conversion of the energy, the energy available with each stepping cycle would be the area of the rectangle above:

$$W = MgH = 70 \text{ kg x } 9.8 \text{ m/s}^2 \text{ x } 0.01 \text{ m}$$

$$W = 6.86 \simeq 7 \text{ Joules}$$

Assuming each step taking 0.5 seconds, the power available during walking would be:

$$P = \frac{W}{T} = \frac{7\text{J}}{0.5\,\text{sec}} = 14 \text{ watt}$$

Higher energy and power may be obtained from greater depth of the shoe sole and with faster walking or running. The energy from jogging or running may be of the order of five times (estimated) greater than for walking.

There are few practical methods of conversion of this mechanical energy to electrical energy. Piezoelectric materials can hardly be made to deform by the above one cm from the movement of stepping.

A low efficiency of 10 % would give 1.4 watt in conversion of walking to electrical energy.

V. Force and Voltage from Piezoelectricity

The option of piezoelectricity for shoes is supported by recent developments in flexible piezoelectric materials.

Layers of piezoelectric material may be placed in the heels and the rest of the soles, lowering the chance of breakage (figure below). The work done will depend largely on the speed of walking or running.

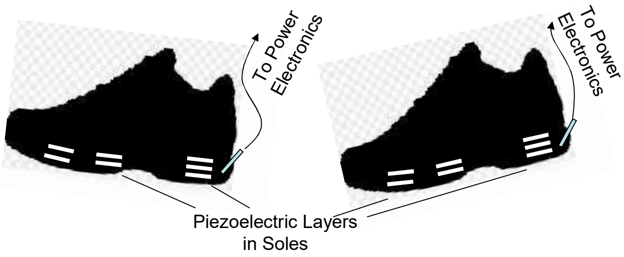

Fig 6. Similar piezoelectric layers may be distributed in both soles of shoes, minimizing chance of breakage. Connections may be in series, so as to maximize voltage.

Identical piezoelectric devices may be placed in both shoes for maximizing energy harvesting.

Series or parallel connection of the above piezoelectric layers in the soles will be largely decided by the needs of the power electronics. However, a series connection appears best, as the voltage would be maximized.

A. Pressure and Generated Voltage

Considering the stepping patterns and speeds of walking, the forces on the soles (heels) and the resulting deformation may be as follows.

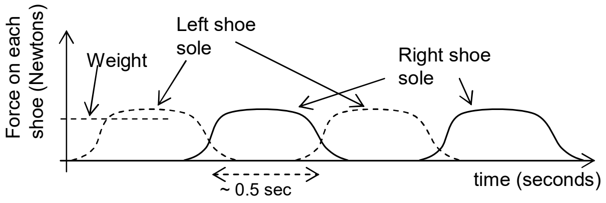

Fig 7. Force (in Newtons) upon each shoe during a simple walking motion

The generated piezoelectric voltages may be proportional to the force, at the right and left shoe (with no output current).

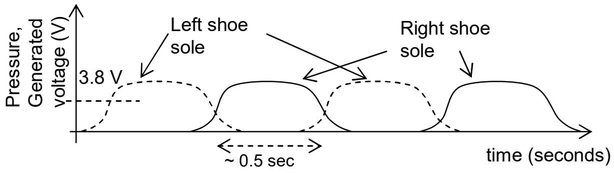

Fig 8. Pressure and voltage generated in the left and right shoes (without flow of current).

When the walking changes to running, the foot kicks up the body. The body will be in the air, and there will be a momentary increase in force at the sole (figure below). The body may stay suspended for about less than a second, during which the force will be zero. As the other foot lands on the ground, there will be an sharp force of impact.

All forces may generate proportional voltage at the piezoelectric material.

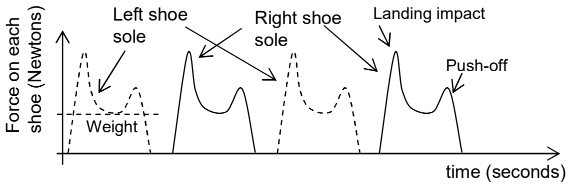

Fig 9. Force upon each shoe for slow running or jogging. Spikes are seen during the landing impact and during the push-off.

VI. Overall Structure

In deciding the overall structure, the power electronics may be placed at the waist or at the shoe. Placing at the waist close to the phone appears best at this time, as the shoe may be too compact, and present a source of additional wear and tear. Also, different phones may require different power electronic circuits.

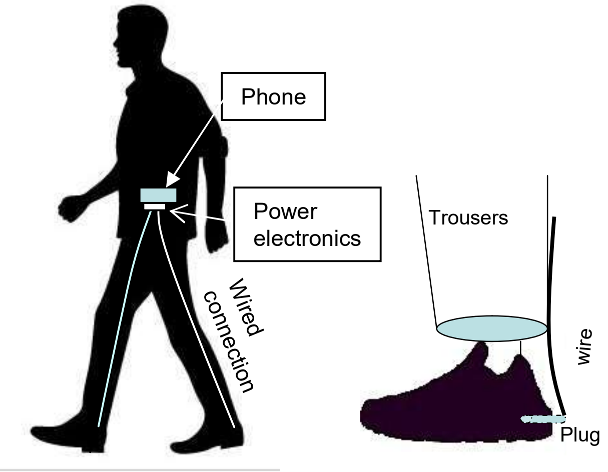

Fig. 10. Wires connect from the piezoelectric soles to the power electronics and then to the phone. A rugged wired connections avoid breakage from running.

Behind the heal of the shoe, there may be a rugged plug, connecting the wire to the power electronics. The wires and connections attached to the legs must also be rugged, in order to withstand walking or running over long distances.

VII. Power Electronics

A switched mode converter in the power electronics will require an additional power source or battery, which would be inconvenient.

For harvesting energy from the generated voltage, a current flow is required. The discharging current from the piezoelectric material may show the pulsed waveform below.

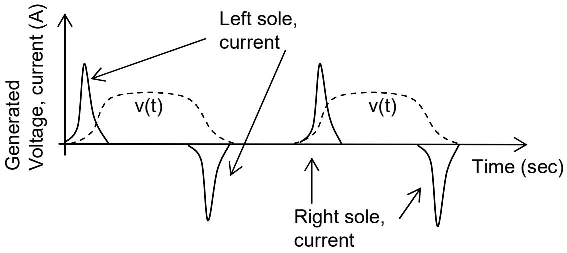

Fig. 11. For piezoelectric shoes, the current may be positive during the downstep, and negative during the upstep.

The alternating current from the piezoelectric material can be passed through a full-wave rectifier and then filtered to give a mostly DC waveform.

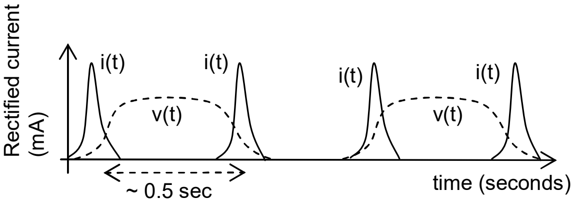

Fig. 13. After passing through a full-wave rectifier, the pulsed current will be in the same direction at intervals of about 0.5 second.

Passing through a full wave rectifier and a filter will give a DC voltage and current with a small ripple, suitable for charging a phone. The two shoes may be placed in series, effectively adding the voltages (figure below).

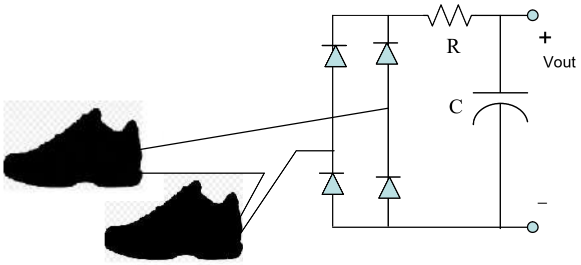

Fig. 12. The piezoelectric materials of the shoe can be connected in series with a full-wave rectifier and a filter.

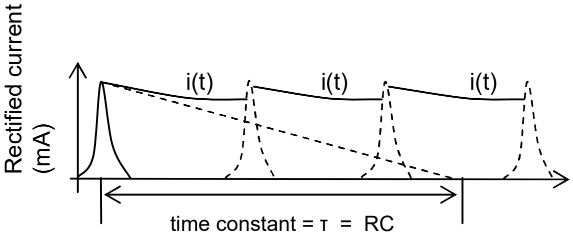

Fig. 14. DC output with ripple after passing through a filter. The time constant may be too large (compared to conventional electronics), meaning the capacitor may need to be large.

The diode rectifier/s may be compact enough to be placed at the shoe or at the plug. However, the filter may require a large capacitance, which may be too bulky to place in or near the shoes.

A. Filter Design

The time constant of the filter is the length of intersection on the time axis of a tangent from the curve (figure above), and will equal the product of the resistance *R* and the capacitance *C*.

$$\tau = RC \text{ seconds}$$

In order to keep the ripple value low, the time constant τ may have to be several times larger than the stepping time. With stepping time of the order of 0.5 second, the time constant may be

$$\tau = RC = 2 - 4 \text{ seconds.}$$

This time constant of 2 - 4 sec is much larger than the order of milliseconds encountered in conventional power electronics. This implies that either *R* or *C* or both must be unusually large. Having a large *R* may be undesirable as it would dissipate too much energy. A large capacitor *C* may be too large and bulky. The electrolytic capacitor may be the best option, as it may have a large value (at the cost of low voltage withstanding capability).

A capacitor of the order of 1 μfarad, would imply a resistance of the order of 2 - 4 Mohms, which would still be too large, consuming the energy generated.

New capacitor technologies may allow capacitors of 1 millifarad, requiring a resistor of the order of 2 - 4 Kilo-ohm.

The voltage and current characteristics of the phone during charging will affect the specifications of *R* and *C* and the rest of the power electronics. The design of *R* and *C* and the filter are clearly design issues that must be overcome.

B. Other Considerations

The voltage generated by the shoe will be proportional to the force during the step, or the weight of the person. This implies that the given circuits will require a minimum threshold of a person's weight, below which the battery charging voltage cannot be reached.

In reality, the power electronics might have added complexity, such as for not charging when the phone battery voltage is less than 1.8 V.

There is the possibility of having intermittent charging of the phone, with pulses every 0.5 seconds, lasting less than 0,1 seconds. However, such pulsed charging may not be accepted by modern phones and their electronic circuitry.

VIII. Conclusion

In spite of great advances in microprocessors and communication technology, the rapid discharge of batteries remains a major problem for phones. Backup charging devices such as power banks have limitations such as bulkiness, and limited ability to hold charge.

The well-cushioned thick-soled shoe provides the human foot an appropriate interface to absorb the impact of walking or running on hard pavement. This raises the possibility of introducing new technologies for recharging phones by harvesting the energy of shoes. Energy harvesting shoes have been of interest for decades, but have not come close to commercial feasibility. Generators with armatures and magnets have been proposed for shoes, but the associated mechanics may be too cumbersome and non-durable. Piezoelectricity at the soles will be simpler in construction. A major challenge is finding a flexible and durable piezoelectric material for the shoe, capable of months of rugged use.

The power electronics for converting the piezoelectric voltage and current at the shoe to the DC for the phone is an additional challenge. The power electronics may be placed in the pocket or the waist region, in close proximity to the phone. A full-wave rectifier and a filter appear the best for initial testing. A large capacitor may be required for the filter prior to the phone.

As different phones have different charging voltage and current requirements, different power electronic circuits may be required for different phones.

In spite of the clear challenges, the design considerations in this paper may be a basis for further research, development and experimentation.

***Abstract*—There is an ongoing increase in development of lightweight electric vehicles. In developing countries, electric three-wheelers in use are mostly limited to low voltage drive systems. They are powered directly from the limited battery voltage without any step-up conversion before connection to the motor controller. Due to low voltage and low power DC motor drives, speed and torque characteristics of the vehicle suffers when compared to other EVs with similar battery storage capacity. This paper presents a novel power electronic drive system of step-up DC-DC converter composed of cascaded boost and SC-Zeta topology, capable of voltage gain as high as 40 times at a duty cycle of 0.8. The boosted output voltage is given to a three phase inverter for control of traction motors up to 4 KW of power which will enable existing three-wheelers to use high performance drive system. The proposed converter is simulated & compared with other existing high gain converters in literature, and the output results are presented graphically.**

Keywords*— electric vehicle, EV, rickshaw, high gain, step-up, hybrid, DC-DC, converter, boost, switched capacitor, SC, zeta, DC-AC, three phase, inverter, motor, control

I. Introduction

With the rise of electric vehicles in the US, there is an ongoing increase in development of lightweight and mini electric vehicles and three wheelers. In developing countries electric three-wheelers, also known as auto-rickshaws, in use are mostly limited to low voltage drive systems. They are powered directly from the limited battery voltage without any step-up conversion before connecting to the motor controller. Owing to low voltage and low power DC motors, the speed and torque characteristics of the vehicle suffers greatly when compared to other EVs with similar battery storage capacity. Adding high powered motors into a low voltage system adds cost and complexity in the vehicle power electronics. A 3 KW DC motor will require currents in ranges of hundreds of amperes to be driven from a 12V – 48V DC supply. Not only are such high current controllers prohibitively expensive for three-wheelers, high currents will cause significant I^2R power losses in the motor as well as all the circuit components. Due to the complexity associated with high current drive systems, most conventional electric three-wheeler and auto-rickshaws tend to be driven by low voltage and low power traction motors, and the maximum torque and speed obtained from such system is severely restricted [1-3].

Most modern EVs in developed regions use three-phase AC motors operating at voltages above 250V. This choice of voltage allows the motor to be powerful enough without drawing excessive currents. To address the poor speed and power performance of existing three-wheelers in developing regions, it is desirable to use motors with voltage ratings in the range of 300V – 600V AC [4]. In this paper, we propose a novel power electronic system for conventional electric three-wheelers that will enable them to use high voltage and high performance three-phase AC motors powered from low voltage but high capacity battery packs. The designed system is divided into two stages, a hybrid DC-DC converter and a three-phase DC-AC inverter. The proposed hybrid converter is composed of a boost converter cascaded with a modified switched capacitor (SC) Zeta converter. This novel combination is responsible for providing necessary high step-up gain and continuous input and output current. Theoretical analysis is performed to derive expressions for voltage gain, average currents, voltage and current stress of components, power loss and efficiency of the converter circuit. Simulation results are presented to show the performance of the designed converter in comparison to existing non-isolated high gain step-up converters in literature.

II. Background Theory

Operating three-phase traction motors of 300V and above, only from 12V – 48V battery input, will require extreme duty cycles for conventional converters, making them impractical. There has been a number of literatures dedicated to high gain step-up voltage conversion techniques [5-8]. Most solutions use transformers or coupled inductors to get the required voltage boost. Use of transformers or coupled inductors where isolation is not required only adds to weight, cost and unnecessary power loss [5]. Switched-capacitor (SC) and switched-inductor (SL) structures proposed in [6] allows various conventional converters to generate additional voltage gain. The capacitors in a SC structure are arranged in such a way that when the converter switches between on and off states, the capacitors are connected in parallel during the charging cycle, and discharged in series during the discharge cycle to provide high voltage gain ratio [9-10].

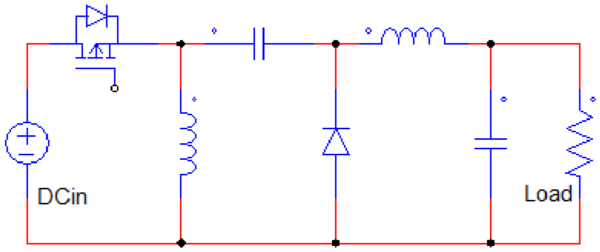

Fig. 1. A conventional step-up Zeta converter

The topology of a conventional Zeta converter, as shown in Fig. 1, allows us to implement a SC structure to obtain hybrid SC-Zeta as in [9]. Although the SC-Zeta has higher gain than the conventional converters, it is still unable to provide the required voltage gain within a reasonable duty cycle. So an improved step-up DC-DC converter capable of the required step-up gain must be designed. To keep enough margin for adjustment of duty cycle and regulation of output voltage to control output power, it is necessary to design a novel converter with the required voltage gain capable of operating within a reasonable duty cycle.

III. Proposed System

In this paper we propose a cascaded boost-SC-zeta hybrid DC-DC converter, shown in Fig. 2, working in tandem with a three-phase DC-AC inverter, shown in Fig. 3. The proposed hybrid DC-DC converter can boost the voltage sufficiently to be fed into the inverter to generate three-phase AC as required by the high performance motor of the electric three-wheelers and other equivalent EVs. The output of this inverter can be regulated to control power and speed of the motor for optimum performance. The proposed DC-DC converter can step-up the input voltage as high as 180 times at duty cycle of 0.9 while keeping both input and output current continuous.

A. Topology of our proposed hybrid DC-DC converter

The proposed DC-DC converter circuit is shown in Fig. 2, which consists of a boost converter cascaded with a modified switched capacitor (SC) zeta. The SC structure consists of two capacitors *C2* and *C3* and two diodes *D2* and *D3*. Similar to existing zeta converter, our designed circuit contains an inductor L_0 and a capacitor C_0 at the output. The presence of an input inductor *L1* and output inductor L_0 provides the additional advantage of maintaining continuous input and output currents.

B. Principles of operation of the designed circuit

The operating states of our designed DC-DC converter can be divided into two states: on-state and off-state. The designed converter circuit is considered to be operating under continuous conduction mode (CCM) in both of the states.

1) On-state ($0 \leqslant t \leqslant DTs$)

In this state, switch *S1* and switch *S2* are simultaneously turned on, while *D1, D2* and *D3* diodes are turned off. The current flow during on-state is shown in Fig. 4. Inductor *L1* is parallel to input V_{in} and stores energy directly from the source. The current I_{L1} increases linearly with the ratio V_{in}/L_1. The inductor L_2 is being energized by the capacitor *C1* as it discharges. The two capacitors *C2* and *C3* that are connected in series, are now being discharged while output inductor L_o is being energized and output capacitor C_o is charged.

2) Off-state ($DTs \leqslant t \leqslant Ts$)

The switch *S1* and switch *S2* are simultaneously turned off in this time interval, while the diodes *D1*, *D2* and *D3* are in forward bias, turning them on. Fig. 5 shows the current flow during this state. In this time period, capacitor *C1* is being charged by inductor *L1*, and inductor *L2* releases its stored energy to capacitors *C2* and *C3*. While *C1*, *C2* and *C3* capacitor charges, C_o is being discharged. Inductor L_o helps to supply continuous current to the load and capacitor C_o helps to maintain constant voltage at the output.

IV. Theoretical Analysis

Some assumptions are made to simplify the theoretical analysis of this circuit. All the components in this converter circuit are considered to be ideal and lossless. To ensure operation in CCM mode, *L1*, *L2 and* L_o inductor values are assumed to be large enough. *C2* and *C3* capacitor values are equal. *C1* and output capacitor C_0 values are large enough to ignore the output voltage ripple. Expressions for voltage gain, average currents, voltage and currents stress of components of this converter is derived in this analysis. Losses in the components are only considered during power loss and efficiency analysis.

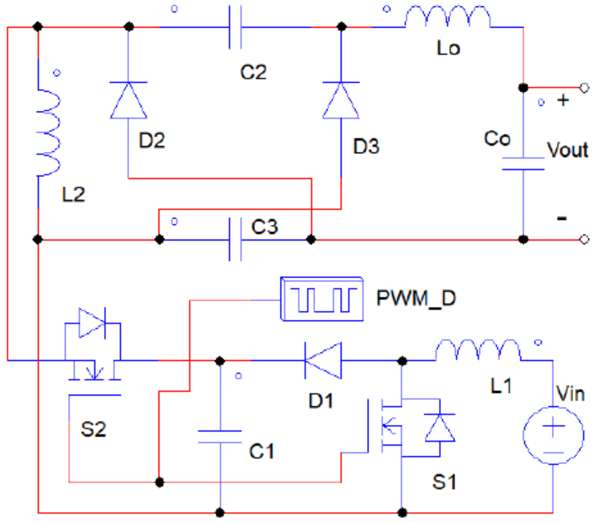

Fig. 2. Proposed Boost-SC-Zeta Hybrid DC-DC Converter Circuit

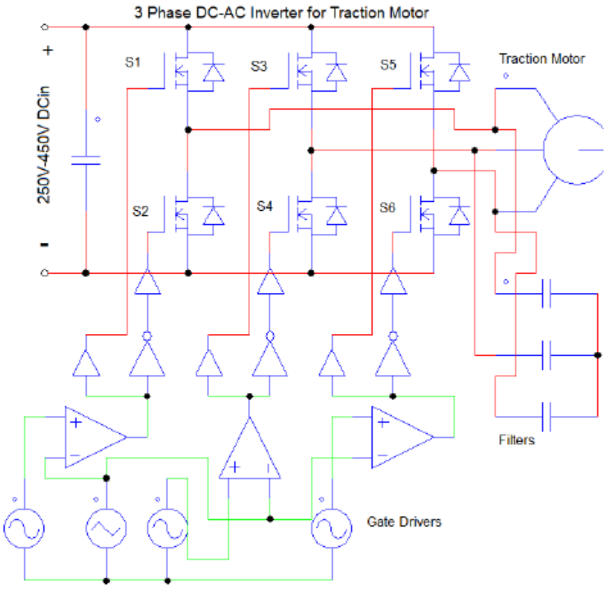

Fig. 3. 3-Phase DC-AC Inverter for Traction Motor Drive System

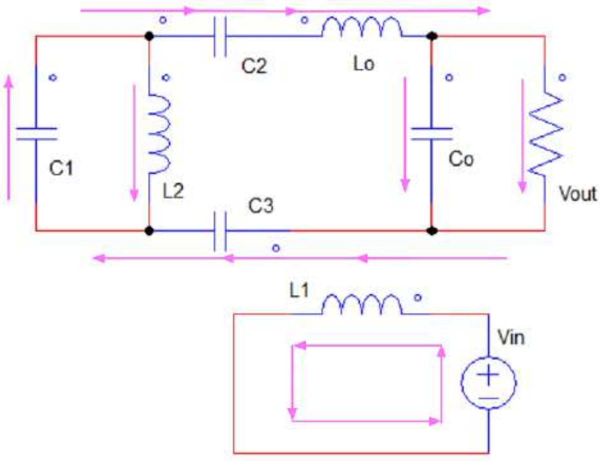

Fig. 4. Current Flow in the proposed hybrid DC-DC converter during on-state of switches *S1* and *S2* in time period $0 \leqslant t \leqslant DT_s$

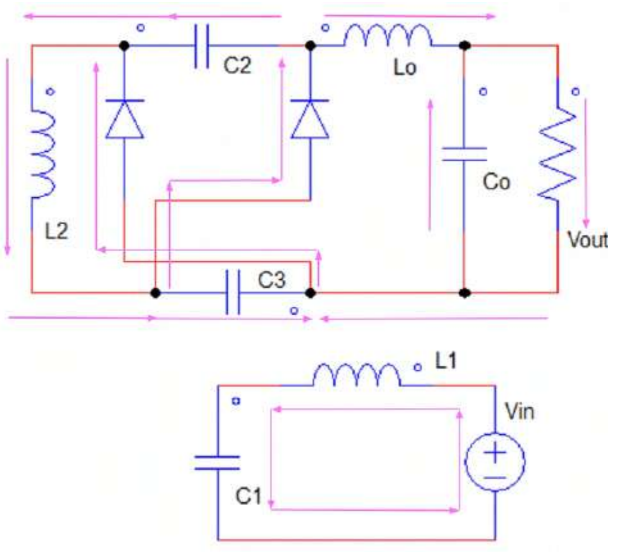

Fig. 5. Current flow of the proposed converter circuit at off-state in time period $DT_s \leqslant t \leqslant T_s$

A. Voltage gain analysis

For operation during the on-state for time $0 \leq t \leq DT_s$, the following equations for the inductors *L1, L2 and L_0* can be obtained:

$$V_{L1} = V_{in}$$

$$V_{L2} = V_{C1}$$

$$V_{L0} = 2V_{C2,3} + V_{C1} - V_{out}$$

For operation during off-state of the switch during time period $DT_s \leq t \leq T_s$, the following equations could be obtained:

$$V_{L1} = V_{C1} - V_{in}$$

$$V_{L2} = V_{C2,3}$$

$$V_{L0} = V_{out} - V_{C2,3}$$

By using the above equations and applying voltage-second balance principles on the inductor *L1*, we get:

$$\frac{1}{T_s}\int_0^{DT_s} V_{L1_{[On]}}\,dt + \int_{DT_s}^{T_s} V_{L1_{[Off]}}\,dt$$

$$V_{in}D - (V_{C1} - V_{in})(1-D) = 0$$

$$V_{C1} = V_{in}\frac{1}{1-D} \qquad (1)$$

Applying voltage-second balance principles on inductor *L2*, we get:

$$\frac{1}{T_s}\int_0^{DT_s} V_{L2_{[On]}}\,dt + \int_{DT_s}^{T_s} V_{L2_{[Off]}}\,dt$$

$$V_{C1}D - V_{C2,3}(1-D) = 0$$

$$V_{C2,3} = V_{C1}\frac{D}{1-D}$$

$$V_{C2,3} = V_{in}\frac{D}{(1-D)^2}$$

By Applying voltage-second principles on inductor $L_{0,}$ we get:

$$\frac{1}{T_s}\int_0^{DT_s} V_{L0_{[On]}}\,dt + \int_{DT_s}^{T_s} V_{L0_{[Off]}}\,dt$$

$$(2V_{C2,3} + V_{C1} - V_{out})D \\ - (V_{out} - V_{C2,3})(1-D) = 0$$

$$V_{out} = V_{C1}\frac{2D}{1-D}$$

Substituting V_{C1} in the above equation, the final output voltage could be written as:

$$V_{out} = V_{in}\frac{1}{1-D} \times \frac{2D}{1-D}$$

$$V_{out} = V_{in}\frac{2D}{(1-D)^2} \qquad (4)$$

The gain of the designed converter is derived to be:

$$G = \frac{V_{out}}{V_{in}} = \frac{2D}{(1-D)^2}$$

B. Analysis of Input Current

$$I_{in} = I_{out}\frac{V_{out}}{V_{in}}$$

$$I_{in} = I_{out}\frac{2D}{(1-D)^2} \qquad (5)$$

$$I_{in} = \frac{V_{out}}{R}\frac{2D}{(1-D)^2}$$

$$I_{in} = \frac{V_{in}}{R}\left[\frac{2D}{(1-D)^2}\right]^2 \qquad (6)$$

C. Analysis of average current

Considering the current flow in the capacitor C_o to be negligible, we get:

$$I_{L0} \cong I_{OUT} = \frac{V_{OUT}}{R} = \frac{V_{IN}}{R}\frac{2D}{(1-D)^2} \qquad (7)$$

$$I_{C2,3_{ON}} = I_{L0} = \frac{V_{IN}}{R}\frac{2D}{(1-D)^2} \qquad (8)$$

By applying the principles of charge-second balance on capacitors *C2* and *C3* to yield:

$$\frac{1}{T_S}\left[\int_0^{DT_S} I_{C2,3_{ON}}\,dt + \int_{DT_S}^{T_S} I_{C2,3_{OFF}}dt\right] = 0$$

$$I_{C2,3_{ON}}D - I_{C2,3_{OFF}}(1-D) = 0$$

$$I_{C2,3_{OFF}} = I_{C2,3_{ON}}\frac{D}{1-D}$$

$$I_{C2,3_{OFF}} = \frac{V_{IN}}{R}\frac{2D^2}{(1-D)^3} \tag{9}$$

Average currents through the inductor *L1* is:

$$I_{L1} = I_{IN} = \frac{V_{IN}}{R}\left[\frac{2D}{(1-D)^2}\right]^2 \tag{10}$$

The average current when capacitor *C1* is off:

$$I_{C1_{OFF}} = I_{IN} = \frac{V_{IN}}{R}\left[\frac{2D}{(1-D)^2}\right]^2 \tag{11}$$

By applying charge-second balance principles on capacitor *C1*, we get:

$$\frac{1}{T_S}\left[\int_0^{DT_S} I_{C1_{ON}}\,dt + \int_{DT_S}^{T_S} I_{C1_{OFF}}dt\right] = 0$$

$$I_{C1_{ON}}D - I_{C1_{OFF}}(1-D) = 0$$

$$I_{C1_{ON}} = I_{C1_{OFF}}\frac{1-D}{D}$$

$$I_{C1_{ON}} = \frac{V_{IN}}{R}\frac{4D}{(1-D)^3} \tag{12}$$

Average currents through the inductor *L2* can be derived as follows:

$$I_{L2_{ON}} = I_{C1_{ON}} - I_{C2_{ON}}$$

$$I_{L2_{ON}} = \frac{V_{IN}}{R}\frac{4D}{(1-D)^3} - \frac{V_{IN}}{R}\frac{2D}{(1-D)^2}$$

$$I_{L2_{ON}} = \frac{V_{IN}}{R}\frac{2D(1+D)}{(1-D)^3} \tag{13}$$

$$I_{L2_{OFF}} = I_D + I_{C2_{OFF}}$$

$$I_{D2} = I_{C2_{OFF}} + I_{L0} = \frac{V_{IN}}{R}\frac{2D}{(1-D)^3} \tag{14}$$

$$I_{L2_{OFF}} = \frac{V_{IN}}{R}\frac{2D(1+D)}{(1-D)^3} \tag{15}$$

$$I_{L2_{OFF}} = I_0\left(\frac{1+D}{1-D}\right) \tag{16}$$

D. Analysis of current stress of switches

Current stress of the switch *S1 (I_{S1})* and switch *S2 (I_{S2})* can be expressed as:

$$I_{S1} = I_{in} = \frac{V_{in}}{R}\left[\frac{2D}{(1-D)^2}\right]^2 \tag{17}$$

$$I_{S1} = I_0\frac{2D}{(1-D)^2} \tag{18}$$

$$I_{S2} = I_{C1_{[On]}} = \frac{V_{in}}{R}\frac{4D}{(1-D)^3} \tag{19}$$

$$I_{S2} = I_0\frac{2D}{1-D} \tag{20}$$

E. Analysis of voltage stress on switches

Voltage stresses on switch *S1* (V_{S1}) and switch *S2* (V_{S2}) can be obtained as follows

$$V_{S1} = V_{in} + V_{L1}$$

$$V_{L1} = V_{C1} - V_{in} = \frac{V_{in}}{1-D} - V_{in} = V_{in}\frac{D}{1-D} \tag{21}$$

$$V_{S1} = V_{in} + V_{in}\frac{D}{1-D}$$

$$V_{S1} = V_{in}\frac{1}{1-D} \tag{22}$$

$$V_{S2} = V_{C1} + V_{L2}$$

$$V_{S2} = V_{in}\frac{1}{1-D} + V_{in}\frac{D}{(1-D)^2}$$

$$V_{S2} = V_{in}\frac{1}{(1-D)^2} \tag{23}$$

F. Power loss and efficiency analysis

For efficiency estimation conduction and parasitic resistances can be defined as:

- Conduction resistance of switches: R_{DS}
- Conduction resistance of diodes: R_{Fx}
- Diode threshold voltage: V_{Fx}
- Inductor ESR: R_{Lx}
- Capacitor ESR: R_{Cx}

1) For Switch

Power loss in switch *S1* during conduction is expressed as:

$$P_{R_{DS_1}} = r_{DS1}I_{S1}{}_{RMS}^{2} = r_{DS1}I_0^2\frac{4D^2}{(1-D)^2} \tag{24}$$

$$P_{SW1} = f_sC_SV_{S1}^2 = f_sC_SV_{in}^2\frac{1}{(1-D)^2} \tag{25}$$

$$P_{S1} = P_{r_{DS1}} + \frac{1}{2}P_{SW1} \tag{26}$$

Power loss in switch *S2* during conduction is expressed as:

$$P_{R_{DS_2}} = r_{DS2}I_{S2}{}_{RMS}^{2} = r_{DS2}I_0^2\frac{4}{(1-D)^2} \tag{27}$$

$$P_{SW2} = f_sC_SV_{S2}^2 = f_sC_SV_{in}^2\frac{1}{(1-D)^4} \tag{28}$$

$$P_{S2} = P_{r_{DS2}} + \frac{1}{2} P_{SW2} \qquad (29)$$

2) For inductors

The power loss of inductors *L1*, *L2* and *Lo* is derived to be:

$$P_{L1} = R_{L1} I_{L1}^2 = R_{L1} I_0^2 \left[\frac{2D}{(1-D)^2}\right]^2 \qquad (30)$$

$$P_{L2} = R_{L2} I_{L2}^2 = R_{L2} I_0^2 \left[\frac{1+D}{1-D}\right]^2 \qquad (31)$$

$$P_{L0} = R_{L0} I_{L0}^2 = R_{L0} I_0 2 \qquad (32)$$

3) For Capacitors

Power loss of capacitors *C1*, *C2* and *C3* is expressed as:

$$P_{C1} = r_{c1} I_{C1_{ON}}^2 + r_{c1} I_{C1_{OFF}}^2$$

$$P_{C1} = r_{C1} \left[\frac{V_{in}}{R} \frac{4D}{(1-D)^3}\right]^2 + r_{C1} \left[\frac{V_{in}}{R} \frac{4D^2}{(1-D)^4}\right]^2 \qquad (33)$$

$$P_{C1} = r_{C1} I_0^2 \left[\frac{2}{1-D}\right]^2 + r_{C1} I_0^2 \left[\frac{2D}{(1-D)^2}\right]^2 \qquad (34)$$

$$P_{C2,3} = r_{c2,3} I_{C2,3_{ON}}^2 + r_{c1} I_{C2,3_{OFF}}^2$$

$$P_{C2,3} = r_{C2,3} \left[\frac{V_{in}}{R} \frac{2D}{(1-D)^2}\right]^2 + r_{C2,3} \left[\frac{V_{in}}{R} \frac{2D}{(1-D)^3}\right]^2 \qquad (35)$$

$$P_{C2,3} = r_{C2,3} I_0^2 + r_{C2,3} I_0^2 \left[\frac{D}{1-D}\right]^2 \qquad (36)$$

4) For Diodes

Power loss in diodes *D1*, *D2* and *D3* is derived to be:

$$P_{D1} = R_{F1} I_0^2 \frac{4D^2}{(1-D)^4} + V_{F1} I_0 \qquad (37)$$

$$P_{D2,3} = R_{F2,3} I_0^2 \frac{1}{(1-D)^2} + V_{F2,3} I_0 \qquad (38)$$

5) Total Loss

Total loss of power and efficiency of the designed converter can be written as follows:

$$P_{LOSS} = \sum (P_{S_{1,2}} + P_{L_{0,1,2}} + P_{C_{1,2,3}} + P_{D_{1,2,3}}) \qquad (39)$$

$$\eta = \frac{P_{OUT}}{P_{OUT} + P_{LOSS}} \qquad (40)$$

V. Simulation Results

For simulation of the designed converter, all the active and passive components in our converter circuit were chosen to be ideal and lossless. Input voltage V_{in} is fixed at 12V DC and the switching frequency is set to be 100 kHz. To ensure operation in CCM mode, values for the inductors *L1*, *L2* and *L0* are chosen to be 0.1 mH, 0.2 mH and 0.5 mH respectively. The values for capacitor *C1* is 220 µF, *C2*, *C3* are equal and 1 µF each, and *C0* is 2.2 µF. Capacitor values are chosen to minimize output ripple voltage.

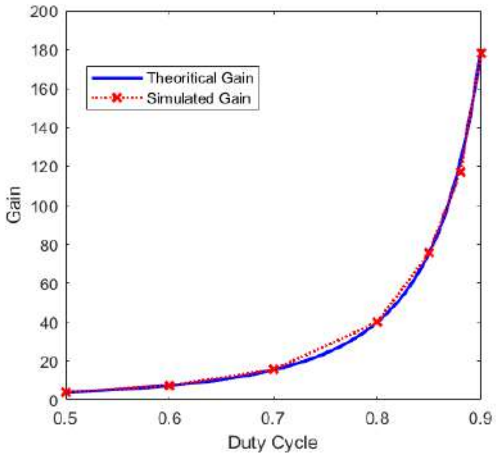

Fig. 6. Graph of theoretically derived gain and software simulated gain against duty cycle

A. Theroretical Gain versus Simulated Gain

The theoretical gain of the circuit *2D/(1-D)*^{2} as derived in (4), is compared with simulation results in Fig. 6. The graph clearly shows that the theoretically derived gain and simulated gain are in agreement with each other which proves the validity and correctness of operation of the proposed converter circuit.

B. Comparison between existing high gain hybrid DC-DC converters

The designed converter is compared to existing non-isolated high gain hybrid DC-DC converters in the literature. From Fig. 7, it is clear that the designed circuit is capable of achieving significantly higher gain compared to existing non-isolated step-up hybrid topologies.

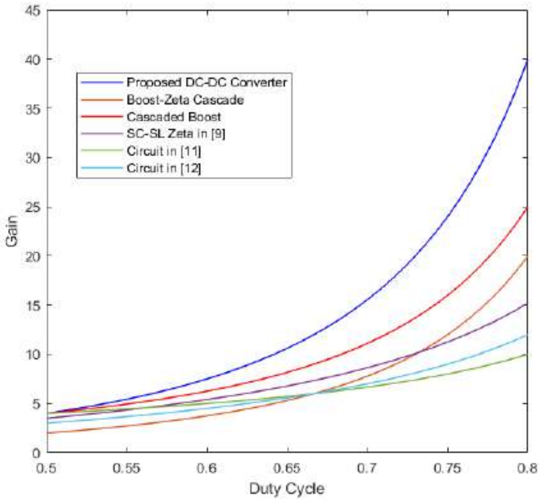

Fig. 7. Comparison of our designed hybrid converter with other existing non-isolated high gain DC-DC converters in the literature

C. Simulation of DC-AC inverter output

The boosted output voltage from the designed DC-DC converter in is fed into a 3-phase DC-AC inverter. Line to line voltages of the inverter output is plotted in Fig. 8. The frequency and magnitude of output voltage from the inverter can be changed for optimal control of the vehicle motor.

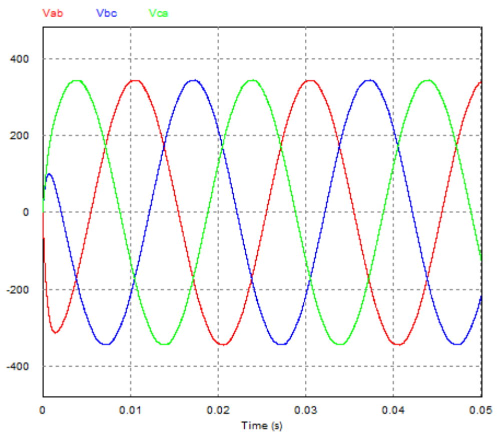

Fig. 8. Line to line ouput voltage of the 3-phase inverter

D. Simulation of Motor Output Performance

A three-phase AC induction motor was connected to the designed system with the converter at 80% duty cycle and inverter at 50 Hz to observe the performance of the motor. A graph of motor speed in RPM is plotted in Fig. 9. Speed up to 3000 RPM can be obtained by operating inverter at 150 Hz.

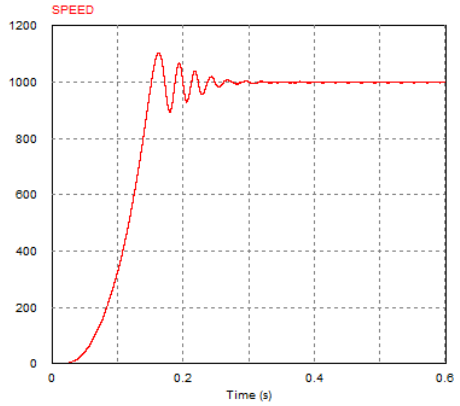

Fig. 9. Simulation of motor speed in RPM against time

TABLE I. COMPARISON BETWEEN PROPOSED COVERTER CIRCUIT AND EXISTING NON-ISOLATED HYBRID DC-DC CONVERTERS IN LITERATURE

	Proposed DC-DC Converter	**Circuit in [9]**	**Circuit in [12]**	**Circuit in [7]**

VI. CONCLUSION

The increased interest in electric vehicles and their motor drives have inspired this study. In developing countries such as Bangladesh, electric three-wheelers are the most common form of EVs currently in use. There is the backdrop of home-grown solutions to local problems and needs for better electric three-wheelers and equivalent EVs. To address the limited performance of conventional three-wheelers, a high gain step-up hybrid DC-DC converter is designed and analyzed in this paper. From the theoretical and simulation results, it is concluded that the designed converter is capable of achieving voltage gain as high as 40 times at a duty cycle of 0.8 and 180 times at a duty cycle of 0.9, significantly higher than existing solutions. The ability to generate such high step-up voltage gain by the proposed converter will allow existing electric three-wheelers and auto-rickshaws to implement traction motors with voltage ratings and performance level comparable to modern EVs, which will greatly improve the vehicle experience. In addition, the ability to deliver up to 4 KW of power with continuous input and output current makes this converter well-suited for applications that requires non-isolated high step-up DC-DC power conversion.

***Abstract*— Spam and non-spam email identification are one of the most challenging tasks for both email service providers and consumers. The spammers try to spread misleading facts through irritating messages by attracting user's attention. Several spam identification-models have previously been proposed and tested but the recorded accuracy has shown that further work in this direction is needed to achieve improved accuracy, low training time, and less error rate. In this research work, we have proposed a model that classifies the e-mail into spam and ham. DBSCAN and Isolation Forest are used to identify the extreme values outside of the specific range. Heatmap, Recursive Feature Elimination, and Chi-Square feature selection techniques are used to select the effective features. The proposed model is implemented in both machine learning and deep learning to establish a comparative analysis. Multinomial Naïve Bayes (MNB), Random Forest (RF), K-Nearest Neighbor (KNN), Gradient Boosting (GB) are used to introduce ensemble method in machine learning implementation. Recurrent Neural Network (RNN), Gradient Descent (GD), Artificial Neural Network (ANN) for deep learning implementation. An ensemble method is constructed to combine multiple classifiers' output. The ensemble methods allow producing better prediction accuracy compared to a single classifier. Our proposed model obtained an accuracy of 100%, AUC=100, MSE error = 0 and RMSE error = 0 for machine learning implementation and accuracy of 99%, loss value= 0.0165 for deep learning implementation based on an email spam base dataset collected from the UCI machine learning repository.**

I. Introduction

Electronic mail is a system used by electronic devices to exchange messages between sender and receiver. Email operates via computer networks, mainly the Internet. Email services are operated by a client server architecture where web-based email is the client and POP3 (Post Office Protocol 3), IMAP (Internet Message Access Protocol), MAPI (Messaging Application Programming Interface) are the email servers. In the developing world, email is commonly used by companies, governments, and non-governmental organizations. The number of global e-mail users reached approximately 3.823 billion, 3.930 billion, and 4.037 billion in 2018, 2019 and 2020 respectively [1]. But the overwhelming nature of unsolicited mail has complicated its use. Unsolicited email spam, also known as junk email, is an email that is sent in bulk. Spam email has an attractive look and most of them contains tempting pictures or text to draw the attention of users. Some spam emails are often used as an advertising tool to deliver advertisements to a large number of target users via the internet. While spam emails of this kind are often not harmful, just waste users time. In addition, spam emails play a vital role in phishing where a fake links are embedded in emails by spammers and directs the users to fake web site [7]. So, it is necessary to identify which emails are spam and which are ham to protect the email users from spammers. In case of spam identification, both machine learning and deep learning model must be able to decide if the sequence of words contained in an email is more similar to spam emails or not.

The main objective of this research work is to design a two-dimensional identification system to predict spam based on email dataset and appropriate preprocessing mechanism to make the data suitable for better classification.

The rest of the paper is organized as follows: section II gives details of the existing works; section III illustrates details about data and methodology. In section IV, we describe the evaluation, validation, experiments. And the last two sections are about conclusion and future work.

II. Related Works

Shreyasi Sinha, Isha Ghosh, and Suresh Chandra Satapathy et. al [2], proposed a model based on backpropagation and backpropagation with momentum to perform spam detection. The authors optimized the model using SGO (Social Group Optimization) to improve the classification performance. Neural network is used to work with any types of data (text, audio, image etc.) for both classification and clustering purpose. The use of backpropagation has one disadvantage that is, it needs more iterations and thus increases computation time. The authors didn't introduce any idea about removing outliers as outliers have a great impact on textual dataset and normalization technique often increases variation among the data points. They have added only 2 hidden layers. Less number of hidden layers do not always produce better performance.

Vashu Gupta, Aman Mehta, Akshay Goel, Utkarsh Dixit et. al [3], presented a spam detection model based on the combinations of classifiers such as Gaussian Naive Bayes, Multinomial Naive Bayes, Bernoulli Naive Bayes, and Decision Tree and produced an ensemble method using voting

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

classifier. They used voting classifier to offer more accurate prediction accuracy than the individual classifiers. This system didn't handle the noisy data point.

Deepika Mallampati, K. Chandra Shekar et. al [4], built an efficient technique to filter spam email using SVM classifier to work with non-linear data. The authors introduced the use of kernel function in SVM. The kernel function is introduced to separate non-linear data by converting data into a higher dimensional feature space. But the use of kernel function often brings a number of difficulties such as it elevates the training time and memory size requirement by creating excessive support vectors. Furthermore, using only a single classifier do not always gives better predictive accuracy.

Haoyu Wang, Bingze Dai et. al [5], developed a predictive scheme using Bayesian linear regression and random forest regression for numerical prediction on spam dataset. The authors achieved better accuracy and lower MSE for random forest regression algorithm than the Bayesian linear regression model. In this work, there is still a need to extract more relevant attributes for developing a spam detection model.

Sunday Olusanya Olatunji [6], proposed support vector machines-based model to differentiate spam and non-spam emails. The author attempted to find optimal parameter set to improve mode's performance. As the performance of SVM depends on its parameter, so a parameter search algorithm has been implemented to apply to SVM. SVM has been deployed in this work as it can work with minimum number of samples to give better predictive accuracy. They have put all the efforts to improve only the detection accuracy. This system has a time complexity to in training phase. A detection system should not only be concerned about predictive accuracy but it should also perform timely.

Rozita Talaei Pashiri, Yaser Rostami et al. [7], emphasized on building a spam detection model based on feature selection method. They selected the relevant features using the Sin-Cosine Algorithm (SCA). The authors had been able to reduce the error in feature selection compared to MLP (Multi-Layer Perceptron). The features were updated using metaheuristic algorithm before applying to MLP. In this work, a single neural network is used that is a drawback.

III. Methodology

This section illustrates a detailed description about the methodology of this research work and the model consists of five steps.

1. **Data Collection:** In this work, a spam-base dataset has been collected from UCI (University of California, Irvine) machine learning repository that contains total 58 attributes where 57 are independent features and one is dependent feature [8].

TABLE I. Information on spam-base dataset.

Attribute Types	Fifty five real and continuous attributes; two integer and continuous attributes; one nominal attribute
Number of Instances	4601
Number of spam instances	1813
Number of non-spam instances	2788
Used for	Classification
Characteristics of Dataset	Multivariate
Number of class in target feature	2 (0 denotes the email as non-spam and 1 represents the email as spam)

2. **Data Cleaning:** Data cleaning means making the data processable for a machine to build an efficient machine learning model.

   I. **Converting to integer:** The data points that are continuous and floating point are converted to integer to increase processing flexibility. The floating-point data values create additional variation (range) among data points. Thus, this variation increases computational complexity. Computational complexity decreases machine's predictive performance.

   II. **Removing Outliers:** Outliers are removed from the dataset after converting the data from continuous and floating point into integer. Outliers are the data points whose distribution are different from the normal data points. These outliers affect the mean, standard deviation, skewness and distribution of the dataset. It causes biasness in machine learning model. So, these outliers should be eradicated from the dataset to stop being affected by these reasons. Outliers can be removed from the dataset using various methods. In this research work, two methods DBSCAN and Isolation Forest are applied to remove outliers.

3. **Feature Engineering:** Feature engineering is a process which is executed to construct a subset of features from the original feature set. It reduces training time, overfitting and improves applicability and accuracy of machine learning model. In this research work, three well-known feature selection techniques are implemented to extract the effective features.

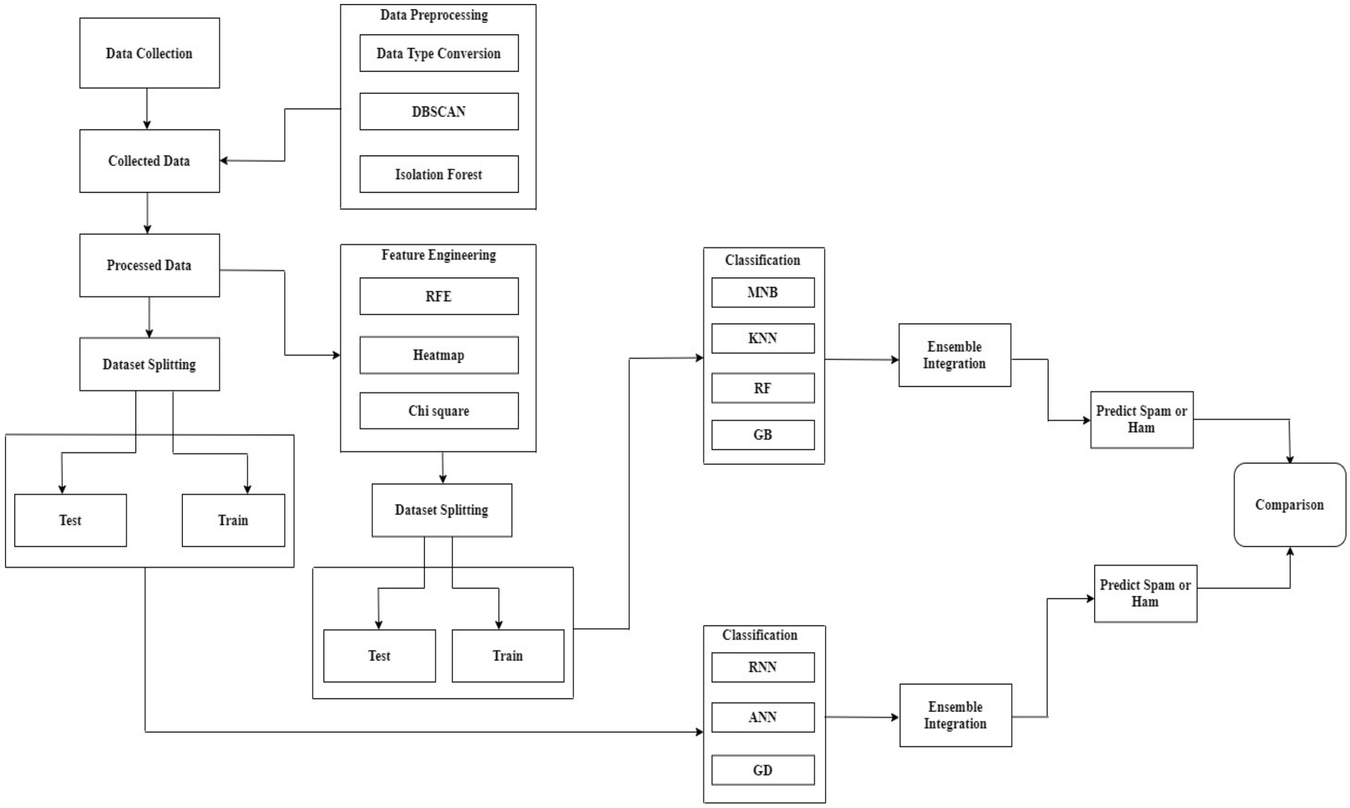

Fig.2. Proposed architecture for spam detection.

4. **Data Splitting:** In this step, the dataset is divided into 80% training set and 20% testing set. Training set will be used to train the model and testing set will be used to validate the performance of the model.

5. **Classification & Prediction:** Both machine learning and deep learning techniques are implemented for classifying the email. The training and testing set are provided to the classification algorithms to classify the email as spam or ham. Four classification algorithms: Multinomial Naïve Bayes, K-Nearest Neighbor, Random Forest and Gradient Boosting are implemented to integrate the output from these base classifiers that is integrated using an ensemble integration method named Stacking. Artificial Neural Network, Recurrent Neural network and Gradient Descent are implemented to get a combined outcome.

   a. **Multinomial Naïve Bayes:** Multinomial Naïve Bayes is an extension of Naïve Bayes where each feature in a feature vector is assigned a weight. Feature vector stores the number of occurrences of a feature. It works comparatively faster than the Naïve Bayes algorithm. It is mainly useful for textual documents to perform word count. To deal with new words, it uses a smoothing technique called Laplacian smoothing (determines how many times the new word appeared). This algorithm works in two steps: training and testing.

   b. **K-Nearest Neighbor:** K-Nearest Neighbor is a type of supervised learning algorithm which can be used for classification and regression purposes. It classifies the new samples depending on the similarity with the training samples.

   c. **Random Forest:** Random forest is a boosting algorithm which is an ensemble learning method. Random forest creates many classification trees. It uses no pruning strategy.

   d. **Gradient Boosting:** Gradient Boosting is also an ensemble method that combines the output from weak learner and produce a model with better accuracy. It builds regression trees starting from a single leaf. Instead of creating trees for each of the attribute it creates trees for all the observations. Then split into two groups the predictor. The predictor is selected in a way that reduces residual error [11]. In the next step, this algorithm tries to minimize the error and iterates continuous to make decision trees.

   e. **Recurrent Neural network (RNN):** RNN is a type of ANN which finds the characteristics of data and from the characteristics extract the pattern. Using these patterns, RNN predict on given data. RNN has one input layer, one output layer and a number of hidden layers. The number of hidden layers vary as per the requirements of a model. Each layer of RNN stores information about the previous layer. It has a memory in the hidden layer to store this information. Same biases and weights are given to each of the layer to convert output from input.

f. **Gradient Descent:** Gradient Descent is an optimization algorithm which tries to find an optimal solution by going through iteratively to reduce the loss function. It is mostly used when we want to reduce the cost function. It tries to fit a line like the one in linear regression. In gradient descent intercept is provided for a random guess. With the value of the intercept, it calculates the predicted value.

g. **Artificial Neural Network (ANN):** ANN, also known as Feed Forward Neural Network is combined with a group of perceptrons in its each layer. Activation function in ANN provides the ability to process non-linear function. This function maps the inputs to outputs. The inputs are converted to output using feed forward method and the inputs are updated using backpropagation method.

IV. Performance Analysis

We got 2504 and 4147 instances from original dataset by applying DBSCAN and Isolation Forest respectively. Using DBSCAN algorithm for data preprocessing, Heatmap selects 29 attributes, Chi-Square selects 44 attributes, Recursive Feature Elimination selects 44 attributes from 58 attributes. The dataset which is processed using Isolation Forest, Heatmap selects 27 attributes, Chi-Square selects 44 attributes and Recursive Feature Elimination selects 22 attributes from 58 attributes. Various measures are used to evaluate the performance of the research work. Confusion matrix, Accuracy, precision, recall, sensitivity, specificity and F1-score are calculated for machine learning techniques. Loss function and accuracy is calculated to measure the performance of the deep learning techniques. Confusion Matrix is a table which separates classes in binary classification problem. Elements of a confusion matrix are False Negative (FN), False Positive (FP), True Negative (TN) and True Positive (TP).

Confusion Matrix after applying DBSCAN,

$$\begin{bmatrix} 630 & 0 \\ 0 & 247 \end{bmatrix}$$

Confusion Matrix after applying Isolation Forest,

$$\begin{bmatrix} 499 & 0 \\ 0 & 331 \end{bmatrix}$$

AUC-ROC is a curve that is used to validate a classification model. In this visualization TPR (True Positive Rate) and FPR (False Positive Rate) is represented along two axes in a graph where X-axis denotes FPR values and Y-axis denotes TPR values. A model with higher AUC means the model has a better chance to classify 0’s as 0’s and 1’s as 1’s.

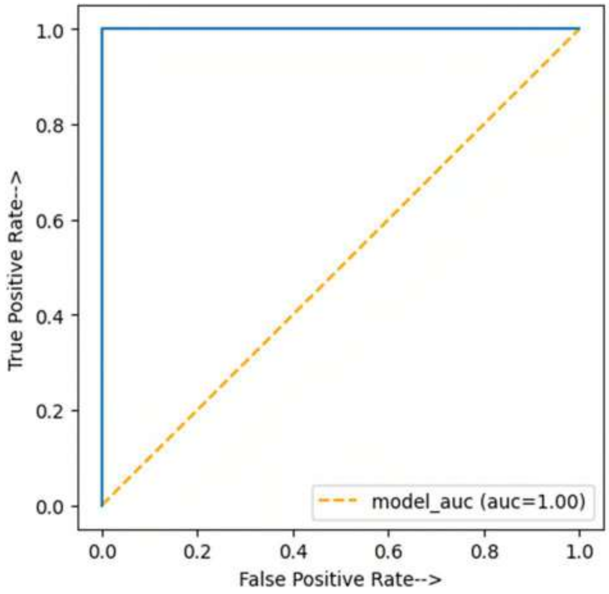

Fig. 3. AURUC Curve for proposed model with ML (Machine Learning).

The proposed machine learning model obtained AUC =1.00. That means, this model has 100% possibility to classify emails as spam or ham.

Conclusion and Future Work

Spam filtering systems secures privacy for the email users. It analyzes the email content to take proper measures on blocking and deleting the identified spam email. In this research work, we have observed the classification performance with and without outliers and irrelevant features.

In this comparative study, we observed that Machine Learning algorithms perform better than deep learning algorithms for tabular dataset to identify spam e-mails. This model helps effectively to detect spam. In future, we will work for image spam, blank spam, backscatter spam detection and we will work with text data direct from text content instead of tabular data using natural language processing.

***Abstract*—Internet of Things (IoT) is a field with tremendous growth that already shows great impact in numerous domains. Simultaneous with this development is the need for better Cyber-security: IoT systems are attacked by various adversaries targeting IoT services, platforms and networks, which can have disruptive consequences. These attacks can be countered using multiple strategies with different effects to the system. The following paper, proposes a novel approach based on Machine Learning and Statistical Hypothesis Testing, which allows the security operator to investigate how using different strategies affects various KPI related to the security of the IoT network and if the KPI resulting from modifications to a mitigation strategy are statistically different when compared to those occurring from a starting mitigation action set.**

***Index Terms*—Internet of Things, Machine Learning, Hypothesis Testing, Cyber-Security, Attack Mitigation**

I. Introduction

From Industry 4.0 to smart cities, the growth of the Internet of Things (IoT) ecosystem has been empowering tremendous advancements and extensive impact in multiple domains while more industrial and commercial opportunities can be foreseen in the future. In tandem with this expansion, has been the rise of attacks against IoT systems, attacks which can potentially become as pervasive as the spread of IoT applications. Successful attacks against the IoT can cause disruption of services provided, breach of sensitive or private data, huge monetary losses, damage to property and even physical harm [1].

Designing secure IoT systems is the first step towards guarding them from malicious acts. However, new exploits and vulnerabilities are constantly discovered, so a robust attack detection system combined with methods and tools to mitigate new threats is an extremely important part to preserve the soundness of any IoT system. This is a challenging task since there are multiple attacks targeting different layers of the IoT network, and each of these attacks can be counter-measured by multiple mitigation actions [2].

The plethora of possible attack responses, creates the need of tools that can help the network operator investigate how different mitigation actions can affect the network so that she can make proper decisions for its safeguarding. The outcomes of different mitigation strategies can be quantified by using carefully selected Key Performance Indicators (KPI). Such a tool is described and evaluated in the remainder of this paper.

A. Key Contributions

This paper presents a novel approach to distinguish differences between sets of mitigation actions used to counter an attack or threat against an IoT network. It allows the Security Operator of the IoT network to modify a set of existing mitigation actions and see the impact of the changes. More specifically, the KPI values resulting from different mitigation sets are used to ascertain clusters of such sets using a machine learning algorithm. Then, the difference between these clusters, is evaluated by means of a p-value provided by a method based on Statistical Hypothesis Testing. To our knowledge, this is a novel approach not suggested elsewhere in available the literature.

The rest of the paper is structured as follows: Section II briefly presents relevant literature and Section III presents the methodology used to formulate the proposed approach while section IV contains the results of experiments that were performed to validate the proposed method. Finally, section V contains the conclusions of this paper along with future research directions and aims.

II. Related Work

This section briefly presents the use of Hypothesis Testing based algorithms in the context of IoT networks through examples found in recently published literature, along with details concerning four KPIs used in this work to quantify the effects of one or more mitigation actions in the system.

A. Statistical Hypothesis Testing in the context of IoT networks

Hypothesis testing in the context of statistics, is the use of a sample of data to evaluate the plausibility of a hypothesis concerning the distributions of the sample data. Numerous applications of algorithms based on Hypothesis testing have been successfully applied to IoT domain specific problems.

This work is supported by the European Unions Horizon 2020 Research and Innovation Program through the SerIoT project under Grant Agreement No. 780139.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Such methods have been extensively employed for attack detection, for example: In [3] such an algorithm is used to detect a Link flooding attack on an IoT Network, in [4] Hypothesis Testing is used against spectrum sensing data falsification in cognitive IoT Networks while in [5] Li et. al use it to empower an distributed attack detection System.

Examples of other uses are numerous: Hypothesis Testing based algorithms were used to perform polling for the values of multiple KPIs in an fog based IoT sensor network [6] , to facilitate protocols for the authentication of IoT devices [7] or manage the privacy of Smart Energy Meters [8]. Moreover, decentralized methods have been proposed, to preserve IoT sensor energy consumption [9], to safeguard privacy [10] or even preserve robustness in the case of existing noise and occurence small data sets [11]. To our knowledge, no other hypothesis-based application for evaluating different mitigation strategies in IoT has been presented in the available literature.

B. Security Related Key Performance Indicators for the selection of Mitigation Actions

The following section presents four Key Performance Indicators (KPIs), selected to be used in this report as the metrics to be describe the mitigation actions that has been deployed to secure an IoT network. These were selected, based on the results of a extensive literature review, which is available in [12].

The first KPI is Common Vulnerability Scoring System (CVSS), which is an open Industry standard for assessing the severity of cyber-security vulnerabilities. This is accomplished by the use of a score between [0,10] with 10 representing a vulnerability with the highest severity. The score is calculated using predefined values and equations, available in [13]. Using CVSS, security experts can easily share discovered vulnerabilities via public databases such as the National Vulnerability Database [14]. Moreover, any attack vector can be easily translated to a vulnerability in the device it affects. In section IV the following formula is used for the calculation of the CVSS score for a number of mitigation actions to be applied to the system: $CVSS = 10 - mean(CVSS_{all\ detected\ vulnerabilities})$.

The second KPI is named Return on Response Investment (RORI), which is used to calculate an index associated to a set of the mitigation actions . This KPI can be used to evaluate optimal plans by ranking them based on their efficiency in stopping potential attacks, and simultaneously preserve the best possible service for users. The authors of [15] provide the formula used in this paper to calculate RORI:

- The financial cost expected to occur annualy, in the absence of applying a mitigation strategy is refered as Annual Loss Expectancy (ALE).
- Risk Mitigation (RM) estimates the coverage of one more actions in the mitigation of an attack.
- The cost expected to occur due to the application of mitigations is called Annual Response Cost (ARC) while
- The fixed cost associated to the system infrastructure, regardless of the application of a mitigation strategy is called Annual infrastructure value (AIC).

Then,

$$RORI\ Score = \frac{ALE * RM - ARC}{ARC + AIC}.$$

The third KPI is named Vulnerability Coverage (VC). VC of a mitigation action cm_i , is defined as the number of vulnerabilities it covers when applied divided by the number of total vulnerabilities so VC $\in [0,1]$ [16]. Disjoint VC includes the vulnerabilities covered by a single countermeasure, whereas joint VSC refers to the vulnerabilities covered by multiple countermeasures.

Finally , the Deployment Cost KPI evaluates the deployment costs of the mitigation actions by considering deployment time, consumed resources and the importance of the device that is affected by the countermeasure as assessed by the network security operator [17]. To calculate it, three quantities are required. First, Deployment Time (DT) which is measured in milliseconds. This is the time required for a mitigation action to be deployed. It can be assessed using historical data and be dynamically updated. Then, the Device Importance (DI) is needed, which is arbitrarily assessed by the network security operator considering the specifics of each use case. A value is assigned to each device, where Device Importance $\in [0,1]$. The last quantity needed is Resource Consumption (RC), can be imputed either by measurements or an arbitrarily chosen ranking scheme can be used based on the network operators' expertise i.e $RC = \{$Very low: 1, Low:2, Medium : 3 , High :4 , Very High : 5$\}$. Finally the KPI value is calculated by the following formula: $Deployment\ Cost = DT * DI * RC$.

III. Proposed Model

In the following section, a method to distinguish between different sets of mitigation actions is presented: More specifically, the KPI values resulting from different mitigation sets are used to cluster the them. Then, the difference between these clusters is evaluated by means of a $p-$value provided by a Monte Carlo (MC) based method named Statistical Significance of Clustering (SigClust) using Soft Thresholds. Figure 1 presents a high level overview of the proposed tool.

A brief presentation of the SigClust method with Soft Thresholds, as shown in [18] follows: Let $X = [x_1, x_2, \cdots, x_n]$, x $\in \mathbb{R}^d$, be a data-set of n observations each containing the values of d different KPIs.The method starts from the null hypothesis that the data of X come form a single multivariate Gaussian distribution $N(\mu, \Sigma)$. A test level α, e.g. $\alpha = 0.95$ is pre-specified to finally test the Hypothesis.

Let C_1 and C_2 be two disjoint sets resulting from the application of a clustering of the data points contained in X i.e. $C_1 \cup C_2 = \{1, 2, \cdots, n\}$. Then, an indicator of the strength of the clusters can be attained by the Cluster Index (CI), that is used as the test statistic of the method:

$$CI = \frac{\sum_{k=1}^{2} \sum_{i \in C_k} ||x_i - \bar{x}^{(k)}||^2}{\sum_{i=1}^{n} ||x_i - \bar{x}^{(k)}||^2}, \qquad (1)$$

Fig. 1. High level overview of the Hypothesis Testing Tool.

where $\bar{x}^k$ is the mean of cluster $k \in [1,2]$ while $\bar{x}$ is the overall mean. Estimate values $(\hat{\lambda}_1, \cdots, \hat{\lambda}_d)$ for the eigenvalues of Σ must be computed. Let $(\tilde{\lambda}_1, \cdots, \tilde{\lambda}_d)$ be the eigenvalues of the sample covariance matrix.The covariance matrix Σ can be written as

$$\Sigma = \Sigma_0 + \sigma_N^2 I \tag{2}$$

for a low rank positive semi-definite matrix Σ_0. Let W_0 be a positive semi-definite matrix W_0 with rank(Σ_0)=rank(W_0). Then the precision matrix C can be defined, where

$$C \equiv \Sigma^{-1} \equiv (\Sigma_0 + \sigma_N^2 I)^{-1} = \frac{1}{\sigma_N^2} I - W_0 \tag{3}$$

To estimate Σ, the negative log-likelihood is minimized to using C and the sample covariance

$$\tilde{\Sigma} = \frac{(X - \bar{X})(X - \bar{X})^T}{n}, \tag{4}$$

to yield,

$$argmin_c[-log|C| + trace(C\tilde{\Sigma})], \tag{5}$$

subject to 3 and $C, W_0 \succeq 0$. Let $M \geq 0$, be a tuning parameter. An additional constrained is set to control the signal versus the noise of the data:

$$trace(W_0) \leq M \tag{6}$$

Finally,

$$\hat{\lambda}_j = \begin{cases} \tilde{\lambda}_k - \tau, \text{if } \tilde{\lambda}_k > \tau + \sigma_N^2 \\ \sigma_N^2, \text{if } \tilde{\lambda}_k \leq \tau + \sigma_N^2 \end{cases} \tag{7}$$

where τ is obtained by solving

$$\sum_{k=1}^{d} \left(\frac{1}{\sigma_N^2} - \frac{1}{(\tilde{\lambda}_k - \tau)_+} \right)_+ \tag{8}$$

Using the computed eigenvalues, the theoretic optimal CI value is obtained by

$$TCI = 1 - \frac{2}{\pi} \frac{max((\hat{\lambda}_1, \cdots, \hat{\lambda}_d))}{\sum_{i=1}^{d} \lambda_i} \tag{9}$$

The rest of the process is comprised by the following four steps:

1) Initially, data from the null distribution is simulated: $(x_1, ..., x_d)$ are independent with $x_j \sim N(0, max(\hat{\lambda}_j, \hat{\sigma}_N^2))$.
2) Then, this data is clustered using the k-means algorithm with k = 2; the corresponding CI value are calculated.
3) By repeating this process a large number of times, an empirical distribution of the values of CI is obtained. Using the CI values obtained by the simulation, calculate a $p-$value for the CI value of X.
4) Finally, a conclusion can be derived based on test level α.

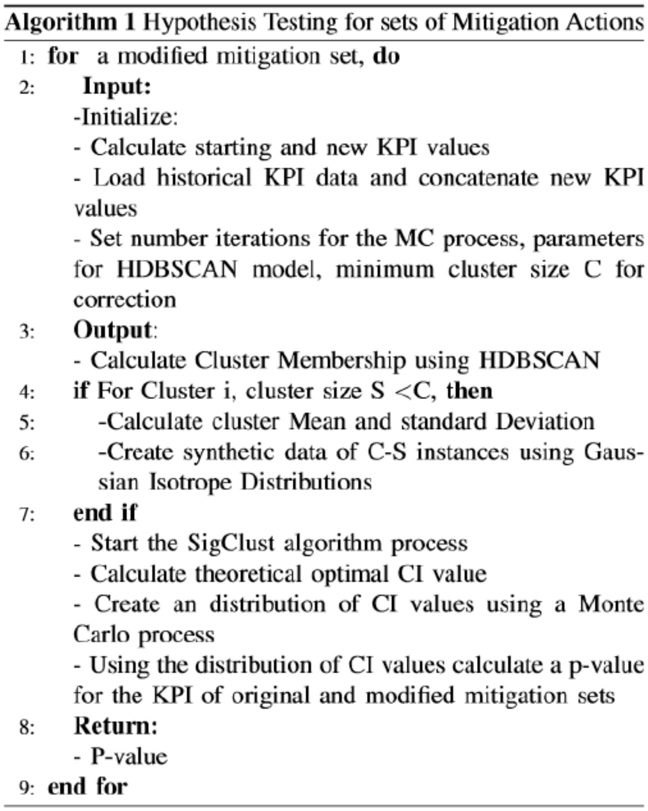
By using the p-value from the final step the following hypothesis is answered:

- H_o The clusters come from the same distribution ($p \leq 0.05$) or
- H_1 The clusters come from a different distribution ($p \geq 0.05$).

To apply this method, to distinguish the difference between different mitigation action sets the following procedure followed: Let $X = [x_1, x_2, \cdots, x_n]$, $x \in \mathbb{R}^d$, be a data set of n historical observations each containing the values of d different KPIs, with x_n being the latest observation. Let x_{n+1} be the KPI values occurring from modifying the mitigation actions that produce x_n. Some clustering algorithm is applied to all data, resulting to a partition of clusters $C = \{C_1, C_2, \cdots C_j\}, j \leq n$ for all data points.

Let C_A, C_B be the clusters, in which the data-points x_n and x_{n+1} belong to. If the size of cluster size S is smaller than a predefined minimum size C, then the following correction is applied: The Mean and Standard Deviation of each KPI is calculated. These are used as input to create and $C - S$ synthetic data points for the cluster using a Gaussian Isotrope Distribution i.e. a Gaussian Distribution where the covariance matrix is represented by the simplified matrix $\Sigma = \sigma^2 I$.

Proceeding the process, in the case when $C_A = C_B$ the case is trivial and no testing is required since the points belong to the same cluster. Else, let $x_{cluster} \subset X$ be the subset of all



Algorithm 1 Hypothesis Testing for sets of Mitigation Actions

```
for  a modified mitigation set, do
    Input:
    -Initialize:
    - Calculate starting and new KPI values
    - Load historical KPI data and concatenate new KPI values
    - Set number iterations for the MC process, parameters for HDBSCAN model, minimum cluster size C for correction
    Output:
    - Calculate Cluster Membership using HDBSCAN
    if For Cluster i, cluster size S <C, then
        -Calculate cluster Mean and standard Deviation
        -Create synthetic data of C-S instances using Gaussian Isotrope Distributions
    end if
    - Start the SigClust algorithm process
    - Calculate theoretical optimal CI value
    - Create an distribution of CI values using a Monte Carlo process
    - Using the distribution of CI values calculate a p-value for the KPI of original and modified mitigation sets
    Return:
    - P-value
end for
```

points that belong either in C_A or C_B. Then the Statistical Significance of Clustering methodology described above is applied as is, answering the question: "Are C_A or C_B different in terms of their underlying distribution and is this difference statistically significant?".

IV. Performance Evaluation

The following section contains the evaluation of the performance of the Hypothesis Testing Tool under two different scenarios. The first scenario is used to showcase the approach in a data-set with clear cluster memberships. Additionally, it is used to investigate the sensitivity of the approach to the change of different parameters of the clustering algorithm and the underlying data set size.

The second scenario, investigates the operations and the effectiveness of the proposed method to a data set with noise and no clear cluster membership. Table III shows the steps of the algorithm used for Hypothesis Testing.

The Hypothesis Testing tool was written in Python. The experiments using the Jackstraw method where performed with the implementation described in [19] using the R Statistical Language.

A. Experimental setup

For the clustering of the KPI values, the Hierarchical Density-Based Spatial Clustering of Applications with Noise (HDBSCAN) [20] algorithm was used. This machine learning algorithm has been shown to operate well in the presence of data with noise and outliers, successfully recognizing clusters with arbitrary shapes, different sizes and dissimilar densities.

Two sets of four KPI values are examined: One is completely synthetic with lack of noise while the second is obtained by simulating a scenario where 150 devices are under attack, i.e. 30 of each type of the devices presented in table I.

The HDBSCAN algorithm is heavily infected by choice of a parameter that indicates the minimum number of members a cluster must have to be considered valid. To determine this number an arbitrarily chosen integer m which is the max number of minimum cluster membership was chosen. Then for cluster minimum membership number $M = \{2, 3, \cdots, m\}$, HDBSCAN was used to cluster the data and calculate the value of the Variance Ratio Criterion score V [21]: a higher value indicates clusters are dense and well separated.

The proposed method, is compared to a similar SoA method originating from the field of Bio-Informatics, termed the Jackstraw method [19] as implemented in [22]. This method calculates the cluster membership significance instead of difference between clusters. It produces a p-value to answer the following Hypothesis:

- H_o The point examined belongs to the same distribution with the other members of thesame cluster ($p \leq 0.05$) or
- H_1 The point comes from a cluster with a different distribution ($p >$0.05).

To compare two clusters using the Jackstraw method, for the experimental results presented, the following assumption was used: two clusters have statistically significant difference only if the Jackstraw algorithm correctly ascertains cluster membership for the cluster members of both clusters.

B. Experimental Results

In all experiments, it is assumed that a data point i.e. the current KPI values of the system belong to a cluster and then a data point representing the modified version of the original is tested for differences, occurring by a set of modified mitigation actions.

C. Experiment 1: Synthetic data-set from three isotropic distributions

In this experiment, the proposed Hypothesis Testing tool is applied to synthetic data with clear cluster membership to investigate the sensitivity of the SigClust and HDBScan algorithms in changes to their underlying parameters: Three clusters are used as the most trivial case. Additionally, experiments with different numbers of iterations for the Monte Carlo process were carried out and the run-time for each is reported, to ascertain an appropriate number for the second experiment.

The synthetic data set was created by sampling 3 discrete isotropic Gaussian distributions with pre-specified centres and deviations, shown in Table II. Data-sets with different sizes were created, to determine the data set size needed for the method to produce correct results. Experiments with the following data set size were performed N =[200, 500, 1000, 2500, 3000, 4000, 5000, 10000] while in each case the clusters were equally sized. For each data-set, the Monte Carlo process for

clustering Significance was run for i iterations where i = [5, 25, 100, 300, 500, 1000].

For all cases, the expected result i.e. statistical significance when the clusters came from the same clusters, was found when the data-set size was larger than N = 1000, for any and all number of iterations. However, for N $\leq$ 1000, the algorithm cannot correctly distinguish between members of the same cluster.

For the experiments three different cases are examined: In the first case, both the original and the modified data point belong to the same cluster (Cluster A). In the second and third cases, the two data points belong to different clusters: A and B, A and C respectively. In all cases, the clusters have an equal point of members.

Table III contains the results for N = 500. In the case where we examine two points from the same cluster, all results are False i.e. the test fails to distinguish that the points belong to the same cluster. However, the opposite holds when comparing points from different clusters: for all different numbers of the iterations, the algorithm correctly indicates that statistical significance is found i.e. the points come from different clusters.

D. Experiment 2: Simulated data-set

In this experiment, the tool is applied to to a data set with noise and no clear cluster membership. This data set was produced by applying the mitigation selection algorithm presented in [12], on the mitigation rules found in table I. The data

examined in this experiment, was found to optimally contain ten clusters, with a minimum of 150 members (variance V = 9240.615), while a lot of the points were determined to be noise i.e. not assigned to any of the clusters. Figure 2 shows the distribution of the data and the clusters found, while Table V contains number of the points belonging to each cluster. The data-set has 6300 unique data points, in some cases not exceeding the threshold of N >1000, determined to be needed in experiment 1.

For this experiment, all clusters were cross-examined for significance (47 unique pairs), using both the Sigclust and the Jackstraw methods. The algorithm was initially tested without the cluster size correction: It correctly assessed only 80.43 %: The majority of the assessments is correct if different clusters are compared but erroneous assessments occur when members of the same cluster were compared.

However, based on the fact there are clusters with membership count lower than 1000, the cluster size correction was applied: For each such cluster, enough synthetic data using Gaussian isotropic distributions are created to reach membership threshold $C = 1000$. This data was only used for the case of a comparison of a cluster with itself and not for clustering or for inter-cluster comparison . Using the correction, the number of correct assessments rose to 95.65 %. The proposed method with the correction outperforms both the method without the correction and the SoA method which achieves 89.13 % accuracy. Finally, the F_1 scores for each method are: 0.8889 for the corrected method, 0.3077 for the method without a correction and 0.7619 for the Jackstraw methods.

V. CONCLUSIONS

This paper presented a novel mechanism to ascertain the difference between a starting and a modified set of mitigation actions was developed. This mechanism allows the system operator to explore the effects of different mitigation plans in the system in terms of four cyber-security KPIs using statistics and machine learning tools.

To reiterate, experiments show that the proposed tool achieves a score of 95.78% accuracy, in discerning whether a statistically significant difference exists between different mitigation plans using a data set with numerous outliers. The algorithm outperforms another similar SoA method by 6.61% in terms of Accuracy.

The Hypothesis testing tool is currently being integrated with the system developed in the SerIoT project [1] and more specifically with an approach using Software Defined Networking (SDN) controllers, an automated Mitigation Engine and a Visual Analytics Dashboard that allows a user-friendly overview and operation in the case where manual intervention to the system is required.

Finally, we plan to further augment the proposed method in order to improve its performance and usability by introducing two enhancements: The first enhancement, will be a mechanism that will automatically fine-tune the model used to cluster the mitigation action set. The second enhancement will involve experimentation using ensemble methods to combine the results of the Sigclust and the Jackstraw models to obtain a method with improved performance.

***Abstract*— The idea of the Internet of Things is to connect every physical device with internet. Each device should be presented by a unique address of Internet Protocol. There are two versions of IP known by IPv4 and IPv6. IPv4 assumed to cover whole network interfaces. Since the appearance of IoT, number of connected devices increased sharply and IPv4 could not afford this enormous numbers. Therefore, the solution came by introduced IPv6 to afford this massive number in IoT environment. Despite IPv4 provided interoperability with several types of protocols, robust and easy implementation but it's vulnerable for several kinds of attacks. Therefore, IPv6 introduced while having security protocols such as IPsec, neighbour discovery protocol and Secure Neighbour Discovery Protocol. However, due to IPv4 still working as well as updated with security components, there is need to interact between both versions of protocol. Therefore, there is need for interacting mechanism between both them. These mechanisms made implantation of IPv6 complicated and consumed more resources. Besides, there are threats for attacks. Therefore, security features in IPv6 are not enough and there is need for a new defense line that can secure network services and IP from attacks. Intrusion Detection mechanism considered good mechanism to provide protection due to it works based on two levels Host and Network. Besides, it uses several security approaches such as signature-based and network-based. However, considering this tool as it's in IoT environment will not bring the light of security in IoT. Therefore, it should be developed while considering features of IoT devices to secure IoT environment. To achieve this, we have to investigate every feature, component and operation in network. This review paper aims to analyse difference between IPv4/IPv6 and point out security threats related to IP in both versions. Also, identifying main security threats to IPv6.**

Keywords*— *IPv4, IPv6, IP Security threats, ICMPv6, Network Layer attacks.

I. INTRODUCTION.

The 21st century is considered the time of development of technology due to the appearance of Internet-Of-Things (IoT). The main core of IoT is to associate physical devices in human life through connections over internet. This association provided several facilities for human activities. IoT has several application such as Smart City, Smart Home, Smart Grids and Smart Buildings [1]. Ideally, it should apply with every industrial fields. This association leads to massive financial gains. Several studies estimate the financial impact of IoT from 2018 to 2023 to have increased from 249.4 to 2,0030.1 Million Dollar respectively [2]. This massive impact came from massive numbers of newly connected devices that interact and share data over internet. Studies suggest the estimated number of connected devices over internet increased from 7 to 21.5 billion device from 2018 to 2025 [3]. However, devices need Internet Protocol/Transmission Control Protocol IP/TCP to exchange data. The main advantage of IP/TCP is to allocate unique addresses to recognise of each device. Since the introduction of IoT, IP has been changed sharply from version 4 (IPv4) to version 6 (IPv6). This amendment introduced several security challenges for security mechanism as well as security attacks due to IPv4 still working and there is need to interacts between both versions while these mechanisms have interoperability challenges and vulnerable for network layer attacks [4]. In this review paper, we are going to draw a roadmap of potential security threats based on IPv4 and IPv6 in IoT/Smart City environment. To achieve this purpose, I am going to use my knowledge in Pentesting as well as most updated works toward it. Updated work will be collected from strong conference and journals. Ideally, there are three main questions to be highlighted through this study:

A. What are differences between IPv4 and IPv6?

B. What are security threats for IPv4 and IPv6?

C. What are specific threats for IPv6?

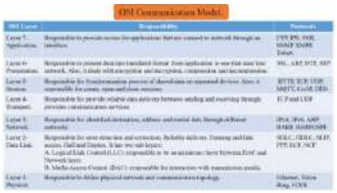
II. IPv4 vs IPv6

A. *Open Source Interconnection model*

The Open Source Interconnection (OSI) model is considered to be the updated model in communication and interacting data between devices. It consists from seven layers known by Application, Presentation, Session, Transport, Network, Data Link and physical layer. Application layer is responsible for providing access to applications that are in connection with an internet. Presentation layer is responsible to present data into translated formats. Session layer is responsible for creating, opening and closing sessions in order to share data between

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

devices. Transport layer is responsible for processing message delivery between senders and receivers. Network layer is responsible for identifying addresses, destinations, and routes of data through different networks. Data link layer is responsible for error detection, corrections, link access, framing and reliable delivery. While the physical layer is responsible to define physical network. Since IP is located in network layer, we can assume rules for IP. Fig1, shows several protocols in each layer [5], [6]



OSI Communication Model

OSI Layer	Responsibility	Protocols
Layer 7- Application	Responsible to provide access for applications that are connect to network through an interface.	FTP, IPS, SSH, SNMP, XMPP, Telnet
Layer 6- Presentation	Responsible to present data into standard format from application to one that used into network. Also, it deals with encryption and decryption, compression and decompression.	SSL, [illegible]
Layer 5- Session	Responsible for Synchronization process of shared data on separated devices. Also, it responsible for create, open and close sessions.	HTTP, TCP, UDP, MQTT, CoAP, DDS
Layer 4- Transport	Responsible for provide reliable data delivery between sending and receiving through provides communication services	TCP and UDP
Layer 3- Network	Responsible for identified destinations, address and routed data through different networks	IPv4, IPv6, ARP, RARP, [illegible]
Layer 2- Data Link	Responsible for error detection and correction, Reliable delivery, Framing and link access, Half and Duplex. It has two sub layers. A. Logical Link Control (LLC): responsible to be an intermediate layer between MAC and Network layer. B. Media Access Control (MAC): responsible for interaction with transmission media.	SDLC, HDLC, SLIP, PPP, LCP, NCP
Layer 1- Physical	Responsible to define physical network and communication topology.	Ethernet, Token Ring, FDDI

Fig 1, OSI communication model.

B. *Length of Address.*

The length/size of IPv4 is 32 bit while it is 128 bit in IPv6. Therefore, the number of available address in IPv4 and IPv6 are 2^{32} and 2^{128} respectively. The format of address used in IPv6 is alphanumeric hexadecimal notation while it is numeric dot decimal notation in IPv4. Prefix notation is 24 in IPv4 while it's 48 in IPv6. Also, IPv6 is represented by four hexadecimal digits in eight groups while in IPv4 is presented by three numeric dot decimal in four groups. Beside IPv6 supports auto configuration while in IPv4 support Dynamic Host Configuration Protocol (DHCP) or manual configuration. Table 1, shows comparison between IPv4 and IPv6 based on address features [7].

Table 1 address features between IPv4 and IPv6.

IPv4	IPv6
Length: 32 bit	Length : 128 bit
Available address: 2^{32}	Available address : 2^{128}
Format: numeric dot decimal notation	Format: Alphanumeric hexadecimal notation
Prefix notation : 24	Prefix notation : 48
Represented by: Four hexadecimal digits with eight groups	Represented by: Three numeric dot decimal in four groups.
Supports: DHCP and Manual configuration.	Supports: Auto configuration.

C. *Header.*

Header in IPv4 consists of 14 fields. Firstly, the version value is 4 bits. Internet Header Length (IHL) have varying sizes between 20 to 60 bytes and is used to avoid errors. The type of services (ToS) used to provide quality of services such as Voice over IP (VoIP). Explicit Congestion notification (ECN) is optional, and it used to notify senders or receivers network updates. Total length size is 16 bits and is used to point out the size of total datagram. The size can be ranged between 20 to 65535 bytes. Since this, fragmentation process has been introduced to deal with packet that have size bigger than this range. Identification (ID) is a feature used to identify fragment of IP uniquely. Flags are used to control and identify fragment. There are three flags known by Bit 0, Bit 1 and Bit 2 which are used for reserved, do not fragment and more fragments respectively. Fragment Offset has a length of 13 bit and is used to specify the offset of a fragment relative to the beginning of IP datagram. Time to live (TTL) has length 8 bit and used to present maximum time of datagram will be live on the internet. TTL is measured in seconds and it range between 0-255. In the case TTL value is zero then datagram will be removed. Protocol is used to present used Protocol in portion of datagram such as 6 present TCP and 17 present UDP. Checksum of header has 16 bit and is used to check errors in header. It is used to compare values of header checksum at each hop and discards packets in case of mismatch. Source Address has 32 bit and it present sender of data. Destination Address has 32 bit and present destination of sent packet Options it used for settings related for security, route, time-stamp and usually used when value of IHL is set to more than 5 [7]–[9].

It is unlikely for IPv4, IPv6 has less than 8 fields. Starting by version and it represent the version of IP and has 4 bits. Traffic Class has 8 bits and is divided into two main parts. First one consists of first six bits and is used to make router familiar with kind of services that should be provided. Secondly, last two bits and used for ECN. Flow label has 20 bits and designed for real-time media and streaming. Also, it used to maintain sequential flow of packets. This help router to identify particular packet belonging to specific flow of information. Therefore, it helps to avoid reordering of packets. Payload length has 16 bits and used to inform router with size of information that packet have. The size can be up to 65535 bytes and it will set for zero in case the maximum size is exceeded. Next header has 8 bits and used to indicate the type of extension header or Upper layer in case header is not present. Hop limit has 8 bits and used to stop looping packet in network. It is the equivalent to TTL in IPv4. Source address and destination address have 128 bits [7]–[9].

D. *Quality of Service.*

Quality of Service (QoS) is a set of requirements that are used to ensure proper delivery for packets. Ideally several parameters are used to construct metrics of QoS such as bandwidth, transmitted data, delay, lost data, received data and other parameters. Therefore, to evaluate the QoS between IPv4 and IPv6, will be based onto fields that indicate proper delivery. In IPv4, the flow of packets will be based on source, destination, ports and type of protocol in transport layer. However, these parameters could be affected due to fragmentation and encryption process. While in IPv6, the flow of packets based on previous fields plus flow labelled which is pre-defined in header. Flow labelled consists of 20 bits. The field of 8 bits for traffic class and used to distinguish between classes or priorities of IPv6 packets. This distinction made by source node and router. Flow labelled provided several advantages such as reduce average time for processing in router in network, reduce delays of packet, reduce the use of resources that caused by frequent change route [10].

E. *Auto Configuration.*

The main aim of this feature is to connect devices such as PC to internet automatically without need for manual configuration or software. Also, it provides a unique IP address to overcome scalability issues. This feature is an improvement of Link Layer Discovery Protocol (LLDP) which uses a set of attributes to discover neighbour devices. The set of attributes known by Type Length Value (TLV) which consists of type, length, and descriptions of value [11]–[14].

Dynamic Host Configuration Protocol (DHCP) is used for automatic configuration of devices in network. It is used elements in configurations such as IP, subnet mask, gateway, and other information. Generally, this process consists of discover, offer, request and Knowledge. There are some similarities on functionality of DHCP in IPv4 and IPV6. Firstly, the components of DHCP are DHCP Client, DHCP Server and DHCP Relay. These components are not changed in both IPv4 and IPv6. DHCP client is a device on a network that utilise a DHCP protocol to get network configuration. DHCP server is a component that provides a network configuration to DHCP client. This server is configured by a network administrator with network parameters to meet client needs. DHCP relay also known by DHCP relay agent and it used to pass messages in DHCP client and DHCP server are in different network. Secondly, scopes and leases. Scopes is a group if information that are used to configure device on network while lease is determine how long device on network can use that configuration. Finally, both use four messages to provide basic configuration of device on network. These configurations are discover message/solicit message, offer message/advertise message, request message/request message and acknowledgment messages/ replay message [11]–[14].

There are differences between DHCP for IPv4 and IPv6. Firstly called a reservation. In IPv4, MAC address been used to obtain IP address while in IPv6 used DHCP unique identifier (DUID) to allocated IP address. This mechanism is more sophisticated. However, reservation always require updating, as IPv4 is based on MAC while in IPv6 is based on DUIDs. The second difference is stateful and stateless. IPv6 have these two methods to configure devices on the network. Stateful stores device configuration while stateless not. In stateful DHCP sever knows IP address for all devices on network while in stateless it does not record any IP address and devices use router advertisement message to configure itself with an IP. A part of this IP is configured by device itself. In IPv4, it's not possible for a device to configure a part of IP for itself due to limitation on number of usable addresses. Second difference is Broadcast and Multicast. IPv6 uses multicast rather than broadcast. Broadcast packets goes to all devices on the network once the device is loaded on a network. This consumes more resources if the network has many devices. IPv6 uses multicast which it sent packets for selected devices on network rather than all devices. This reduce traffic on network [11]–[14].

F. *Mobility.*

The main idea behind Mobile IP protocol (MIP) is to keep devices connected to the internet while device in continuous mobility. In IPv4, mobility mechanism consists from three functional units known by home agent (HA), forgiven agent (FA) and mobile node (MN). Every MN has permanent home address allocated from home network but when it moves out, it gets a temporary address (CoA) which is used to identify MN in visited network. However, routing issue cause delays in mobility in IPv4. While IPv6 provide a great support for mobility due to its uses two IP address known by home address and CoA. However, routing has been improved in IPv6 [15].

G. *Security.*

IPv6 loaded with IP security series (IPsec) for security, authentication and data integrity provides authentication on header and encapsulating security payload extension (ESP). Also, it is designed based on end-to-end encryption and it supports more-secure name resolution. Besides, the secure neighbour discover protocol (SEND) added extra security features to neighbour discovery protocol (NDP) which is responsible for discovering other node on local link. However, NDP is not secure but SEND secure it with cryptographic method. Updated IPv4 include IPsec features. Therefore, security is different but not that big [4] [7].

III. SECURITY THREATS TOWARDS IPV4 AND IPV6.

In this section, we are going to investigate Cyber security attacks based on bothIP addresses. We would like to mention new sophisticated attacks are multi-use which means it will be based on IP and other services. However, we are going to classify attacks based onto previous features and operations in IPv4 and IPv6..

A. *Fragmentation attacks*

Fragmentation process is used when sent packet in more than maximum size therefore, attacks related for this process are:

1) *Ping of death.*

The main aim of this attack is to destroy services on destination machine. Idyllically, this attack used ping feature to create a small fragment and when these fragments assemble at destination, they exceed the max size of IP packet of 65535 bytes. This attack belong for Denial of Service (DoS) but it utilised connection features to be conducted [16].

2) *Drop attack.*

This attack based on reassemble rules of fragmentation. One of these rules is to indicate location of fragment to reassemble successfully at destination. Hence, hackers utilise this rule through sending fragment with overlap in order to make destination node unable to reassemble sent packet [16].

3) Overlapping.

The main aim of this attack is to gain access based on TCP flags. It sends first fragment with TCP flag in order to reach the destination. The second fragment is sent with different value of TCP flag. This fragment is not blocked due to verification conducted only at the first fragment and when both fragments reach the destination, flag of first fragment will be over written with value of second fragment [16].

4) UDP and ICMP attack.

The main aim of this attack is to consume resources through sending UDP or ICMP packets bigger than network MTU [16].

B. Routing attacks.

Routing is a process to identify path of traffic inside or outside the network. It works in both versions of IP. Therefore, there is a threat for several attacks such as:

1) Flood attack.

This attack is based on sending large amount of traffic that make the destination unable to process sent packets. This attack belong for DoS. This attack utilises several types of protocols such as TCP, UDP and ICMP [17]–[19].

2) Sniffing attack.

This attack aims to capture traffic while being sent through a network. It has many aims such as stealing confidential data or dropping some packet. The best example of this attack is Man in the Middle (MiTM) which is based on fool router and source to make traffic passed through it [17]–[19].

3) Fake attack.

This attack is based on introducing a fake device or access point which is not authorised to be inside a network. Once this fake device is installed inside a network, it can pass traffic through it in order to steal data [17]–[19].

4) ARP spoofing.

ARP protocol is used to enable network communication between devices. It is used to map MAC and IP address and this mapping information stored in ARP table. This attack is based on sending wrong ARP messages over local networks to connect hacker MAC addresses with legitimate devices. Hence, hacker devices will obtain IP address and start spoofing, modifying and blocking communication. This attack belongs for MITM [17]–[19].

IV. Security Threats towards IPv6.

There are some threats toward IPv6 such as:

1) ICMP Threat.

IPv6 networks use ICMP message to conduct some important mechanisms such as router discovery when router respond for end node with router solicitation message (RS) with router advertisement (RA). This information saved for a time in routing tables. Therefore a threat here hackers could fool victims with RA messages to present itself as a router. Therefore, hackers can steal and see traffic. This attack conducted by MiTM tools. Unlikely in IPv4, blocking messages of ICMP is common development of secure features in IPv4 network [7].

2) Fragmentation process.

In IPv6, fragmentation processes are denied by an intermediate node and it conducts only by source node. The minimum recommendation size for MTU is 1280 bytes. Some security features recommend discarding all fragment with less than that value except if it’s in the last round of flow. Using fragments, an attacker establishes that port numbers are not in the first fragment. This helps in overcoming security mechanisms and in order to send massive numbers of small fragments which cause system crashes. Therefore, it is recommended to limit number of fragments [20].

3) Transition mechanism.

IPv4 and IPv6 protocols still coexist. Therefore, there is a need for compatible transmission in order to avoid risk of failure in internet connection. Despite the core of IPv6 is to provide improvements of IPv4 but different between both protocols resulting in two completely different protocols. This case compatibility problem means IPv4 hosts and routers will not be in a position to directly manage IPv6 neither IPv6 will directly manage Ipv4. Therefore, there is a need for transition mechanisms such as tunnelling, and dual-stack configuration. Tunnelling is capable of dealing with address selection and DNS resolution but it increases routing process and consumes more memory and CPU. Once it increased routing process, it will be vulnerable for routing attacks. Translation is easy to implement, works with private address and configured NAT node but it shows administration challenges due to its complexity and requires extra configuration which causes slow packet flow. Finally, it poses security threats with NAT due to it keeping sessions to apply address and port transition for inbound and outbound traffic. So, in case an injection of unknown packet came from inside network, a new session will be created. Tunnelling mechanism allows IPv6 packets to transport over IPv4 but it causes problems such as delay loaded CPU to perform encapsulation [21]. To clarify these threats, we use NAT64 which used to translate between IPv6 and IPv4. It consists from three main parts known by NAT64 prefix, DNS64 server and NAT64 router. Let’s presume, two networks A and B needs to communicate. Network A is a network IPv6-based and Network B is a network IPv4-based. In network A, there is a device need to communicate with a Website in network B. The first step is a device in network A communicate with DNS64 server asking about IPv6 for website in network B. Suppose, DNS64 server does not have record about this website. So, it will communicate IPv6 DNS server asking about it. IPv6 DNS server communicate with IPv4 DNS server about address of website. IPv4 DNS server replies with address of website in Network B due to it is located at the same network. Then IPv6 DNS server forward it to DNS64 which will do prefixing for it in hexadecimal. After that, it will forward it for a device which it used to communicate with NAT64 router which be the main components between both networks. NAT64 router made translation between IPv6 and IPv4 header. Finally, translated IPv4 packet will be forward it for website to conduct communication. This whole process is very complicated and need high resources such as CPU and routing process. Hence, it will be vulnerable for several attacks such as sniffing, DoS and routing.

4) *Secure Neighbour Discovery Protocol.*

ICMPv6 include Neighbor discovery Protocol (NDP). It is designed for several services in IP such as multicast, NDP, and neighbor discover (ND). It uses several messages such as router solicitation, router advertisement, neighbor solicitation, and neighbor advertisement. However, security in NDP is based on its scope and without securing NDP, IPv6 is still vulnerable for several attack such as MiTM, rouge and replay.

Secure Neighbour Discovery protocol (SEND) introduced to protect NDP and make IPv6 safe protocol. However, deployment of SEND is not easy and it computes intensively besides massive bandwidth consumption. So, IPv6 is still vulnerable for these attacks [22].

5) *IPsec.*

Internet Protocol Security (IPsec) is used to secure network packets at IP through enables cryptographic. It used widely in build Virtual Private Network (VPNs) by establishing Internet Key Exchange Protocol (IKE). IKE consists from two versions, each one in different mode and phases. Also it uses several authentication methods and configuration options. In case pair keys refused at different versions and modes in IKE, can introduce bypass authentication and made network vulnerable for authentication attack [23].

V. FUTURE WORK.

The main aim of this review paper is to point out security threats for IP in both versions. I plan to use this knowledge in my PhD research which is titled "identify security architecture compromised Intrusion Detection Mechanisms (IDS) to detect major attack in IoT and Smart City context". IDS is considered a promising security mechanism but not suitable to apply as it currently stands and should be improved, therefore we need to recognise threats related to IPv4 and IPv6 [24].

VI. CONCLUSION.

IPv6 have been introduced in order to overcome of IPv4 challenges in IoT context which it's limited to number of address while scalability issue is very clear in IoT. Besides, it introduced to overcome security issues in IPv4 through adapting several security protocols such as IPsec and SEND. However, existing of IPv4 introduced requirement of interoperability issue with IPv6. Several mechanism been introduced to server this purpose such as tunneling. These mechanism consumed many resources and this made network vulnerable for several types of network attacks. Besides, security features in IPv6 such as IPsec is also vulnerable for authentication and MiTM attacks.

There are several feature of IoT nodes, one of them is lightweight due to only capability to send small size of packet. Therefore, adapting IPv6 while holding translation mechanism that consumed plenty of resource introduced challenges for interoperability in IoT devices. Therefore, proposed solution for adapting IPv6 in IoT network, should be lightweight.

Ado-Ekiti, Nigeria
onibonojemo@abuad.edu.ng

Abstract—**Poultry farming has contributed immensely to global food security and the economy. Its produces are favourites and hugely subscribed, due to the uniqueness of their nutrients to all categories of people and the alternatives they provide to other high-cholesterol proteins. The increase in the world's population will continuously stretch for an increase in demands for poultry products. A smart way to ensure continuous production and increased yields in various farms is to adopt automated and remote management of poultries. This paper modelled and developed a collaborative system using the synergistic wireless sensor network technology and the internet of things. The system integrated resourcefully selected wireless sensors, mobile phone, other autonomous devices and the internet to remotely monitor and control environmental parameters and activities within the farm. Parameters such as temperature, humidity, water level, food valve level, ammonia gas, illumination are sensed, benchmarked against selected thresholds, and communicated wirelessly to the sink node and the internet cloud. The required control actions can also be initiated remotely by the administrator through messages or command signal. Also, the various parameters and actions can be read or documented in real-time over the web. The system was tested and evaluated to give an average of about 93.7% accuracy in parameters detection and 2s delay in real-time response. Therefore, a modelled system has been developed to provide robust and more intuitive solutions in poultry farming.**

Keywords—internet of things, early chicken, monitoring system, poultry, wireless sensors.

I. Introduction

Food security and food quality enhancement is an important global issue being addressed by the sustainable development goals (SDG). The increasing world population has also pressurized the food production capacity to be drastically increased and improved upon, to cater for the survival of people. The past few years have experienced increased awareness around the globe about the need for increased agricultural yields and food safety. Poultry farming has contributed immensely to the economies of many nations and global food security. Poultry has been described by [1], [2] to include a range of domestic bird species. Poultry farming identifies specifically with the agro-food sector for raising chicken for meat and eggs. However, food security is directly affected by poultry farming due to consumer issues linked to availability for meeting demands, affordability, accessibility, and consumption safety [3]–[5]. Good productivity and profitability in the sector have a crucial impact on national revenues and incomes to the farmers [6]. The profitability of a poultry farm is a measure of the revenue fewer costs, and dependent on the efficient economics of productivity [7]. Human civilization and industrial revolutions have introduced synergistic technologies to help the agri-food sector to grow and thrive [8]. Nations are adopting new measures and protocols to digitalize food production and automate agricultural practices. Beyond the impending possibilities from traditional ways of managing poultries and others, food production continues to present the need to incorporate innovative disruptions for automated systems [9], [10]. Poultry management systems characteristically contain three basic separate functions which include sensing or monitoring, decoding and decision-making, and necessary intervention [11].

Internet-connected objects can collaborate with other autonomous devices, and with themselves to execute tasks in poultry management and food production. Internet of things (IoT) has been described as a revolutionary technology associated with devices such as sensors and personal computers being connected to communication infrastructure and the internet via software solutions for self-sufficient actions devoid of human interference. In recent times, the IoT capacity being utilized by machinery, modern tools, information technologies, and emerging communication, is a major consideration for the agri-food sector. The aim is to bolster the food regime with automation, connectivity, digitalization and efficient use of resources [12], [13]. IoT is poised for a far-reaching inference on the agri-food sector and becomes an important part of a smart poultry farm. Implementing IoT technology in smart poultry production will incorporate internet-based devices to autonomously act, while humans are only to intervene at a point requiring a higher intelligent level [14]–[19]. The communication capability between sensors and various equipment used on the farm remains the main advantage of IoT in the process of process and tasks automation, to enhance management efficiency. The feasible communication types within the IoT network include device-device, human-device, and device-human communications. A simple communication signal can initiate the automation of different procedures within the system. Presently, most nodes of sensors within the IoT network are homogenous, thereby making the required communication architecture very similar to that of a wireless sensor network.

The new complex IoT-based multi-device communications are meant to face greater challenges associated with heterogenous nodes such as limitation in power supply, storage, processing units, and the inconsistency of the network access. The multi-device challenges can be addressed through instrumented algorithms, thereby allowing a higher capability of farm automation and processes such as precision feeding instrumentation in which feeds are administered based on prior weight determination of the broilers [15]. The application of radiofrequency tags is also very useful in poultry systems to monitor the feeding frequency, the frequency of egg-laying, and health status detailing. The data on the birds can then be used to decide and initiate control of the previously measured parameters. Therefore, an IoT infrastructure can be implemented in the poultry farms by ensuring the processes and methods for data protection, data overseeing and governance to ensure continuous data integrity and quality [20], [21]. Existing poultry management systems are attributed to automated condition monitoring, but manual intervention methods. The

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

manual feeding process has its unique limitations which include injurious over-feeding, and delayed supply of feeds. This paper aims at combining a synergistic approach in combining autonomously designed devices with the internet to solve ecological monitoring, decision-making, and interventionist action automatedly.

II. Materials and Methods

The poultry management system is modelled and developed using resourcefully selected devices and validated algorithms.

A. System Model

The multiple function decision-making model [22] is adopted in designing the poultry management system. The intervention provided by the system at any particular time is a subject of the decision-making pitch arising from multiple monitored input parameters.

The system is considered as a large entity with m subsystems and n major actions being taken. Assuming b_{ij}^k is the value of the input environmental factor i being monitored in initiating a unit action j, and r_j^k is the total output of action j in the subsystem k. Consider p_i as the final relevance of factor i in the entire system. Therefore, the representative equation of the entire system is as stated in equation (1).

$$\sum_{k=1}^{m} \sum_{j=1}^{n} b_{ij}^k r_j^k + p_i = \sum_{k=1}^{m} r_i^k \qquad i = 1,2, \dots, n \qquad (1)$$

Assuming d_j^k represents the total output of action j in subsystem k as determined by the decision-making of the subsystem. Meanwhile, if all $d_j^k (k = 1, 2, , m, j = 1, 2, \dots . n)$ is the solution to equation (1), the decision-making of the entire system should agree with the collective decision made by the subsystems which set the decision-making plan of the entire system as $r_j^k = d_j^k (k = 1, 2, , m, j = 1, 2, \dots . n)$. However, this is observed not to always be true as d_j^k does not often satisfy equation (1), thereby making the requirement for a further procedure necessary.

Meanwhile, if any of the solutions of $d_j^k (k = 1, 2, , m, j = 1, 2, \dots . n)$ minimizes all the differences amongst r_j^k and d_j^k, a satisfactory solution of the entire system can be established. Weighted measure multi-criteria decision-making technique is hereby proposed as a mathematical model solution as highlighted in equations (2) and (3).

$$\min \left[\sum_{k=1}^{m} \sum_{j=1}^{n} \frac{1}{2} c_j^k (r_j^k - d_j^k)^2 \right] \qquad (2)$$

$$\sum_{k=1}^{m} \sum_{j=1}^{n} b_{ij}^k r_j^k + p_i = \sum_{k=1}^{m} r_i^k \qquad (3)$$

where $c_j^k (k = 1, 2, , m, j = 1, 2, \dots . n)$ are the weighting coefficients, while $c_j^k \geq 0$ and $\sum_{k=1}^{m} \sum_{j=1}^{n} c_j^k = 1$.

B. Hardware Design

The system has the main objective of monitoring some ecological parameters and initiating interventionist corrective measures, while the system status is related through the internet. For instance, a low-level feed could be an indication for an automatic supply of feed from the food shelf and a message to place an order to the feed suppliers. Also, a high-level of sensed ammonia gas and humidity is a signal for automated increased ventilation rate and the need to evacuate chicken droppings/wastes. The block diagram of the system hardware is as shown in Fig 1.

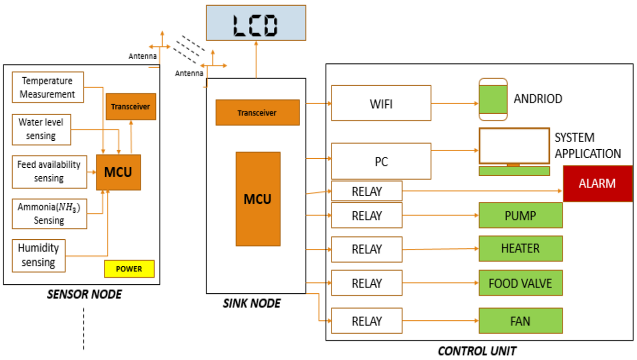

Fig. 1. The hardware block diagram of the system

The hardware unit of the system was designed with wireless and autonomous sensor nodes to monitor temperature, humidity, air quality, water level and feed availability in interested poultry space, and communicate the processed data via their transceiver to the access node. The access node communicates the data to the internet where it can be accessed in real-time. The interventionist actions being initiated by the access node and the cloud, based on the data from the sensor nodes are also being relayed in real-time to the necessary stakeholders and administrator of the poultry system.

For accurate calibration of the temperature and humidity requirement in the system, the thermal neutral zone of the chicks/birds is required. This is often required weekly. However, this changes on an approximately daily basis due to poultry growth from 'placing' to 'lifting', hence the need for the system to cover the daily weight average. For instance, the bodyweight difference of chicks from day 7 to day 13 is often significance, just preceding the weekly change occurrence. A 7-day old chick can weigh 190 – 200 grams while weighing 490 – 500 grams at 14 days.

The system consists of two heterogeneous sensor nodes. The first node contains the temperature, humidity and air quality sensors, while the second node had the water level and feed availability sensors which measured its required parameters with a 1kg load cell. The hardware devices are selected from the comparative analysis of some alternatives and decided upon based on resourceful considerations. DHT21 AM2301 was selected for temperature and humidity sensing having analyzed its features against LM series, TMP series, SHT series, and DHT variants for temperature, and HR202 series, SENS-HYD2, SHT series and other DHT variants for humidity.

This study has selected MQ137 as its gas sensor. It took into account the possibility of some gases in the air such as CO_2, H_2S, CH_4, NH_3, but it focused on the presence of the ammonia gas (NH_3) due to the poultry droppings and waste. Ammonia gas affects the growth of chickens and can cause several diseases like hand foot disease, mouth disease, bird flu etc. The threshold value of ammonia gas in the air is 40%. The capacitive 2-probe sensor was selected for water detection, while a weight sensor was chosen for the feed sensing. Arduino Nano was selected for the microcontroller unit due to size, compatibility in voltage and current requirement, and the grove pins. The microcontroller board is based on the ATmega328, having 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analogue inputs, a 16 MHz crystal oscillator, a USB connection, a power jack, an ICSP header, and a reset button. XBee RF module was selected for the transceiver unit after comparing the ZigBee, Bluetooth, and WIFI communication network standards. The modules are designed to meet IEEE 802.15.4/Zigbee standards. This standard defines a dual physical (PHY) layer and media access (MAC) layer, which is 2.4Ghz and 868/915Mhz. The Xbee has the capability of communicating these modules with the microcontroller (MCU) through a universal asynchronous receiver/transmitter. The General Packet Radio Service (GPRS) module was selected for mobile connectivity, having compared it with the Enhanced Data rate for GSM Evolution (EDGE) and High-Speed Packet Access (HSPA) technologies.

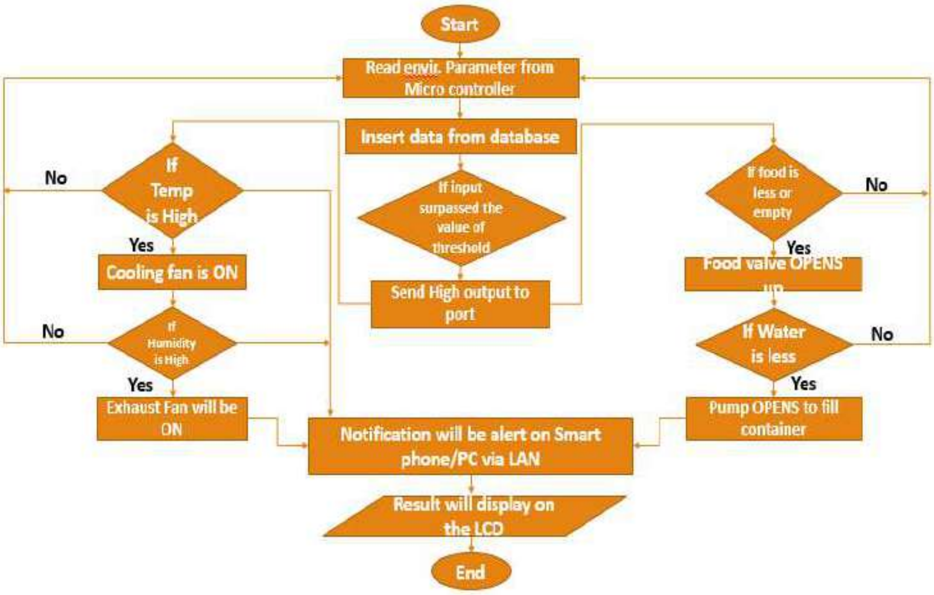
C. *Software Design*

The algorithm of the system was designed and developed in two sections, to report the changes in parameters (temperature, humidity, water level, feed availability, ammonia gas level) in the poultry farm; and initiate the appropriate control measure to normalize the changes as designed with the overall system. The algorithm flowchart of the system working model is as shown in Fig 2. The flowchart mainly highlights the specific operational details of the system, while the configuration details of the transceivers and microcontroller modules are accordingly generic. The system was developed to cover the three main units: the monitoring sensor node, the network coordinating node, the internet and mobile unit, and the control unit.

III. Results and Discussion

The implemented IoT-based poultry management system incorporated the proposed model, and the resulted hardware and software units. The resulted system nodes are as shown in Fig 3. The sensor node monitoring the temperature, humidity and ammonia gas is shown in Fig 3(a), while the sensor node measuring the water level and food availability is shown in Fig 3(b). The critical temperature for layers is 20°C. For every 1°C lower than 20°C, the birds require an extra 1.5 g of feed per day. The most efficient temperatures for layers are between 20 – 24°C. When temperatures rise above 24°C, shell quality and egg weight will reduce. The critical temperature for broilers and rearing birds is highly dependent on age. The load cell measures the quantity of feed in grams and was calibrated to measure the food weight in the percentage of the standard value. As the feed is being gradually consumed, the digital scale measures the reduction in the weight and once the quantity of feed reduced beneath 25% of the standard which is the maximum quantity of feed the load cell can accommodate, it will turn the servo motor which in-turn opens the nozzle for grains to pour back into the plate. Also, as water is being consumed, the digital scale measures the reduction in the weight and once the quantity of water reduced beneath 25% of the maximum water capacity, the solenoid valve opens the tap for the water chamber to be refilled.

The ventilation unit and the coordinating node with the internet gateway and the display LCD are as shown in Figs 3(c) and 3(d) respectively, while the prototype system unit during testing is shown in Fig 3(e). The average parameters reading and the corresponding intervention action taken by the system is as highlighted in Table 1, while the user application interface result connected to the internet cloud and the corresponding indicated result on the LCD at around 16:20 hours on Wednesday 6th of January, 2021 is as shown in Fig 4. It can be deduced that the Temperature was higher during the day and lower at night and the relative humidity was higher in the night time and lower in the day. The bulb is controlled based on the temperature, if the temperature dropped below 24°C the bulb automatically came ON and it remained ON until the temperature rose above 35°C then it went OFF after which the fan was turned ON.



Start

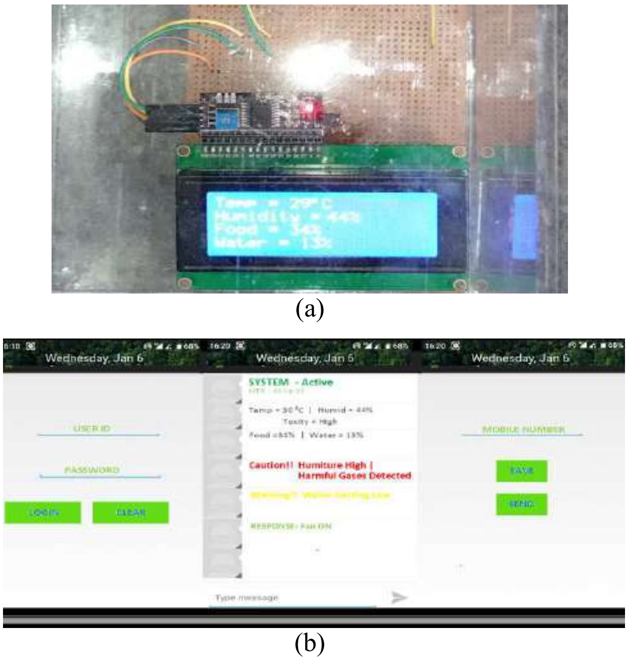
TABLE I. AVERAGE TEMPERATURE AND HUMIDITY READING WITH THE CORRESPONDING SYSTEM RESPONSE

Period (GMT)	Measurement		System Response
	Average temperature (^0C)	*Average relative humidity (%)*	
00:00 - 02:00	25	63	No response
02:00 - 04:00	24.	67	Bulb turns ON
04:00 - 06:00	23.7	70	Bulb stays ON
06:00 - 08:00	23.5	68	Bulb stays ON
08:00 – 10:00	25	58	Bulb turns OFF
10:00 – 12:00	27.3	50	No response
12:00 – 14:00	29.7	46	No response
14:00 – 16:00	31	43	Fan turns ON
16:00 – 18:00	30	44	Fan stays ON
18:00 – 20:00	28.8	47	Fan turns OFF
20:00 – 22:00	26.9	53	No response
22:00 – 24:00	26	58	No response

The smart poultry management system was integrated with an MQ2 gas sensor senses toxic smoke, dust and gases. However, ammonia was the most important gas to measure. If the concentration of the gas was below recommended levels whereby the system was designed to have an upper critical level for ammonia as 20 ppm. The Alarm comes ON whenever the threshold value is triggered, this prompts the farmer to re-evaluate the nutrient of the feed given to the chickens. The Fan was also controlled by the MQ2 gas sensor to achieve optimization of the system ventilation whenever the system faces certain irregularities of been smoky, dusty or increased levels of ammonia.

The indicated results on the system local LCD and that of the user application interface are almost the same, with about 2s delay response time.



Temp = 29° C
Humidity = 44%
Food = 34%
Water = 13%

Wednesday, Jan 6

SYSTEM - Active

Temp = 30 °C | Humid = 44%
Toxity = High
Food =84% | Water = 13%

Caution!! Humiture High | Harmful Gases Detected

Warning!! Water Getting Low

RESPONSE: Fan ON

Fig. 4. The interface results (a) LCD, (b) Application interface

IV. CONCLUSION

A precision poultry management system based on IoT synergistic approach has been developed. The system monitors and regulates the condition of the poultry chickens through the internet in real-time. This study synergized among sensor technology, wireless communication, internet-of-things and automation in the implementation of the system. The achieved aim was to improve the health and growth of the birds by preventing infectious diseases among the birds, ensure increased egg production, reduce the gaseous pollutants, reduce human intervention, and maximize the overall profit. The system consists of resourcefully selected node components and internet-enabled autonomous devices and networks. This study has modelled and developed the management system to enable the farmers or administrators of the poultry farms to relate with or control the conditioning parameters of the birds based on the temperature, humidity, water level values, food dispensing, and ammonia gas coefficients in the poultry farm. In further works, the system would be more robust by incorporating energy rechargeability and portability to the nodes. Also, the proposed model would be validated and evaluated to depict the real-timeliness of the developed system. Furthermore, the system portends a possibility for integrating more than one poultry farm in the same neighbourhood and monitored over the same internet space and infrastructure.

***Abstract*—A granary is designed to manage and control different environmental factors to ensure the desirable quality of the stored bulked grains, hence an effective monitoring system. This paper aims at establishing a model for an effective granary system to achieve multi-objective balance on real-time monitoring, minimum deployable nodes, coverage efficiency, longer node life, reduced cost and reduced power consumption. Multi-variable linear regression analysis was used to develop the mathematical model which formed the basis for formulating the objective function of the generic algorithm requisite. The simulated result of the model was validated by using a weighted sum method. The optimized model by using the available constraints is a template for a developed network of wireless nodes approach to establish a promising and resourceful representation of an operable granary monitoring system design.**

Keywords*— *granary, model, monitoring system, multi-objective design, optimization

I. Introduction

In recent times, researchers have established the possible and tremendous gains of applying wireless sensor networks in the condition monitoring of stored agricultural produces. Considerably, grains contribute well to the global economy and food security. Adequate monitoring is a necessity to ensure the desired quality of grains across the entire value chain, especially storage [1]. A granary is effectively designed to store grains, and also manage and control the different environmental factors that can affect the desirable quality of the stored bulked grains. Losses during storage can have relative economic impact on small-scale farmers and the nation, causes mainly due to poor storage infrastructure. The important factors to be monitored and controlled during storage include relative humidity, temperature, moisture, carbon gases and others [2]. Storage of agricultural produces is a very crucial component of ensuring food security. A poor and unscientific design of storage bins cannot guarantee the desired storage objective of the produces. Cereals and grains are the major agri-food products and income source for the dwellers of most developing countries. Globally, the annual losses during the storage of the products are being estimated at 30% [3], [4]. Beyond the losses due to other factors and effects, the quality of the post storage grains is an important area of consideration. The diffusion of moisture contents from warmer region of a storage bin to the colder end as a result of the temperature gradients is the main cause of grain deterioration. Therefore, effective monitoring of grain quality requires a distributed detection of the temperature gradients and other parameters at the different locations within the bin [5], [6]. In effect, an efficient storage setup demands to be designed to cater for both the multiple factors and the constant varying temperature gradients within it.

Various designs and measures are being developed to provide the needed schemes to solving the problems associated with granaries as being illustrated in Figure 1 [1]. A pilot test is good a measure to provide the experimental details of the desired designs due to the large variability of the involved parameters. However, on-site natural experiments present a time-consuming, irreproducible and expensive feasibility. Also, most devices for grain monitoring have been discovered to generally under-predict parameters for freshly dried grains. This is a basis established from the assumption that most devices are relatively sensitive to the outside layer of the grains. Consequently, a veritably developed mathematical model is the out-to-out scheme to be simulated, validated and implemented as the solution [7].

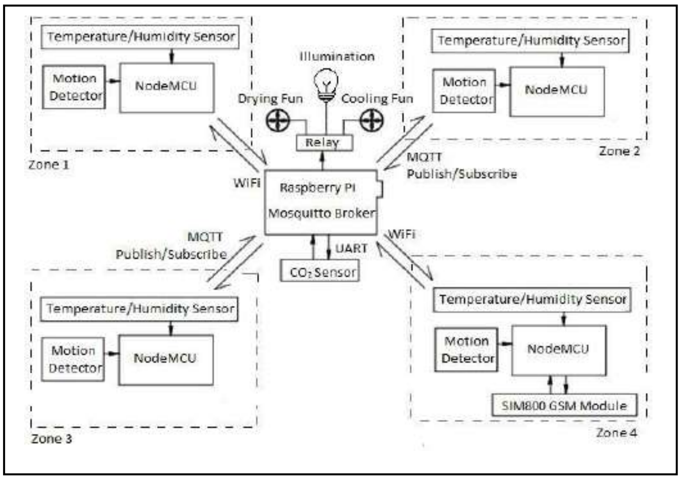

Fig. 1. A typical distributed scheme of granary monitoring [1]

Designing granaries and the attendant monitoring systems to minimize grain losses requires the requisite prediction of the temperature and moisture distribution within the bins. The prediction will also assist in developing and evaluating the strategies necessary for ventilation or aeration [8], [9]. Predictive models are particularly based of simplified observations and assumptions, and embedded in mechanistic theories when acceptably substantiated. This is recognized in [10] by developing a probabilistic model to generate a strain in predicting the other behaviour of the same species using maize grain extracts. The model is useful for introducing

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

strategies to improve grain storage conditions and preventing economic losses. Meanwhile, to establish a practical predictive model to cater for the generation of mycotoxin in the post-harvest period of storage is difficult, because of the constant changes in stored grains temperature and humidity, and the complexity of the granary environment. Also, multi-fungal grain loading which enables interaction among different fungi can lead to nonconformity between the modelled and real-life acquired results [11]. Other literature have also indicated that most methods and models employed in diagnosing the condition of grains during storage could not provide sufficient information that adequately determine the required parameters. Mathematical models for convective wheat drying, and the drying characteristics prediction is reported by [12]. In many of the cases, the analysis of the models are implemented by numerical methods, which foists some restrictions on their real-time application for detecting defects in grain mass. The discrete-element approach has been discussed to be suitable in modelling particulate structures like silos and bins. Calibration and validations have been introduced alongside the simplifications approach of numerical models, in reference to obtaining consistent results for comparison with the experimental outputs [13]–[15]. The implementation of derivable expert systems from the models of technological ecosystems yields the new approach to solving the dire problems [16], [17].

A system to adequately predict, monitor and control the various parameters to ensure a safe storage of grains should be designed using a multi-objective scheme [2]. The existing systems in the monitoring of the grains conditions do not solve issues related to inefficient coverage, high power consumptions, high rate of monitoring node failure, and data acquisition delays. An efficient solution will be required to overcome these issues and ensure optimal trade-off among them. Wireless sensor networks (WSNs) have been designed into a promising field as granary and greenhouse monitoring systems. Mathematical models involve the representation of the real-world problems with mathematical equations, and the solutions predicted from the simulated and validated results of such equations. The issues and the representative parameters to be considered in designing a monitored granary are many, therefore, the solutions to be proposed should be multi-objective in nature [18]. Different models related to specific features of WSN had been discussed [19], [20]. The various existing WSN models concentrate on addressing at most two or three of the several issues at stake. Hence, this study presents a multi-objective approach to designing an environmentally monitored granary system using the genetic algorithm. Genetic algorithm effectively adopts the useful info within a set of solutions to produce new solutions with enhanced performance. The remaining parts of the work is structured under the sections that include: methodology, results and discussion, conclusion and the references.

II. Methodology

The design optimization adopted in this study is the artificial genetic approach as earlier being proposed by Goldberg [21], [22]. Design optimization involves the process of determining the minimum/maximum of the objective function parameters, and must satisfy certain set of specific constraints. In this multi-objective optimization problem, all the vectors components that store the different objectives are being optimized simultaneously. The pilot bin was constructed with a capacity of one tonne of maize grains. The internal configuration was designed for monitoring nodes localization which was determined using Zigzag pattern deployment algorithm by [23]

A. *Mathematical Model*

The model equations of the multivariable linear regression (MVLR) analysis used here were incorporated in the adopted generic algorithm. Assuming there are '*r*' independent variables, having a functional relationship with the dependent variable *Y*. Therefore, the dependent variable can be approximated by using [24].

$$Y_i = \propto_0 + \propto_{1i}\, x_{1i} + \propto_{2i}\, x_{2i} + \cdots + \propto_{ri}\, x_{ri} + \in, \quad i = 1, 2, 3 \ldots . n \qquad (1)$$

In the determination of the threshold interests, the grain quality *Q* is the dependent variable with the main independent variables taken basically as moisture content *m*, temperature *t* and other factors represented as *g*. Therefore, the variables are related in equation (2).

$$Q = \propto_0 + \propto_1\, m + \propto_2\, t + \propto_2\, g \qquad (2)$$

For control measures, the two major means in controlling the uneven airflow, temperature and the humidity concentration are the operable heater, *H* and fan, *F* within the designed storage bin. The operation of the two control components is dependent upon all the variables in equation (2) as expressed in the form shown in equation (3) and (4)

$$H(x) = \propto'_0 + \propto'_1\, m + \propto'_2\, t + \propto'_2\, Q \qquad (3)$$

$$F(x) = \propto''_0 + \propto''_1\, m + \propto''_2\, t + \propto''_2\, Q \qquad (4)$$

By substituting the regression coefficients in Table I, the final model equations to determine the ultimate conditions for the control measures can be determined as,

$$H(x) = 237.5692 + 0.3451m - 0.0453t - 0.2101Q \qquad (5)$$

$$F(x) = 86.7592 + 0.1512m - 0.0118t - 0.0817Q \qquad (6)$$

$$Q(x) = w_1 \times H(x) + w_2 \times F(x) \qquad (7)$$

TABLE I. Experimentalvalues in chromosomes reproduction and objectives functions of the optimized process

Initial Population of the chromosomes	**Objective function *H(x)***	**Objective function *F(x)***	**Initial channel number**	**Quality function value *Q(x)***	**Probability in selection *P(x)***	**Random number set**	**Final channel number**	**Cumulative probability in selection *P'(x)***
231456545612987	235.34	85.441	1	163.54	0.1541	0.453	3	0.1541
632657451123854	238.68	88.431	2	167.77	0.1553	0.675	2	0.3094
843222345624427	245.56	89.218	3	169.56	0.1632	0.143	2	0.4726
951239874352356	242.56	86.754	4	165.11	0.2210	0.743	5	0.6936
754219765992316	248.21	87.381	5	170.21	0.2304	0.563	4	0.9240

Using the weighted function method to obtain the objective function, this can be expressed as shown in equation (7), where c and w_2 are the weight functions. The conformity of minimizing the effect of the uneven air-flow through the constant use of the fan is much higher than the necessity for intermittent drying process through the circulation of drying air. Hence, w_1 and w_2 can take values of 0.1 and 0.9 respectively.

B. Genetic Algorithm Supporting Approach

The genetic algorithm (GA) approach resolves optimization problems by replicating the nature of evolution of life. GA randomize the survival of the fittest within a set of string structures and exchange of information used to form searched algorithms. Repeatedly across generations, different new sets of artificial strings are created from the evolution of the old sets of strings with the fittest features. GA works on the contents of reproduction, mutation and crossover operators. The step-by-step GA approach used in this work follows a pattern as expressed, using an *‘n’* number of populations with 1-bit chromosomes randomly generated.

- The fitness *F(x)* was calculated for each chromosome *‘x’*
- Using three operators: selection, mutation and crossover; *‘n’* offspring was created from the current population
- A different new population is adapted to replace the current population
- The iteration “i” – “iii” continues repeatedly to achieve the termination criterion.

In validating the model for both the correlation coefficient and the MVLR, the analysis of variance (ANOVA) approach is the best choice [25]. The square of the correlation coefficient (R^2) relates to the significance (or otherwise) of the link between the objective function and the design input variables. The aim of the design in using the MVLR is to ensure a large value of the R^2 in between 0 and 1. The coefficients and constants of the accepted model were expressed using the multiple regression analysis in terms of air temperature (drying) by adapting the Page Model.

- $R^2 = 0.713$ for the modelling equation of heating temperature
- $R^2 = 0.727$ for the modelling equation for drying air flow

The closeness of the values of R^2 to unity in both cases validates the model approach.

III. Results and Discussion

The different genetic algorithm input parameters were varied during test-runs being carried out on the GA for both the sensing unit and the control units. Better results were achieved with more tests being run. The GA parameters are as shown in Table II. The grains temperature within varying bin column height were recorded across 4 *hours* for air velocities of 0.25 *m/s* and 0.1 *m/s* respectively. The simulated results for the control heating temperature and fan airflow for the composite nodes within the monitoring system are as shown in Figs 2 – 3.

The final solutions of the optimization front by Pareto method is as shown in Figure 4. It is observed that the optimization model can find different solutions based on the constituent variable parameters of the quality of grains in focus.

TABLE II. THE RESULTING GA PARAMETERS

Details	Values
Population	45
Iteration number	100
Probability (Cross-over)	0.870
Probability (Mutation)	0.032

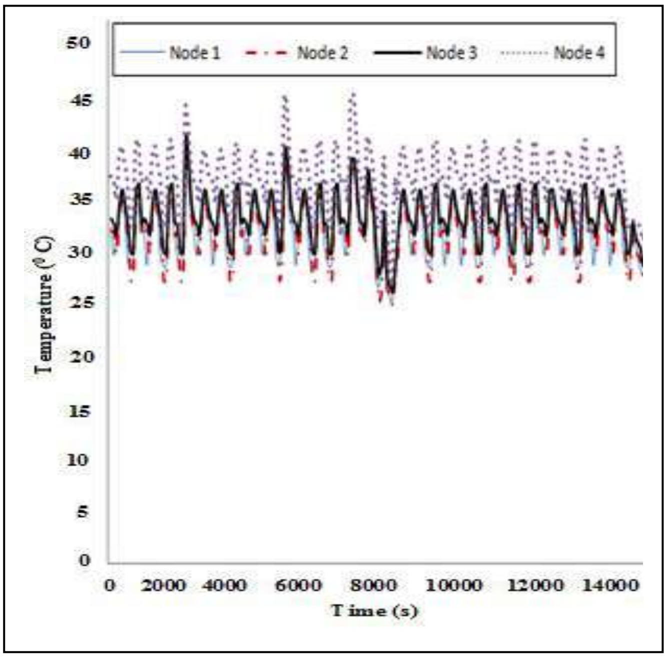

Fig. 2. The simulated heating temperature variation

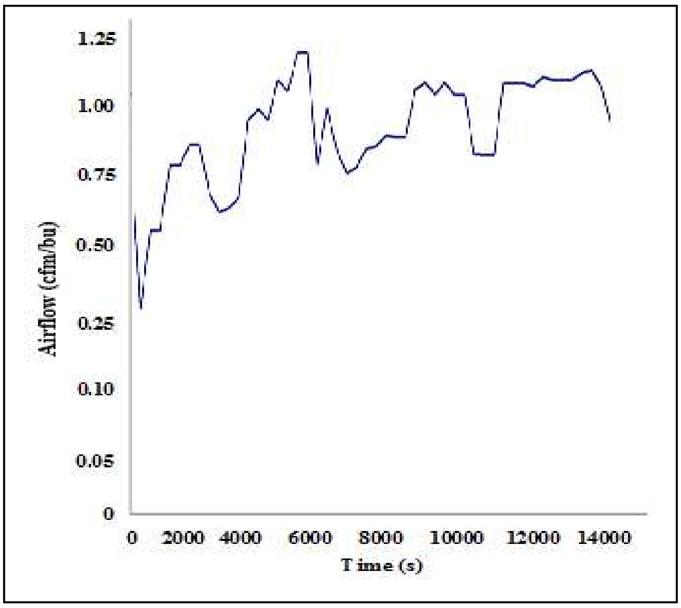

Fig. 3. The simulated air-flow variation

IV. Conclusion

In this paper, a multi-objective optimization technique has been proposed for granary systems. The approach focusses on the possibilities of monitoring and controlling the parameters affecting the quality of stored grains. The airflow constraint from the controlling fan and the mitigating heating temperature are the parameters of interest in the optimization process of the model. The genetic approach combines the multiple objectives into a singular scalar function and randomly specify for each selection. The model has a good application for storage in modular forms and suitable for middle-level farmers and marketers of grains.

***Abstract*—This research provides a comparative study of the genre classification performance of deep-learning and traditional machine-learning models. Furthermore, we investigate the performance of machine-learning models implemented on three-second duration features, to that of those implemented on thirty-seconds duration features.**

We present the categories of features utilized for automatic genre classification and implement Information Gain Ranking algorithm to determine the features most contributing to the correct classification of a music piece. Machine-learning models and Convolutional Neural Network (CNN) were then trained and tested on ten GTZAN dataset genres. The k-Nearest Neighbours (kNN) provided the best classification accuracy at 92.69% on three-seconds duration input features.

***Index Terms*—machine-learning, deep-learning, music genre classification, CNN, MFCC**

I. Introduction

Genre is one of the most common of factors distinguishing music pieces. Human responses to genre can be biased, however, broad genre definitions exist worldwide. Observing the shift of music to digital platforms, it becomes clear that the automating the task of music classification would be beneficial to all parties involved.

This research explores automatic music genre classification with the aim to show that machine-learning and deep-learning approaches can be utilized to classify music from only the audio signal itself, reducing search-time for music pieces within the large music databases that have emerged with digital music platforms. We compare the deep-learning approach to traditional machine-learning models, furthermore, we investigate the performance of machine-learning classifiers with three-seconds duration features, to those implemented with thirty-second duration features.

This study was conducted in three phases, namely, 'phase A', 'phase B, and 'phase C'. Phase 'A' and 'B' utilized six traditional machine learning classifiers to perform automatic music genre classification, however, the two phases experiment with different dimensions of input features. Phase 'C' provides the deep-learning approach and a machine-learning approach with more audio excerpts but shorter duration.

Related literature shows that digital music platform users are more likely to browse music by genre than artist similarity or recommendations, therefore, successful music genre classification will allow end-users to efficiently browse music within genre categories [10].

This paper continues with a brief background and review of related literature, followed by Section III with the procedures implemented. Section IV presents the automatic music genre classification results, and Section V concludes the paper.

A. Music Features

We present four categories of features utilized for music genre classification. The correct set of features needs to be selected in order to perform correct and informed classification.

1) Magnitude-based features: these features can be described as timbral features, describing the loudness, pitch, and compactness of music [1]. Timbral features of music are essential for humans to categorize and group together different sounds coming from a single source [19]. Some examples of features belonging to this category are spectral features which are embedded in the magnitude spectrum, a spectrum obtained from the absolute value of the Fourier transform of a music chord [1], this examples include: spectral rolloff, spectral flux, spectral centroid, spectral spread, spectral decrease, spectral slope, spectral flatness, and Mel Frequency Cepstral Coefficients (MFCCs).

2) Tempo-based features: these are the features that describe the rhythmic aspects of music such as the rhythm and tempo [1]. Examples of features belonging to this category are; Tempo measured in beats per minute (BPM), Energy (audio signal intensity) measured using the root mean square (RMS), and the Beat Histogram to visualize important properties of audio signals through evaluation of the histogram peak, amplitude, and other statistical measures.

Author(s)	Dataset	Model used	Classification Accuracy
Sturm (2013) [20]	GTZAN	Sparse Representation Classification	83.00%
Bergstra *et al.* (2006) [5]	GTZAN	ADABOOST	82.50%
Li *et al.* (2003) [12]	GTZAN	Support Vector Machines	78.50%
Lidy *et al.* (2007) [13]	GTZAN	Sequential Minimal Optimization	76.80%
Benetos and Kotropoulos (2008) [4]	GTZAN	Non-negative Tensor Factorization	75.00%
Choi *et al.* (2016) [6]	Navier Music	CNN	75.00%
Bahuleyan (2018) [3]	Audio Set	CNN	65.00%
Tzanetakis and Cook (2002) [21]	GTZAN	Gaussian Mixture Mode	61.00%

Table I: Various studies that have shown capability to perform genre classification. The columns list the author(s), dataset utilized, model implemented, and the classification accuracy attained.

3) Pitch-based features: features belonging to this category describe the pitch of a music piece, this is an essential building block of the harmony, key, and melody of an audio piece [11]. This category is important to explore because pitch perception determines the frequency level of the underlying audio signal [11]. An example of a pitch-based feature is the ‘zero crossing rate’, which is the count of sign changes in consecutive blocks of an audio excerpt [1].

4) Chordal progression features: these group of features explore the pitch ‘chroma’, which is a twelve-dimensional vector with each dimension representing one pitch class [11]. Chroma can also be viewed as a distribution, where both the number of occurrences of a pitch and its energy can be deduced from the class values [11].

B. Related Work Results

A review of related literature reveals that several studies have displayed the capability to solve the problem of music genre classification. We present notable genre classification algorithms in Table I.

II. Methodology

This section outlines the method and set of experiments performed in the studies reviewed. The procedures carried out include further preprocessing of the dataset, feature selection, and a description of the machine learning classifiers employed.

A. Data Description

The dataset utilized for all three studies conducted was the GTZAN dataset [17]. This GTZAN dataset is an ensemble of 1000 excerpts of thirty second duration each. The 1000 music pieces are categorized into 10 genres with 100 music pieces for each genre.

For one of the studies conducted [9], the original dataset was duplicated and divided into 10 000 excerpts of three seconds duration each. This procedure provided more training data, however, the dataset did not have a consistent number of samples per genre, with some genres having slightly less or more than 1000 music pieces.

B. Feature Extraction and Representation

We have identified four categories of features that are generally hypothesized to contribute in the correct classification of music genre. Prior to the selection of these features for model implementation, vital preprocessing experiments have to be conducted to make the raw data suitable for the classification task. Feature extraction was performed in this study for two purposes:

- **Dimensionality reduction:** the raw data dimensions are usually too large, that is, an entire raw audio file may be too large to process efficiently. Related studies show that a feature set is used to present the data with fewer values, a single feature value may be produced for an entire audio signal [11].
- **Meaningful representation:** the raw audio fie contains all the information we can possibly extract and use, however, it is important that we represent the musical aspects in an interpretable manner by machines or humans [16].

The computation of features from a music excerpt usually gives rise to an n-dimensional vector, where the value of n is dependent on the length of the audio piece under analysis. If the value of n is large, we deal with high dimensional feature vectors which are inefficient to process, therefore, for a feature vector $V = (v_1, v_2, v_3 \ldots, v_n)$, the following feature representations were explored:

- **Mean:** the average value of feature V, computed as:

$$\mu V = \frac{1}{n}\sum_{i=1}^{n} v_i \tag{1}$$

- **Standard deviation:** a measure of the spread of values of feature V, computed as:

$$\sigma V = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(vi - \mu v)^2} \tag{2}$$

- **The Feature Histogram:** obtained by arranging the feature’s local window intensities into bin ranges then taking a count of each bin’s contents and modelling a frequency histogram [1]. The normalized histogram bin values can be used for classification.

- **Mel Frequency Cepstral Coefficients (MFCC) Aggregation:** this representation takes the first n coefficients that form part of the short-term sound power-spectrum [8], [14]. Independently, each dimension is assessed, producing n coefficients per dimension. For this work, $n = 4$ was selected.
- **Area Moments:** this is an important concept in computer vision and image processing. This work follows a classic image moments implementation where 10 area moments were produced for image processing, treating each image as a two-dimensional vector $V(v_1 v_2)$, with v_1, v_2 indexing the underlying matrix [14]. We treat the extracted feature values from the audio signal as two-dimensional images and apply the moments algorithm in the work cited above.

C. Feature Selection

In this section, we present the various features utilized to perform automatic music genre classification in the studies this paper extends [1], [9], [16]. Feature selection is essential for the reduction of irrelevant and redundant data, the reduction of which may result in improved model learning accuracy, and reduced training time. Information gain ranking algorithm was utilized for comparison of the various features' contribution to a correct classification.

Features Maintained	**Rep.**	**Dim. 54**

Chroma	Mean	12

Table IV: The set of features selected for training the employed machine learning classifiers in ‘phase C’. The upper shaded portion the table presents the features maintained after using Information Gain Ranking (IGR) algorithm, while the lower portion presents the eliminated features. The column heading acronym Rep. and Dim. are the feature representation and feature dimension respectively. A total of 57 features were selected in ‘phase C’, [9](sic).

the Scikit Learn library [20]: k-Nearest Neighbours, Linear Logistic Regression, Multilayer Perceptron, Random Forests trees, and Support Vector Machines. The hyperparameters for each model are provided in Section III.

E. Deep-Learning Approach

The Convolutional Neural Network (CNN) architecture in this research was constructed using Keras [7]. The CNN built here has an input layer and five convolutional blocks, with each convolutional block consisting the following: The Convolutional Neural Network (CNN) architecture in this research was constructed using Keras [7]. The CNN built here has an input layer and five convolutional blocks, with each convolutional block consisting the following:

- Convolutional layer with mirrored padding, 1x1 stride, and 3x3 filter
- The rectified linear activation function (ReLu)
- Maximum pooling with 2x2 stride and window size
- Probability of 0.2 for dropout regularization

The last layer of the CNN outputs the probabilities of ten label classes through a fully-connected layer implementing the SoftMax activation function. The class that attains the highest probability becomes the classified label for a given input. The CNNs were trained on the spectrograms, twenty Mel Frequency Cepstral Coefficients (MFCC) of the three-or-thirty-seconds feature set, and the extracted spectrograms.

F. Evaluation Metrics

To reduce bias and produce credible results, we performed 3-reapeted 10-fold cross-validation prior to the models classifying the test dataset. We utilize the classification accuracy and training time to evaluate the performance of all employed models.

III. Results and Discussion

This section outlines the results obtained when we use the features provided in Table III, IV, and II to perform genre cassification on ten GTZAN genres.

A. Traditional Machine-Learning Models

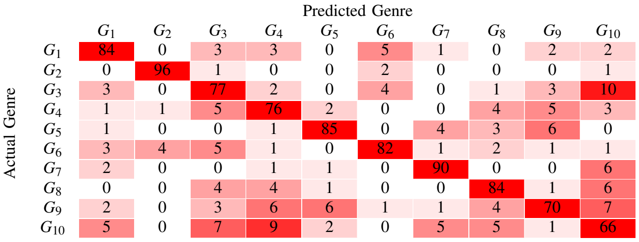
The traditional machine-learning models implemented in this research were tested on the GTZAN dataset, the results are presented in Table V, VI, and VII.

Table V presents the results obtained during ‘phase A’ of this research. The Linear Logistic Regression provided the best classification accuracy at 81%, however, with the exception of the Multilayer Perceptron, we note that the logistic regression had the longest training time. We also note that the níve Bayes classifier was outperformed by all the trained classifiers.

Table VI presents the results obtained during ‘phase B’ of this research. The Support Vector Machines (SVM) provided the best classification accuracy at 80.80%. The SVM also attained a relatively low training time taking 0.3 seconds to build. Logistic Regression displayed notable accuracy again with a classification accuracy of 75.80%, however, failing to outperform the LogitBoost implementation followed in ‘phase A’.

Table VII presents the various models’ hyperparameters and performance during ‘phase C’ of this research. The k-Nearest Neighbour (kNN) provided the best classification accuracy at 92.69%, furthermore, the kNN attained the shortest training time of 78 milliseconds. We note that ‘phase C’ utilized a three-seconds duration feature set as opposed to the thirty-seconds duration dataset utilized in ‘phase A’ and ‘B’ of this research.

Figure 1 presents the confusion matrix attained when classifying music into ten GTZAN genres using Linear Logistic Regression models during ‘phase A’ of this research. We note the significant overlap between rock and country music, where ten country music excerpts were classified as rock music. Furthermore, rock music was the most misclassified genre, with rock music excerpts classified as blues, country, disco, metal, and pop.



Actual Genre	Predicted Genre									
	G_1	G_2	G_3	G_4	G_5	G_6	G_7	G_8	G_9	G_{10}
G_1	84	0	3	3	0	5	1	0	2	2
G_2	0	96	1	0	0	2	0	0	0	1
G_3	3	0	77	2	0	4	0	1	3	10
G_4	1	1	5	76	2	0	0	4	5	3
G_5	1	0	0	1	85	0	4	3	6	0
G_6	3	4	5	1	0	82	1	2	1	1
G_7	2	0	0	1	1	0	90	0	0	6
G_8	0	0	4	4	1	0	0	84	1	6
G_9	2	0	3	6	6	1	1	4	70	7
G_{10}	5	0	7	9	2	0	5	5	1	66

Figure 1: A confusion matrix obtained in the classification of music into ten GTZAN genres using Linear Logistic Regression during ‘phase A’ of this research. The row labels represent actual genre labels, while the column labels represent the predicted genre labels, where: G_1 = **Blues**, G_2 = **Classical**, G_3 = **Country**, G_4 = **Disco**, G_5 = **Hiphop**, G_6 = **Jazz**, G_7 = **Metal**, G_8 = **Pop**, G_9 = **Reggae**, and G_{10} = **Rock**.

Classifier	Accuracy	Training Time (s)	Hyperparameters
Linear Logistic Regression	81.00%	25.2500	maximum number of itterations for LogitBoost=500
Random Forests	75.70%	18.0800	number of trees = 1000
Support Vector Machines	75.40%	3.8200	kernel degree=3, tolerance=0.001, epsilon for loss function=0.1, used polynomial kernal: $\gamma u' v + coef_o$, and did not normalize
Multilayer Perceptron	75.20%	27.480	number of hidden layers= number of hidden classes, learning rate=0.3, training time=500 epochs, validation threshold=20
k-Nearest Neighbour	72.80%	0.0100	number of neighbours=1, using absolute error for cross-validation, and appied linear search algorithm
naíve Bayes	53.20%	0.5600	used normal distribution for numeric attributes and supervised discretization

Table V: Classification results and implementation details of each of the models employed during ‘phase A’ of this research. The columns list the accuracy, training time and hyperparameters related to the implementation of each classifier, [1](sic).

Classifier	Accuracy	Training Time (s)	Hyperparameters
Support Vector Machines	80.80%	0.3000	radial basis function kernel, tolerance=0.001, and regularization=0.17
Multilayer Perceptron	77.30%	0.2300	hidden layers=2, learning rate=0.02, activation=ReLu, max iterations=200, solver=adam, and tolerance=0.0001
Logistic Regression	75.80%	0.0800	solver=newton-cg and max itterations=500
Random Forests	72.40%	61.080	split function=gini, number of trees = 100, and max depth 100
k-Nearest Neighbour	69.70%	0.0110	k=7 with manhattan distance metric, weighting=distance
naíve Bayes	54.50%	0.0019	Gaussian naíve Bayes with smoothing

Table VI: Classification results and implementation details of each of the models employed during ‘phase B’ of this research. The columns list the accuracy, training time and hyperparameters related to the implementation of each classifier, [16](sic).

Classifier	Accuracy	Training Time (s)	Hyperparameters
k-Nearest Neighbours	92.69%	0.0780	nearest neighbours=1
Multilayer Perceptron	81.73%	60.620	activation=ReLu solver lbfgs

Support Vector Machines	74.72%	3.8720	decision function shape=ovo
Logistic Regression	67.52%	3.6720	penaty=12, multi class=multinomial

Table VII: Classification results and implementation details of each of the models employed during ‘phase C’ of this research. The columns list the accuracy, training time and hyperparameters related to the implementation of each classifier, [9](sic).

B. Deep-Learning Approach

In this subsection, we present the classification results of the Convolutional Neural Network (CNN) when trained on spectrograms, three-seconds features, and thirty-seconds features. Table VIII compares the accuracy attained and brief details of the implementation followed.

We see that the classification accuracy provided by the CNN is relatively lower than that provided by traditional machine learning models. The highest classification accuracy attained with the CNN is 72.40%, where the three-second feature

Classifier	Epochs	Test Loss	Accuracy
CNN (3-Sec Features)	50	0.873	72.40%
CNN (Spectrograms)	120	2.254	66.50%
CNN (30-Sec Features)	30	1.609	53.50%

Table VIII: Classification results attained from CNN implementation using the three-seconds duration, thirty-second duration, and spectrogram input feature sets, [9](sic).

set was utilized. The three-second feature set provides more training data which could explain the higher accuracy attained through it. Thirty-seconds duration features gave the CNN implementation the lowest accuracy at 53.50%. We note that the implementation of CNN with spectrograms attains higher accuracy as the number of epochs is increased, however, time and computational constraints did not allow increasing epochs further than 120 in this research.

IV. Conclusion

This work aimed at automatic music genre classification using deep-learning and traditional machine-learning models. A review of related literature revealed the capability of these classifiers and a benchmark to compare the work of this research. We note that the reliability of a learning model is dependent on the quality of its ground truth, therefore, it is essential to ensure the ground truth is well-founded and motivated.

This research was conducted in three phases, namely, 'phase A', 'phase B', and, 'phase C'. Each phase had a significance that aligns with the contribution made by this research to the current body of work. We present music genre classification via machine-learning and deep-learning approaches, furthermore, this work provides a comparison of the accuracy of machine-learning models and deep-learning models in completing the classification task.

After training several classifiers, the k-Nearest Neighbours (kNN) provided the best accuracy at 92.69%, furthermore, the kNN had a relatively low training time of 78 milliseconds. The higher accuracy attained by kNN relative to related literature can be explained by the three-seconds duration feature set which provides more training data. Backed by these findings, We conclude that three-second duration input features can provide better accuracy than thirty-second duration input features.

Further noteworthy performances were provided by the Linear Logistic Regression and Support Vector Machines (SVM), attaining 81.00% and 80.80% respectively. The Convolutional Neural Network (CNN) implementations followed in this research provided relatively low accuracy, with the most accurate CNN implementation attaining 72.40%.

This work has shown that automatic music genre classification is possible, furthermore, traditional machine learning models tend to outperform deep-learning approaches.

***Abstract*—On-device AI is one of the latest cutting-edge technologies which allows devices to run the machine learning models on the device. This provides low latency, fewer privacy concerns, and many other advantages. But even though modern mobile devices come with great performance, there are situations where these mobile devices cannot handle the resource requirements of these on-device based mobile applications. As a solution for this lack of resources issue, mobile devices can transfer their heavy computational tasks to other devices such as nearby devices to minimize the burden. Transferring all computational tasks to resource-rich devices will not yield favorable under all circumstances. Depending on various conditions such as network strength and execution time, the mobile device should be able to choose a way to execute the task, either execute locally or execute remotely with the help of a resource-rich device. This paper will discuss the implementation of a decision making engine that decides when to offload machine learning tasks in on-device inference based Android mobile applications. Main objective of the proposed solution is to minimize the execution delay. Experimental results show that our decision making engine has an accuracy of 81.33% in identifying the best decision. The proposed research is a novel approach designed for on-device inference based Android mobile applications.**

Keywords—offloading decision making, smartphones, on-device Inference

I. Introduction

Smartphones are intertwined with day-to-day activities. Over the years, smartphones have faced advances in increasing computational power, integrating the latest technologies, and so on. These latest technologies have led to the development of more and more sophisticated and complex mobile applications. As a result of that, today cutting-edge technologies such as artificial intelligence, prediction, and recommendation using machine learning, etc. can be found in many mobile applications.

A. On-device AI and the smartphone

Machine learning was able to transform the mobile applications into more person-oriented applications that can provide accurate predictions and recommendations based on user's behavior. Usually, machine learning models used in these mobile applications are hosted in the cloud, which allows mobile applications to send data to the cloud, execute and get the results back. Recently there is an increasing movement towards On-Device AI, which allows the mobile applications to run the machine learning models on the devices due to the various drawbacks of the cloud-based approach such as high latency and privacy concerns.

According to Gartner, by 2022, most of the smartphones shipped by the percentage which is 80% will have on-device AI capability [1]. Since the model is much closer to the data sources such as sensors and cameras, the latency is very much lower compared to the cloud-based paradigm. Since the data does not need to upload to anywhere, there is no need to worry about privacy concerns.

Even though On-device AI seems to be the best approach, it has some drawbacks as well. Since the machine learning model runs on the device, it needs much processing power and energy. Recent research shows that there is a visible difference between on-device inference based mobile applications and cloud-based mobile applications when it comes to energy consumption [2]. Mobile devices are made lightweight and smaller to fulfill their main objective, mobility. Thus, there could be situations when required resources for on-device AI based tasks in the mobile application cannot bridge the available resources in the mobile device. This is where task offloading comes to the scene.

There is a pervasive computing technique called Cyber Foraging, which allows resource-limited mobile devices to offload their heavy computational tasks to powerful devices in the vicinity to boost mobile devices' performance [3]. Thus, it has opened the door for resource-limited mobile devices to use unused resources in resource-rich devices.

Offload machine learning-based tasks every time is not the preferred approach due to many reasons; sometimes the smartphone may have enough resources to execute the task, current network conditions might take lots of time to send the data to the resourceful device and get the result back. Due to these reasons, there should be a mechanism that decides when and what to offload based on the environment. This paper introduces a decision making engine for task offloading in on-device AI based mobile applications to resourceful personal devices such as laptops.

Further, the major contributions of this paper can be summarized as follows.

- The proposed Decision Making Engine is a novel approach designed for on-device inference based Android mobile applications. The proposed approach minimizes the execution time of the machine learning tasks in the application, considering the Round Trip Time (RTT), historical data such as previous execution times for each task, the current situation of the smartphone as well as the connected resource-rich device. The decision making engine decides when to offload based on the given parameters.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

- Unlike decision making algorithms based on pre-trained machine learning models, the decision making algorithm is based on both real time data and historical data gathered from the application itself. Even though the algorithm is same for any offload enabled application that runs on any smartphone, it will not executes in the same way for two different applications in the same device nor the same application in two different devices. This makes the developer to worry less about the compatibility of the application in smartphones in various range since the decision making algorithm acts in own way in all these devices.
- The decision making engine has an automated offloading process terminating functionality to prevent the halting problem.
- The decision making engine resides in the mobile application, that stating all the data used for the decision making engine remain within the application, which ensures the privacy of the user's application usage.

The remainder of this paper can be structured as follows. Section II describes the recent related work on the decision making process on mobile devices. Section III proposes the decision making engine for on-device AI based task offloading. Subsequently, Section IV evaluates the proposed approach. Discussion, conclusions, and future work are discussed in Section V and VI, respectively.

II. Related Work

Existing work on offloading decision making can be divided into 3 components based on the used approach; Reinforcement learning-based decision making approaches, traditional approaches that use algorithms such as the Lyapunov function, and deep learning-based approaches.

A. Reinforcement Learning Based Decision Making

Markov Decision Process (MDP) is used for modeling and solving decision making situations under stochastic conditions [4]. Predicts of the Markov Decision Process are only based on the information provided by the current state. Yang et al. [5] used MDP model to find an optimal place to offload. Notable factor in this research is it shows how the available network bandwidth of the edge servers and the mobile device location can be used in selecting the optimal place to offload.

B. Traditional Approaches Based Decision Making

Optimal Stopping Theory (OST) is concerned with the cases of choosing a time to take a particular action for the sake of maximizing the anticipated reward or minimizing the anticipated cost [6]. Alghamdi et al. [7] proposed an offloading decision-making process based on optimal stopping theory. The objective is to minimize the execution delay.

Lyapunov function, which is a scalar function, is used to prove the stability of an equilibrium point [8]. Using the Lyapunov function to control a dynamic system in an ideal way can be defined as Lyapunov optimization. Wu et al. [9] proposed a Lyapunov optimization based energy-efficient decision algorithm to minimize energy consumption while satisfying a delay constraint.

C. Deep Learning-Based Decision Making

Ali et al. [10] proposed a deep learning-based computation offloading decision-making approach for mobile edge computing. To train the DNN model, they created a dataset that is generated using a mathematical model. Yu et al. [11] proposed a Deep Supervised Learning (DSL) method for offloading decision-making processes. The decision is based on the local execution overheads and the conditions in the network side.

Learning with trial and error by being rewarded or penalized is known as Reinforcement Learning [12]. Deep-Q-Network is one of the most popular algorithms in Deep Reinforcement Learning. Van Le and Tham [13] proposed a Deep Reinforcement Learning approach for computation offload decision-making approach. It is noteworthy that the decision-making process is based on the unreliability of both users' and cloudlet's movement and the resource availability in the cloudlet. Park et al. [14] proposed a deep reinforcement learning-based (Deep-Q-Network) framework for real time offloading to make decisions related to offloading. Results shows that the proposed algorithm was able minimize energy consumption and while providing low latency.

Yu et al. [15] proposed a Deep Imitation Learning-based offloading model which could minimize the offloading cost. The decision is based on the local execution cost and remote network resource usage consideration.

It is identified that even though there are various researches to identify the best decision for executing computational tasks in mobile devices, there is a lack of research focused on task offloading in on-device inference based mobile applications and finding solutions for the halting problem.

Each approach discussed in the literature review has its advantages and disadvantages and they are shown in table I.

TABLE I. Comparison of the Approaches

Approach	Advantages	Disadvantages
Reinforcement learning Algorithms	Does not require a prior knowledge	High Complexity Curse of dimensionality
Traditional Algorithms	Ideal for slowly changing/ stable envirenments	High Complexity Hard to implement on unknown environments
Deep Learning	Can be used in dynamic environments	Long training time Requires a lot of data

Traditional algorithms and reinforcement learning algorithms are ideal approaches if the environment is known. Due to the high complexity of the traditional algorithms and reinforcement learning algorithms, it might be hard to implement these in a practical environment. When it comes to deep learning based approaches, it requires a lot of data to learn. Further, since smartphones have a wider performance and resource range, the same trained machine learning model might not be successful for all the devices. It would be an added advantage if the decision making algorithm can use the smartphone's data itself. Thus, the error that occurred by the data will be reduced. It is identified that most of the previous work does not consider the devices' own historical data such as execution times. As stated in the previous publication, historical data can be used to prevent the halting problem in computation task offloading. Thus, it was decided to investigate how historical data can be used in machine learning related tasks offloading to prevent the halting problem and further how it can be used in the decision making process. It is identified that there is a possibility of developing a decision making algorithm by using a decision tree algorithm for this purpose. Since decision trees are less complex compared to traditional algorithms mentioned in the literature review and there is a possibility that they would fit for the practical environment as well.

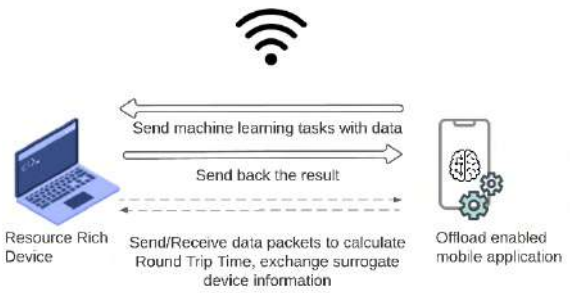
Therefore, in this project, the decision tree algorithm is chosen, and the most important parameters defined in the literature review are chosen. Therefore, parameters such as Round Trip Time (RTT), surrogate device information such as CPU usage and memory usage, and mobile device usage are selected to use in the decision making system.

In order to secure the privacy of the user's and device's interactions which are used in the decision making engine, it was decided to keep the decision making engine within the application. Hence, no data movement is done. Further, personal devices such as laptops were used as resource-rich devices, thus the data is only being transferred to personal devices which minimizes privacy concerns. Since the discussed approaches such as deep learning models, reinforcement learning, and complex algorithms might take considerable energy and time cost to execute, the research was focused on decision tree algorithms.

III. Methodology

A high-level diagram of the proposed system is shown in Fig. 1. Initially, the smartphone and the resource-rich device (hereinafter called the surrogate device) are connected through Wi-Fi. In the background, the surrogate device shares some information related to the surrogate device such as its Central Processing Unit (CPU) usage, memory usage with the mobile application. Further, the mobile application periodically sends data packets and waits for the surrogate device to send back data packets to the mobile phone in order to measure Round Trip Time (RTT). Round Trip Time is used for the expected remote execution time calculations. When there is a task to be executed, the decision making engine will decide whether the task needs to be offloaded or executed locally depend on various parameters.

Architecture of the proposed solution is shown in Fig. 2. One of the key characteristics of the proposed decision making engine is that it resides in the mobile application. Thus, there is no data movement in the decision making engine.



Send machine learning tasks with data
Send back the result

Send/Receive data packets to calculate Round Trip Time, exchange surrogate device information
Offload enabled mobile application

Fig. 1 – High level diagram of the on-device inference machine learning tasks offloading system

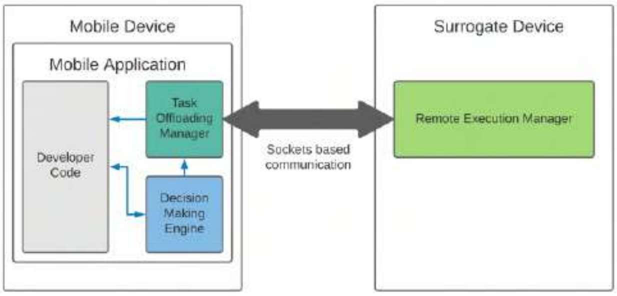

Fig. 2 - High level architecture of the offloading process

The system can be mainly divided into 5 parts: (1) Decision Maker, (2) Network Profiler, (3) Surrogate Profiler, (4) Device Profiler and (5) Database with historical data.

A high-level architecture of the decision making system is shown in Fig. 3.

A. Network Profiler

The Network profiler is used to monitor the network. It provides Round Trip Time (RTT) to the decision maker periodically. After the mobile application is connected to the surrogate device, the mobile application sends data packets to the surrogate device via the network. After the data packets are received, the surrogate device sends data packets back to the smartphone. This process is a recursive process that executes periodically. The decision making engine will measure the time spent on the above process.

B. Surrogate Profiler

The Surrogate profiler provides information related to the surrogate device to the decision maker. Occasionally the profiler gathers data from the surrogate device. It collects CPU usage, memory usage, available power, and battery status (plugged in or not connected to a power source).

C. Device Profiler

Information related to the current memory usage of the smartphone is provided by the device profiler. It provides current memory usage and whether the mobile device is currently in a low memory situation.

D. Database with Historical data

The database consists of historical data. It contains local execution times, average execution times for both local and remote executions, execution time which the remote execution takes with the task ID. Each machine learning task in the

Fig. 3 - High level architecture of the decision making engine

mobile application has a unique ID. When the task is executed, the average executed time will send to the decision maker, and update the necessary record in the database with the execution times and calculate the new average execution time once the task is completed. There might be outliers in the execution times due to reasons such as network interruptions. These outliers will be identified before the database insertions and these data will be ignored.

E. Decision Maker

The algorithm used in the decision maker is a decision tree algorithm that interacts with network profiler, surrogate profiler, device profiler, and database with historical data every time.

Historical data plays a huge role in this algorithm. Not only it is used to decide whether the task needs to offload or not but also it is used to prevent the halting problem. Each time when the task is executed locally or remotely the average execution time (local and remote execution have separate average values) related to the task will be used in the decision making process and halting problem preventing process.

Since the execution happens in another device, the smartphone does not know whether the task runs forever (runs in an infinite loop) or it will halt. In 1936, Alan Turing proved that there is no general procedure to solve the halting problem [16]. Therefore, a mechanism to prevent halting issues has been implemented in this decision maker using historical data. When a task is executing remotely, the decision maker terminates the offloading session when the time consumed by the offloading task reaches the calculated remote execution delay for that task and then the decision maker executes the task locally. Formula to calculate remote execution delay for a task (hereinafter is referred to as T_r) is given (1). It is calculated using the Round Trip Time (T_{rtt}) and the average execution time which the surrogate device takes (T_{set}), which is fetched from the database.

$$T_r = T_{rtt} + T_{set} \tag{1}$$

The decision maker also checks the current memory usage of the smartphone. If the smartphone is in a low memory situation, the decision maker decides not to execute the task locally and offload it to the surrogate device.

The decision maker not only considers the smartphone's resource availability but also cares about the surrogate device's resource availability as well. When there is a task to be executed, the decision maker checks whether the surrogate device's CPU usage and memory usage are high, and the surrogate device is currently connected to a power source or it is running using its battery. If yes, it checks whether the battery is in its lower battery level. The decision maker decides whether the task needs to be offloaded or executed locally based on these parameters. How the decision maker uses these parameters in decision making is given in the full algorithm which is given in Algorithm 1.

TABLE II. NOTATIONS

Notations	Meaning
T_r	Remote execution delay for a task
T_{rtt}	Round Trip Time (RTT)
T_l	Estimated time spend for local execution
M_{low}	The mobile device is in low memory situation
S_{cpu}	CPU usage in the surrogate device
S_{memory}	Memory usage in the surrogate device
S_{power}	Power status in the surrogate device (whether the device is connected to a power source or in the battery)
$S_{battery}$	Battery percentage in the surrogate device
H_l	Historical data related to local execution
H_r	Historical data related to remote execution

Algorithm 1 Decision Maker

```
Input: $T_l$, $T_r$, $M_{low}$, $S_{cpu}$, $S_{memory}$, $S_{power}$, $S_{battery}$
Output: Decision of whether the task needs to be offloaded or executed locally
IF $M_{low}$ = True THEN
  Return 'REMOTE_EXECUTION'
ELSE
  IF $H_l$ not found THEN
    Return 'LOCAL_EXECUTION'
  ELSE IF $H_r$ not found THEN
    IF $S_{power}$ is in battery AND $S_{battery}$ is low THEN
      Return 'LOCAL_EXECUTION'
    ELSE IF $S_{cpu}$ is not in high usage AND $S_{memory}$ is not in high usage THEN
      Return 'REMOTE_EXECUTION'
    ELSE
      Return 'LOCAL_EXECUTION'
  ELSE
    IF $T_l < T_r$. or $T_l = T_r$ THEN
      Return 'LOCAL_EXECUTION'
    ELSE
      IF $S_{power}$ is in battery AND $S_{battery}$ is low THEN
        Return 'LOCAL_EXECUTION'
      ELSE IF $S_{cpu}$ is not in high usage AND $S_{memory}$ is not in high usage THEN
        Return 'REMOTE_EXECUTION'
      ELSE
        Return 'LOCAL_EXECUTION'
```

After checking all the parameters described above, the decision maker finally compares the estimated execution times in both local (T_l) and remote (T_r) execution for the given task. Average local execution time for the task is used as estimated local execution time (T_l). The task will be offloaded to the surrogate device for the remote execution if $T_l > T_r$. The task will be executed locally if $T_l < T_r$ or $T_l = T_r$.

There is a possibility that errors could occur when the remote execution happens due to network interruptions, issues from the surrogate device, and so on. Thus, apart from the above algorithm, it is handled by executing local execution when there is an error.

IV. Experiment Design

Since the execution time for a machine learning task gets longer when the smartphone is struggling with managing its resources due to limited resources, as stated in section I, the objective of this decision making engine is to minimize execution delay. The decision making engine will check which option either offload or local execution might take the minimum execution time based on the parameters.

The connection between the smartphone and the surrogate device is done using TCP (Transmission Control Protocol) socket connection and the connection is established within the Local Area Network (LAN) using Wi-Fi.

Application for the surrogate device is developed using Python to manage task execution and send data to the surrogate profiler. Psutil [17], which is a Python library for process and system monitoring is used to get surrogate system-related information.

Various Android libraries such as ActivityManager [18] are used to get the necessary information for the decision maker. TensorFlow Lite [19] is used to developing and executing the on-device inference machine learning model (tflite file).

A. *Evaluation*

To conduct the testing and evaluation, an on-device inference based Android application was developed and integrated offload and decision making functionalities. The application is developed using Android Studio and TensorFlow Lite.

Initially, testing was conducted to check the algorithm logic, followed by the performance testing. Performance testing was conducted in both a controlled environment and a realistic environment.

Since the objective of the decision making engine is to minimize execution delay, the accuracy of the decision making engine is based on the execution time of both tasks offloading and local execution. For the testing purpose, the machine learning task is executed both locally and remotely despite the decision makes by the decision making engine. It was done to measure the task execution time on both remote execution and local execution at that time. The decisions made by the decision making engine is compared with the time spend on offloading process and the time spent on local execution. If the decision of the decision making engine is the approach that took the lowest execution time, that decision is considered as a correct decision. The accuracy was calculated as the following formula given in (2).

$$Accuracy = \frac{\underline{Number\ of\ the\ correct\ decisions}}{Number\ of\ the\ total\ decisions} \qquad (2)$$

The evaluation was accomplished by conducting a self-evaluation, getting feedback from the related expertise. Expertise feedback was collected based on a criterion of the depth of the research and the impression of the project, architectural design, and the prototype implementation.

V. Results and Discussion

The proposed offloading decision making engine was tested under various situations. Initially, algorithm logic was tested, by conducting 192 test cases. The test was conducted to make sure that the decision making algorithm gives the correct output under the given conditions. It was able to achieve 100% accuracy for the logical testing. After the logical testing was conducted, performance testing was performed. For the testing, Nokia 1 Plus [20], Nokia 4.2 [21], and Nokia 8 [22] smartphones were used. The test was conducted both in a controlled environment and a realistic environment.

The results are summarized in Table III. Based on the results, the decision making engines were able to achieve an average accuracy of 92% in the controlled environment. In the realistic environment, the average accuracy was reduced to 81.33%. It is noted that the decision largely depends on the historical data. It is identified that the accuracy of the decision making engine is keeping high as long as the network is stable. The decision making engine gives wrong decisions when there are sudden unexpected interruptions.

TABLE III. ACCURACY

Smartphone	Environment	Accuracy
Nokia 1 Plus	Realistic Environment	76%
Nokia 1 Plus	Controlled Environment	84%
Nokia 4.2	Realistic Environment	72%
Nokia 4.2	Controlled Environment	96%
Nokia 8	Realistic Environment	96%
Nokia 8	Controlled Environment	96%

VI. Conclusion and Future Work

Most of the research analyzed did not consider much about the role of the device's historical data in decision making. In this project, the past data of execution times were taken into account in the decision making process. Thus, the decision making engine is personalized to that device up to a certain amount. The results show that despite using machine learning models and complex algorithms, high accuracy can be also achieved from a decision tree algorithm based on historical data. The decision making engine was able to achieve 92% average accuracy in the controlled environment while maintaining an average accuracy of 81.33% in the realistic environment. The limitation of this approach is that the accuracy of the decision making engine might get reduced if there is less or no historical data. The following points and the limitation mentioned above are considered as future enhancements.

- Advance this algorithm further to support multi-user environments.
- When decision making, network interruptions take into account.

This is a part of the ongoing research which is focused on offloading machine learning tasks in mobile devices to nearby devices. It was decided to integrate the decision making approach discussed in this paper into a fully-fledged on-device AI framework for machine learning tasks offloading for Android mobile applications.

Scattering-based Quality Measures

Rasha Kashef

rkashef@ryerson.ca

Abstract- Various clustering algorithms use diverse settings, parameters, and initializations, generally result in different clustering solutions. Therefore, it is essential to compare and evaluate the clustering results and select the methods that best fits the "actual" data distribution. This can be achieved by using informative quality metrics that reflect the "goodness" of the resulting solutions compared to the ground truth. Different Extrinsic validation metrics have been provided in the literature, including F-measure, Entropy, Rand Index, and Purity. However, there is a gap in the literature in evaluating the level of divergence between multiple clusterings in an aggregate, especially in consensus clustering. In this paper, we propose three scattering measures that calculate the divergence level (i.e., scattering level) between two or more clustering algorithms. The proposed metrics are Scatter F-score, Scatter Entropy, and Scatter Purity. The proposed scattering measures are variants of the traditional F-measure, Entropy, and Purity quality measures. The scattering measures are used as pre-assessment criteria for deciding which clustering algorithms to combine in an aggregate. Experimental results on artificial, real, and text datasets show that the scattering measures play an important role in enhancing the clustering quality in consensus clustering and increasing the feasibility of the consensus.

***Index Terms*—Machine Learning, Clustering, Classification, Validation Measures, Divergence, Internal and External metrics**.

I. INTRODUCTION

Machine learning has received great attraction in many applications, including gene expression analysis [1][2], segmentation [3]-[5], prediction and time-series analytics [6]-[11], distributed computing [12]-[15], outlier detection [16]-[18], recommendation systems [19]-[24], text mining [25][26], and beyond. Machine learning can be classified into unsupervised and supervised methods [27][28]. In unsupervised learning, the training of the algorithm does not depend on any external knowledge, i.e., it does not use any external labeling for building the model [29]. However, in the supervised approach, to build a prediction, classification, or regression model, the data must be labeled to develop the required model. At some point during the learning process, the solutions provided must be assessed using validations metrics. There are many validation metrics in the literature used to determine the quality of the machine learning method's solutions. In clustering analysis, the validation process estimates how well a partition fits the underlying structure of the data. Cluster validation measures can be categorized into two classes, external clustering validation and internal clustering validation [30]. External measures evaluate the result based on some supervised information available, while internal ones only evaluate the result based on the information intrinsic to the raw data. F-measure, NMI measure, Entropy, and Purity are popular external clustering measures [31]. A good validation should be invariant to data size changes, cluster size, and the number of clusters [32].

The traditional external quality metrics measure the disparity between the original labeling of the dataset (i.e., class labels) and the resulting clusterings. In consensus clustering [4][18][26], two or more clustering algorithms are combined to provide better clustering solutions than individual-based methods. However, there is a research gap in assessing the quality of the aggregate before building the consensus. Various work has been done by trial and error without a solid evaluation of the feasibility or the quality of the combined collection of the clustering algorithms. This pre-assessment stage before building the consensus is mandatory to reduce the computational time and increase the chance of obtaining a high-quality aggregate with the proper set of combined algorithms. In this paper, we propose the scattering-based validation metrics that measure the diversity of the clustering solutions obtained from two or more clustering algorithms. These measures can be easily applied to the aggregate before actually building the consensus to evaluate the feasibility of the aggregate. The scattering-based validation measures are considered variants of the original extrinsic measures in which we consider the ground truth as the opposed clustering method. We proposed the scatter F-score (SF), scatter-Entropy (SE), and scatter-Purity (SP) evaluation measures. The effectiveness of using the scattering measured is shown through the application on six datasets with various levels of overlapping and sparsity. Two single-based clustering algorithms and one consensus clustering is used in the experiments. It has been shown that using the proposed metrics assesses in determining which

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

clustering aggregates should be combined to obtain a successful ensemble or consensus.

The rest of the paper is organized as follows: In section 2, extrinsic quality measures are introduced. Section 3 discussed the adopted clustering algorithms. In section 4, the proposed scattering measures are presented. Experimental analysis and results are shown in Section5. Finally, the conclusion and future directions are given in Section 6.

II. EXTRINSIC QUALITY MEASURES

The external clustering measures are based on external criteria. Such that these measures are used when the real partition of the clustered data is given a priori. A cluster validity has two features: (1) the quality of clusters using homogeneity and separation, and (2) the second feature relies on a given "ground truth. The "ground truth" is obtained from domain knowledge or other knowledge repositories. Thus, the evaluation depends on prior knowledge, i.e., class labels. This labeling compares the resulting clusters with the original labels; these measures are known as extrinsic metrics.

A. F-measure-based Measures

F-measure is based on pairing similar clusters in two clusterings solutions [31]. It relies on a pre-processing step such that each cluster is mapped to a class [33]. F-measure is broadly used in text mining based on precision and recall concepts [34]-[36].

$$\mathrm{R}(Si, Lj) = \frac{n_{ij}}{n_i} \quad (1)$$

$$\mathrm{P}(Si, Lj) = \frac{n_{ij}}{n_j} \quad (2)$$

where n_{ij} is the number of instances of class Si that are mapped to cluster j, n_j is the number of instances in cluster Sj, and n_i is the number of instances in class Li. For a cluster Si and class Lj, the F-measure is:

$$\mathrm{F(Si, Lj)} = \frac{2*R(i,j)P(i,j)}{P(i,j)+R(i,j)} \, (3)$$

The total F-Measure is formulated as the weighted sum of the *max* values of the F-Measures for each cluster.

$$F = \frac{1}{N}\sum_{i=1}^{k} n_i \max_j \frac{2n_{ij}}{n_i+n_j} (4)$$

F-measure cannot be applied for cases where nested clustering is presented [36], and it cannot handle the problem of class size imbalance properly [34]. However, F-measure is appropriate for partitional clustering since it tends to split a large and pure cluster into many smaller disjoint partitions. The **hF-measure** is commonly used for nested clustering [36]. The **L-measure** is a derivative of the F-measure to compute the quality of a computational lexicon using some clustering criterion. The L-measure achieved significant results when applied to small-sized data [37].

B. Homogeneity-based Measures

Entropy provides a solution to the "matching problem by measuring the homogeneity of a solution [33]. The entropy of a cluster is computed as:

$$E_j = \sum_i p_i \log{(p_i)} \;\; (5)$$

Pi is the percentage of instances mapped from the clustering to the defined initial classes. The overall entropy is calculated as the weighted sum of the cluster-wise entropies.

$$E = \sum_{j=1}^{m} \frac{n_j}{n} E_j \; (6)$$

V-measure (values lie in [0, 1]) is an entropy-based measure that measures the relative satisfaction of the criteria of homogeneity and completeness. It depends on the number of clusters, the size of the data set, and the adopted clustering algorithm [33]. The ***V-measure*** favors solutions with many clusters, and it strongly favors a clustering having many small clusters [38]. The V-measure is computed as the harmonic mean of homogeneity h and completeness c of the clustering with a tuning parameter β [33].

$$v_\beta = (1+\beta)\frac{h*c}{\beta*h+c} \, (7)$$

where h stands for homogeneity, and c stands for completeness.

VI is the variation of information with two properties: it satisfies the metric axioms, and it is convexly additive [39]. The range of scores given by VI depends on the size of the dataset [38]. The possible values of VI lie in [0, 2log *n*], where *n* is the size of the dataset. The VI has limited use when evaluating the performance on different datasets. The VI is defined as:

$$\mathrm{VI(C, K)} = \mathrm{H(C|K)} + \mathrm{H(K|C)}(8)$$

where H(C|K) is the conditional entropy of the class distribution C given the proposed clustering K, and H(K|C) is the conditional entropy of the clustering distribution given the proposed class [38].

Normalized Variation of Information (NVI) lies in [0, 1], and it keeps the convex additivity property of VI but not its metric axioms. Perfect solution means that the NVI = 0. NVI achieves better performance on a highly non-trivial NLP application with large datasets[38][39].

Purity measures the homogeneity of a solution such that a clustering solution with purity values close to 0 is considered a poor solution [31][33]. The difference between Purity, normalized Van Dongen (NVD) [40], Criterion H (CH)[41], and Centroid Similarity Index (CSI) [42], is related to their matching. If the matching result is the same, these indexes will provide equivalent results [31]. The purity of a set of clusters is calculated as below.

$$Purity = \sum_{r=1}^{k} \frac{1}{n} max_i(n_r^i) \quad (9)$$

n_r^i is the points in class *i* that are grouped in cluster *r*.

The **Normalized Mutual Information (NMI)** quantifies the shared information between the clustering and the true partition. The NMI values are in the range [0, 1] such that a value close to 1 indicates a decent clustering [32].

$$NMI(K,C) = \frac{I(K,C)}{\sqrt{H(K)H(C)}} \quad (10)$$

Where I(K,C) denotes the mutual information between the consensus clustering K and the true class C. H(K) denotes the entropy of K.

III. ADOPTED CLUSTERING ALGORITHMS

Clustering algorithms can be classified into two main categories, partitional and hierarchical methods. In partitional clustering, the clusters are obtained as partitions (crisp or overlapping), while in hierarchal clustering, the clustering solutions are obtained in the form of a hierarchy called dendrograms. In this paper, we will adopt two clustering algorithms and their variants, the k-means (KM) and fuzzy c-means clustering (FCM) [43]. We have also used the Cooperative Clustering (CC) clustering algorithm [4] as a consensus clustering to show the proposed scattering measures' efficiency in enhancing the clustering quality of a given aggregate.

A. The Crisp Clustering

The crisp clustering algorithm, k-means algorithm (KM) (Fig.1), chooses *k* cases randomly as initial cluster's centroids and then maps each instance x to the closest center c_i, i=1,2,..*k*. The centroids are then updated as the mean of the cases set assigned to each cluster. The objective function J defined in (Eq.11) is invoked as the stopping criterion of the iterative clustering process.

$$J = \sum_{j=1}^{k} \sum_{j=1}^{n} DisSimilaity\ (x_j, c_i) \quad (11)$$

DisSimilarity(x_j,c_i) is the distance between the point x_j and the centroids c_i. The Euclidian distance $||x_j\text{-}c_i||^2$ is used as a dissimilarity measure. A similarity measure explicitly used in document clustering is the cosine correlation measure (Eq.12). The J values can be updated as shown in Eq.13.

$$CosineSim(x,y) = \frac{x.y}{||x||\,||y||} \quad (12)$$

$$J = \sum_{j=1}^{k} \sum_{j=1}^{n} (1 - CosineSim\ (x_j, c_i)) \quad (13)$$

```
Algorithm: Crisp Clustering (KM)
Input: dataset X, and the number of clusters k.
Output: Set of k clusters S
S= {}, Randomly, select k initial centroids c_i
Begin
 Repeat
  Step1 (Assignment Stage): instances are mapped to the closest centroid,
  the objective function J (Eq.11) is calculated.
  Step2 (Revising Step): new centers c_i are computed as the average of the instances in each new cluster S_i
  Step3: Modify the set S with the new clusters S_i
 Until a stopping criterion is satisfied
Return S
```

Fig.1. The Crisp Clustering Algorithm

B. The Fuzzy Clustering

In the fuzzy c-means (FCM) algorithm (Fig.2), each point is assigned multiple membership values $u_{ij} \in [0,1]$. Initially, random memberships are designated for data point $\boldsymbol{x}_j$ such that $\sum_{i=1}^{k} u_{ij} \forall\, j = 1,..,n$, u_{ij} represents the membership of object $\boldsymbol{x}_j$ to cluster S_i, *i*=1,…,*k* and *j*=1,…,*n*.. For text datasets, we use a similarity function (e.g., *Cosine Similarity*), the cluster centers and membership formulas are modified as:

$$c_i = \sum_{j=1}^{n} u_{ij}^m * x_j \left[\sum_{\propto=1}^{d}\left[\sum_{j=1}^{n} u_{ij}^m * x_{i\propto}\right]\right]^{-1/2} (14)$$

$$u_{ij} = \left[\sum_{r=1}^{k}\left[\frac{DisSimilaity\ (x_j, c_i)}{DisSimilaity\ (x_i, c_r)}\right]^{1/(m-1)}\right]^{-1}$$

$$u_{ij} = \left[\sum_{r=1}^{k}\left[\frac{CosineSim\ (x_j,c_i)}{CosineSim\ (x_i,c_r)}\right]^{1/(m-1)}\right]^{-1} (15)$$

The objective function *J* (Eq. 16) is also used as a convergence criterion to be minimized, where *m* is the weighting exponent.

$$J = \sum_{j=1}^{k} \sum_{j=1}^{n} u_{ij}^m (1 - CosineSim\ (x_j, c_i)\ ) \ (16)$$

```
Algorithm: (FCM)
Input: Dataset X, weighting exponent $m$, and number of clusters $k$.
Output: Set of $k$ clusters S
S={}, randomly initialize the membership matrix $u_{ij}$.
Begin
  Repeat
    Step1: Compute $k$ centers using Eq.14.
    Step2: Calculate object's membership to the $k$ clusters as in Eq.15.
    Step3: Evaluate the objective function $J$ using Eq.16.
    Step4: update the set S with the newly obtained clusters
  Until a stopping criterion is satisfied
Return S
```

Fig. 2. The Fuzzy Clustering Algorithm

C. Cooperative Clustering (CC)

Combining clusterings invokes an aggregate of multiple clustering algorithms in the clustering process. Cooperative Clustering (CC) (Fig.3) enables concurrent execution of multiple clustering algorithms to achieve better performance synchronously. The cooperative clustering model is established in four stages, mainly (1) executing individual clusterings, 2) obtaining the set of co-occurred sub-clusters, (3) building sub-clusters histogram representation of the pair-wise similarities, and (4) merging of sub-clusters until *k* clusters are obtained.

```
Algorithm: Cooperative Clustering (CC)
Input: Dataset X, $A_i$ algorithms, $i$=1,..,c, and number of clusters $k$.
Output: Set of $k$ clusters S={$S_1$,$S_2$,..,$S_k$}
Initialization: S={}.
Begin
    Step 1: Generate $c$ clusterings each of size k
    Step 2: Find the set of subclusters Sb
    Step 3: build similarity histograms and assign $S=Sb$
Step 4: Repeat
    Find the most homogenous two clusters in Sb, A, and B.
    Merge A and B into C
    Remove A and B from the set S
    Add the cluster C
  Until the number of clusters in the set S equals k
Return S
```

Fig. 2. The CC Algorithm

IV. THE PROPOSED SCATTERING-BASED EVALUATION METRICS

In the proposed measures, assume we have two clustering algorithms A and B, with k clusters $S^A(k)$={ S_i^A, $1\leq i \leq k$}, and $S_B(k)$={ S_j^B, $1\leq j\leq k$}, respectively. Assume $|S_i^A|$ is the number of instances in cluster S_i (obtained by A), and $|S_J^B|$ is the number of instances in cluster S_j (obtained by B).

A. The Scattering F-score (SF)

The scatter F-score of a cluster S_i^A is defined as:

$$scatter\ Fscore(S_i^A) = max\ (\frac{2*n_{ij})}{|S_i^A|+|S_j^B|}\ (17)$$

Where n_{ij} is the number of instances in the cluster S_i^A that co-occurred in the cluster S_j^B, with respect to cluster S_i^A, the cluster with the maximum F-score value is considered the cluster S_j^B that is mapped to $S_i^{A.}$ That value is considered as the score for cluster S_i^A. The overall scattering F-score for the clustering result of k clusters is the weighted average of the F-score for each cluster S_i^A.

$$SF = \frac{\sum_{i=1}^{k}\left|S_i^A\right|*F-score(S_i^A)}{\sum_{i=1}^{k}|S_i^A|}\ (18)$$

The higher values of the overall Scatter F-score indicate a closer solution both A and B produce. This is mainly due to the greater accuracy of the resulting clusters of A mapping to B's clusters. In a consensus clustering model, we seek lower values of the scatter F-score between the adopted clustering approaches to obtain significant improvement in the clustering performance, otherwise combing two similarity clustering algorithms will not generate any significantly better results than the two methods.

B. The Scattering Entropy (SE)

The Scattering Entropy provides a measure of "homogeneity". The SE metric tells shows how homogenous two clustering solutions are. Lower values for the SE measure indicate that the two clustering solutions are of high similarity (low divergence) and vice versa. The SE of two exact clustering solutions (perfect homogeneity) is zero. Assume two partitioning results of clustering algorithms A and B consisting of *k* clusters. For a cluster S_i^A , we calculate p_{ij}, the probability that a member of cluster S_i^A is mapped to class S_j^B. The scatter entropy of each cluster S_i^A is calculated using Eq.19, where we compute the sum over all clusters in S^B:

$$\mathrm{SE}(S_i^A) = \sum_j p_{ij}\log(p_{ij})\ \ (19)$$

The total SE for S^A and S^B is formulated as the weighted sum of the cluster-wise scattering entropies.

$$SE = \sum_{i=1}^{k}\frac{|(S_i^A)|}{n}\mathrm{E}(S_i^A)\ (20)$$

The overall weighted scattering entropy avoids supporting smaller clusters compared to larger clusters. Typically, the

SE measure reports a complete matching if the cluster's Entropy is zero (i.e., the perfect similarity between A and B). If a cluster contains all the cases from two different clusters in B, its entropy will be zero, and the SE measure does not convey if a cluster is fully mapped to one or more classes, which is not the case in the SF.

C. The Scattering Purity (SP)

The Scattering Purity (SP) of solution A is calculated by averaging the cluster's precision wrt. their best matching clusters generated by B. For a single cluster S_i^A, the scatter purity is calculated as the ratio of the number of instances in the leading cluster to the total number of instances within the cluster:

$$SP(S_i^A) = \frac{1}{|S_i^A|} * \max\left({}^{i=1,..k}_{j=1,..,k} n_{ij}\right) \ (21)$$

n_{ij} is the number of instances from cluster S_i^A into cluster S_j^B, and $|S_i^A|$ is the number of instances in cluster S_i^A. To evaluate the total scattering purity for the entire *k* clusters, the cluster's purities are weighted by the cluster size, and the average value is calculated:

$$SP = \sum_{i=1}^{k} \frac{|S_i^A|}{n} SP(S_i^A) \ (22)$$

High values of the SP indicate closer solutions of A and B. The above formulation for the SF, SE, and SP can be generalized to any extrinsic quality measure with two clustering solutions labels S^A and S^B.

V. EXPERIMENTAL RESULTS

In this section, we used two single-based clustering methods as KM and FCM, and one aggregate-based (consensus) method, as the cooperative clustering (CC) method. The goal is to show that the scattering measures are used as an efficient assessment tool to decide which algorithms to combine (i.e., the feasibility of the aggregate). We evaluate the performance of each algorithm using the traditional F-measure, Entropy, and Purity.

A. Datasets

In this paper, we have used two artificial datasets, two real-world datasets, and two text documents datasets.

Synthetic Datasets: We have generated two artificial datasets, DataSet1 and DataSet2. DataSet1 contains two overlapped clusters in 3-dimensional feature space with the same covariance matrix. DataSet2 contains three overlapped clusters in 2-dimensional feature space with different covariance matrices. The number of data instances in DataSet1 and DataSet2 is 100,000 and 150,000 instances, respectively. DataSet1 and DataSet2 are generated from Gaussian distribution. Experiments were also performed where the synthetic datasets were randomized before feeding into the KM, BKM, and CC.

Real-World Datasets: The pageblocks dataset involves five classes of page layout blocks of documents that a segmentation process has detected. The dataset has 5473 instances with ten numeric are obtained from 54 documents. Such that each observation belongs to one block. The pageblocks dataset was used in both [45] and [46]. In the Imgseg dataset [47], 2310 instances with 19 numeric features were drawn randomly from a database of 7 outdoor images. The hand-segmented images create a classification for every pixel. Each instance is a 3x3 region.

Document Datasets: The UW dataset is a manually collected text corpus from the University of Waterloo[1] various websites. The data set also has many documents from other Canadian websites. The UW dataset has 314 documents, categorized into ten categories, with 469 average words per document [42]. The ReutersNews contains 2340 documents classified into 20 different categories, with an average of 289 words per document [29] [40]. A summary of the datasets is shown in Table 1.

Table 1: Summary of the Datasets

Dataset	***k***	***d***	***n***
DataSet1	2	3	100000
DataSet2	3	2	150000
pageblocks	5	10	5473
Imgseg	7	19	2310
UW	10	15133	314
ReutersNews	20	28298	2340

B. Experimental and Computational Analysis

As KM and FCM depend on the initial assignment of instances to clusters, we have used random variations of each method based on changing the initial conditions. As shown in Fig.3, the KM and FCM have similar performance for the DataSet1 and pageblocks datasets measures by the large values for the SF and SP and lower SP values (almost zero for the two datasets). On the other hand, the two algorithm shows great diversity in their solutions for the UW, ReutersNews, ImgSegm, and DataSet2. The diversity (i.e., scattering) level is measured by small SF and SP values and

[1] www.uwaterloo.ca

large SP values (as shown for the UW dataset as an example). The expectation is that when we combine the KM and FCM in an ensemble (i.e., consensus), there is a low chance of obtaining better solutions as they both have similar partitions, especially for the DataSet1 and pageblocks. As there is a higher level of divergence between KM and FCM in the UW, ReutersNews, ImgSegm, and DataSet2, there is an opportunity to find a better aggregate with better results than both algorithms. Thus, the scattering measures, SF, SE, and SP, indicate that KM and FCM can be combined for the four datasets, UW, ReutersNews, ImgSegm, and DataSet2. Simultaneously, it is not feasible to combine them for the DataSet1 and pageblocks as no better aggregate can be obtained.

Figures 4-5 show the quality of the single-based algorithms and the consensus CC algorithm. It can clearly be demonstrated that as KM and FCM have very similar performance for the DataSet1 and pageblocks, the percentage of improvement is low (only up to 2%, 10%, and 7% for the F-measure, Entropy, and Purity, respectively). On the other hand, due to the highly diverse solution between the two methods for the other four datasets, the consensus CC achieved an improvement of up to 63%, 34%, and 52% improvement in the F-measure, Entropy, and Purity, respectively. These results conclude that the proposed scattering measures are effective pre-assessment tools to decide on the feasibility of the ensemble prior to the design of an aggregate. These measures can be applied for supervised and unsupervised ensemble learning as a significant validation step in the preprocessing stags.

VI. CONCLUSION AND FUTURE DIRECTIONS

Validation metrics play an important factor in assessing the performance of various machine learning algorithms. The process of unsupervised learning is a more challenging task than supervised learning as no class labels are provided to evaluate the quality of the adopted algorithm, especially for building an ensemble. Thus, there is a need to provide a pre-assessment of the invoked algorithm before designing an aggregate. In this paper, we have proposed three scattering measures that effectively evaluate the divergence or the diversity in the clustering solutions to build a successful and feasible consensus. Experimental results have shown that clustering solutions with similar partitioning show no improvement when combined, while high diverse solutions indicate a high level of refinement when aggregated. These results are confirmed using the proposed three scattering measures. The proposed measures can be generalized to evaluate the performance of both supervised and unsupervised methods prior to the ensemble modeling stage. Future directions include investigating the scalability of the scattering measures if we have more than two methods, such iterative pair-wise evaluation of the scattering measures is used. We also plan to investigate the application of the proposed measures for different consensus learning approaches.

***Abstract*— In the current era robots play vital role in several industries, hospitals, and research organizations etc. In hospitals robots support and nursing staff currently may also use in this era during COVID19 Pandemic to transport such patient sample or dispose of their usage belonging to avoid spreading of this pandemic to clinical staff. From making deliveries, dispensing medication, visiting patients to aiding surgeries, robots are improving the way hospitals function. Central Sterilization Supply Department (CSSD) offers sterilization amenities to Outpatient Department (OPDs), wards and operation theatre (OT) of hospitals. It provides facilities to receive, clean, pack, disinfects, sterilizes, store and distribute instruments, in accordance with well-delineated protocols and standardizes procedures. An alarming boost in Hospital Ac-quired Infections (HAI) demonstrates the necessity of a well-organized CSSD to prevent surge in HAI. Although quality assurance procedures are followed to ensure safety and efficiency at all levels: appropriate handling of contaminated items, decontamination, proper cleansing, and instrument care, but the necessity of human presence to implement these procedure in-creases the threat of HAI. Thus, an intelligent autonomous multi-sensor wireless controlled NXT robot using MATLAB is proposed to handle contaminated items and sterilize equipments in the centralized sterilization sup-ply department. The proposed system is entirely automated and eliminates the need of human presence to implement quality assurance procedures, thus decreasing the threat of HAI. An archetype using Lego NXT robotic kit is developed to implement tasks performed in CSSD. MATLAB is used to control NXT robot instead of Lego Mindstorms software, due to its versatility, capability to perform computationally intensive tasks and wide usage by researchers. A powerful control system is designed that allows user to interrupt, control and monitor autonomous NXT robots.**

Keywords— ***COVID19 , Robotics Invention System, Central Sterilization Supply Department, Hospital Acquired Infection, Operation Theater.***

Introduction

In the current era robots play vital role in several industries, hospitals, and research organizations etc. In hospitals robots are the newest members of the hospital support and nursing staff. This project focuses on design of an intelligent autonomous multi-sensor wireless controlled NXT robot using MATLAB to handle contaminated item and sterilize equipments in the centralized sterilization supply department specially to protect clinical professional. The

system is entirely automated and quality assurance procedures, thus decreasing the threat of HAI. The choice of robotic podium for this project is the Lego Mind storms NXT. This system facility to collect, clean, pack, disinfects, sterilizes, stores, and distributes instruments, in accordance with well-delineated protocols and standardizes procedures [1-5].

Proposed System works as a single unit, which is control by MATLAB. MATLAB runs in monitoring computer which is wirelessly connected with robot via Bluetooth dongle and all other equipment in CSSD is connected with the serial port connection. We have to use advance software for controlling dongle. The dongle works as bi-direction serial port which enables us to use serial commands to communicate with Lego robot. For establishment of strong link between MATLAB and Lego NXT we have to install some program files in brick. This file helps us to easily communicate with robot by using MATLAB. First of all, we upgrade firmware of Lego NXT from 1.21 to 1.26. This was done because old firmware does not support RWTH toolbox. This Toolbox provides communication with robots with Bluetooth or USB. The toolbox includes routines for supporting interactions between robots and MATLAB. We use RWTH toolbox in MATLAB the commands were send through the MATLAB after creating the connections and robot work according to the given instructions remember as the robot have motors and sensors all were activated by via wireless connection no user or wire interface is there. as we know that the CSSD staff work manually al the process, they take contaminated material from the O.T and they enter into the department and processed it through washer and autoclaves there are some indications which already known by the staff that the equipment shows it become sterile, in short all work done by the staff according to the instructions. Same process is performing by the robot technology NXT ROBOT more accurate more smoothly and shows best performance there according to the instructions. The washer and autoclave are controlled by the microprocessor which also takes instructions through MATLAB. All the equipments of the department are interconnected with each other, there data is transfer via port to the main circuit board and then via serial port the data is transfer to the computer placed in an operating room. In this way a continues

feedback is provided and robot is monitored continuously so there is almost no chance of human error. The instructions of doors open, and robot enter and exit all timing are set and command by MATLAB [6-18]

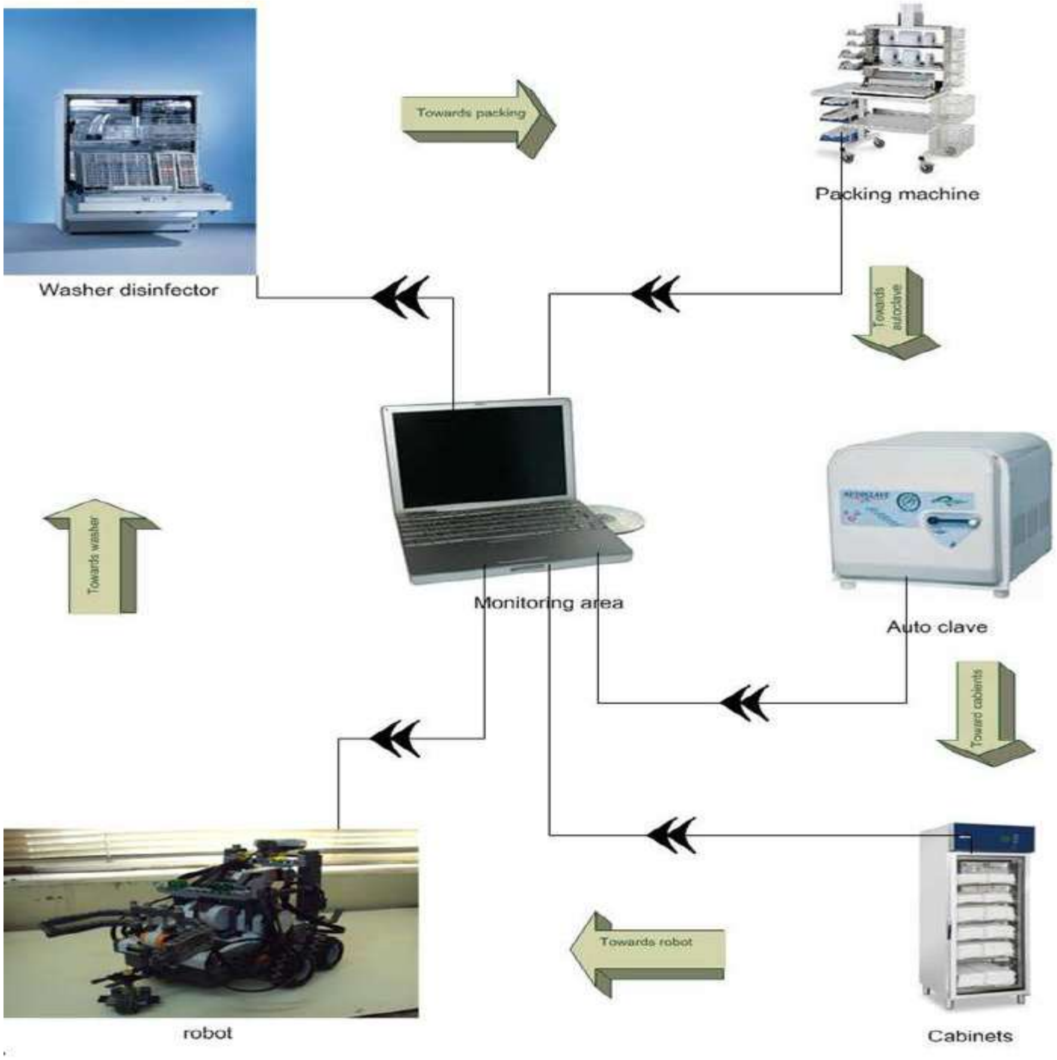

Figure 1. Shows the Working Principle of the proposed designed

I. Design Methodology

A. Material Selection in proposed designed

Lego Mindstorms kit with MATLAB software were used in this project, in addition to design whole prototype some extra materials are also used in the completion of complete prototype design as shown in Figure 2. Lego Mindstorms consists of different construction blocks, sensors and controlling brick [6], The controller brick used in the proposed system in controlling all functions of Lego robot, which includes ,4 input ports,3 output ports,1 Bluetooth connection. Light Sensors used to help the Robots to move on the desired location where the object placed, Ultrasonic Sensors are integrated with designed robot to assure not to collide with any surface or objects, Sound Sensor also used to identify if the hazardous material or object detected by the robots or not, Touch Sensor were also incorporated with robots to hold the object after feeling touch sensation. Three servo motors are also used to control the robots' gripper and arm angle. Shaft Encoder used to measure the speed of the servo motor to ensure that the designed robot manipulate its task accurately, finally Blue tooth dongle were also used, this wireless system helps robot to easily move anywhere and send back its location and status to monitoring system. This adapter is high speed and medium range which is about 100m in circle. Adapter is capable to operate in bi-direction mode. [6]. The conveyer belt is used inside the equipments to transfer the material from entrance to exit which is placed by the robot. The conveyer belt has widely used in industries for the supply chain and transfer of the material from the idea of that industries make me an example to provide a better way to hold and control the material through conveyer belt. It consists of single motor which is the center of the belt and belt is rotate on it when the motor allows to move clockwise or anti clockwise.

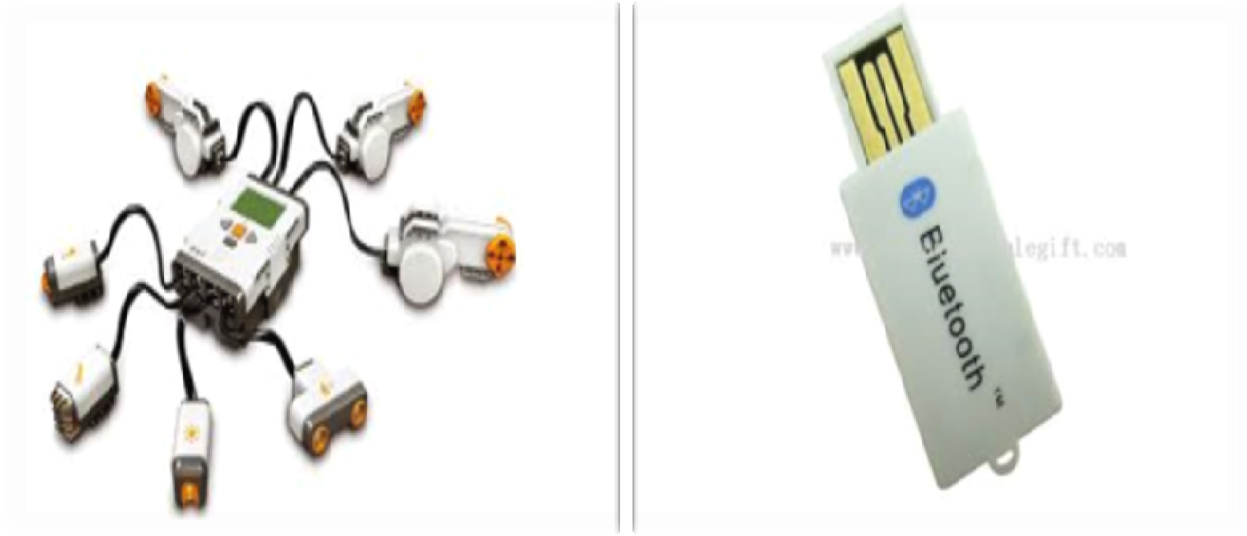

Figure 2. At Left: Lego NXT Controller units connected with different sensors, At Right shows the Bluetooth dongle used with the system for wirelessly controlling the whole system.

B. HARDWARE ARCHITECTURE

C. SOFTWARE DECSRIPTION

In Robot designing two NXT Robots' bricks were used to control severe servo motors especially four motors used among which two were used for driving and steering wheels of designed robot while one used for robotic gripper and one for robotic lifter as shown in Figure 1-2. The proposed designed system also has ability to sense different color packages with the help of color sensor to detect and distinguish visible colors based on these color sections Robot can easily pick and place of different color and shape objects, an ultrasonic sensors also used to detect obstacle during the Robot moving towards the object for handling or dispose of contaminated object like the mask or any belonging used by COVID 19 patient to protect the direct interaction of ward boy form this pandemic. ,an ultrasonic sensor may also use to retrieve the robot's distance to its staring point and light sensor was also used to rover the Robot in the straight path which may detect the lines for its path findings where user want to move the robot to move. The wireless BLUETOOTH communication used in the proposed system which provides access to control and communicate with robot from computer. 8-bit microcontroller and a 100x64 LCD monitor. This brick supports up to four sensorial inputs and can control up to three servomotors. It also has an interface displayed by the LCD System works as a single unit which is control by MATLAB. MATLAB runs in monitoring computer which is wirelessly connected with robot via Bluetooth dongle and all other equipment in CSSD relates to the serial port connection. We have to use advance software for controlling dongle. The dongle works as bi-direction serial port which enables us to use serial commands to communicate with Lego robot. For establishment of strong link between MATLAB and Lego NXT we have to install some program files in brick. This file helps us to easily communicate with robot by using MATLAB. First, we upgrade firmware of Lego NXT from 1.21 to 1.26. This was done because old firmware does not support RWTH toolbox. The toolbox includes routines for supporting interactions between robots and MATLAB. We use RWTH toolbox in MATLAB the commands were send through the MATLAB after creating the connections and robot work according to the given instructions remember as the robot have motors and sensors all were activated by via wireless connection no user or wire interface is there. as we know that the CSSD staff work manually al the process, they take contaminated material from the O.T and they enter into the department and processed it through washer and autoclaves there are some indications which already known by the staff that the equipment shows it become sterile, in short all work done by the staff according to the instructions. Same process is performing by the robot technology NXT ROBOT more accurate more smoothly and shows best performance there according to the instructions. The washer and autoclave are controlled by the microprocessor which also takes instructions through MATLAB. All the equipments of the department are interconnected with each other, there data is transfer via port to the main circuit board and then via serial port the data is transfer to the computer placed in an operating room. In this way a continues feedback is provided and robot is monitored continuously so there is almost no chance of human error. The instructions of doors open, and robot enter and exit all timing are set and command by MATLAB. The robot performs the task till packaging process after the completion of the task it will come back to its starting position.

The Robot receive command from PC from the execution of its work wirelessly for this purpose Bluetooth adapter was uses through the wireless Bluetooth adapter. The MATHLAB NXT toolbox has been used in this system [14]. The software used in this designing is a free open source subject to the GNU GENERAL PUBLIC LICENSE (GPL). Desired task commands are sent to NXT robot to achieve task by using this connection, it is also use for receiving data from sensors like distance from ultrasonic sensor of each robot. A replica of CSSD was designed as shown in Figure 1 (Working Principle Diagram) to A replica of CSSD was designed as shown in Figure 1 (Working Principle Diagram) to provide better practical approach system, we built replica of whole department with all necessary equipment use in process. Prototype includes model of washer disinfector, autoclave, supply cabinet and special chamber for sterilizing robot, all equipments are design by acrylic sheets. Models are mechanically active to perform basic functions like opening and closing of doors, receiving, and transmitting commands to main controlling computer. [15]. PIC controller is use as Communication Bridge between CSSD replica and PC server. C high level programming language is used to program PIC controller, PIC-C compiler. The main board is connecting the departments equipment with computer in monitoring area. this is done in a simple way that first data is sent via port to the main circuit board and then it is transfer serially to the computer where it is monitored as shown in Figure 1 and Figure 4 respectively.

For the safety of complete Robotic system used in proposed design , The system will be stopped if the system started malfunctioning for example if the user give the system instructions command to follow the straight path and execute their work as per command received through PC software if system started malfunctioning and does acts upon received instructions the system will be because of many sensors are being incorporated within the system to assure the system behaves properly without or with minim error during execution of any task performed by the system. ,whenever a robot is about to going outside the workspace or lost its path, the whole process is stopped, and robot come back to their initial position for this purpose an emergency button access given to operator in system control console which is shown in Figure 8 . This option may use if operator realized there is any automatic shut off needed in any emergency case.

II. CONCLUSION

Proposed designed project may provide provides fast and hygienically secure environment to hospital Central Sterilization Supply Department especially now a days to cope the spreading of COVDID19 in clinical staff special in ward. Our system helps hospital administration to keep their hygienic quality at top. Whole system is cost effective and able to do those works which are hazardous for health of human. All hazardous material will be carrying out by robot. Whole process will automatic so very less chance of any error. In case of emergency whole system will auto, shutoff and inform operators immediately. System ensures sterilization process more reliable and accurate. We hope in future our design plays important role in maintaining hygienic quality of hospital and also make whole process faster. Robot can work freely without any risk of infections. System will able to work 24x7 without any stop. Designing of GUI for simplicity for user. System can be monitor by wireless. This phase covers all monitoring and feedback systems. In this part we try to make our robot vision intelligent so it can differentiate between objects and equipments. Image processing also helps us to find out location of robot in CSSD.

MicroPython-based Sensor Node with Asymmetric Encryption for Ubiquitous Sensor Networks

Ulrich ter Horst, Hagen Hasberg, Stephan Schulz
Faculty of Engineering and Computer Science
Hamburg University of Applied Sciences, D-20099 Hamburg, Germany
Email: {stephan.schulz, ulrich.terhorst, hagen.hasberg}@haw-hamburg.de

***Abstract*—This work introduces a new microcomputing node with long-term resistant data security, based on asymmetric and symmetric encryption combined with the modern and established scripting language Python. The presented microcomputing node integrates a MicroPython runtime environment to address a wide audience of application engineers as user base instead of a selected group of embedded engineers, who have deep knowledge in programming IoT devices using C/C++. It combines its scripting capabilities with security features of modern smartcards and secure cellular networking based on 4G.**

***Index Terms*—IoT, MicroPython, smartcard, sensor node, encryption**

I. Introduction

The acquisition and processing of real-time sensor data with real-time forecasts and downstream control is becoming a standardized tool in the industrial sector and general automation thanks to powerful networks and power-saving processors. The research area Internet of Things (IoT) lives from the connection of cyber physical systems (CPS) to data centers or other cloud instances. Over the last few years, a paradigm shift from a classic industrial control system to powerful, reliable and secure decentralized embedded systems based on wireless networks has developed. The pre-processing in fog computing corresponds to the worldwide highly available cloud systems of large providers. A central element of acceptance in the industrial sector is data security and encryption of process data and configurations of industrial systems. Data centers of industrial suppliers stand next to large companies that offer highly developed evaluation methods. The monitoring of systems for predictive maintenance by IoT is becoming increasingly easier to implement. The expansion of existing industrial plants in brownfield sites or the integration of sensor nodes in urban areas will be an important technological application in the upcoming years.

This paper presents a microcomputing node with secure 4G connectivity, which is capable to interface a wide variety of sensors, actuators and industrial networks in order to perform both sensory and control tasks simultaneously. Data streams such as process data, configurations or scripts can be securely encrypted via OpenPGP similar to RFC4880 by the use of a smartcard [1]. The microcomputing node is based on an adapted implementation of MicroPython and thus ensures easy access via a high-level programming language.

II. Applications of Sensor Nodes

Modern cloud providers offer REST-APIs and M2M protocols to integrate microcomputing nodes into solutions running on their servers. A commonly used protocol is MQTT. A simple sensor node application in the context of industrial IoT is illustrated in Fig. 1. Sensor data is received by the microcomputing node and uploaded into the AWS cloud. If necessary the data can be filtered and pre conditioned within the node itself. Afterwards the data is marshalled into a JSON string and inserted into an MQTT message. Fig. 1 shows two use cases. In the first case the data within the MQTT message is cleartext information and the messages topic belongs to an AWS Thing shadow, which can be understood as the digital twin of the microcomputing node. The message updates the shadows state and according to the attached rules, the sent data will be extracted and forwarded to any AWS cloud service. It can be displayed in a semi-realtime dashboard using AWS SiteWise, it can be processed further using AWS Analytics or it can be stored into an S3 Bucket to be processed by an A.I. application using AWS SageMaker.

All these applications are possible, because the data can be read and interpreted by AWS, the cloud provider. If this does not fit the users needs, then the cryptography features of the nodes smartcard can be applied before the data is marshalled for the transmission. In both cases the sensor data is securely transmitted via TLS, but in the second case it is already signed and encrypted using asymmetric cryptography before the transport encryption applies. The cloud provider still gets the necessary meta data to assign the message to the correct digital twin but the sensor data payload itself is unreadable ciphertext from the perspective of the cloud provider. By this procedure the user has excluded the cloud provider from his applications chain of trust. Due to asymmetric encryption it is guaranteed, that the data can only have been sent from the trusted microcomputing node, that it is unmodified and that only the user can decrypt it.

Both use cases can also be combined within one application. A logistic service provider for example can detect, upload and analyze unwanted incidents during operation without disclosing critical insights of his business to the cloud provider. If any cargo stays in one place unexpectedly long or it gets

978-1-6654-4067-7/21/$31.00 ©2021 European Union

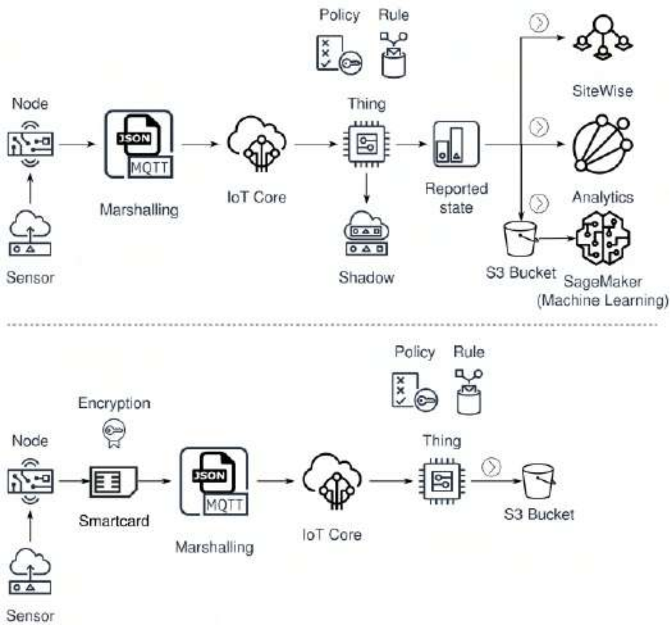

Fig. 1. Illustration of two AWS solution architectures. In the first solution the data is only encrypted during the upload into the cloud. All AWS Services can be applied to interpret the data. The solution below shows an encrypted upload. Here AWS can only act as storage hoster and has no insight into the process data.

exposed to vibrations and shocks of unacceptable amplitudes, these incidents can be logged into the cloud. The incidents date and location of occurrence can then be utilized as features for further analysis to avoid or reduce the amount of these incidents in the future. So these features are wanted to be shared with the cloud provider to use the cloud based analytic services. But other features like type of cargo or customers associated with the cargo may be not wanted to be disclosed. Hence this information is better uploaded in ciphertext form. This procedure offers the logistic service provider to examine the undisclosed information in the future outside of the cloud. Without the custom encryption inside the sensor node, the logistic service provider has to associate an incidents information to a unique identifier and store the critical information on self hosted instrastructure, which is wanted to be avoided in the first place, so that both data sets can be linked by the identifier for further inspection.

III. Platforms

The node is expected to be a realtime-capable and generic foundation, on which specialized solutions can be created. Therefore the platform, on which the MicroPython runtime environment operates, must weigh in several and partially conflicting requirements to support the scripting languages universal applicability. For example several IoT use cases do rely on solar and battery powered sensor node solutions. So energy efficiency and short response times out of deep sleep states are requirements that have a higher impact on platform decisions than data rates or bandwidths. IoT devices are also often considered as insecure and easy targets in IT security and hence as threats for a corporate networks integrity [5], [6]. So it is important to minimize the IoT devices attack surface, because often they use the same network as other corporate computers and thus have the same thread level [7]. Also the formfactor can be important in terms of size. Sometimes IoT devices are required to blend in into their surroundings, or they have to be integrated in space constrained environments, or their deployment itself must be simplified and be more cost efficient, because their destination is in a remote area.

The main decision in identifying the right platform for the microcomputing node is the choice between a Linux-capable System on Chip (SoC) and a more constrained microcontroller unit (MCU). The presented node is based on an MCU. The computing performance of MCUs can be considered as generally lower than the performance of SoCs. So bandwidth intense use cases like computer vision applications or the use of interfaces like fast ethernet are excluded from the nodes scope. But in most cases IoT applications require lower data rates. The limited computing performance is an acceptable constraint of MCUs, which outperform Linux capable SoCs in other categories. MCUs consume less energy than SoCs, because of lower clock frequencies, simplier hardware architecture and less software overhead. The Linux kernel is not realtime capable by default and must be patched to guarantee the required response times. And even if a Linux based system is patched and configured correctly, it is harder to maintain than a more minimalistic firmware of an MCU, because of the complexity of Linux operating systems in terms of their code size. Linux based SoCs have to execute several utility processes, like systemd. Every peace of software in the system does not only offer comfort for the developers and users, it also offers potential vulnerabilities to be exploited by attackers. An MCUs firmware is advantageous through its simplicity. If implemented correctly, it not only offers less attack surface, it also switches faster and therefore more often between deep sleep states and working phases, which helps to save even more energy.

The chosen MCU is an STM32F415. Its set of peripherals allows the microcomputing node to implement a sufficient set of hardware interfaces and timing capabilities. A first prototype based on a commercial off the shelf development board, that is based on the STM32F415 is shown inf fig. 2. The microcontroller board in the middle is adapted by a custom designed PCB to offer the required hardware interfaces via boxed headers. Configurable pull up/down resistors, two CAN transceivers and three load switches are also integrated on the prototypes adapter board.

Some of the firmwares internal modes of operation play an important role for data security, although all signing and encryption processes are sourced out into the trusted hardware of a smartcard. The protection against firmware readouts by unauthorized parties is a required feature. Many MCUs have insufficient readout protection capabilites and also other STM32 MCU families have shortages here, but an STM32F4 based microcontroller seems to offer sufficient protection to date [2]. Another important aspect of the choice to use an

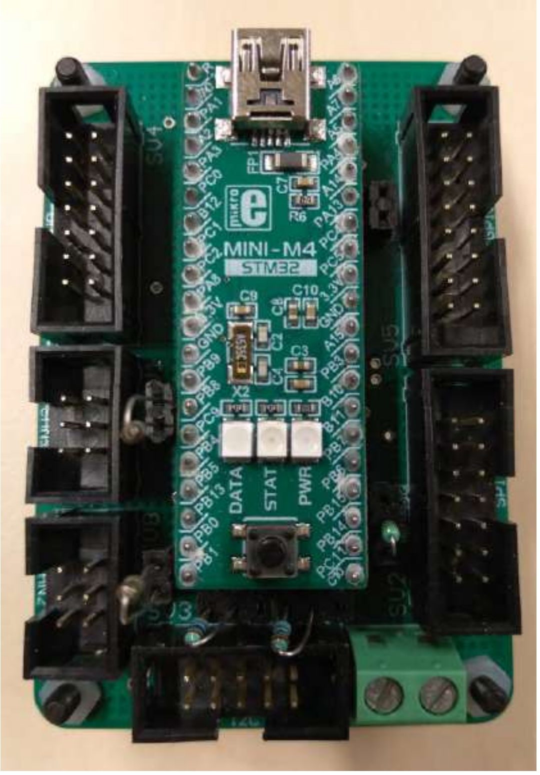

Fig. 2. A first prototype, based on a commercial off the shelf development board and a custom designed adapter PCB.

STM32 based MCU is the quality of existing libraries for the Hardware Abstraction Layer (HAL) and the quality of documentation.

IV. System Architecture

To optimize the cost efficiency of IoT sensor network deployments, it is advantageous to design the microcomputing node in such a way, that deployments do not require the installation of additional infrastructure like routers, switches or relays. Therefore the presented node integrates a cellular (4G) modem and can fully rely on existing infrastructure.

After the internet connection is established by the modem, the cloud provider can be chosen freely, because of standardized messaging protocols like MQTT, which uses TCP/IP on the transport layer and is secured with TLS. Since most of the common cloud providers like Amazon Web Services (AWS), Google Cloud, Microsoft Azure, SAP Hana and Bosch IoT Suite use MQTT, a switch between providers demands only configuration changes on the application layer. Although the presented microcomputing node supports Over-The-Air (OTA) updates of the whole firmware, these updates are rarely needed, because e.g. configurations, business logic and device drivers can be implemented in the form of MicroPython script files, that are exchangeable remotely via MQTT. Hence the sensor network solution is capable to grow and evolve along with the industrial business operation it has to conrol and monitor. It is able to adapt to new problems and challenges without demanding replacements or any manual labour on site, which results in substantial cost savings during operation.

All cryptographic and thus security-relevant functions and operations are outsourced onto a smartcard module, which offers several advantages including a less constrained selection of microprocessors as main processing unit, because it is not mandatory to have specific ciphers or other cryptographic hardware integrated in the MCU. Smartcards contain certified hardware specifically hardened against physical attacks to prevent any manipulations of the cryptographic operations and to maintain the secrecy of all private key information. Since the secret information is stored on the same trusted hardware device that executes the cryptographic operations, there is no reason for any private key to ever leave the trusted device. In contrast to permanently soldered cryptographic ASICs, a smartcard offers more flexibility. In case of compromised key information or outdated and no longer secure cryptography standards the smartcard can easily be replaced or updated and can remain in the microcomputing node. Also when the application demands new specific features like domain specific ciphers for PGP, block chain applications or MiFARE compatibility, then a smartcard offers the requested diversity without the replacement of the whole microcomputing node.

The nodes firmware is built around the MicroPython runtime environment. The layered structures of the firmware is illustrated in fig. 3. The application layer consists of MicroPython scripts. Below that is the MicroPython runtime environment and the operating system situated. Both of these subsystems are built on top of the middleware layer, that implements utilities like input/output orchestration of the MicroPython runtime environment, block devices for file systems and routines to print system information for MicroPython application developers. Below the middleware is the Hardware Abstraction Layer (HAL) located as exchangeable foundation for maximum portability.

MicroPython offers the user to implement an IoT solution in the modern and established scripting language Python. The microcomputing node is capable to execute a subset of Python 3 instructions that can be loaded from a script or entered during runtime via a Read Evaluate Print Loop (REPL). The firmware is designed in such a way, that any hardware interface can be used as input/output for the REPL. Hence MicroPython instructions can be tunneled via UART, CAN, SPI, I²C or USB-VCP and the user can interact with the node locally or remotely via a cellular connection for example. The REPL demands parsing and compiling during runtime before the instructions can be executed. Scripts on the other hand can also be uploaded in a previously cross-compiled bytecode format for immediate execution to save runtime and memory resources. The microcomputing node supports three sources of MicroPython scripts. They can be loaded over the REPL, they can be imported from the internal file system or they are statically flashed into the firmware as a so called frozen module and can be imported from ROM. The REPL and the file system are accessible remotely via the cellular network. The set of frozen modules can also be altered when

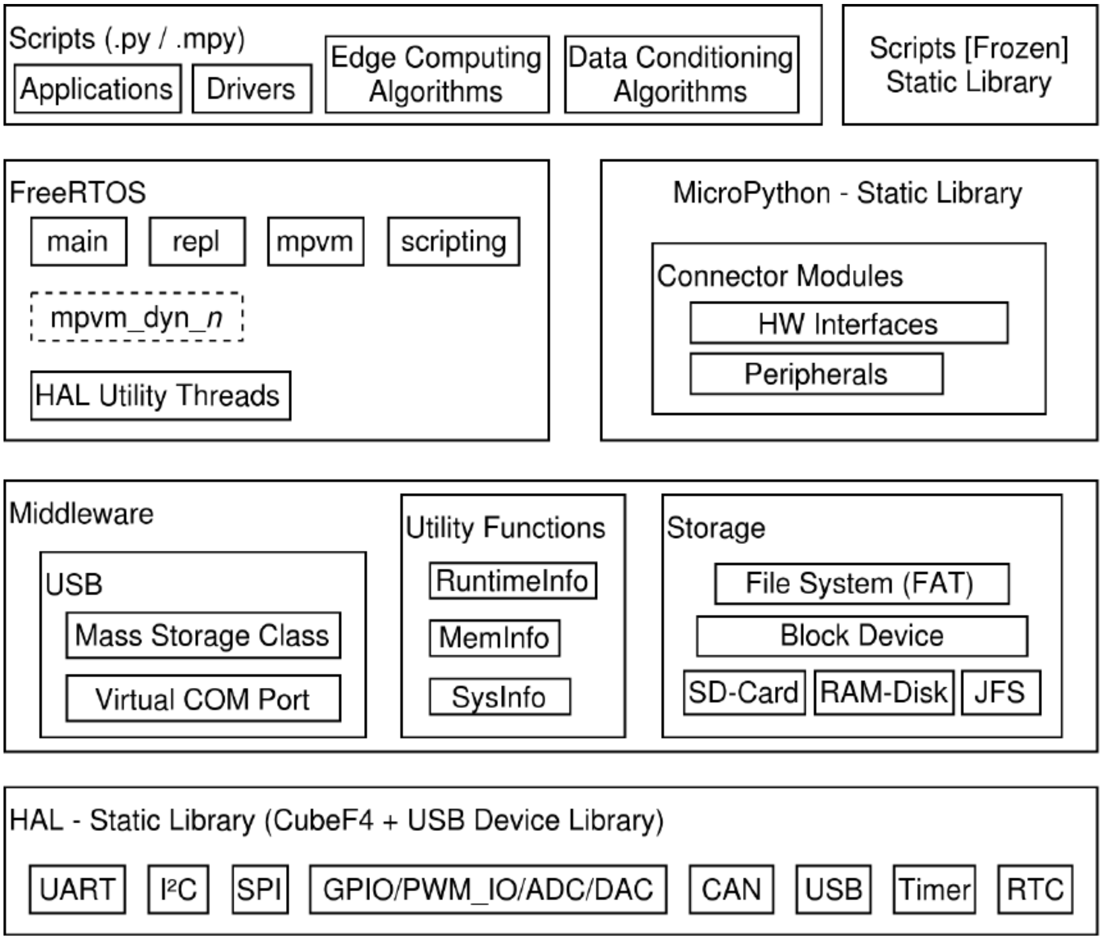

Fig. 3. Layered illustration of the microcomputing nodes firmware components.

an OTA update of the firmware is applied.

The firmwares application layer consists of MicroPython scripts, possibly also including device drivers of connected sensors or application specific algorithms for data conditioning or process state detections to generate warnings and other information, that can be uploaded to connected cloud systems.

The MicroPython runtime environment exists in the operating system layer in form of a static library so that it can be upgraded to newer MicroPython versions quickly and independently. MicroPython offers multithreading and the REPL is available anytime regardless of any scripts running in the background. To support these features and to maintain the realtime capability in parallel to responsive hardware interface handling for sensor communications the realtime operating system FreeRTOS is used. Different HAL utility threads facilitate deferred interrupt handling of the hardware interfaces. Every user generated python thread is managed through its own FreeRTOS thread. Interactions of the REPL are maintained by a seperate REPL thread. A scripting thread listens for incoming scripts via proprietary protocols on different hardware interfaces. The MicroPython runtime environment has a dedicated thread to run all incoming instructions from the other threads.

In order to make use of any microcontroller peripherals from within the MicroPython runtime environment a variety of MicroPython modules is defined in C and C++ language. The user can import these modules in REPL mode or from a script. They act as glue code to the middleware and the HAl. The HAL is based on STMicroelectronics CubeF4 HAL and like the MicroPython port it is linked into the firmware as static library. The firmware and especially its HAL follows the Ressource Acquisition Is Initialisation (RAII) ideom and avoids dynamic memory allocation from the heap at its abstraction layer. All input and output buffers are allocated from the application layer during firmware startup. Additionally the call of *malloc* is strictly avoided to offer maximum safety during runtime. The only free-storage (heap) allocation is done by the MicropPython runtime environment. therefore out of memory exceptions from heap overruns or heap fragmentation can only occur within the MicroPython heap and there overruns can be caught from the firmware, which allows for graceful reset procedures.

V. MCU Flash Memory Utilization

The MCUs flash memory serves as nonvolatile storage for three Firmware components. It holds the bootloader, that is necessary for OTA-Updates. Further it contains the actual firmware and the internal file system. Table I shows the flash distribution between these three subsystems. One can see, that the MCUs flash memory is organized in twelve sectors of different sizes. The bootloader is the smallest subsystem, it uses three of the smallest sectors. At the current state of development the bootloader is still rudimental and listens for update instructions on CAN bus only. So it is still small enough to fit in less than three sectors, but because of its internal mode of operation it must be distributed among at least three separate sectors.The firmware is located at dedicated sectors, independent from the bootloader, so that the bootloader does not overwrite itself or its fallback state information during updates, which ensures robustness against power losses. When all features are included in the compilation process and when debugging symbols are enabled, the firmware uses 58% of the flash memory. The file system needs at least two sectors to operate, so that the firmware is allowed to grow even further. But without debugging symbols it is possible to shrink the firmware down by two sectors to about 33% of flash and thus to increase the file system.

TABLE I
Flash memory sectors of STM32F415

Index	Usage	Size$[KiB]$	Percentage
0	Bootloader	16	5 %
1	Bootloader	16	
2	Bootloader	16	
3	Firmware	16	58 %
4	Firmware	64	
5	Firmware	128	
6	Firmware	128	
7	Firmware	128	
8	Firmware	128	
9	File System	128	37 %
10	File System	128	
11	File System	128	

Sector sizes vary between 16 and 128 kibibytes, which is common for MCUs. The internal file system of the microcomputing node demands the flash storage to modify its content during runtime. Flash memory is only rewritable in units of sectors. So even when the file system needs to modify a single bit, a whole sector must be rewritten and every erase cycle wears out the flash cells. The block device below the file system must compensate for the sector rewrite limitation and implement a wear leveling algorithm to enhance the flash cells life cycle. As shown in fig. 3 three different block devices are implemented for the file system. The sd-card version implements an SDIO interface, which outsources the wear leveling to a connected sd-card and makes the internal file system obsolete. The RAM-disk also avoids the usage of the internal flash, but due to its volatile nature, it is unable to hold its content persistently throughout a power outage. Persistent storage is a mandatory feature of the microcomputing node and since an sd-card can fail because of mechanical malfunction and would also increase the formfactor, the internal flash storage is used as block device. Therefore a third block device based on a journaling flash storage (JFS) is implemented. A flash sector has a size of 128 kibibytes and contains 250 blocks of 512 bytes. Flash cells can not be erased from zero to one individually but an individual conversion from one to zero is possible. The JFS uses these individual changes from one to zero to change block states in header bytes and to create new copies of blocks. So when a blocks content must be changed, first a new copy of that block is written into a free space of the sector, containing only ones. Then the new blocks state is set to valid and at last the state of the old version of the block is set to invalid, which can also mean deprecated. When a sector is full, it gets transferred to an available free sector. That is why not all sectors can be used to hold data at once and that is also why at least two separate sectors must be assigned to the JFS. The sector transfer process is implemented in a similar way as the block modification, to ensure that power outages do not corrupt the block devices content. This implementation can be the foundation of a robust journaling file system, like LittleFS [3], [4]. But in the current state the FAT file system is used to be compatible to Windows and Linux based host systems by default. By using FAT within the microcomputing node, it is possible to share the block device with the host system as USB Mass Storage Device (MSC) and to exchange files without the usage of the REPL. A journaling flash storage is necessary to maximize the microcomputing nodes lifespan, even if no journaling file system is used on top of it, because by journaling write operations between flash cells, a wear leveling is accomplished.

VI. Proof of Concept Applications

During its development the microcomputing node was used as a sensor node and as a bus converter unit (BCU) in several research projects. The BCU was e.g. the basis for several subsystems within a test-stand for small electric ducted fans for unmanned aerial vehicles.

Multiple sensors with different hardware interfaces were controlled and sampled by the microcomputing node, which was called BCU within that context. The aggregated data was broadcasted on a CAN bus by each BCU, so that all data could be read out by a workstation via a CAN-USB bridge. All BCUs were supervised and updated from that workstation via CAN bus. The bootloader mentioned above offered a way to update the BCUs firmware and MicroPython scripts were also exchanged via CAN bus. Fig. 4 gives an overview of the test-stands system design.

Four BCUs integrated the sensors using a variety of hardware interfaces. The power supply unit and the load cell were connected via UART. They delivered data for power to thrust ratio measurements. SPI and I²C busses were used for pitot tubes, microphones and three-axes accelerometers to measure air stream velocities and vibrations at different locations. New protocols or interfaces were also implemented during this use case. For example a OneWire interface was

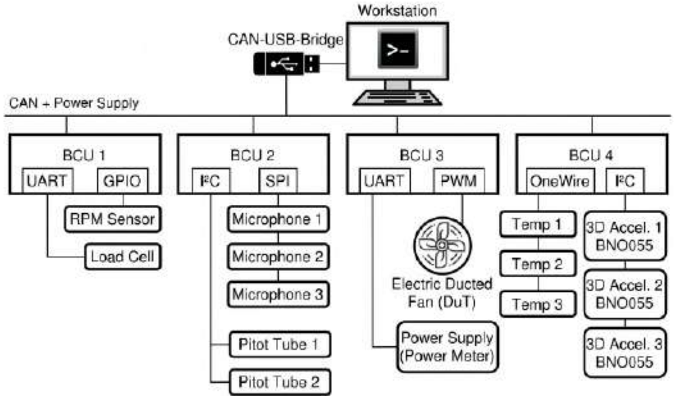

Fig. 4. System design of a test-stand for electric ducted fans for unmanned aerial vehicles. The component that aggregates different sensor data and broadcasts it via CAN bus is based on the presended microcomputing node and is called Bus Converter Unit (BCU) within this project.

added for temperature measurements and a pulse counter was implemented to measure the ducted fans rotational speed. Thus the microcomputing node has proven as convenient and generic sensor node solution for the development of the test-stand.

The microcomputing nodes reliability in terms of the IoT cloud connection was examined with another prototype. It was designed as sensor node, that is mounted on a DIN rail, which is established in industrial applications. The prototype is based on a commercial off the shelf perfboard as shown in fig. 5.

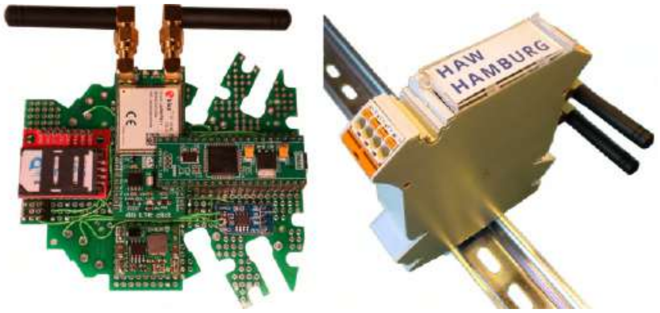

Fig. 5. A prototype focused on industrial IoT applications with 4G connectivity and a small formfactor to be mounted on a DIN rail.

In this approach the microcomputing node offers CAN bus connectivity, REPL interaction via UART and USB-VCP, as well as file system accessability over USB-MSC. A GPIO pin is configurable to interface OneWire sensors, act as 3.3V ADC/DAC or can be used as digital input/output. The focus of this prototype was to create an industry suitable sensor/actor node with 4G connectivity in a small form factor, which can be mounted onto standard DIN rails together with other industrial electronics like PLCs.

Multiple temperature sensors were connected to this prototype using the OneWire interface. It was then integrated as AWS Thing within the two AWS solutions shown in fig. 1 and described in section two. The sensor node successfully passed endurance tests in which it uploaded temperature data to its AWS Thing shadow with an update interval of one minute. It was located in a remote area with poor cellular network coverage and successfully maintained operation based on EDGE network. To harden the microcomputing node against connection losses, the MicroPython based modem driver had to be modified multiple times. This was successfully done over the air via the REPL, without requiring a complete firmware update.

VII. Conclusion

The presented microcomputing node introduces an innovative foundation for IoT sensor/actor nodes based on the established scripting language Python. With its trusted hardware in form of an intergrated smartcard, it offers sufficient security features, based on asymmetric and symmetric encryption. Thus a smartcard is a valid and flexible approach to meet the security requirements of modern IoT applications based on MCUs.

It is capable to interface a wide variety of sensors and actors and integrates these reliably in an IoT cloud solution. Because of the scripting capability the microcomputing node represents an accessible technology to a wide audience of application engineers, who do not need to have deep knowledge in programming constrained embedded systems. This is considered as key advantage of the presented microcomputing node, because experienced embedded system engineers have become an increasingly constrained resource.

Future research must show to what extent it is applicable to switch from classical C/C++ programming to script-based application development in the area of IoT. The presented microcomputing node has proven, that it is possible to solve complex measurement and monitoring tasks by the use of a scripting language on a constraint device according to current status.

An IoT Design Approach to Residential Energy Metering, Billing and Protection

Moses Oluwafemi Onibonoje, *Member, IEEE*
Department of Electrical/Electronics and Computer Engineering
Afe Babalola University
Ado-Ekiti, Nigeria
onibonojemo@abuad.edu.ng

***Abstract*—The fairness of electricity services lies in the provider being able to deliver the expected quality power, and recover the returns on investment. Energy theft, metering lapses, billing errors, and cumbersome payment procedures constitute the bulk of the non-technical power losses and contribute majorly to the incapacity of the electricity vendors to run a profitable business, and serve the customers effectively. A real-time approach has been identified as the innovative need at resolving the enumerated issues within the electricity value chain. This study is leveraging on the Internet of Things (IoT) technology to propose an extended modelled system capable of providing real-time data management, residential power system control, interactive platform for the vendors and consumers. The energy billing was modelled and developed from resourceful components. A website was developed with user-friendly interface. The unique features of the system design are the possibility of customers to load their electricity credit online, and the supplier being able to lock or disconnect any defaulting customer remotely.**

***Keywords*— electricity billing, energy theft, internet-of-things, residential power system, smart metering.**

I. Introduction

Electricity is a commodity with high-valued demand and supply, as it contributes extensively to the economy and better life for both corporate and individual entities. The monitoring and protection of the power devices in homes and facilities are very important. Meanwhile, ensuring that the actual electricity consumed is accurately tariffed is also crucial [1]. The fairness of any service relationship lies in the provider being able to deliver the expected quality service, and recover the invested capital through profitable returns on investment (ROI). The process of monitoring the track of electricity being consumed for verification is presently tedious and non-assuring, as manual meters are employed for data reading and recording. The metering strategy of the customers' facilities has experience various evolutions in recent times [2].

In Nigeria, energy metering by human data collection has been the major practice, until lately that pre-paid metering is gradually being introduced. The process involves human operators visiting the targeted facilities to collect the energy meter readings on a monthly basis, and use the collected to bill the customers. The process has been faulted by many errors associated with human interference and lapses, thereby resulting in consumers being billed on an estimated basis. Also, the pre-paid metering being introduced in batches as the new solution is being reported with cases of energy theft by connection bypass, and credit inconsistency [3]. The energy theft largely results in huge revenue loss by the providers. Energy theft is a major problem that manual, analog, digital and pre-paid meters have been unable to adequately curtail. In analog meters previously introduced, many consumers could slow down the rotation of the device by using the permanent magnet. In a similar way, digital and prepaid meters are being bypassed by consumers aiming at stealing electricity [4], [5]. The electricity theft, billing errors, and the customers payment debts constitute the bulk of the non-technical power losses, and the subsequent revenue losses. These are electricity problems that can therefore, be mitigated by real-time energy monitoring and billing over the internet, innovative technologies and integrated devices and infrastructure [6]. The growing population of electricity consumers [7], and the need to efficiently deliver their required electricity has made the adoption of Internet of Things (IoT) imperative.

The IoT is a brilliantly evolving technology which has integrated the global space with established and intelligent computing. IoT enables interconnectivity among smart devices such as mobile phones and computers, the internet, people and things. IoT has successfully formed a synergistic bond with other evolving technologies such as blockchain and machine learning to build autonomous systems that can communicate with, and control devices and objects necessary for various innovative solutions. The IoT technology has helped to propel the importance of improved electronic devices in the provision of better living condition, and enabling profitable business venturing through cost-effective and timely transactions and business executions. It has birthed attractive ideas for solution provision in various sectors including safety, protections, accounting, entertainment and security [8]–[12].

The IoT technology has been introduced in many other areas of the electricity value chain. The three cardinal sectors of power chain: generation, transmission and distribution have had benefits of integrated IoT technology [13]–[21]. A transition towards a digitized and decentralized mode of energy billing and payment will be a major milestone in ensuring profitable ROI for interested investors. The energy billing system will be efficiently and effectively managed using the IoT. The management will involve such real-time systems that can gather data on electricity connections status, metering, billing, consumer payment, and energy audit. Importantly, the stakeholders at both the supply and demand ends could be integrated into the interfacing platforms of such systems to benefit in the real-time engagements for energy solutions.

The study in [1] is herewith leveraging on IoT to extend the monitoring and protection of residential power systems capability to real-time billing, monitoring, recharge and control. This paper presents an advanced metering, billing and payment system with interactive application interface for consumers and the electricity supplier. The remaining part of the paper is structure as thus. Section II consists of the material and method of the system. Section III contains the results and discussion, while the conclusion is presented in section IV.

II. Methodology

The approach is to advance the IoT model and design to make available a system capable to provide real-time metering, billing, and recharge payment., in addition to the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

monitoring, control and protection of residential power system. The modified system is modelled, hardware and software designed, and then implemented. The system is designed based on the energy consumed on a line within a power supply section.

A. System Model

The energy consumed on a line, j over a period of time interval, t is defined by $e_{j,t}$ as indicated in equation (1).

$$e_{j,t} = P_{j,t}t = I_{j,t}V_{j,t}\cos\theta \qquad (1)$$

where $P_{j,t}$ defines the power consumed on the line within the period.

The tariff mechanism adopted is the progressive pricing technique referred to as the stepwise energy pricing (SEP) [22]. The assumption is that the energy quantity is categorized into n-steps, with each step corresponding to a unit price increase with the step. The monthly clearing price is equal to the sum of product (SOP) of electricity quantity across all the steps and the corresponding price. Considering the SEP schematic as shown in Fig 1, the energy quantity vector across all the steps is given by equation (2) while the unit pricing vector is given by equation (3).

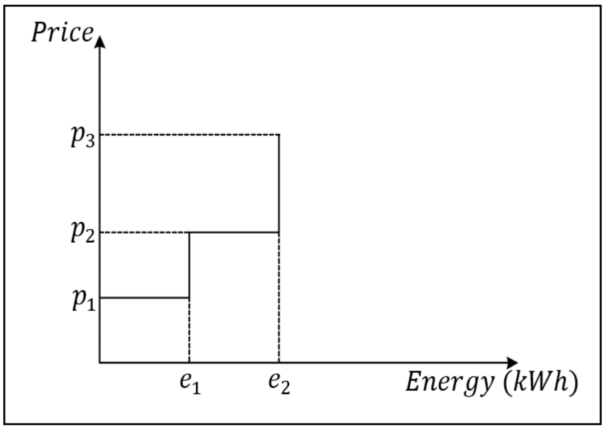

Fig. 1. The schematic of the SEP model

$$e_j = [e_{1,}, e_{2,}, \dots \dots .] \qquad (2)$$

$$p = [p_1, p_2, p_3] \qquad (3)$$

The monthly clearing price, P_c is a function of the price and the quantity of energy usage on a stepwise basis, as expressed by equation (4), where e_T is the total energy usage after the implementation of SEP.

$$P_c = p_1 e_1 + p_2(e_2 - e_1) + p_3(e_T - e_2) \qquad (4)$$

The stepwise tariff model can be optimized to encourage energy efficiency, using the genetic algorithm analysis.

B. Harware Design

The system architecture is as shown in the block diagram of Fig 2. A unique website was designed for the system to connect and interface the smart devices with the internet.

The building blocks of the system include four main units: the sensor module for current, voltage and temperature parameters measurement; the transceiver unit being integrated with the WIFI and GPRS modules for internet connection for the website and the mobile application; the relay unit which performs the make-or-break connection to the end power users; and the Arduino microcontroller which processes the received signal and output control signal to the relay unit. The ACS712 current sensor combined with the LM35 temperature sensor, an input voltage capacity measurement of about 400Vac. The radio frequency XBee 2.4 GHz by Digimesh was the transceiver module integrated with the antenna as shown in the hardware connection of Fig 3.

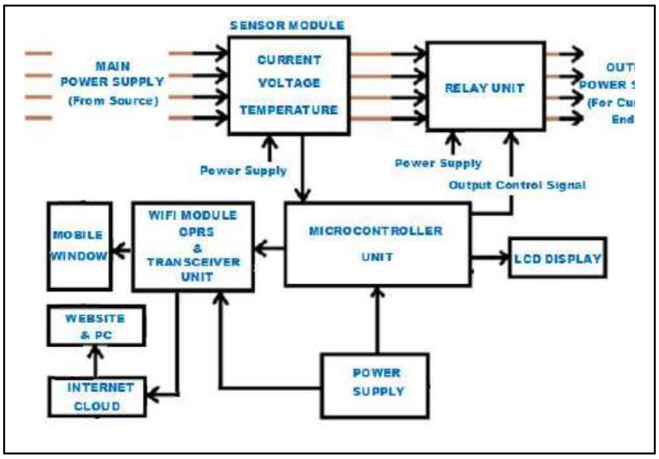

Fig. 2. The system block diagram

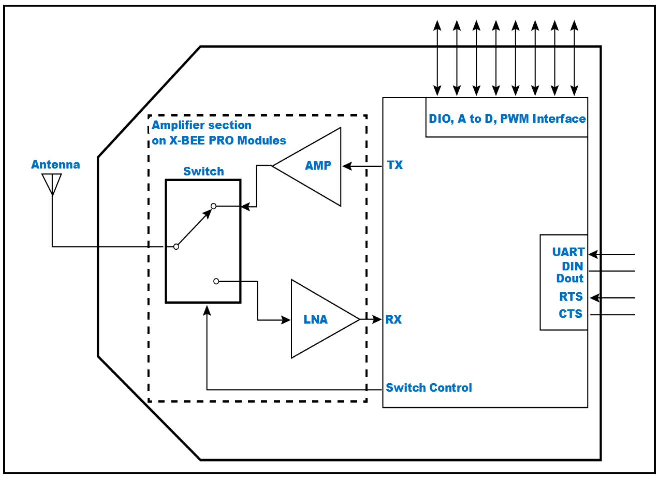

Fig. 3. Internal block diagram of the transceiver module

C. Software Design

The software unit of the system is designed for a two-way communication feature. The main functions include the initialization with the commands over the internet website and to integrate the microcontroller and adjoining electronic units for control. The data for power consumption and the corresponding the billing information are directly transferred to the cloud and available on the website in real-time. The algorithm for the operational details of the system is as shown in Fig 4.

III. Results and Discussion

The resulting system from the implementation of the design, and the operation of the developed user platforms are presented in this section. The hardware components of the IoT based metering system was developed as shown in Fig 5. It consists of an Arduino nano being connected to an integrated transceiver with the WIFI and GPRS module for internet connectivity. Also, there is a four-channel relay section for disconnecting the supply to the end user, while the LCD unit displays all the data in real-time.

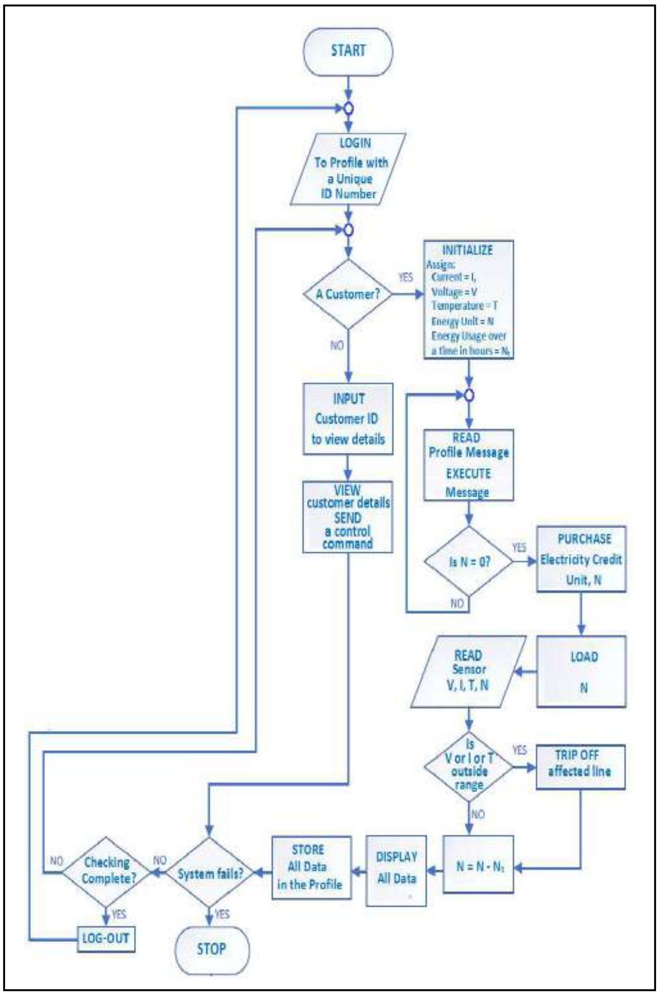

Fig. 4. Flowchart of the system operation

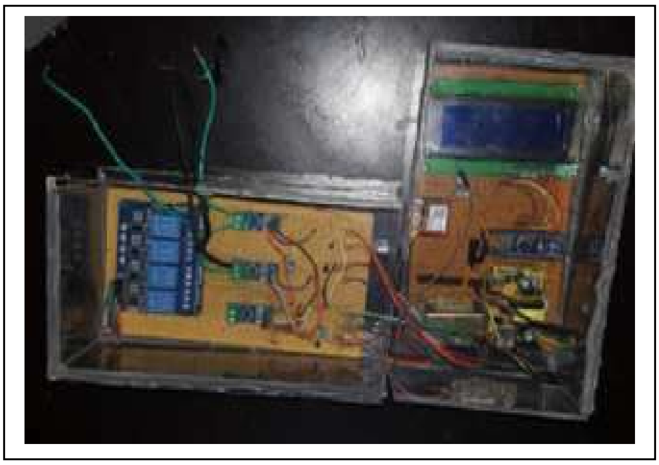

Fig. 5. The developed hardware of the IoT-based metering system

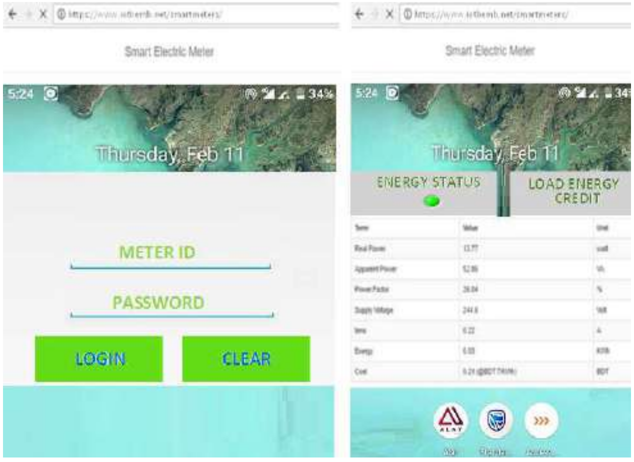
The webpage and mobile application window developed is as shown in Fig 6. The webpage has an easy-to-use interface with good outlook. A user needs a unique identity number (ID) to login and navigate through the page. After profile login, there is an option to select between a customer or supplier. A customer selects accordingly and read the message available in the inbox. If there is no electricity credit, it is indicated, and the he cannot go further unless the system is recharged with credit unit. The system is linked with a payment platform, to be activated, for automated payment.



Term	Value	Unit
Real Power	13.77	watt
Apparent Power	52.86	VA
Power Factor	26.04	%
Supply Voltage	244.8	Volt
Irms	0.22	A
Energy	0.03	KWh
Cost	0.21 (@BDT 7/kWh)	BDT

Fig. 6. The user application interface

The credit unit can be purchased and loaded manually. The sensors readings and the credit unit value are collected and stored. If any of the benchmarked parameters: current, voltage or temperature exceeds the threshold, the affected line is tripped off. All data and notifications are displayed on the LCD, and stored in the customer profile as a message. The supplier representative can also login with a unique ID, view the status of any customer power supply facility to monitor any discrepancies in the energy usage, and sends a control command to disconnect a defaulting customer. There is an automated 3 Kb/s data refreshing of the website every five seconds to allow for data update in real-time. Therefore, the data usage for the refresh is minimal.

IV. Conclusion

In this paper, an Internet of Things (IoT) based energy metering system for residential facilities has been developed. The study has extended and improved the existing work on the real-time monitoring and protection of a residential power system using IoT technology. The various units of the system were implemented on a resourceful-selection basis of the electronic devices. A user-friendly website and mobile application interface were also designed for real-time monitoring, collection of the metering and billing information for both the supplier and the customers with exclusive access codes. Previous methods and approaches adopted in energy metering and billing such as demand side load method, analog meter reading and digital prepaid metering were examined with relative flaws which have, therefore, been addressed with this IoT developed system. The developed IoT-based system is a combination of subsystems as energy meter, billing device, payment platform and residential power system controller. The customer credit is counts down according to electricity unit's usage and automatically logs off whenever the credits exhausted. The unique features of the system design are the possibility of customers to load their electricity credit online, and the supplier being able to lock or disconnect any defaulting customer remotely.

ACKNOWLEDGMENT

The authors gratefully acknowledge the contributions of Ass. Professor N. Nnamdi and Ass. Professor P. Bokoro for their contribution to the earlier part of the work which had been previously published.

qaiser_ijaz@etu.u-bourgogne.fr, ebourenn@u-bourgogne.fr

***Abstract*— The new era of computing is not CPU-centric but enriched with all the heterogeneous computing resources including the reconfigurable fabric. In multi-FPGA architecture, either deployed within a data center or as a standalone model, inter-FPGA communication is crucial. Network-on-chip exhibits a promising performance for the integration of one FPGA. A sustainable communication architecture requires stable performance as the number of applications or users grows. Wireless network-on-chip has the potential to be that communication architecture, as it boasts the same performance capability as wired solutions in addition to its multicast capacities. We conducted an exploratory study to investigate different performance parameters using the Noxim simulator. The preliminary results showed better average delay and network throughput for wireless network-on-chip as compared to the wired counterpart.**

Keywords—Wireless NoC, multi-FPGAs, reconfigurable computing

I. Introduction

Datacenter architectures provide for the need of computing workloads today, that is acceleration for more performance. Datacenters have heterogeneous computing resources, comprising of different processing fabrics that are suitable for a certain set of operations [1]. We have more choices than ever. GPUs offer better parallel performance, more efficient computing, and an easy-to-use programming model. On the other hand, FPGAs bring higher performance-per-watt, improved hardware acceleration, and lower inter-device latency. Assigning the right resource for the right job is mandatory for high performance and maximum utilization at the system level. Enhanced scalability and parallelism increase the possibilities for optimization at the algorithmic level, improved architecture and micro-architecture, and design methods focused on the target platform [2]. FPGAs is a competitive computing resource known for lower power consumption. The lifetime cost of data centers is majorly the cost of electrical power [3]. Therefore, data centers are looking for energy-efficient computing fabric and that opens new horizons in High-Performance Reconfigurable Computing (HRC).

FPGAs have been used to accelerate datacenter services in both academia and industry. The choice of FPGA over GPU in Catapult [4] was driven mainly by power demand. The proprietary search engine of Microsoft achieved a 90x speedup as compared to the software-only solution, at the cost of a 10% increase in power consumption. Sustainable deployment of FPGAs in data centers requires an operating system to be designed in such a way that it can serve multiple users simultaneously. Without this vital virtualization characteristic, the investment would neither be economically feasible nor sustainable. Communication architecture and an operating system to virtualize the reconfigurable fabric in heterogeneous datacenters are two prime challenges to address in this area. We published a comprehensive review [5] of the area last year to direct the scientific community towards the most pressing problems. In this study, we explored the Wireless Network on Chip (WiNoC) to solve the bottleneck communication problem in the context of multi-tenant multi-FPGAs in a datacenter. Please refer to the mentioned review for the detailed context of the problem.

Section II presents the state of the art on multi-FPGA virtualization techniques. Section III presents the theoretical foundation of WiNoC as a potential communication architecture in the given context. Section IV presents the results with an ample discussion on the limitations of this study.

II. Multi-Node Level Virtualization

The nomenclature of the node is being used in the continuity of the previous research that simply means an FPGA. The architecture depends on the organization of FPGAs to the host as illustrated in Fig. 1. In the direct model, nodes directly communicate, while the link represents the interface. In the slave model, the FPGAs are hosted on CPUs via PCIe. This means if FPGA wants to communicate with another FPGA then it must send the data through CPUs and network. In a standalone model, the FPGAs and CPUs are accessible to every node directly through the network. The hybrid models can be attained by combining two models to meet the specific requirements.

Byma and colleagues focused to minimize the virtualization overhead of standard size datacenter that provides commercial cloud services [6]. They managed to attain remarkable performance when compared to regular virtual machines while reducing the iteration time of design. Kondel and his colleagues presented the work on maximizing the utilization of high-end FPGAs by paravirtualization [7]. They provided homogeneous virtualized FPGA regions for multiple users. This accommodating multi-tenancy approach allows the individual resources to embrace the user requirements. Zhang and colleagues implemented an operating system to share the single FPGA chip among multiple users at the run-time along with an upgraded resource manager [8]. These works did not write a detailed account of communication architecture and interfaces. Weerasinghe et al. [9] illustrated a different approach where FPGAs are connected through the datacenter network. This decoupled approach is useful for hyper-scale data centers where FPGA acts as an equal and distinct computing resource. They provided the detailed architecture of the system combined with an analysis on resource estimation, from a scaling perspective. The development of tightly coupled platforms is a recent trend, for example, IMB CAPI and Intel HARP collaborated to yield. The community responded to the call for proposals and since then significant contributions have been made using these platforms.

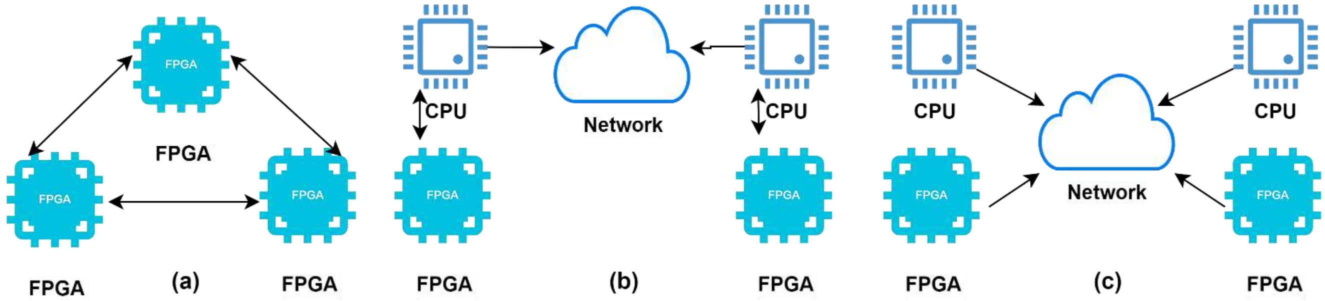

Fig. 1. Possible Arrangement and Connectivity of multiple FPGAs: a) Direct Model; b) Slave Model with PCIe interface; c) Standalone Model

Some recent examples are [10,11]. There are three sub-classes of multi-node virtualization that will be briefly revisited for the readers.

A. Custom Clusters

In parallel computing architecture, the concept of the systolic array model is based on custom clusters, where every node processes the data, and the processed data is moved from one node to another through a first-in-first-out (FIFO) buffer or network semantics. Some of these architectures [12–15] make use of fast series transceivers with FIFO buffers, Peer to Peer (P2P) connection MaxRing, and Peripheral Component Interconnect Express (PCIe) links, to transmit data across several nodes. Customized designs permit direct communication among the nodes through specific network connections. A systolic array model has been exploited by the cluster of 512 FPGAs [16] to distribute and execute the computations on multiple FPGAs. This work is a good representative of a small to medium scale datacenter.

B. Frameworks

Frameworks make use of the conventional server-client architecture, where the computational part is dedicated to one or more FPGAs and the CPU server manages the rest, including application-related data, configuration, and scheduling. The central part of this architecture is data management. Architectures specified for CPU are extendible to FPGAs. For example, the concept of the MapReduce framework has been extended where the mapping and reduction operations are accomplished by FPGA accelerators [17-19] in the same way as in CPU client-server architecture. The advantage of these frameworks is that they helped in overcoming the gap between the heterogeneity of datacenters. An example of such a cluster consisting of FPGAs and GPUs based on MapReduce is [20]. In another work [21], the researchers used the Apache Spark to accommodate the FPGAs by extending the java virtual machine (JVM) framework, however, this requires precision and increases communication overhead.

OpenCL is utilized through the Xilinx SDAccel framework to assign the data to multiple FPGAs by using an abstract layer and managing a transparent directory to virtualize the FPGAs at the lower abstraction level [22]. A few FPGA works [23] discussed an approach where multiple FPGAs can be shared by one group but configured within a setup of a matching accelerator. This approach comes with the drawback of occupying a complete FPGA that results in under-utilization, but it can be improved by the automation of the scaling algorithm. A similar approach has been proposed in [24] based on Hadoop YARN that comes with the advantage of the ease of programming. In a heterogeneous computing environment, the performance relies on a function of execution strategy. To explore the alternative execution strategies in disaggregated environments, a work based on the evaluation platform presented in [25] can be useful.

C. Cloud Service Architectures

Cloud service architectures promise computational correctness and guarantee Quality of Service (QoS) while abstracting the underlying complexity. The user is not concerned about the assigned computational node if the required acceleration or high-performance is delivered. Amazon EC2 F1 instance does not fall under this category but Microsoft's Catapult achieved a substantial speed-up in search ranking. This is a hybrid architecture as it can distribute the acceleration jobs to either of the underlying node, standalone FPGA, or a host CPU. The same performance was achieved by Baidu [26] for deep neural networks. While in [27], the FPGAs have been used as co-processors in complex problems for exploiting the multiple data streams. The architectures with network support broaden the choice of connectivity, which allows the CPU provisioning either as embedded on-chip or as a soft-core. OpenStack is known as the most common method that directly allows the user to program the FPGA through a physical or virtual address [6, 22, 28]. It offers the flexibility to the user for exploiting socket or remote routine approach to establish connectivity with an FPGA.

III. Network on Chip as Communication Backbone

In most high-performance architectures the data transfers are limited due to communication architecture and memory hierarchy, as summarized in [29,30]. The use of NoC and dedicated links in a system with a huge number of processing cores are an effective replacement for buses [31-33]. NoC comprises of multiple tunable parameters like routing algorithm, network architecture, flow control, and network topology. These endless possibilities and given the rich FPGA resources today, System on Chip (SoC) designers prefer to use it as a central communication component. It ensures the high communication bandwidth with low latency as compared to the alternative methods of communication within an FPGA.

A. Basic Architecture

The architecture of the 2D mesh of size 2x2, comprising of four routers is shown in Fig. 2, presenting exposed edge ports, that are unused ports of the corner routers. Each router has five ports, in which the local port is connected to the network interface whereas the rest of the four ports communicate with the neighboring routers or processing elements. A network interface is connected to the core,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

which represents any processing element.

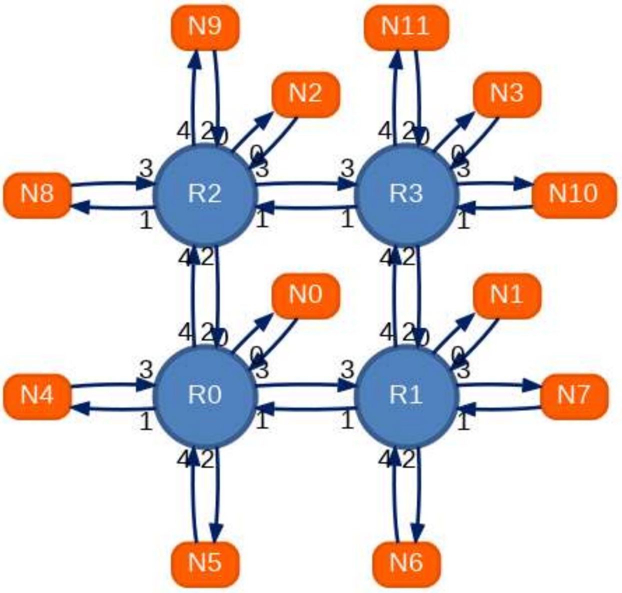

Fig. 2. A typical 2D mesh of size 2x2 with visible ports.

B. Network Layered Model

The layered model is shown in Fig. 3 along with the OSI reference model.

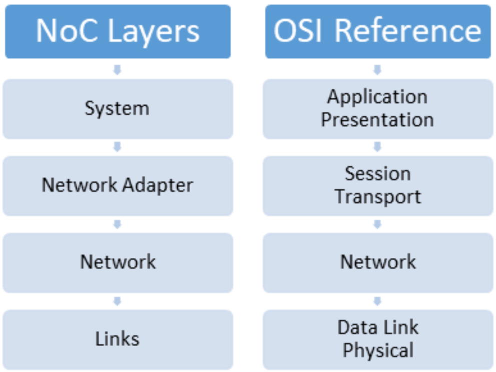

Fig. 3. Network Layered Model

Layered representation of network-on-chip contributes to the better understanding, as the top two layers of the OSI reference model are combined in the system layer. Likewise, session and transport layers correspond to the network adapter layer in NoC and the last two layers of the reference model are represented by links in NoC.

C. Wireless NoC

A case based on wireless network-on-chip was proposed by a scientist in 2012 as a potential backbone for all the multicore and manycore chips [35], another derived architecture using the same source is shown in Fig. 4. The router has a similar architecture but with an addition of a radio hub for wireless communication. The organization is illustrated in Fig. 6. The purpose of a radio hub is to govern the communication, typically single hop, between distant routers [36].

D. Objective

This exploratory study is designed to have a proof of concept of this naïve idea that wireless network-on-chip can enable inter-FPGA communication in the given context. For the comprehensive state of the art and a deeper understating of the context of the problem, readers are invited to refer to our previous published work [37-45]

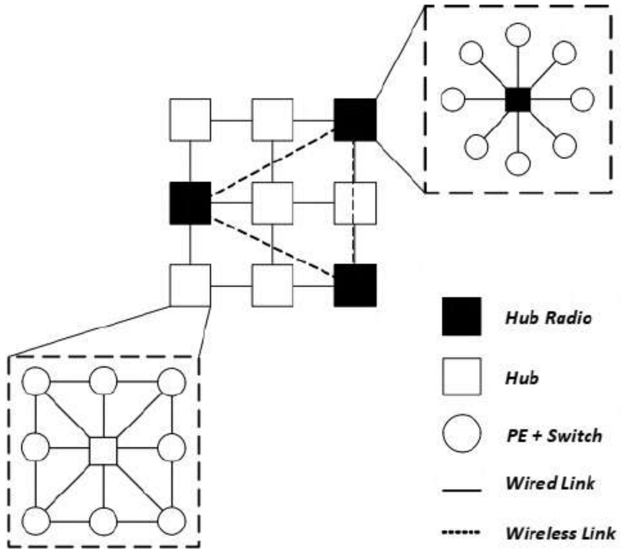

Fig. 4. 2D Mesh of Size 3x3 with Radio Hub

The inquiry-based iterative simulations were designed to establish the outcome. Fig. 5 depicts the basic idea through a concept diagram that we are aiming to achieve for multi-FPGAs in the given context.

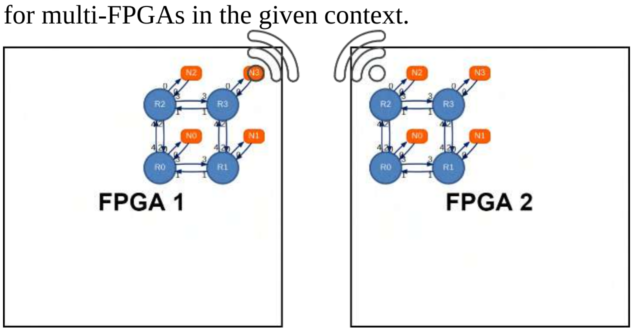

Fig. 5. Depiction of the Basic Idea

E. Choice of NoC Simulator

Simulation provides an early estimation of the decision variables that drive the physical implementation in the future. There are many simulators with a high level of abstraction that offer high code portability but lower efficiency, which we will discuss one by one.

Booksim [46] is a cycle-accurate simulator developed in C++. The first version was not intended for a specific on-chip environment but mostly a generic simulator. Booksim2 provides a wide diversity of topologies, routing algorithms, and several options to customize the micro-architecture of routers to simulate.

DARSIM [47] is a cycle-level, parallel simulator, that allows simulating both 2D and 3D mesh architectures. It provides an advanced set of NoC parameters such as different virtual channel allocation and memory models. One of the strengths of this simulator is the ability of the hardware configuration, such as bandwidth, pipeline depth, and geometry. Besides, it allows to split the tasks between cores equally and achieves cycle-accurate simulations.

Heterogeneous NoC Simulator (HNOCS) [48] is dedicated to heterogeneous NoC architectures and is based on OMNet++. OMNet++ provides C++ APIs to a

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

wide range of services to describe in detail the network topology. It also provides parallelism, various Quality-of-Service (QoS), different arbitrary technologies, and power estimation. It offers three different router types, asynchronous, synchronous, and synchronous virtual output queue, and performance statistics such as throughput, VC acquisition, and transfer latency.

Nigram [49] is a cycle-accurate and discrete event simulator developed in SystemC. It provides various network configuration commands to simulate different NoC architectures such as routing algorithms, topologies, flow control techniques. The simulation statistics include throughput and latency.

Noxim [50] is a low-level, open-source, and cycle-accurate simulator written in C++/SystemC. Noxim provides various configuration parameters such as packet and buffer sizes, packet injection rate, different routing algorithms, traffic distributions, structures, and topologies. In addition to the wired NoC simulation, Noxim also supports Wireless NoC (WiNoC) [51] evaluation and provides power consumption, throughput, and latency as performance analysis. Table 1 summarizes the NoC simulators.

TABLE 1. NOC SIMULATORS SUMMARY

Reference	Simulator	Abstraction Level	Supported Topologies
[46]	BookSim	High	Multiple
[47]	DARSIM	High	All
[48]	HNOCS	High	Mesh
[49]	Nigram	Low	All
[50]	Noxim	Low	Multiple

IV. RESULTS AND DISCUSSION

Table 2 present the evaluation environment with all the fixed and experimental configurations. The evaluation platform was based on 2D mesh platform. To ensure correctness, the simulation was repeated three times. The warmup and simulation times were 1000 and 10000 clock cycles. The routing algorithm was fixed XY as this evaluation of the routing algorithm was not the objective of the study, however, this can be studied separately. Changes in average delay, network throughput, and the total energy were observed under various traffic distributions, random, transpose, shuffle, and butterfly. The use of synthetic traffic is a limitation to address, as it does not necessarily reflect the traffic patterns of a real application. We collated the performance and power analysis for a wireless and wired network-on-chip under similar conditions. We designed the experiment for three different sizes as the network-on-chip will grow as the users or applications increase.

Results are straightforward but we would like to discuss a few trends. Better average delay and network throughput were observed for wireless network-on-chip as compared to the wired counterpart, with an exception for the butterfly traffic distribution and size 16x16, which can be an outlier. Total energy consumption in wireless network-on-chip is higher for obvious reasons, radio hub and wireless transmission that is a function of average wireless utilization, that varies in each simulation iteration. As the size of the network increases, the throughput reaches the same point, which can be seen in the second last column of the table. Although the results look favorable, yet hard to quantify the delay reduction or increase in throughput from this preliminary study due to its limitations, absence of real traffic, and complete system simulation. Recent research [52], however, has reported a 45% of delay reduction with real traffic and system simulation.

V. CONCLUSION

Sustainable deployment of FPGAs in the data center requires multi-tenancy and a dynamically scalable communication architecture. Dynamically growing network-on-chip showed significant performance. Given the context, the choice of wireless network-on-chip as an inter-FPGA communication backbone has been explored under certain configurations using Noxim simulator. The observed preliminary results showed better average delay and network throughput for wireless network-on-chip as compared to the wired counterpart. The results are however limited by simulator used, synthetic traffic patterns, absence of system-level simulation, and lack of support for heterogeneity. Further investigations and performance comparisons with reference to benchmarks are required to draw any concrete conclusion.

TABLE 2. UNCHANGED AND EXPLORATORY CONFIGURATIONS WITH RESULTS FOR DIFFERENT TRAFFIC DISTRIBUTION AND SIZES

Unchanged Configurations:
Topology = 2D Mesh
Routing Algorithm = XY
Warm Up Time = 1000 cycles
Simulation Time = 10000 cycles

***Abstract*— Online learning environments are vulnerable to disruption due to the present state of Wi-Fi security on the common at-home router. Current WPA2-protected devices are susceptible to a type of attack that uses disassociation and deauthentication packets to remove all connected users and prevent new users from connecting to the target access point. This paper seeks to display an example of this attack in the context of online learning environments, showing the disruptive potential of this vulnerability and the impact it could have on online instruction. We begin with target discovery and information gathering, then move on to executing the attack while an instructor and several students are connected to various video conferencing platforms. We conclude by discussing potential mitigation and prevention strategies, such as using protected management frames and upgrading to WPA3 when possible.**

***Keywords—component, formatting, style, styling, insert** (key words)*

I. Introduction

The COVID-19 pandemic forced millions of teachers and students to quickly convert to online meetings for education, such as Zoom, Google Meet, and Microsoft Teams. As these videoconferencing platforms became more heavily used for educational meetings, the vulnerabilities of these online meeting platforms became increasingly visible. When discussing vulnerabilities of this new wave of online learning, one may consider the online conferencing application Zoom, who's user count jumped from approximately 10 million users per day in December of 2019 to over 200 million [1]. Among these users was a church group in California whose bible study session was intruded on by a user showing child pornography [1] [2]. Such attacks can play out in a variety of ways, such as a similar attack on instructional meetings for students.

While attacks can target vulnerabilities in the platforms themselves, the vulnerability discussed in this paper focuses on issues with connection to the internet itself. Specifically, modern routers that are using WPA2 encryption are vulnerable to disassociation attacks that prevent all wireless access to the internet for as long as the attack persists. Though various means of launching disassociation attacks are available, we will use the Aircrack-ng suite (a set of tools used for testing Wi-Fi security) to gather information about the target router and MDK3 (a tool used for exploring 802.11 vulnerabilities) to launch our disassociation attack. Our goal is to remove the instructor from the online meeting environment in Zoom, Google Meet, and Microsoft Teams, thus effectively disrupting the online learning experience.

II. Background

Wi-Fi Protected Access 2 (WPA2) was introduced in 2006 as a security enhancement to the pre-existing WPA. WPA was intended to be compatible with devices that used WEP so that businesses and individuals would not need to purchase new hardware to accommodate this security update; however, this also meant that some of the same vulnerabilities present in WEP also appear in WPA [3]. WPA2 utilizes pre-shared keys and implements the National Institute of Standards and Technology's Advanced Encryption Standard. Access points using WPA2 have two options available to users: WPA2-Personal and WPA2-Enterprise. WPA2-Personal uses a key exchange between the user and the access point while WPA2-Enterprise utilizes a server to grant access to users. Though considered highly secure against unauthorized users, several vulnerabilities have been discovered since WPA2's deployment, such as the KRACK exploit and disassociation/deauthentication attacks [4]. Some of these vulnerabilities have been patched; however, disassociation/deauthentication attacks remain a threat to WPA2 devices that do not use protected management frames.

When discussing wireless access points and their vulnerabilities, the terms disassociation and deauthentication are frequently found. The two antonyms, association and authentication, must be somewhat understood to grasp attacks that leverage such vulnerabilities. Authentication occurs at the beginning of the access process. This is the stage in which a device that wants to connect to the wireless network must supply valid credentials to the access point. After a device is authenticated for access to the network it is recorded to the access point for frame delivery and gains full access to the network [5]. This is known as association.

The term "hacking" has long been a buzzword in cybersecurity and generally evokes thoughts of cybercriminals, intrusions, and stolen data. While there is no shortage of malicious users on the internet, they do not comprise the entirety of the hacking community; in fact, there are those who dedicate their proficiency with computers to benefiting the system that they hack. In its purest form, this is known as ethical hacking. Three main types of hackers are generally defined in the computing world: Blackhat, Greyhat, and Whitehat hackers. The principle separation amongst these three groups is the drive and intent for hacking. Blackhat hackers are cybercriminals who employ malicious program writing and exploitation of security holes for their own benefit. They gain illegitimate access to systems and cause harm to people and property. Greyhat hackers operate in the area between Whitehat and Blackhat hacking, using their skills to find issues and security holes, but not always using this position for their own gain. This group may contain curious but non-malicious users that want to explore their capabilities and individuals who want to benefit from finding issues themselves rather than from gathering sensitive information. For example, these users may ask for payment from a target in exchange for fixing the hole that they found and threaten to publish the issue if not compensated. Finally, Whitehat hackers are motivated by improving security through hacking. They obtain permission from a network administrator (or other relevant figures) to test security and report on issues found. These hackers are also known as ethical hackers.

Penetration testing is a vital element of any serious network security plan. To protect a system from intruders, one must think and act as an intruder. A Whitehat or Greyhat hacker may be employed by a business or an individual to attempt to breach a network in some pre-agreed upon way. This gives the employer a third-party perspective on their security measures. In this scenario, Whitehat penetration testing methods will mirror those of Blackhat hackers. The attack itself may have been discussed previously to target a specific subsystem in a business or home or may have been left more general to allow for a wider range of intrusion attempts to test for preparedness. The key to ethical hacking and penetration testing is legality and consent. Though the attack may be disruptive, the impact of the attack should be controlled and should not pose a serious threat to data integrity or confidentiality. Penetration testing is a form of ethical hacking and seeks to better the security of a given system.

III. Literature Review

Aung and Thant [6] seek to educate the reader on a variety of Wi-Fi attacks, focusing on general methods and attack techniques and listing specific examples later in the paper. The authors concisely explain an array of attack types, such as deauthentication, disassociation, dictionary attacks, etc. and their requirements (some attacks only work on WEP, for example). In addition, Aung and Thant discuss defenses for these attacks and list general tactics for detecting intruders and preventing unauthorized tampering. Finally, Aung and Thant set up a testing environment and use Aircrack-ng to execute each of the attacks described in their paper. Aung and Thant conclude by restating the importance of implementing and maintaining solid security methods in wireless networks.

Kristiyanto and Ernastuti [7] aim to test wireless security and how vulnerabilities to deauthentication attacks in Wi-Fi networks can put IoT devices at risk. They note that IoT is a growing quickly in the modern world and with this comes growing security concerns for the safety of IoT devices, in particular those devices that individuals may trust with their privacy and safety (i.e. autonomous cars, home security cameras, home alarms, etc.). Kristiyanto and Ernastuti establish a testing environment and use penetration testing tools to attempt a deauthentication attack on the test network, starting with no inside knowledge of the network. Kristiyanto and Ernastuti find success with their attack and conclude that the IEEE 802.11 frame management methods need to be updated for a long-term solution. For a short-term mitigation strategy, Kristiyanto and Ernastuti suggest APs to hold more than one MAC address to advertise in the event of an attack.

Until recently, WPA2 was the standard Wi-Fi security measure in many wireless access points. Lounis and Zulkernine [8]begin by introducing WPA3 as the next generation in the line of Wi-Fi security. WPA3 features added security measures to be more secure than its predecessor WPA2. Lounis and Zulkernine, however, identify a vulnerability in WPA3 and seek to exploit it. In their work, they show that while a legitimate user attempts to access the network an attacker can flood a WPA3 access point with messages that indicate that the legitimate user is entering the wrong password, thus preventing that user from accessing the network and effectively denying service to any target users. Lounis and Zulkernine conclude by stating WPA3 access points should implement a feature that examines authentication requests with more care by not seeking to reply as soon as a message is received; rather, the access point should respond based on a group of collected requests. If one message contains the correct authentication parameters, then that user should be allowed to proceed. This would likely need to be coupled with other measures to prevent unauthorized access. Lounis and Zulkernine show that despite the increased security provided by WPA3, attacks are still feasible.

As IoT devices become more prevalent in modern society, the security of these devices becomes a greater concern. Where once a few extra Internet-enabled may be sprinkled around a home, now we begin to see important items such as security cameras and alarms become Internet and Wi-Fi dependent. Raghuprasad et al. [9] seek to educate about attack methods (such as DoS and Man-in-the-Middle) and defense strategies for common IoT devices. They establish a small testing network consisting of a temperature/humidity sensor, a personal hotspot with internet connection, and a cloud device. It is then demonstrated that the data stream from the sensor cannot reach the hotspot when the attacker launches their DoS attack, which is launched with the help of aireplay-ng. To conclude, Raghuprasad et al. implement a “MAC changer” to their proposed system, thus preventing similar attacks (that require a machine’s MAC address) in the future.

Wireless jamming has become a greater issue as wireless technologies have spread throughout our society. Grover [10] seeks to educate the reader on three main topics: types of jamming devices and techniques, how to find an active jamming device within a network, and methods for detection and response to a jamming scenario. Grover lists an impressive number of jamming tools, categories, and types within this paper and gives summaries of each jamming method covered. Continuing this trend, Grover lists several methods for localizing jamming devices within a network and states that jamming localization methods generally fall into two categories: range-based and range-free. Finally, Grover explains detection and response methods for jamming attacks by listing fifteen methods and tools for identifying and neutralizing a jamming attack.

IV. Methods

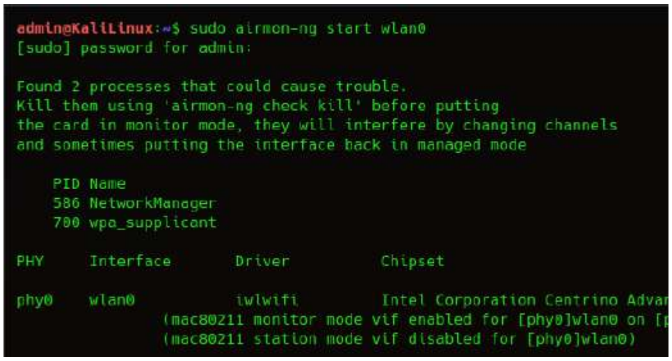
We set up a testing environment with a host connected to the target router and multiple guests operating on other networks (see Table 1 at the end of this section). The host will act as the instructor and will invite the guests to sessions on Zoom, Google Meet, and Microsoft Teams. Our goal is to disconnect the host from these meetings, thus successfully interrupting our established online learning environments. Our attack will occur in two parts. First, we discover information about the target network, specifically the router's MAC address and the channels it is broadcasting on. We then execute our attack using MDK3 on a Kali Linux machine.

A. Target Discovery

For target discovery and information gathering we will use the Aircrack-ng suite, a collection of tools used to test Wi-Fi security [11]. Once we are withing range of the target router, we place our Kali Linux machine into monitor mode using the following command:

```
sudo airmon-ng start wlan0
```

This will change our interface from *wlan0* to *wlan0mon* and allows our wireless NIC to capture data packets from all surrounding wireless access points (see Figure 1).



```
admin@KaliLinux:~$ sudo airmon-ng start wlan0
[sudo] password for admin:

Found 2 processes that could cause trouble.
Kill them using 'airmon-ng check kill' before putting
the card in monitor mode, they will interfere by changing channels
and sometimes putting the interface back in managed mode

    PID Name
    586 NetworkManager
    700 wpa_supplicant

PHY     Interface       Driver          Chipset

phy0    wlan0           iwlwifi         Intel Corporation Centrino Advar
                (mac80211 monitor mode vif enabled for [phy0]wlan0 on [p
                (mac80211 station mode vif disabled for [phy0]wlan0)
```

Figure 1 - Airmon-ng start. This command places our wireless NIC into monitor mode, allowing us to capture beacons from access points

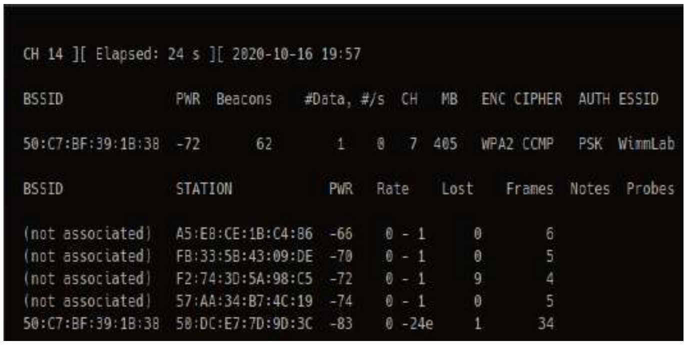
Using a separate terminal window, we activate airodump-ng (a tool provided within the Aircrack-ng suite to capture 802.11 packets from targeted access points [12]) so that all the data captured is displayed to us using the following command:

```
sudo airodump-ng wlan0mon
```

In a decently busy area this can yield a large list of available networks and will constantly be changing and reordering itself. To combat this, we will use the ESSID of the target network to narrow the search. This should make the information more manageable.

```
sudo airodump-ng --essid WimmLab wlan0mon
```

We are now able to concentrate on our target AP and gather the MAC address and the channels that the WimmLab router is broadcasting on (see Figure 2).



```
CH 14 ][ Elapsed: 24 s ][ 2020-10-16 19:57

```

Figure 2 - Our airodump-ng screen, showing information for surrounding access points. In this case, we have focused our search on routers with the ESSID of WimmLab

Having recorded this information, we are ready to move on to attacking our target.

B. Jamming Attack with MDK3

Wireless jamming is a broad term used to describe intentional disruption of wireless communication [10]. This can be accomplished in a variety of ways, from utilizing a device that emits radio waves to counter the target frequency to flooding a router with packets to the degree that it cannot process the legitimate user traffic. In this usage example, we will flood a target router with deauthentication packets to remove all connected users and keep any other users from joining.

We now open another terminal window and enter the following command:

```
sudo mdk3 wlan0mon d -c 1 -b Desktop/black.txt
```

This command will utilize MDK3, a tool created to test 802.11 networks for common vulnerabilities [13]. We use MDK3's deauthentication attack (*d*) and specify channel 1 (*-c 1*) and look to the text file titled "black.txt" for the MAC address to target (*-b Desktop/black.txt*). This feature of MDK3 reads a list of MAC addresses on a text file and can either blacklist or whitelist those addresses (in the case of whitelisting, MDK3 would target all addresses except those specified). In our case, we seek to target one specific address and jam the traffic from the router.

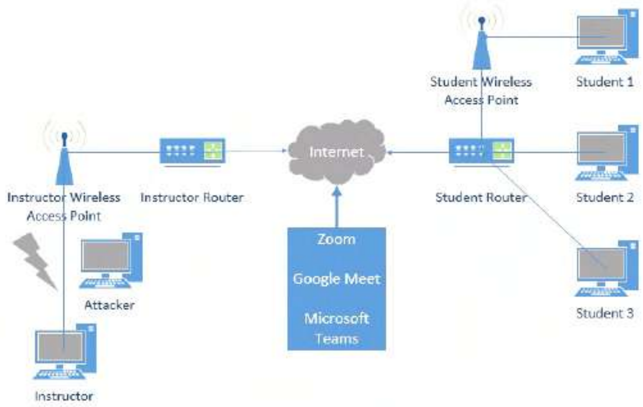

Table 1 - Test network diagram

V. Results

Within 10-20 seconds of executing the attack the host is removed from the meetings and is given some form of a "Trying to connect" message by the platform in question (see Figures 3 - 8). As the router is being jammed, all wireless access to the internet is also prevented until either the attack is cancelled by the attacker or the user switches to an unaffected router. It should be noted that this attack does not impact wired traffic from the target router.

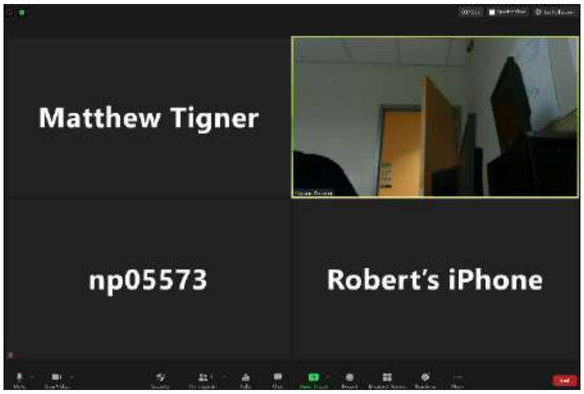

Figure 3 – Student view of a Zoom meeting with several colleagues

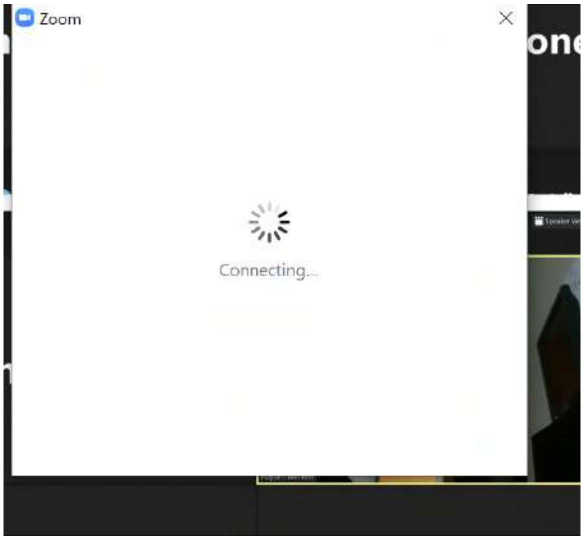

Connecting...

Figure 4 - The host is disconnected from the meeting

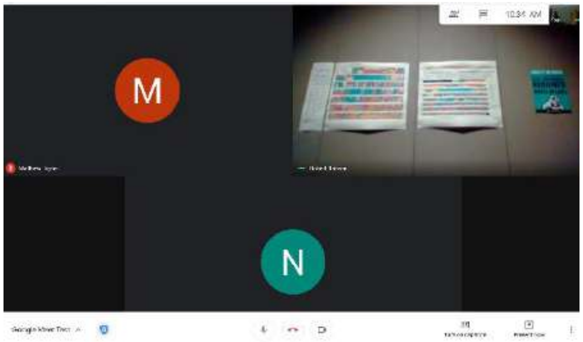

Figure 5 - Google Meet session with colleagues

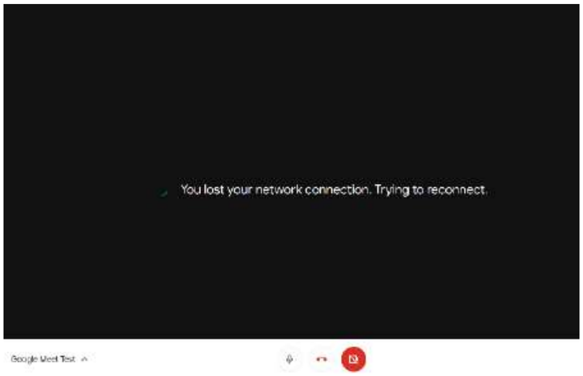

You lost your network connection. Trying to reconnect.

Figure 6 – Host's connection severed after attack is launched

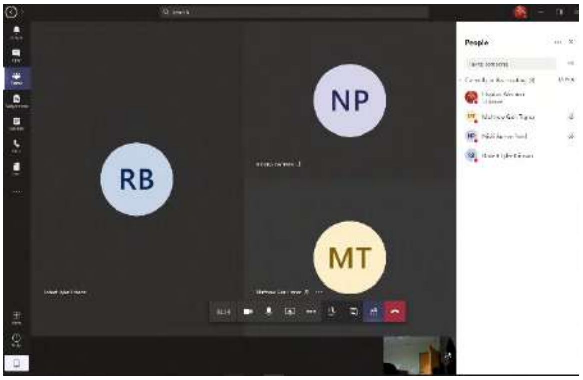

Figure 7 - A Microsoft Teams meeting is in progress with multiple colleagues

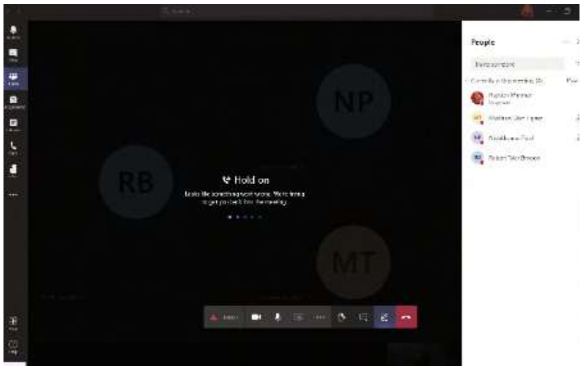

Hold on

Figure 8 - Host is successfully disconnected from MS Team meeting. In this case, the effect was immediate

VI. Implications and Defense

With online learning becoming so prevalent during the COVID-19 pandemic, attackers find themselves rich with opportunities to negatively impact online instruction. The immediate implication of this research is that malicious users could easily interfere with online learning environments if they are within range of a target, which could be a student or an instructor. Worth restating are the facts that an attacker needs no private information about the target router and only needs to be in range of the router to launch the attack. A hacker could easily park outside the home of an instructor and, using the methods described above, could completely halt all of that instructor's classes. Furthermore, it can be assumed that IoT devices in the home that rely on wireless connections are vulnerable to this attack. This creates potential for attackers to inhibit security devices around the home, thus posing a risk for harm to people and/or property.

There are several methods available to help to counteract this threat. Implementation of Intrusion Detection Systems (IDS) such as Kismet will help to mitigate an attack by notifying the victim once the system notices unusual traffic. This would be useful as a victim could immediately tell if their failed connection was due to network performance issues or if it was malicious. Beyond detection methods, the use of protected management frames in compatible devices will hinder this attack as packet forging is prevented, meaning that an attacker could no longer flood the router with disassociation packets [14]. The next generation of Wi-Fi Protected Access, WPA3, will require these management frames on its network [15]. Therefore, this attack vector should become obsolete on devices using WPA3. Additionally, the use of a wired connection would also secure this attack vector, as disassociation/deauthentication packets only apply to wireless communication.

VII. Conclusion

Using the Aircrack-ng suite and MDK3, we successfully gathered enough information to launch a disassociation attack against an instructor's router, successfully removing the host from the educational instruction sessions on Zoom, Google Meet, and Microsoft Teams. This effectively halts the educational environment as students would be left without an instructor, severely hindering their education in the event of a persistent attacker that repeatedly targets the same instructor. Familiarizing one's self with the current industry standards for Wi-Fi security and diligently upgrading all related devices can reduce the risk of victimization from this attack, resulting in safer and more secure environments for education and learning.

***Abstract*—The main challenges related to water affect human settlements' sustainability: the lack of access to safe and clean water at all times. These problems have massive consequences on human health, safety, economic growth, and development. Rujban city faces this crisis despite more than five decades trying to resolve this problem. In this paper, we describe the existing water supply system, which consists of three main components: Karthoom Automated Control System (KACS), Idref Automated Control System 1 (IACS1), and Idref Automated Control System 2 (IACS2). We propose the control system design of the KACS to meet the city's demand and keep the collecting tank with an acceptable level of water continuously. This paper presents the Karthoom Automatic Control System (KACS) design to control the water supply system using the Programmable Logic Controller (PLC). PLC controller is a central part of the proposed automatic control system due to its reliability and ease of installing and maintenance. Besides, we use PLC to carry out the water level control, sequencing, monitoring, display, and control functions, such as logic, sequence, timing, counting, and arithmetic logic. To maintain an appropriate water level in the collecting tank, we control the operation of the feeding submersible pumps ("on" or "off") by sensing the collecting tank's water levels. This is accomplished by utilizing four-stage-level sensors, seven water flow sensors, and an RF transmitter/receiver to monitor and control all pumps' operations and protect them from dry running and then accomplish the sensing stage. We introduce the control system components, the operation flow chart, and the proposed system's implementation. Finally, we implemented and conducted a simulation experiment using the Siemens S7-200 PLC to control the overall water supply system and evaluate the proposed control approach's performance.**

***Index Terms*—An automatic control system, Programmable Logic Controller (PLC), Siemens S7-200 PLC, water flow sensors, submersible pumps, Wireless communication network.**

I. Introduction

Despite a sufficient number of deep wells and a reservoir for collecting water in the Karthoom area, the lack of water availability is considered a problem that is elevating and rising, especially with the population's growth in the city. To develop root solutions for these obstacles which led to the lack of water supply in the Rujban town, we propose a design of an automatic control system to control water flow from seven wells located in the Karthoom area water level in the local collecting tank. The water level in the tank was measured using the sensors. Four different water levels were considered, we then decided which submersible pump must turn "on" accordingly by sending an "on" signal wirelessly to the target pump(s). The system also prioritizes which of the pumps must be operated based on each pump's number of working hours. The lifetime of each pump is maintained in which each of them has to run periodically. Besides, the flow of water from the operating wells was monitored using a flow sensor for each well while protecting the submersible pumps from dry running by sending an "off" signal through a wireless link to the target pump to turn it off.

PLC controllers are usually a central part of many automatic control systems in the industry due to their reliability and ease of installing and maintenance. PLCs are used for the internal storage of instructions to carry out control functions, such as logic, sequence, timing, counting, and arithmetic. They are also widely used to monitor and control plants or equipment in industries such as oil and gas refining, water and waste control, energy, transportation, etc.

The KACS system is located in harsh desert environments that can damage any cabling. The long distances between the wells' locations and the collecting tank lead to higher installation and maintenance costs due to low scalability and connectors' high failure rate. These reasons have inspired us to use advanced wireless technologies as appropriate solutions to these problems and reduce the installation cost of the KACS system, which is distributed over a vast land area. Moreover, the system will display each pump's operational status (Run or Stop) and the water level in the collecting tank.

The PLC controller will run or stop any pump by sending RF signals "on" or "off" signal" via a transmitter. The transmitter can send the RF signal to seven different receivers with Omni-directional antennae. The receiver at the other end can receive signals sent by the transmitter, which are only specified for it by a specific unique code that uses ZigBee technology.

There are two main contextual areas of focus and problem studying: wireless networks (WSN) and control systems. At the same time, the previous paper's primary focus is on WSN [19, 14], Crucial consideration needs to be given to other areas. There are many existing technologies and various approaches in WSN regarding outdoor applications, but we depend mostly on the reference (book) and radio mobile information. In [3],

978-1-6654-4067-7/21/31.00 ©2021 *IEEE*

a smart wireless technology designed and developed using a microcontroller for various crops with irrigation systems. The authors of this work use the Zigbee wireless control system to create an intelligent irrigation system that provides an efficient water supply for use by humans and agriculture, which is crucial to reduce water use and reduce the workforce needed for irrigation. The concept of water level monitoring and management introduced by [16]. This paper presented water level monitoring and management within the context of water's electrical conductivity. This paper also proposed a web and cellular-based monitoring service protocol to determine and sense water levels globally. The researchers in [17] analyzed the existing oil pumping system and discovered that it has a high power-consuming process and should entail more manual power. They proposed a sensor network-based intelligent control system for saving power and efficient monitoring of oil wells' health. If any abnormality is detected in the oil well data sensing, the maintenance manager is notified through an SMS via GSM. This system allows oil wells to be monitored from remote places. In [7], designed an approach to help people living in multi-storied buildings that face inconvenience when there is a shortage of water in the tank. This system automatically pumps water from the reservoir to the tank whenever the water level decreases. The water level is checked using a ping sensor connected to a micro stamp controller to switch on the pump as soon as it is empty. Automatic irrigation to the plants is provided by [8], which helps in saving money and water. An 8051 microcontroller was used to control the entire system. The proposed controller is programmed as giving the interrupt signal to the sprinkler. The solar-powered water pump controller was designed and deployed remotely by [12] to detect the tank's water levels and pumping the water from a remote source such as a pond or well when required. For more details on wireless communication, vision, and technical challenges, see [13], and [4] and their reference in which described the current wireless systems and emerging systems and standards. The gap between these systems and the vision for future wireless applications indicates that much work remains to be done to make this vision a reality. In [5] a low-cost solution to apply fuzzy logic control for a water level control system using an Arduino was proposed. It also gives a low-cost hardware solution and a practical procedure for system identification and control. A prototype system for artificial control and monitoring was implemented by [1] using IoTs, two control systems were introduced: classical PID (Proportional Integral Derivative) and fuzzy logic with a comparison between them. For more information about designing an implementation of water systems' control using some existing techniques raised in the literature, see [10, 18, 9, 2], and their cited references.

This paper proposes a control mechanism to control Rujban's water supply system using the Siemens S7-200 PLC. We present several distinct contributions:

- First, we described the existing water supply system and its components.
- Second, we proposed the control system's main components in more detail, including the PLC controller, the water tank, water level/flow sensors, transmitter/receiver stations, and auxiliary components.
- Third, we proposed the Karthoom Automatic Control System (KACS) design to control the water supply system using the Programmable Logic Controller (PLC).
- Finally, we implemented a simulation experiment using the Siemens S7-200 PLC to control and evaluate the proposed control system for the overall water supply system.
- This paper's primary goals:
  1) Reducing energy consumption.
  2) Eliminating water wastage.
  3) Providing continuous water flow.
  4) Maintaining the service life of the pumps.
  5) Reducing the labor power of maintenance.
  6) Ensuring the city's necessary daily water usage.

The paper's organization as follows: In Section II, we define the problem statement. Section III describes the existing water supply system, which consists of three main components: Karthoom Automated Control System (KACS), Idref Automated Control System 1 (IACS1), and Idref Automated Control System 2 (IACS2). In Section IV, we propose the control system's main components in more detail, including the PLC controller, the water tank, water level sensors, water flow sensors, transmitter/receiver stations, and auxiliary components. The implementation and experimental simulation results are conducted in Section V using the Siemens S7-200 PLC to control the overall water supply system and evaluate the proposed control approach's performance.

II. Problem Statement

To fully understand the water dilemma and its infrastructure and history in Rujban, you could review previous papers [15, 19]. The whole water providing system of the Rujban city can be divided into three subsystems, and each subsystem is divided into two parts, a wireless communication network and an automatic control system, as follows:

1) Pumping water from the producing wells into the collecting tank in the Karthoom area: There are seven wells currently producing water and connected to the karthoom collecting tank. The KACS is divided into wireless communication network part [15], and the automatic control system, which is the subject of this paper.
2) Pumping water from Karthoom collecting tank using big centrifugal pumps to the collecting tank located in the Rujban center. The wireless communication network part is studied in the previous paper [15, 19], and the automatic control system is addressed in this paper.
3) Pumping water from the Rujban center collecting tank to the upper distribution tanks and water providing management ”IACS2” will be another future research.

After conducting a thorough study on the Karthoom water operation and management dilemma, we discovered the following:

- Manual operation of submersible pumps for wells and their remoteness from the central station where the distance is sometimes greater than 3 kilometers.
- Lack of high-level water monitoring in the collecting tank.
- Lack of means of transportation and difficulty in moving from the station to wells.
- Power cuts from time to time and the consequent stop of water pumping and being obliged to operate it.
- Lack of knowledge of water interruption.
- High labor prices. The primary motivation for conducting this study and suggesting possible economic solutions is to solve this problem and promote the city, especially since the bulk of the expenses necessary to provide water for residential communities have been paid. One of those costs is the big modern water distribution network, which cost 16 million Libyan dinars for all city districts.

III. Design and Development

In this section, we divide this KACS system into two parts. The first part is related to the control process, which is the subject of this paper. The other is related to wireless communication, and it is addressed in our previous research. The block diagram of the KACS is shown in Fig. 1.

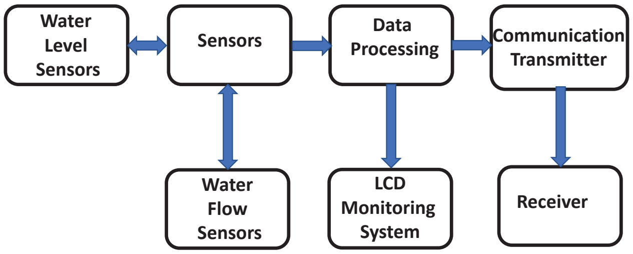

Figure 1. Block diagram of the KACS.

The water pumping process is controlled according to the tank's water level measured by the four-level sensors. Thus, the process control mode is on/off control. In this process, the on/off controller turns pumps ”on” when the water level is measured at its minimum value. And turns the pumps ”off” when the water level reaches its maximum value. The system block diagram, designed according to environmental conditions and the desired process control.

The water pumping process from the seven water wells to the collecting tank at the Karthoom area requires water level monitoring in the tank to avoid flooding and wastage of water or completely drain the water tank. Furthermore, the daily travel from and to the remote wells located away from the collecting tank, as shown in Fig. 2, could keep a worker busy without maintenance. The low efficiency of this type of system prompted Rujban city to install an automatic control system. The control system will enable water level monitoring and distribution from a central location, reduce overall operating costs, and maintain a running water distribution system. The proposed control system can gather data, monitor, and control remote pumps from a central location at the Karthoom area. The control process consists of monitoring the collecting tank's level and accordingly controlling the seven submersible pumps' operation and the two centrifugal pumps. The centrifugal pumps are used to pump water from the collecting tank to the Rujban city center's assembly tank. The PLC controller checks the tank's water level using four-level sensors (i.e., very Low, Low, High, and Very High water levels). These four-level values are inputs to the PLC controller, which starts and stops the submersible pumps based on the measured water level (this will be discussed in more details in Section IV). The digital inputs of the PLC controller will also include seven water flow sensors, one for each pipe that connected the well with the collecting tank and two push button to start/stop the two centrifugal pumps, and another push button to be used in the case of an emergency shutdown to disable the PLC control system or to change the control process to a manual mode. The PLC controller will send the control signals to remote far away, from 1.8 to 3.2 km, pumps via an RF modem. One transmitter unit is located on the collecting tank's side, connected to the central PLC controller, and shares a base code for initializing registers for the communication protocol (txrx.c) [12]. A receiver stations at each well, which will receive an ”on/off signals” sent by the PLC via the transmitter end. The site layout is shown in Fig. 2.

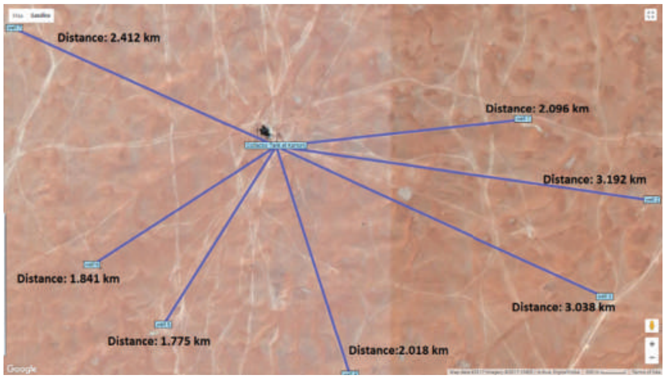

Figure 2. Wireless links layout

The main goal is to develop an automatic control system to control the collecting tank's water level using a PLC controller. The following are the objectives that need to be achieved; these objectives will act as a guide and will restrict the system to be implemented for certain situations:

1) To check the water level in the tank: the PLC controller will respond based on the detected water level and run the well pumps accordingly:
   - If the tank's water level is high high (>= 98%), an alarm will be generated, and the labor has to convert to manual process to turn off all submersible pumps and may turn ”on” centrifugal pumps.

- If the tank's water level is very high ($>= 95\%$), all submersible pumps must be turned "off" and may centrifugal pumps turned "on".
- If the water level in the tank is high ($>= 80\%$), two out of the seven submersible pumps will continue in an "on" situation.
- If the water level in the tank is low ($>= 60\%$), the PLC controller will turn "on" four pumps.
- If the tank's water level is very low ($>= 10\%$), all seven water pumps will be turned on, and the centrifugal pumps will be stopped to protect the motor from dry running.
- If the tank's water level is low low ($<= 8\%$), an alarm will be generated and the labor has to convert the control system to a manual process to turn on all submersible pumps and turn "off" centrifugal pumps.

2) If the PLC controller detects no water flow from any particular running pump, the corresponding pump will be turned off after a specific time.
3) The PLC controller code will be written using the Ladder diagram language: the code is implemented and simulated using the Delta WPLSoft 2.49 software [6], And it will include all control sequences in the process as explained in the previous steps. There are different PLC brands available in the market, such as Siemens, Allen Bradley, Mitsubishi, ABB, Schneider, etc.

IV. Control System Components

This section will describe our proposed control system's main components in more detail, including the PLC controller, the water tank, water level sensors, water flow sensors, transmitter/receiver stations, and auxiliary components.

A. The PLC Controller

The PLC controller is a computer programmed to perform almost any control, sequencing, monitoring, and display function. The primary function of the PLC is to send wireless signals to the water pump to turn it on or off, based on the water level in the tank, using floating limit switches that indicate the current water level in the tank. This work will introduce a convenient solution to the process plants where cabling is expensive or not possible. It also has lower installation and maintenance costs, provides reliable operation, and robust and flexible construction. Usually, a PLC system's essential functional components are a processor unit, memory, power supply unit, input/output interface section, communications interface, and programming device, as shown in Fig. 3. The input and output sections are where the processor receives external devices' information and sends control commands to external devices. In our case, the PLC's inputs will include four digital level sensors and seven flow sensors. The outputs might be connected to motor starter coils or other visual and audible alarms. All input and output signals in this project are digital, and no existence analog signals. The pumps are connected to the PLC controller's digital output wireless via specific relay circuits connected to the receiver station at each well. For this paper, the Siemens S7-200 PLC was proposed to automatically control the overall system and reduce the design and control complexity. Siemens provides different S7-200 CPU models with various features and capabilities to create sufficient water pumping process solutions. The CPU 222 [16] is a perfect candidate for the presented control system with eight inputs/6 outputs and two expansion modules to increase the number of inputs/outputs up to 94 maximum, see Fig. 4, [11]. Typically, PCs are used to write the control program using the PLC Ladder logic. The control program is then downloaded to the PLC memory through a physical connection such as the RS 485 cable. The first step of the system implementation is to download the Ladder logic program into the PLC. The S7-200 CPU Models contain all instructions and logic circuits required to control the whole system, as shown in Fig. 5.

B. Water Level Sensors: Limit Switches

The level sensor's assembly consists of four float switches, these float switches are placed inside the collecting tank, and they are arranged at very low water level (10%), low water level (60%), high water level (80%), and very high water level (the tank is full). These limit switches are connected to the digital input of the PLC controller. The basic operation is as follows: when the water level reaches one of the four limit switches, the contact of that switch will close, and a +24 V signal is set on the PLC's digital input, which makes the control system respond by opening or closing the relay contacts to turn the pump on/off according to the detected water level. A very high alarm switch would be positioned at a level of 98% to turn off all submersible pumps, prevent flooding and wastage of water from the tank, and activate a warning audibly and a flashlight. A very low alarm switch of 10% can be utilized to detect a low water level near the bottom of the tank and activate audibly and flashing light alarms; accordingly, any operating discharge pump of the two pumps will be turned off.

C. Water Flow sensors

The flow sensors are generally open contacts that close if water flows from a specific well's pipeline connected to the collecting tank. There will be one flow sensor for each submersible pump. The flow sensors are used to protect pumps from dry running or leakage in the piping system. Therefore, the control system will help prevent unwanted failures and costly repairs.

D. Transmitter Unit

Data are transferred from the PLC to the transmitter, and the USART module with Atmega 32 controls it. When initialization occurs, tasks are timed on a $1ms$ time scale given by timer 0 Afterward, it interrupts the timer 0 compare, match, and (USARTUDREvect), triggered by an empty transmitter buffer. The serial model's baud rate is set to 4000 bps. The MCU sends one packet of information every $200ms$, and

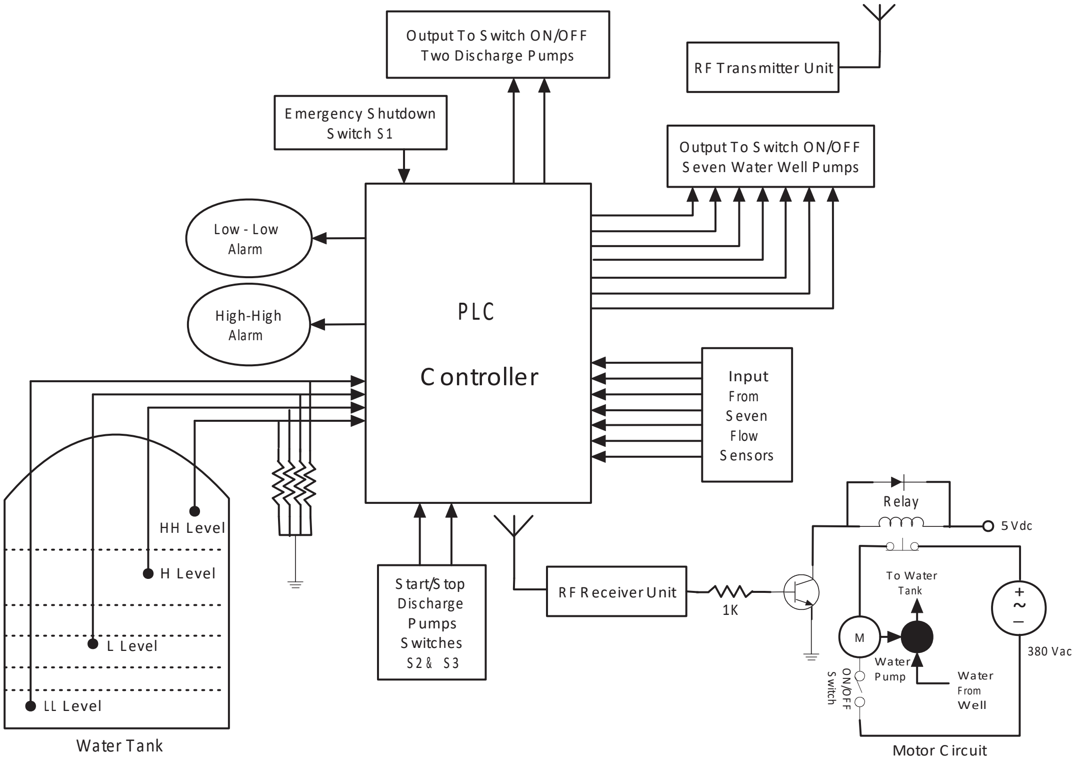

Figure 3. Block diagram of the control system.

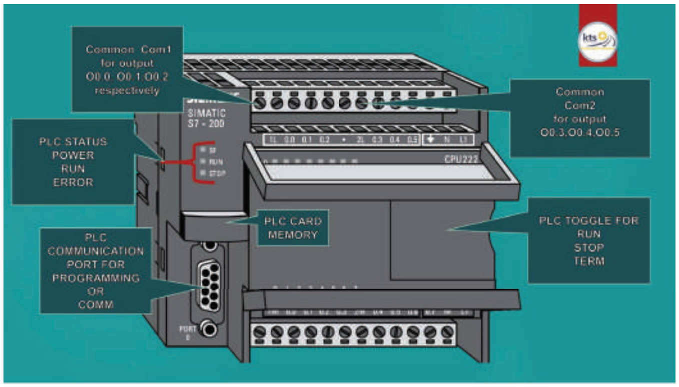

Figure 4. The Siemens S7-200 PLC CPU 222, [11].

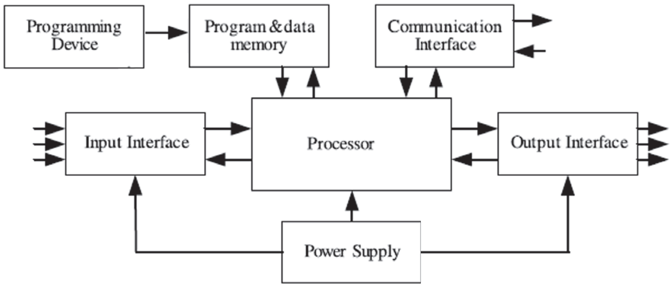

Figure 5. Basic Structure of PLC.

at the end of each $200ms$ unit, the float switch's State is checked, where the character symbol "on" is transmitted when the button is "on" and the character sign "off" is sent when it isn't. A modified version of the packet structure available by Desai et al. is used. It consists of three synchronization bytes: a start character, a single data byte, and an end character. Each byte that is transmitted is governed by DC balancing, meaning that it consists of an equal number of $0s$ and $1s$; this ensures that the receiver's calibration is not lost during the first transmission. Symbol "off" (149) and Symbol "on" (180) are the data symbols that are transmitted one at a time when the empty transmit buffer occurs (USARTUDREvect). Afterward, the bits are outputted by the USART module out of PIN $D.1$, which happens to be sent connected to an NPN transistor base to turn the transmitter on and off. At least two-bit flips are required before one symbol is falsely decoded as another, which benefits the characters used above.

E. Receiver Unit

The receiver unit must detect its data and turn the voltage on or off to control the pump. Here, the timer "0" is used once again to generate a 1 ms timer to compare match interrupts, and the baud rate is also once again set to 4000 bps because it must see that the receiver and the transmitter operate at the same baud rate. When the USART buffer (UDR) receives a byte of data, the (USARTRXCvectISR) gets triggered. At this time, the program checks for the synchronization character, and if it is not there, the program ignores the received byte, but if it is there, then the program finds the start character by searching the next three bytes, and if it is found., the program would receive the data byte. The reception of data bytes stops if the stop character is found or 32 bytes are received, which is the maximum number of received bytes. Afterward, the data's validity is checked by the program (if the 2nd element of the message array is the start character). The 3rd element of the message array is checked if the data is valid to see if its symbol is in the ”on” sign. Pin B.0 is written as a logical high to turn the pump on if the 3rd character is the symbol ”on” Still, if it is not, then the pin B.0 is written as a logic low to turn it on if and only if the Symbol ”On” is received, and the pump gets turned off if after 3 minutes no other symbol ”on” is obtained, which is to account for any problems at the transmitter end.

F. Auxiliary Components

Two bush buttons will be installed to start and stop the two discharge pumps, and another bush button will be used in the case of an emergency to shut down the PLC control system or if the operator wants to set the whole system in manual mode. In addition, to control some high-power devices such as flashing lights, speakers, and high voltage electric motors using a low volt PLC controller, interface devices between the PLC and the high power devices are required. Usually, mechanical relays (contractors) are available to switch currents from milli-amperes to higher amperes. We should use a relay circuit in the water pump system to adapt to a high voltage AC. The relay circuit's output is connected to the motor's negative side of the cable—the positive side of the line combined with 380V AC [3].

V. System Implementation and Experimental Simulation Results

A. Software Description

The ladder logic diagram for the PLC controller was written and simulated using the Delta WPLSoft 2.49 software [6].

When the system is powered up, the PLC controller senses the digital inputs connected to the level limit switch and flow sensors; if the PLC digital inputs receive any changes, then the controller sends signals to the digital outputs of the PLC accordingly. The whole operation makes a cycle or repeats itself concerning the input signals according to the flow chart shown in Fig. 6.

B. Operation Description

The designed control system aims to meet the city's demand for water by using an automatic control system to operate the pumping water process as a cycle and keep the collecting tank full of water at all times. The control process will be achieved by monitoring the input signals' level and then sending control output signals according to turn on/off water pumps or sending alert signals when the tank's water level is almost full (HH alarm) or nearly empty (LL alarm). As shown in Fig. 6, the control process can be described in the following points:

1) Suppose the water level is very low (LL Level $< 10\%$), which means the tank almost empty. In this case, the PLC turns “off” any operating discharging pump, and ”on” signals will be sent wirelessly to all submersible pumps via the RF transmitter to restore the low water level in the tank at 60%. Moreover, a ”LL alarm” signal will be activated. Audible alarms and flashing lights will be activated to alert the collecting tank operator's near emptiness and protect the two discharging pump motors from dry running.
2) If the water level reached the low level's limit switch (60%). In this case, the PLC input connected to the L limit switch will send a +24v signal, which means the water level is at 60%; accordingly, the PLC will turn ”off” three pumps, and the other four pumps will continue operating. Until the tank's water level reaches a high level at 80%, the PLC input connected to the H limit switch will receive a +24v signal. Therefore, the PLC will turn ”off” two pumps out of the four operating pumps. Table I shows the description of the tank filling and draining control procedure.

Table I
Tank Filing and Draining Control Procedure

Tank Level	Water Level	Pumps Status	Draining
”HH”	97%	Alarm	”on”
”VH”	95%	All Pumps ”off”	”on”
”H”	80%	Two Pumps ”on”	”on”
”L”	40%	Four Pumps ”on”	”on”
”VL”	10%	All Pumps ”on”	”off”
”LL”	8%	Alarm	”off”

3) If the tank is almost full and the water level becomes High High (”HH”) at 98%, that means the PLC system does not work. An audible / flashing alarm signal will be activated to let the labor convert the system to manual operation and turn all submersible pumps off.
4) If the tank is almost full and the water level becomes Very High (”VH”) at 95%, the PLC will send turn ”off” signals to all operating submersible pumps. And at the same time, the PLC will send a ”VH” alarm” signal note.
5) Furthermore, the pump priority based on the number of working hours will be used as an indicator by the PLC controller to determine the next pump(s) to be turned ”on”. Each pump will run cumulative 24 hours before the next pump takes over priority in this control system.
6) Finally, after sending an ”on” signal to any pump, the PLC will wait 5 minutes before checking the flow sensor for that particular pump; if the PLC digital input connected to that flow sensor receives a positive signal (+24v), then this means the submersible pump is producing water. The pump's motor will continue running. Otherwise, the PLC will send an ”off” signal to stop that pump and protecting the pump's motor from dry running.

C. Control Mechanism

During operation and to start any pump, the PLC controller will send an ”on” signal to a particular submersible pump

Figure 6. Flow chart of system design.

through the RF transmitter using 5700 MHz wireless links. The receiver unit on that water well will catch that signal. Upon receiving this signal, the receiver unit sends a logic high signal (+24V) to the motor's relay circuit. The output of the relay circuit is connected to the motor pump's cable as a neutral. The other side of the motor's line is connected to AC 380 v. This will start the motor of that particular pump, and the water is pumped from the well to the collecting tank. If the PLC controller sends an ”off” signal to a specific submersible pump, the receiver unit on that well will catch that signal. Upon receiving this signal, the receiver unit sends a logic low signal (0V) to the motor's relay circuit. This will disconnect the pump's engine from the AC 380V power source, and the pump will be turned off. The motor circuit is shown in Fig. 3 is used to control the motor on the receiver side [12]. An ”on/off” switch is used to manage the motor driver circuit manually. The transmitter and receiver units share a base code for initializing registers for the communication protocol (txrx.c). We will describe the program of the transmitter end later in this paper.

To sum our results up, we implemented the PLC with the S7-200 model to convert manual operation and management into a fully automatic operation for KACS. Because of the limited number of pages of this conference, we omitted the PLC ladder program and some simulation results. We hope to add them to future journals. Our results showed many rewards, including reducing energy consumption, eliminating water wastage, providing continuous water flow, protecting pump damage, maintaining the service life of the equipment, reducing the labor intensity of maintenance, avoiding stealing water from the water distribution system, and ensuring the city's necessary daily water usage.

VI. Conclusion and Future Work

Most Middle East and African countries suffer from water shortages due to insufficient and old water supply systems. This paper presented an efficient, low-cost, flexible, economical, and easily configurable approach for water level control using a wireless solution; we proposed an Automatic control of Rujban's water supply system based on PLC. The water level control system combines two parts; wireless sensors and PLCs. This paper focused on the control system design for efficient automated water pumping through water level/water flow sensors, which turn on/off a specific number of pumps, and Siemens S7-200 PLC controller. First, we described the existing water supply system and its main elements. Second, we proposed the control system's main features in more detail, including the Siemens S7-200 PLC controller, water level/flow sensors, transmitter/receiver units, and auxiliary components. Third, we provided the overall operation procedure to convert it from fully manual to 100% automatic with pumps operation time recycling. Finally, we implemented a simulation experiment using the PLC to control, manage, and evaluate the proposed control system. Our results showed many rewards, including reducing energy consumption, eliminating water wastage, providing continuous water flow, protecting pump damage, maintaining the service life of the equipment, reducing the labor intensity of maintenance, avoiding stealing water from the water distribution system, and ensuring the city's necessary daily water usage. As future work, to solve the city's complete water problem, we will design and implement two other automatic control systems; the first system for IACS1 and the second system for IACS2. Furthermore, we will design and implement the overall water level control system in real-time, including wireless communication and control using PLC.

***Abstract*—Brain Cancer and Tumors are common death factors over the world. Determining the location of a brain tumor at an early stage is difficult due to its minimal size and some disadvantages of the mechanisms used for the diagnosis of the brain tumor. In this paper, a Rectangular Microstrip Patch Antenna has been designed for Microwave Imaging (MI) with a frequency range of 1.5 GHz to 3 GHz at a resonant frequency of 2.3 GHz (5G-Band) in the CST Studio Suite Software to identify brain tumors. FR-4 Substrate material has been used to design the Antenna. The Antenna dimension that has been designed in this paper is 60.46*78.73*1.7 mm^3 and the radiating patch of the Antenna was fed by a feedline, which is rectangular in size. The human brain phantom has been created in the CST software with six different homogenous layers of skin, fat, skull, dura, CSF (Cerebrospinal Fluid), and the Brain. Besides, a 5mm tumor was also placed inside that human brain. The Antenna was applied in the brain phantom both with and without the tumor to analyze the Antenna's performance. A Reflection Factor ($S_{1,1}$) of -30.76 dB and -30.88 dB were also achieved respectively after applying the Antenna in the brain phantom with and without the tumor. Other obtained performance parameter values were also provided in this paper, such as Directivity (2D & 3D), Radiation Efficiency, Polar Radiation, Specific Absorption Radiation (SAR), etc. the Antenna will be a safer choice for the detection of brain tumor. 5G frequency band has been used here because the free space antenna can be used in communication (5G mobile communication, WLAN, Wi-Fi), and as well as for body applications.**

Keywords*—*Brain Cancer, Microwave Imaging, Patch Antenna, 5G-Band, SAR, Reflection Factor, VSWR, Directivity.

I. Introduction

Cancer has recently become the second-largest mortality cause globally, and it is responsible for the deaths of 9.6 million people every year all over the world, according to the World Health Organization (WHO). There are numerous types of Cancer according to their symptoms, and Brain Cancer is one of them. The cancers of the central nervous system and Brain form a group of tumors that are rare and heterogeneous. These kinds of tumors are liable for 3% of cancer cases and are more prominent in males than females. Though the incidence rate is low, brain cancer ranks in the top 10 in cancer deaths [1]. The variables that define the tumor state are its scale, location, and development status [2]. There are two forms of a tumor which include benign and malignant. A benign tumor is a type of tumor without any cancerous cells and is not very much harmful. Moreover, its tissue development is prolonged [3]. On the other hand, a malignant tumor is the formation of cancerous cells and is considered deadly, risky, and unpredictable. Moreover, it spreads very quickly to the surrounding tissue and hampers its respective functions to a significant extent [2]. Earlier, various approaches such as X-ray Mammography, Computed Tomography (CT scan), Magnetic Resonance Imaging (MRI), Ultrasound, Radiography, and many other techniques could be used for detecting brain tumors or brain cancer cells [4]. But all these approaches have some drawbacks, such as their high ionizing radiations, and sometimes, they are unable to make the difference between the tumors that are benign and malignant [5].

One of the recent successful invented approaches for detecting the brain tumor is Microwave Imaging (MI) using a Microstrip patch antenna due to its low price, non-ionizing radiation, and faster working process over the previous approaches. The working mechanism of the Microwave Imaging (MI) system depends on the dielectric properties (such as permittivity, conductivity) of the stable cells and the tumor-affected cells of the human brain [6]. A microstrip patch antenna is an integral factor of the Microwave Imaging systems that irradiates the human head under examination with microwaves

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

that pass around the head and then detect another antenna that acts as a receiver. The receiver antenna produces the tumor-mirrored information that has been analyzed with an appropriate signal processing technique for receiving 3D images of the brain under tests [7]. However, for better diagnosis, specific microstrip patch antennas' performance parameters, such as SAR (Specific Absorption Rate), Reflection Factor ($S_{1,1}$), Radiation Pattern, Directivity, and Polarization, requires to be adequately analyzed [8]. A Microstrip Patch Antenna aims to design in this paper to diagnose brain cancer and tumor by using as a part of its improvement from the past. The operating frequency of the Antenna is 2.3GHz which is under Sub-6 GHz 5th Generation spans (450 MHz - 6 GHz) [9].

II. Modelling of the Microstrip Patch Antenna in Free Space

At first, an operating frequency of 2.3 GHz (5G-Band) has been selected, which varies from 1.5-3 GHz. The Width of the patch was calculated from Equation-1 using the Velocity of Light (C_o), Operating frequency (f_r), and the Dielectric Constant (ε_r) value of 4.3.

$$W = \frac{c_0}{2f_r\sqrt{\frac{\varepsilon_r+1}{2}}} \quad (1)$$

The Effective Dielectric Constant, ε_{reff} has also been calculated using Equation (2) [10].

$$\varepsilon_{reff} = \frac{\varepsilon_r+1}{2} + \frac{\varepsilon_r-1}{2}\left(1+12\frac{h}{w}\right)^{-0.5} \quad (2)$$

Here *h* represents the height of the substrate, and *w* represents the width of the patch.

After that, the Effective Length, $L_{eff,}$ is calculated using Equation (3) [10].

$$L_{eff} = \frac{c_0}{2f_r\sqrt{\varepsilon_{reff}}} \quad (3)$$

The actual length of the patch has been determined. To determine it, the fringing factor is subtracted from the effective length, which was shown in the following Equation (4) [9].

$$\Delta L = 0.412\frac{\left(\frac{w}{h}+0.264\right)(\varepsilon_{reff}+0.3)}{(\varepsilon_{reff}-0.258)\left(\frac{w}{h}+0.813\right)} \quad (4)$$

The patch's actual length has been determined using the following Equation (5) [10].

$$L = L_{eff} - 2\Delta L \quad (5)$$

Following that, the Width of the Ground Plane's corresponding values, $W_g=2*W$, and the Ground Plane's Length, $L_g=2*L$, have been calculated [5].

TABLE I. Parameters of the Proposed Model

Parameter with Symbols	Dimensions (mm)
Patch Length, *L*	30.23
Ground Plane Length, L_g	60.46
Patch Width, *W*	38.5
Ground Plane Width, W_g	77
Ground Thickness, h_t	0.035
Substrate Height, h_s	1.7
Feedline Width, W_f	3.2
Feedline Insertion, F_i	8.9295
The Gap between Patch and the Feedline, G_{pf}	1

An inset feed transmission feedline which is 50-ohm were also connected to the proposed antenna model. The free space parameter of the Antenna have been represented in Table I.

The 3D model and the proposed Antenna model's geometry are shown in Figures 1 and 2, respectively.

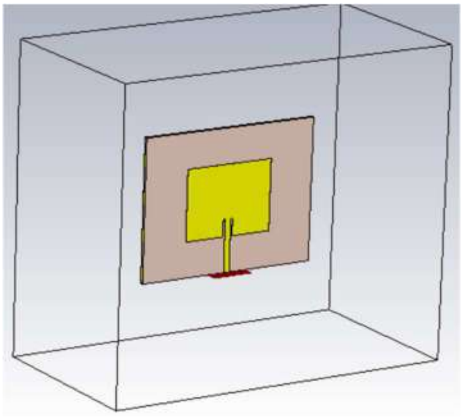

Fig. 1. 3D model of the Microstrip Patch Antenna

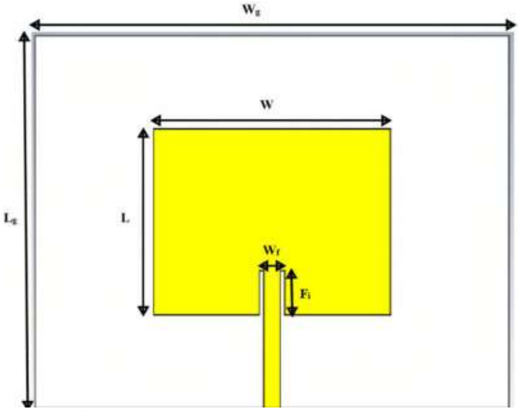

Fig. 2. Geometry of the Designed Microstrip Patch Antenna

III. Modeling of the Microstrip Patch Antenna in Brain Phantom

A human head model consisting of six different layers has been designed and simulated using the CST Studio Suite 2019 software. These layers include Skin, Fat, Skull, Dura, Cerebrospinal Fluid (CSF), and the Brain (white matter). While preparing the human head design, a radius of 81 mm was considered, and the dimensions & electrical properties of each layer have been listed in Table II. Figure 3 shows the six-layered healthy Human Head Phantom, and Figure 4 shows the entire Head Phantom.

TABLE II. Parameter Values of the Brain Phantom

Tissue	*Permittivity*	*Conductivity (S/m)*	*Density (Kg/m^3)*	*Thickness Mm*	*Thermal Conductance KJ/Kg/K*	*Heat Capacity W/m/K*
Skin	42.85	1.59	1090	1.50	0.50	3.662
Fat	10.82	0.26	910	0.15	0.24	2.973
Skull	14.96	0.59	1850	0.60	0.36	2.524
Dura	42.03	1.66	1130	0.40	0.44	3.364
CSF	66.24	3.45	1005.9	0.50	0.62	4.200
Brain	42.53	1.51	1030	82.25	0.56	3.682
Tumor	55.8	4.1	1070	5	-	-

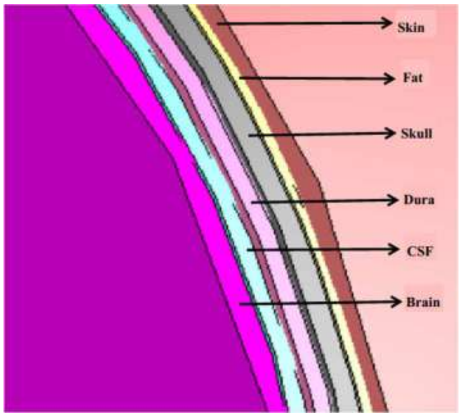

Fig. 3. Six-Layered healthy Human Head Model

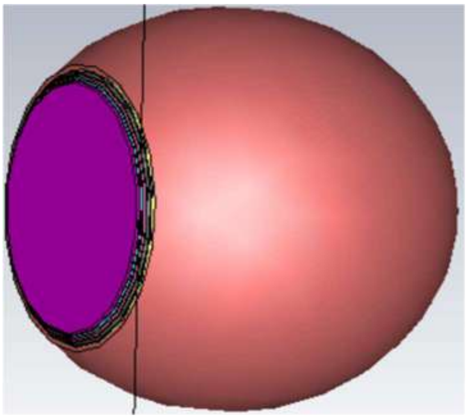

Fig. 4. The Full Head Phantom

Since there are variations in each layer's dimensions, each layer possesses different electrical properties such as Heat Capacity, Conductivity, Permittivity, etc. After designing the human brain phantom, a 5 mm tumor was placed on the Human Brain. Then, the Microstrip Patch Antenna was applied to the brain phantom both with and without the tumor. For avoiding the negative effect of the electromagnetic field, the ground plane of the Antenna has been attached to the head phantom's surface [9]. The coordinates of the proposed Antenna's position were (x=0, y=0, z=85). Figure 5 shows the tumor-affected brain Phantom with the Microstrip Patch Antenna, and Figure 6 represents the Location of the Tumor after applying the Microstrip Patch Antenna.

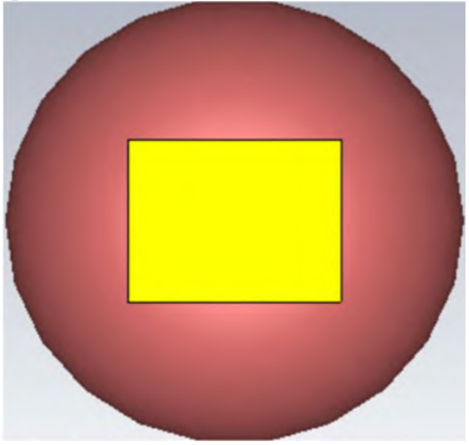

Fig. 5. Tumor affected Brain Phantom with Microstrip Patch Antenna

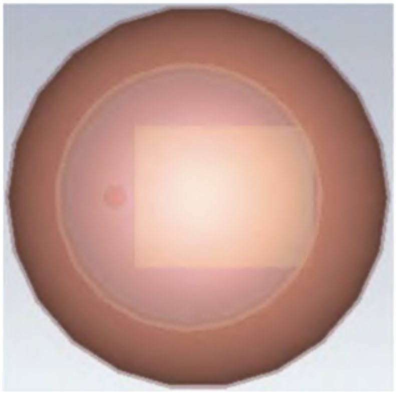

Fig. 6. Location of the Tumor after applying the Microstrip Patch Antenna

IV. Result Analysis

The designed Antenna has been applied in the Brain Phantom consisting of without the tumor and with a tumor, respectively. All the determined results from the simulation have been discussed below.

A. *Reflection Factor*

Reflection Factor is the measure of the RF energy that an Antenna can accept, and it is measured in terms of dB [11]. However, a smaller magnitude of Reflection Factor means less energy is being passed to the proposed Antenna, reducing its effectiveness. Therefore, as the proposed Antenna in this research work is for body applications, therefore from that perspective, a higher magnitude of Reflection Factor is always preferable. For the tumor-less Brain phantom implemented in this research work, a Reflection Factor of -30.87 dB and a Bandwidth of 82.8 MHz have been successfully obtained. Moreover, the Brain Phantom consisting of the tumor has also been implemented from which a Reflection Factor of -30.76 dB and a Bandwidth of 82.8 MHz has also been successfully obtained. All the results have been obtained at an operating frequency of 2.3 GHz. Figures 7 & 8 shows the Reflection Factor ($S_{1,1}$) value of the Brain Phantom without the tumor and as well as with the tumor, respectively.

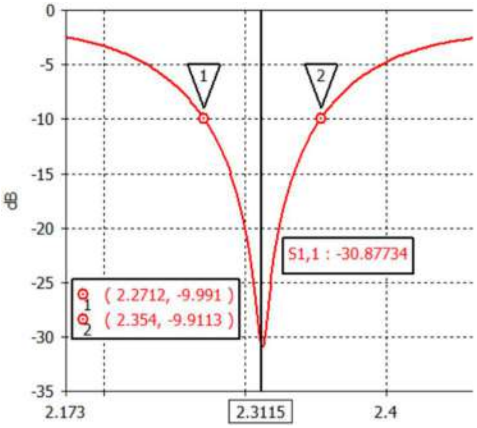

Fig. 7. Reflection Factor of the Brain Phantom without Tumor

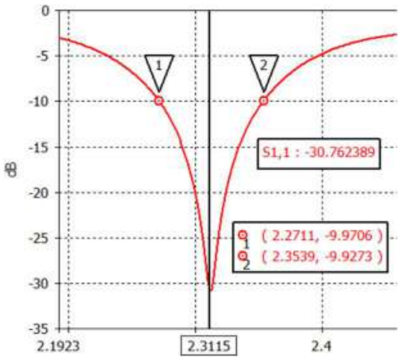

Fig. 8. Reflection Factor of the Brain Phantom with Tumor

B. Directivity

It is the measure of the radiation pattern concentration of an antenna in a particular direction, and it is expressed in terms of dB [12]. An antenna radiates more concentrated beams when the magnitude of the Directivity of that Antenna is higher. However, a higher directivity also resembles that the beam will travel to a significant distance. Here, after applying the proposed antenna model on the Brain Phantom consisting of the tumor, a 2D and 3D Directivity of dB has been successfully achieved. Figures 9 & 10 shows the 2D and 3D Radiation Pattern (Directivity) of the Brain Phantom Efficiency Pattern of the Brain Phantom with Tumor, respectively.

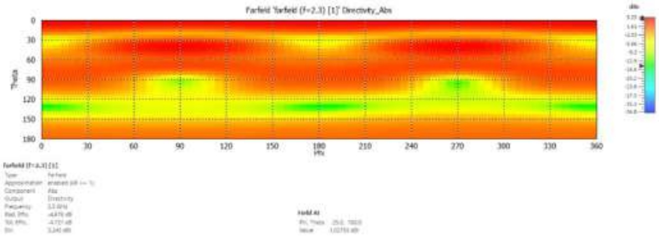

Fig. 9. 2D Radiation Pattern (Directivity) of the Brain Phantom with Tumor

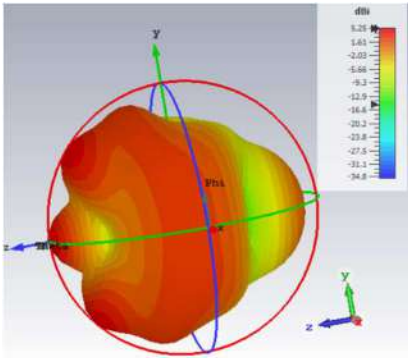

Fig. 10. 3D Radiation Pattern (Directivity) of the Brain Phantom with Tumor

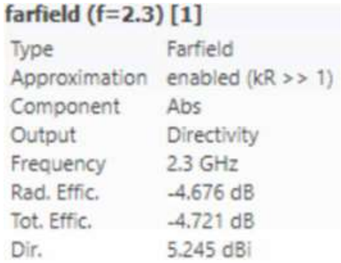


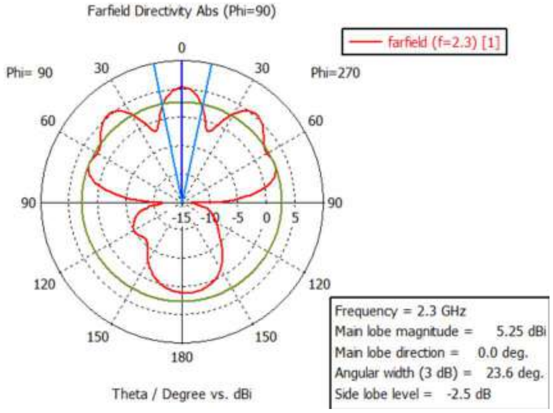
farfield (f=2.3) [1]

Type	Farfield
Approximation	enabled (kR >> 1)
Component	Abs
Output	Directivity
Frequency	2.3 GHz
Rad. Effic.	-4.676 dB
Tot. Effic.	-4.721 dB
Dir.	5.245 dBi

Fig. 11. 3D Radiation Pattern (Directivity) value of the Brain Phantom with Tumor

C. Farfield Radiation (Polar Form)

In this work, the proposed antenna model has been placed on the Brain Phantom consisting of a tumor. From the simulation, the Farfield Radiation has been determined (Polar form, Phi=90°). From the simulation, the main lobe magnitude of 5.25 dBi and a side lobe level of -2.5 dB has been successfully achieved for the Operating Frequency of 2.3 GHz. Figure 12 shows the Farfield Radiation (Polar Form) of the Brain Phantom with Tumor.



Frequency = 2.3 GHz
Main lobe magnitude = 5.25 dBi
Main lobe direction = 0.0 deg.
Angular width (3 dB) = 23.6 deg.
Side lobe level = -2.5 dB

Fig. 12. Farfield Radiation (Polar Form) of the Brain Phantom with Tumor

D. Surface Current

The applied electromagnetic field induces an actual electric current, known as Surface Current, especially in metallic antennas [13]. After applying the proposed antenna model in the Brain Phantom consisting of the tumor, a Surface Current of 34.6 A/m has been successfully achieved from the simulation. Figure 13 shows the Surface Current of the Brain Phantom with Tumor.

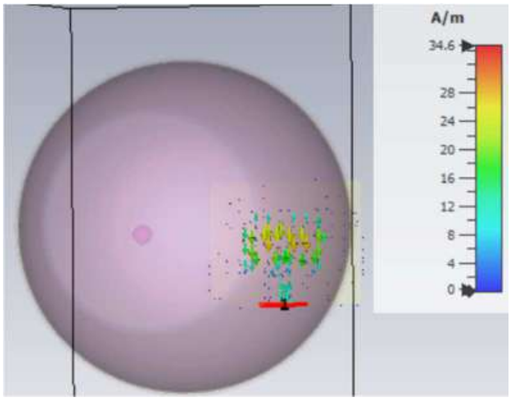


Fig. 13. Surface Current of the Brain Phantom with Tumor

E. Specific Absorption Rate (SAR)

SAR is the measure of the maximum allowable level of Electromagnetic Radiation produced by a Communication Antenna in numerous wireless devices. It is an important parameter, and it requires to be maintained within a standard level. The IEEE C95.3-2002 standard governs the standard level of SAR, which specifies that for one gram of average body tissue, the level of SAR does not exceed 1.6 W/kg, as per the ICNIRP and FCC guidelines [2].

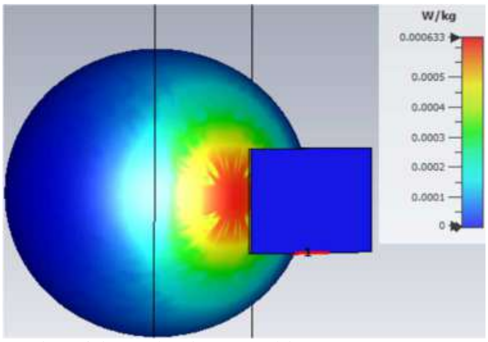

Fig. 14. SAR value of the Brain Phantom without Tumor

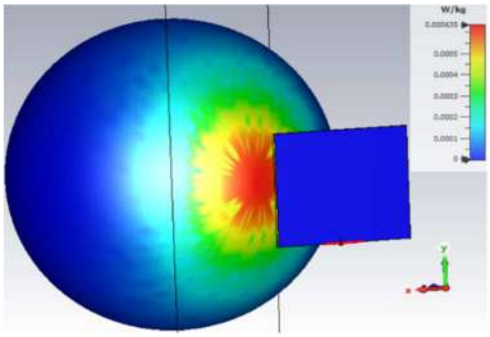

Fig. 15. SAR value of the Brain Phantom with Tumor

Here, after applying the Antenna's model on the Brain Phantom consisting of no-tumor, a SAR value of 0.000633 W/kg has been achieved. Similarly, after using the Antenna on the Brain Phantom consisting of the tumor, a SAR value of 0.000635 W/kg has also been successfully determined. Figures 14 & 15 shows the SAR value of the Brain Phantom without the tumor and as well as with the tumor, respectively.

V. Comparative Study

As a part of the comparative study, numerous past research works have been thoroughly analyzed and compared with the current works. After the brief comparison, it can be determined that the antenna model that has been proposed in this research work is much more effective and advantageous, which includes its ability to detect low sized tumors precisely. Table III portrays the brief comparison of the proposed antenna model with the past research works. Since the distance of the proposed antenna from the human brain phantom is bigger than the compared research, as a result, the SAR value is much lower than the compared research works. Due to the antenna’s long distance from the human brain phantom, the proposed antenna is also safer due to its low SAR and low ionizing radiation.

TABLE III. Comparison of the Antenna model with previous Research Paper

Reflection Factor ($S_{1,1}$), dB	*Directivity, (in dBi)*	*SAR, (in W/kg)*	*Tumor Size (in mm)*	*Distance of the Antenna from Brain Phantom*	*Ref.*
-18.2	-	0.9501	10	3 mm	[4]
-9.15	-	0.4610	35	10 mm	[14]
-26.69	6.469	1.95	5	10 mm	[8]
-26	6.60	-	5	-	[6]
-22.30	4.731	0.03101	5	83.79 mm	[15]
-30.76	5.425	0.000635	5	85 mm	Proposed Model

VI. Conclusion

In this research work, a Rectangular Microstrip Patch Antenna has been designed to diagnose brain cancer in the early stage. This paper exhibits a precise pathway for characterizing numerous tissues in various simulated scenarios after applying the Antenna in the healthy human brain model and the tumor-affected brain model. At first, a human head phantom model has been prepared in the CST Studio Suite Software 2019. The designed Antenna operates at a frequency of 2.3 GHz was placed on the head's phantom. Therefore, a better performance was achieved by using the 2.3 GHz operating frequency after applying the antenna on the tumor-affected brain phantom. Thus, 2.3 GHz was used as the operating frequency. The Antenna's Reflection Factor was determined -30.87 dB after applying the Antenna on the tumor-free brain phantom and -30.76 dB after applying the Antenna on the tumor-affected brain phantom. A Radiation Efficiency was found to be -4.6820749 dB and -4.6753968 dB after using the Antenna on the Cancer free brain phantom, and the Cancer affected brain phantom respectively. A Surface Current of 34.6 A/m and a Directivity of 5.245dBi was received with Cancer-affected brain phantom. A SAR value of 0.000633 W/kg and 0.000635W/kg were also obtained after applying the Antenna on the tumor-free brain phantom and the tumor-affected brain phantom. From all the determined data, it has been learned that the proposed antenna model has been susceptible to Diagnose Brain Cancer from the cancer-affected brain. After analyzing the SAR and other performance parameters such as Reflection Factor, VSWR, Directivity, Radiation Pattern, Radiation Efficiency, etc. of the Antenna in the presence and absence of tumor, it can be concluded that the designed Antenna is very much feasible and capable enough for detecting the tumor in the Human Brain. However, near the edge of the human head model's brain, the tumor was being placed. Therefore, considering the tumor's location in another area of the human head or the center of the brain, further testing and analysis are required.

***Abstract*—Due to the vulnerability of deep neural networks to adversarial examples, numerous works on adversarial attacks and defenses have been burgeoning over the past several years. However, there seem to be some conventional views regarding adversarial attacks and object detection approaches that most researchers take for granted. In this work, we bring a fresh perspective on those procedures by evaluating the impact of universal perturbations on object detection at a class-level. We apply it to a carefully curated data set related to autonomous driving. We use Faster-RCNN object detector on images of five different categories: person, car, truck, stop sign and traffic light from the COCO data set, while carefully perturbing the images using Universal Dense Object Suppression algorithm. Our results indicate that person, car, traffic light, truck and stop sign are resilient in that order (most to least) to universal perturbations. To the best of our knowledge, this is the first time such a ranking has been established which is significant for the security of the data sets pertaining to autonomous vehicles and object detection in general.**

I. Introduction

In an autonomous vehicle set up we can categorize the interactions between various components based on the interactions of a vehicle and one or more of the following: landscape (e.g., roads, barriers, buildings, trees etc.), other automobiles, people, and road signs. Autonomous vehicles often recognize each of these categories through the use of Machine Learning models for object detection. While objection detection techniques have made a huge progress, so have the various adversarial attacks, as explained in the next few sections. Most of the studies have heavily concentrated on the techniques of adversarial attacks and the means of making them more and more efficient in breaking the object detector. A lot of research has also concentrated on defense approaches. However, there is very limited or no research done to empirically understand robustness of each individual object category. In this work, we mostly concentrate on specific object categories and their ability to withstand adversarial attacks.

More specifically, we answer questions like, is it more difficult to recognize a person in comparison to a car when an object detector is subjected to universal perturbations? It is very important to understand the impact of such adversarial attacks at a category level so that targeted efforts could be made to address such weaknesses in object detection. Also, different object categories have different features and understanding the affects on them individually would enable us to build systems that can encompass methods to overcome the weaknesses of an object detector.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Due to the vulnerability of deep neural networks to adversarial examples, adversarial attacks have been receiving huge attention over the past several years [1]. In the context of the adversarial attacks, universal perturbations research has also received a lot of interest [2] since it is much more efficient and transferable than image-specific attacks. However, most of it is directed toward image classification and not much toward object detection [3]. More importantly, we observed that there are two conventions that most work on adversarial attacks seem to be holding on: evaluation of adversarial attacks on all (1) **classes** and (2) **images**.

In this paper, we address issues pertaining to the impact of dataset curation and its need, and, the effect of universal perturbations on individual categories of objects. First of all, we question whether the experiments on adversarial attacks have been measuring their impact rigorously, for instance, quantified by the fooling rate (the proportion of images that change labels when perturbed by our universal perturbation). Many experiments have been naively using the whole data set which may lead to assessing the effect of an attack in a more optimistic way. It is owing to the fact that the object detector may already have some incorrect predictions on some of the images in the first place, regardless of the perturbation. The number of those images could be quite high. This is supported by the fact that the mAPs on many data sets are still not high enough to ensure this even on clean images, for example, the COCO AP for the state-of-the-art object detector is still less than 60. Thus, we argue that those examples should not be counted as an example of a successful attack and also be removed from the data set to prevent data set bias from the evaluation.

Secondly, we also observed that there is less research toward understanding the impact of universal perturbations on specific categories related to autonomous driving. Most of the experiments and evaluations are conducted while including all the classes in a data set. This may widen the gap between understanding the effect of universal perturbations in general. In more specific applications a successful adversarial attack may perform differently in the self-driving car domain. Given that deep learning has various applications beyond just self-driving cars, we need to also consider evaluating adversarial attacks at a class-specific level and compare which attack is more deadly to a specific problem, and not just in general. To those who are closely related to the domain, this could have more meaningful implications rather than a general evaluation on a general-purpose data set. In the context of autonomous vehicles, we would like our system to be more reliable, and robust to attacks on the person class than may be those on stop signs. This is due to the fact that the consequences for a vehicle to crash into a person in comparison to a stop sign is vastly different.

In this work, we incorporate data set curation and class-level evaluation of robustness into experimental framework. We present a rigorous evaluation on the impact of universal perturbations on detecting specifically five object categories related to autonomous vehicles: person, stop sign, car, truck and traffic light. We run a series of controlled experiments by perturbing images of these categories using universal perturbations. Finally, we rank the vulnerability of detecting each object category by calculating the metrics for each object category individually and compare them.

We summarize the main contributions of this paper as follows: (1) firstly, we demonstrate the vulnerability of object detectors in detecting autonomous vehicle-related categories to universal perturbations. This is achieved using a simple iterative method of using the gradient of soft-max output with respect to input image and perturbation, (2) secondly, we establish a class-level vulnerability ranking with regards to adversarial attacks, and (3) thirdly, we isolate the impact of adversarial perturbations. This is done by including only those images wherein the detector correctly predicted at least one of the designated classes.

II. Related Works

A. Adversarial Attacks on Object Detection

Deep Neural Networks are ubiquitous in today's world within and outside the lab that have been built to alter the way applications are run. Its impact can be seen all around us. However, it does not come without its pitfalls. They are susceptible to adversarial attacks [4] [5][6][7]. This is a result of many noise injection techniques that cause failure in object detection and classification

Object detection in images, specifically related to autonomous vehicles, that is the focus of this work, come under adversarial attacks as well [8]. Adversarial examples are generated to be similar to the actual data, $\mathbb{D}$, with the goal of a mis-classification. Consider a classification function, f that correctly classifies an image, x, with a label y, and x' gets incorrectly classified with a label $\hat{y}$: $\arg\min_{\eta} f(x+\eta) = \hat{y}$. According to Szegedy et al. [4] we can solve the following optimization problem to find the perturbation

$$\min_{x'} ||x' - x||_p, \qquad s.t. \quad f(x') = \hat{y}$$

where $||.||_p$ is a distance defined on the metric space X. The most commonly used distance metric for object recognition in adversarial attacks is the p-norm:

$$||x||_p = \left(\sum_{i=1}^{n} |x_i|^p \right)^{1/p},$$

where $p \in \{0, 2, \infty\}$. According to Serban et al. [8] the choice of p is picked as follows:

- $p = 0$ measures the dissimilarity in coordinates between the perturbed and original images with regards to the number of pixels altered in the original image.
- $p = 2$ measures the Euclidean distance between the original and the adversarial image.
- $p = \infty$ measures the maximum bound for altering each pixel in an image without restricting the number of changed pixels.

Deng et al. [9] presented an analysis of adversarial attacks on autonomous driving models using five adversarial attacks and four defense methods on three driving models and found them to be vulnerable. Sharma et al. [10] demonstrated the vulnerability of the machine learning models of autonomous vehicles in their failure of detecting adversarial attacks.

B. Universal Adversarial Perturbation

The attacks explained above are mostly image-specific, However, a much stronger class of adversarial attacks, called universal attack generates a single adversarial example to misclassify all images in the data set [3]. Benz et al. [11] introduced a double targeted universal adversarial perturbations (DT-UAPs) to bridge the gap between the instance discriminative image-dependent perturbations and the generic universal perturbations and its potential as a physical attack. Sitawarin et al. [12] expand the scope of adversarial attacks using Out-of-distribution attacks by enabling the adversary to generate these starting from an arbitrary point in the image space. Prior attacks are restricted to existing training/test data (In-Distribution). They demonstrated that Out-of-Distribution attacks can outperform In-Distribution attacks on classifiers and exposed a new attack vector for these defenses.

Metzen et al. [13] proposed attacks against semantic image segmentation which removes a target class, such as, pedestrians, from the segmentation while leaving the segmentation otherwise unchanged. Li et al. [14] propose, for the first time, an iterative method to generate universal adversarial perturbations against object detection. Yingwei et al. [15] propose that regionally homogeneous perturbations can well transfer across different vision tasks (attacking with the semantic segmentation task and testing on the object detection task) and the defenses are less robust to regionally homogeneous perturbations.

As is noticed in the previous works the emphasis has been on the different adversarial attacks and defenses against such attacks. However, to the best of our knowledge, very little to no work has been performed to understand the robustness of the image categories. Our work focuses on the area of generating

TABLE I: Autonomous vehicle object categories in COCO dataset

category	Number of training samples
person	64115
bicycle	3252
car	12251
truck	6127
bus	3952
motorcycle	3502
traffic light	4139
stop sign	1734

universal adversarial perturbations against object detection, but proposes a new evaluation framework.

III. Dataset curation

In this research, we curate image categories from the popular and challenging COCO dataset by focusing on the categories specific to autonomous vehicles. Since it is an object detection dataset, most of the images would contain more than one category in a single image. This is done by design, since in a real world scenario a given scene would contain more than a single object category. Table I contains the number of such instances for each class in the COCO training set.

Among the vehicle categories, we only look at the top two by the number of instances and leave out bicycle, bus, and motorcycle and finalized with 5 categories: person, car, truck, stop sign, and traffic light for this experiment. Also, we only include the training set in COCO because the number of instances of each category is large enough, and most importantly, we meticulously study the independent impact of perturbations and leave out any incorrect classifications due to the object detection failure. To this end, using the training set on which an object detector has been trained would give us higher probability of collecting images with true positives. Some of the sample images from the dataset are shown in Figure 1.

In order to rule out missed detections due to the failure of object detector, we curate the dataset based on the results of the object detector prior to perturbing an image. As long as the object detector is able to detect at least one instance of the object category, we would retain that image in our dataset. In case the detector missed all the object instances of a target class in an image, that image would not be used further.

IV. Methods

A. Adversarial perturbation

Universal perturbation is an image-independent perturbation that would cause a label change for a number of images [3]. Our goal is to test the impact of such perturbations in object detection. Li et al. [14] introduced Universal Dense Object Suppression (U-DOS) algorithm to find universal perturbations that would blind an object detector on training set, I, so that it may fail to find objects in most of the images in I and at the same time remain imperceptible to a human eye. We use this approach since it is for the first time that the existence of universal perturbations on object detection tasks is performed. We made two modifications to the approach, though: 1) to simplify the loss function, we do not include the background probability in the objective function , and, 2) we use a normalized L1-norm by dividing it by the number of pixels.

U-DOS is an iterative algorithm that updates the universal perturbation, $\mathbf{v}$, by generating a vector, v_i, for each image, $I_i \in I$, so that the detector, D, fails to find any objects in the perturbed image, $I_i + \mathbf{v} + v_i$. We modify the original objective function in Li et al. [14] to only include the sum of class confidence probabilities of detection instances. The modified objective function is given as,

$$\mathcal{F}(I_i, \mathbf{v}, v_i) = \sum_{r_n \in \mathcal{R}_{D, I_i, \mathbf{v}+v_i}} P_{obj}(r_n | I_i + \mathbf{v} + v_i) \tag{1}$$

where, $P_{obj}(r_n|I_i + \mathbf{v} + v_i)$ is the probability of the object class with the highest confidence, and $\mathcal{R}_{D,I_i,\mathbf{v}+v_i}$, is the set of detection results on the perturbed image. Equation 1 is minimized while limiting the magnitude of the perturbation, v_i, as

$$v_i \leftarrow \underset{v_i'}{\text{argmin}} \left[\mathcal{F}(I_i, \mathbf{v}, v_i') + ||\mathbf{v} + v_i'|| \right] \tag{2}$$

To solve for v_i, the algorithm starts with a zero-vector and optimizes it with gradient descent.

$$\begin{aligned} v_i^{(0)} &= \mathbf{0} \\ v_i^{(n+1)} &= v_i^{(n)} - \alpha \nabla_{v_i^{(n)}} (\mathcal{F}(I_i, \mathbf{v}, v_i^{(n)}) + ||\mathbf{v} + v_i^{(n)}||) \end{aligned} \tag{3}$$

where, α is the learning rate and the gradient, $\nabla_{v_i^{(n)}}(*)$, is computed with back-propagation.

We modified Li et al.'s objective function to make it more applicable to object detectors in general: originally the paper included the term of increasing the background class probability and decreasing the ones for specific/all object class, but we removed the term increasing the probability of the background class because not all object detectors output a soft max probability that includes the background class.

B. Metrics

In order to evaluate the performance of the universal perturbations in blinding the object detector, we use two metrics proposed by [14]: **image-level blind degree** and **instance-level blind degree**.

1) Image-level blind degree: Image-level blind degree is defined as the ratio of the images in which the object detector, D, can find at least one object with confidence above a threshold, θ, to the total number of images, N. It is expressed as

$$B_{img}(D, \mathbf{v}, \theta) = \frac{\sum_{i=1}^{N} ind(I_i, D, \mathbf{v}, \theta)}{N} \tag{4}$$

where, N is the total number of images, and I_i denotes the i-th image, $\mathbf{v}$ the universal perturbation added to these images, $ind(I_i, D, \mathbf{v}, \theta)$ is an indicator function represented as

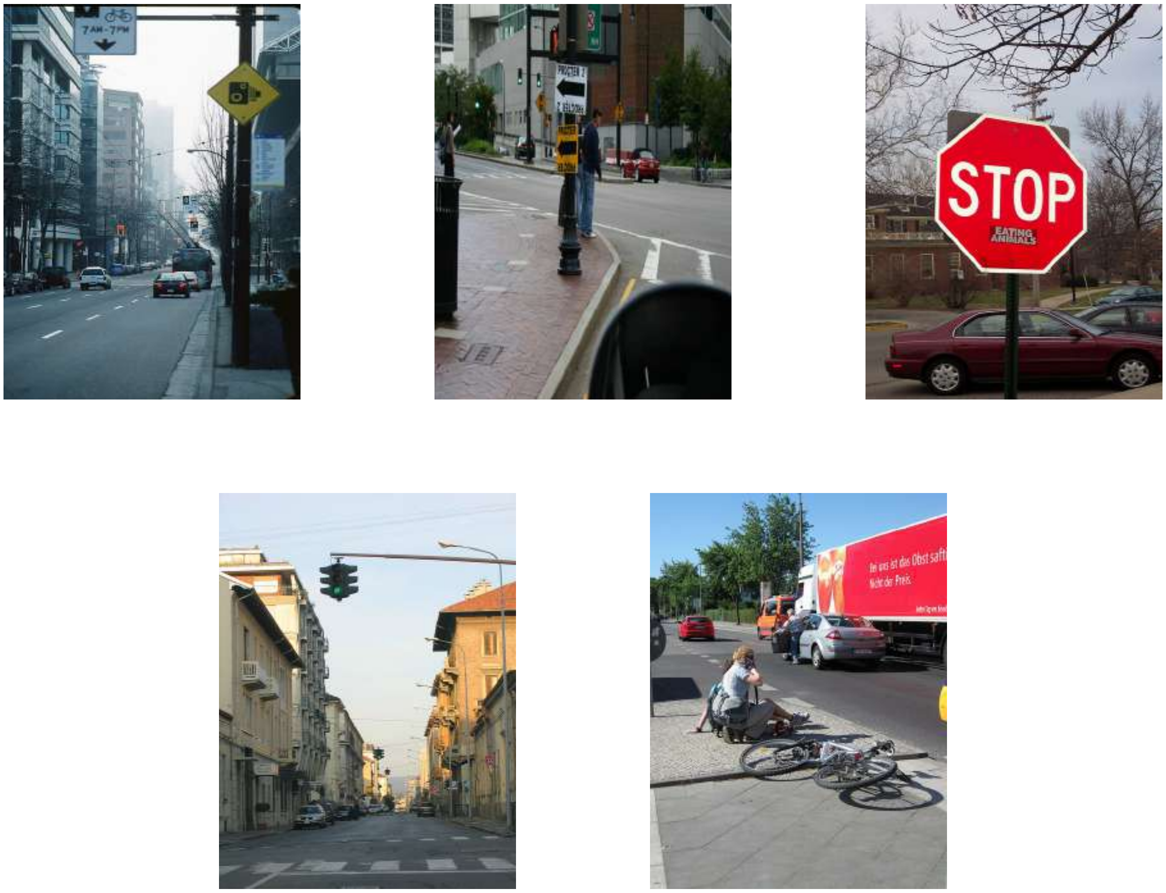

Fig. 1: Sample images of the selected object categories

$$ind(I_i, D, \mathbf{v}, \theta) = \begin{cases} 1, & \text{if } \exists r \in \Re_{D,I_i,\mathbf{v}}, P_{obj}(r|I_i + \mathbf{v}) > \theta \\ 0, & \text{otherwise} \end{cases}$$

where the set of detection results on the perturbed image is $D(I_i+\mathbf{v})$ given by $\Re_{D,I_i,\mathbf{v}} = D(I_i+\mathbf{v})$, with $\mathbf{v} \in \mathbb{R}^d$ being the perturbation. $P_{obj}(r_n|I_i+\mathbf{v}+v_i)$ is the probability of the object class with the highest confidence and the image-independent perturbation, $\mathbf{v}$, must satisfy the following two constraints:

1) $\Re_{D,I_i,\mathbf{v}} = \emptyset$
2) $||\mathbf{v}||_\infty < \xi$

2) *Instance-level blind degree:* Instance-level blind degree calculates the average number of instances that the detector, D finds in each image with confidence beyond the given threshold θ and is expressed as

$$\mathcal{B}_{ins}(D, \mathbf{v}, \theta) = \frac{\sum_{i=1}^{N} |\{r|r \in \mathcal{R}_{D,I_i,\mathbf{v}} \text{ and } P_{obj}(r|I_i + \mathbf{v}) > \theta\}|}{N} \tag{5}$$

where $|*|$ denotes the number of elements in the set.

V. Experiments

In order to test the impact of perturbations on our selected categories, we use Faster-RCNN-FPN-Resnet50 (trained on COCO2017 train) model in Detectron2 [16] [17] library because of its high mean Average Precision (mAP) on the COCO2017 test. We also fine-tuned three hyperparameters: number of epochs(n_epoch), step size (α) and ξ for the max inf-norm of the perturbations. After a series of pilot experiments, we settled on the following values for the parameters: $n\_epoch = 250, \xi$ (max l_p norm) = 10, $\alpha = 20, max\_imgs = 500$, and $score\_threshold, \theta = 0.7$. In our experiments, we keep track of the instance-level and image-level blind degree as we vary perturbation norm for each of the five categories of objects. This is done so that the object detector fails to find objects of a given class at a certain norm. Figure 2 visually shows two examples of the object detector blindness before and after the perturbations.

To evaluate universal perturbations on each category, we conduct a targeted attack on each category. We compute an universal perturbation that attacks only the targeted category by considering only the object proposal classified that category

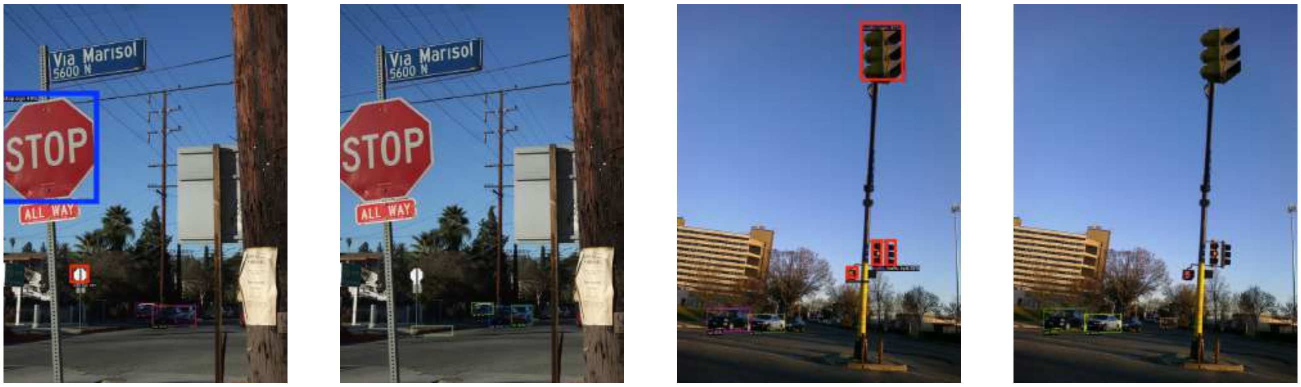

Fig. 2: Samples detection results with and without perturbation. 1st and 3rd columns: detection with clean images. 2nd and 4th columns: detection with perturbed images.

TABLE II: Rank of image level and instance level blind degree resilience of different categories to perturbations as epochs and norm increase

Epochs		Norm	
Image	**Instance**	**Image**	**Instance**
person	person	person	person
stop sign	car	car	car
car	traffic light	traffic light	traffic light
traffic light	stop sign	truck	truck
truck	truck	stop sign	stop sign

and optimizing on the loss based on those object proposals to remove final detections of that class. Figure 3 presents the effect of perturbations on each category as the epochs and the norm are increased.

Based on Figure 3, Table II presents the ranks of resilience of each of our categories. It is evident that the person is the most resilient category at image-level as well as instance-level, followed by car, traffic light, truck and stop sign as the norm is increased. It is also clear that person category is again most resilient to perturbations as you increase the number of steps in projected gradient descent to find a stronger perturbation. However, norm is a more significant metric as it is related to the visibility of the perturbations. It is also notable that a single universal perturbation is able to make the detector fail in detecting objects of all categories, except for, the person category in most of the images, at a norm which is imperceptible to humans.

VI. Conclusion

In this paper, we explore the vulnerability of object detection on five autonomous vehicle object categories to universal perturbations. In diligently designed experiments, we carefully curated the realistic and diverse COCO data set and isolate the failure of object detection without perturbations, from the failure with perturbations. This work lies at the core of the security of data sets in the realm of autonomous vehicle driving. To the best of our knowledge, this is the first study of its kind that ranks the resilience of these five categories to universal perturbations. These results are significant since the perturbations can be imperceptible to humans while causing real harm in an adversarial attack. We believe a more fine-grained and detailed view on the experiments can be beneficial to the rigorous and evaluation of adversarial attacks.

VII. Future Work

Having established a categorical order based on the resilience of image categories to adversarial attacks, this research could take many different directions. One of the possible future effort would be to build and train object detectors while incorporating special features of each of the categories. Another possible direction would be to study the reasons behind the resilience of each of these categories and employ that in training robust object detectors. A different approach of future work would involve studying various new perturbation techniques to further impact the resilience of the object categories. We could also explore multiple new vehicle data sets and explore the effect of perturbations across data sets and algorithms.

***Abstract*—Ontology can describe real-world objects and relationships. It can be used for searching, web mining, and semantic analysis. However, creating the ontology for a different domain is a labor-intensive and computationally expensive task. This work introduces a new model to automate ontology creation for the real estate domain based on a natural language processing approach. The new model can save significant time and human labor in ontology creation in several domains. Also, the new model can enhance retrieval information systems in advanced semantic web search engines.**

I. Introduction

In this work, we apply attention model in natural language processing to create real estate ontology. The real estate market has two main categories, commercial and residential. several studies have been done in the creation of ontology for the commercial real estate [1] [2] [3] [4]. Real estate website provides a wide range of housing data, which includes: property address, number of bedrooms, bathroom and all information related to the house [5] [6], like Zillow [7] and Trulia [8]. Figure 1 shows the example of information that is available on the Zillow website for each house.

Machine learning models can be used in different aspect of scientific research such as business [9]health [10], [11] [12] [13] [14], cyber security [15] [16], [16], environment [17], IOT [18] [19], Data maintenance systems [20]–[22], computer science applications [23], [24] [25] and social science [26].

Natural language processing models [27] [28] and computer vision models [29], [30] [31] can be used in advanced semantic web applications. Model optimization for graph neural networks [32] [33] [34] algorithms play an important role to make artificial intelligence applications more powerful. Natural language processing applications in social media [35] [36] [37] [38] can be used to enhance semantic web search and ontology creation.

In this work, we create an ontology for residential real estate. Each house on the Zillow website has the " overview section," which is a rich source of textual information for creating real estate ontology. This section provides a textual description of the house, which can help extract different contexts related to the real estate domain. Building the ontology for the entities and their relationships in the house description can help analyze and mine interesting knowledge, such as finding the relationship between house price and house properties, the influence of the neighborhood, and cluster similar real estate properties.

Fig. 2. Real estate data example

This project can enhance information retrieval systems and increase customer satisfaction in commercial and residential real estate. For example, when someone wants to sell a house, the system can estimate the house's price based on statistical and textual information and find a potential buyer. Another benefit of real estate ontology is that it improves clustering models for a real estate property and makes it more convenient to search for a specific house. In this way, our project has two major contributions, house price estimation and advanced semantic search for real estate properties. First, we build a domain-specified ontology based on a semi-automated approach since we use human annotators to extract entities and make a ground truth to test the new proposed model. Second, we automate the ontology creation process by using a natural language processing approach, attention model in transformers [39]–[41].

In this project, the main goal is to extract internal and external house features from the textual information to create

Working from home is a breeze with the sun-soaked library/den on the main level with a walk-in closet and built-ins. A fantastic floor plan for entertaining with a living room (with fireplace), dining room, and spacious family room that leads out to the deck overlooking the serene flat backyard. A cook's dream

Fig. 3. Ontology creation process by human annotators

real estate ontology. We have three milestones for doing this project: data collection, building ontology, and testing the model.

1) For each house on the Zillow website, we collect both house descriptions and house features. Data includes house description(textual information), address, zip code, number of bedrooms and bathrooms, rent price, and city.
2) In the semi-automated step, human annotators extract information from real estate descriptions and find real state entities and their relationships. The human-created ontology is the ground truth for our new model. Also, this ontology is checked by a human expert in the real estate domain. Moreover, we modify this ontology based on the expert's idea.
3) Design an NLP model which can automate ontology creation. Test the final model with a ground truth ontology which is created in the first phase.

II. Data Collection

We write a customized software application to collect real estate data by using Zillow API. Using Zillow APIs, we collect about one million real estate records from the website based on three different house types: single-family, townhouse, and condo. The data will be separated into two parts. One part is for ontology creation, and the other part is for testing the ontology. Figure 2 shows our application and the example of data provided by this application.

In this data set, we fully utilize the text part, which describes the real estate information. The texts are unstructured datasets, and they need to be clean before doing text mining. Each record in this work is a text which property owner provides. For example, in the house description, the textual information includes bedroom, kitchen, living room, floor description. These words are the entity that we need to provide more annotation for them. All records in the data set need to have semantic annotation. The adjective words are also important entities for our ontology.

III. Method

A. Text mining and Building ontology by human expert

Figure 3 shows the process of building ontology by human annotators. All textual information is extracted and divided into two groups—one for ontology implementation and the other for testing.

In the First step, We use amazon sage maker ground truth [42] to annotate all entities and create the original real estate ontology by a human expert.

In the second step, to test the created ontology in the first step, human annotators use the ontology in step one to annotate unseen real estate text data set to test the entity annotation method: real estate entities includes bedrooms, bathrooms, area space from the description section on the Zillow website. The entities extracted in the second step show that how much the first step should be repeated to create a more precise and reliable ontology as a ground truth. We continue this iterative process until the model achieves 94% accuracy.

B. Building ontology with OntoGen

OntoGen is software for ontology creation. We use OntoGen to extract the real estate entities and then compare the results with the ground truth ontology for this research. OntoGen assigns the words into several clusters. Also, These clusters give a conceptual idea about how many clusters we should expect in the ground truth ontology. The word frequency in the home description's texts should be similar to the word frequency of the annotated texts by ground truth ontology. Each word is considered as an element or entity. We compare the most frequent elements with our ontology entities to check the correct entity extraction by ontology.

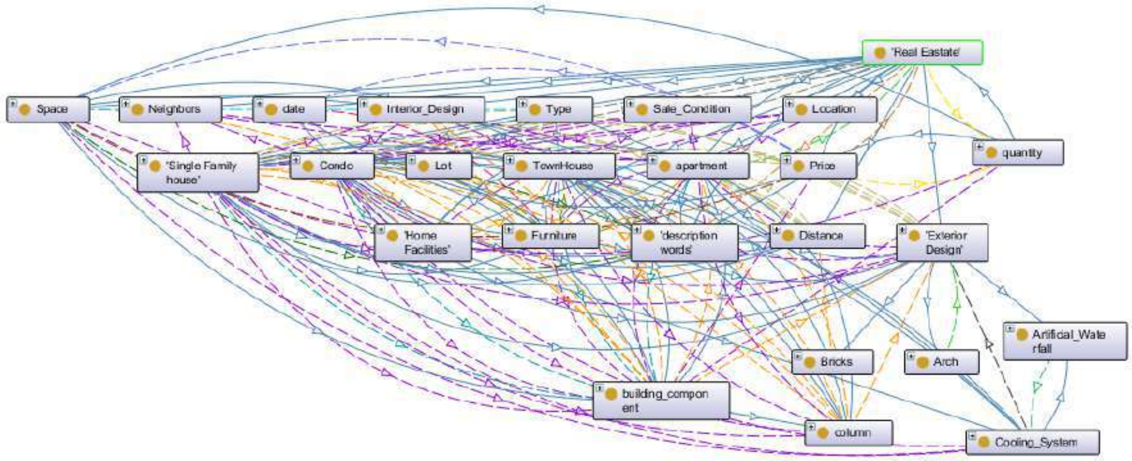

Fig. 4. Ontology based on attention mechanism

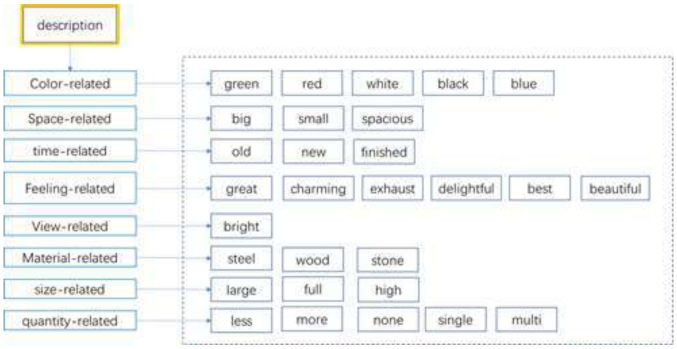

Fig. 5. Descriptive words

C. Building ontology with Protege

We build the ontology with the Protégé. There are four classes: date, description words, quantity, and real estate words. Date class has a subclass of day, month, and year. Description words include all descriptive words in the text. Figure 5 shows descriptive words. The real estate class includes many elements of house features, including room, exteriors, indoor places. The ground truth ontology has the same elements and classes as the Protege ontology.

D. Building ontology with attention model as a natural language processing approach

In this work, to automate the ontology creation, we use the self-attention mechanism in the transformer [43] [44]. We create embedding for each sentence in the real estate data set. Each transformer contains multi-head attention layers that can create multi attention mechanism about each specific real estate word and learn how to get several aspects about one single word in the house description [45]. Figure4 shows the ontology which is created based on the attention mechanism. Self-attention mechanism can be explained as embedding vector for token input, the query (Q), key (K) and value (V) are created from each three parameter matrices where $W^Q \in \mathbb{R}^{d_{model}\times d_k}$,$W^K \in \mathbb{R}^{d_{model}\times d_k}$ and $W^V \in \mathbb{R}^{d_{model}\times d_v}$. So this mechanism can be shown as [46]:

$$Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \tag{1}$$

$d_k = d_v = d_{model} = 768$ in BERT base version which is used in this research.

The class label's occurrence in the ontology entity is shown with $C \in \mathbb{R}^H$, and H is the embedding size of each sentence. So a dense neural layer is treated as a classification layer, which consists of parameters $W \in \mathbb{R}^{K\times H}$, where K is the number of possible class labels that we have in our data set. The class label here means each entity will be paired by multiple entities in ontology, but we choose the one with the highest probability. The prediction probabilities $P \in \mathbb{R}^K$ are calculated by a softmax activation function is:

$$P = softmax(CW^T + b) \tag{2}$$

In this research, all the parameters optimized to minimize the loss function [46].

$$\mathcal{L} = -\frac{1}{N}\sum log\left(\hat{p_c}^{(i)}\right) \tag{3}$$

IV. Test the Ontology Based on Attention Mechanism

To test the ontology with the attention mechanism, we compare the ground truth ontology results with our new ontology. Here are two examples of the results.

In name annotation, we consider the words of the same meaning but in different formats. For example, the words ”high” and ”High” should denote the same word. To distinguish these similar words, we assign each class some neighbor's words. The neighbors help to correct mapping from an instance to an entity. For example, the word ”garden” can be recognized as a garden within the house or park. We give park the neighbors “go” “to” “near” “around”. We give the garden within the house the neighbors of ”have,” ”within.” For the

TABLE I
EXAMPLE OF ENTITY ANNOTATION BY NEW ONTOLOGY BASED ON ATTENTION

Raw text	The Remington Place II model is a gorgeous luxury home that opens into a two-story foyer with a full window wall. The main floor features an expansive kitchen and family room area with an open layout that is perfect for entertaining or dining in. The Remington Place II is designed with a flexible floor plan layout ∼with a choice for the laundry room to located on either the first or second floor. Additionally ∼residents can choose to upgrade with another bedroom and full bathroom on the main level. The upstairs is built with four full bedrooms and a landing space that overlooks the family room. The Remington Place . . .
Annotation by machine	Full, window, kitchen, bedroom, full, More, Less
Mapping by machine	Less ['is type of quantity_realted', 'is subclass of description words'] More ['is type of quantity_realted', 'is subclass of description words'] bedroom ['is type of space', 'is subclass of realestate'] full ['is type of size_realted', 'is subclass of description words'] kitchen ['is type of space', 'is subclass of realestate'] window ['is type of exterior_design', 'is subclass of realestate']
Annotation by human	Story, foyer, window, wall, floor, kitchen, family room, area, plan, laundry, bedroom, bathroom, door, ceiling, closet, vanity mirrors, shower, soaking tube,
Mapping by human	Story [' is type of building component ', 'is subclass of space', 'has a level'] Foyer [' is type of space', 'is subclass of real estate', 'has a size'] Window [' is type of building component', 'is subclass of space', 'has a size'] Wall [' is type of building component', 'is subclass of space', 'has a size'] Floor [' is type of building component', 'is subclass of space', 'has a floor covering'] Kitchen [' is type of space ', 'is subclass of real estate', 'has a tubing system] Family room [' is type of room ', 'is subclass of space', 'has some wall'] Area [' is type of size', 'is subclass of description words', 'has a value'] Plan [' is type of design', 'is subclass of architecture', 'has a location'] Laundry [' is type of cleaning space', 'is subclass of space', 'has a watering system'] Door [' is type of building component', 'is subclass of space', 'has a color'] Ceiling [' is type of building component ', 'is subclass of space', 'has an area']

recognized word "Garden," we find its won neighbors. Then we can compute the probability of these words belong to the two promising entities based on the matching neighbors.

Table I are examples based on our new ontology. The new ontology can extract the real estate entities with high accuracy. Each table contains raw data, annotated data, and mapped data.

V. CONCLUSION

This work created a human-annotated ontology by a human expert in the real estate domain, which can be used as ground truth for ontology creation in this domain. We also introduce a new model for the automated creation of ontology based on the transformer model's attention mechanism to save computational resources and time. In future work, The proposed ontology and annotation function can help to store the information of a house in a structured format for advanced semantic web search engines for the real estate market.

***Abstract*—Social media bots can change society's perspective in different aspects of life. This paper analyzes sentiment features and their effect on the accuracy of machine learning models for social media bot detection. Social bots can use tweet sentiment to create a backfire effect and confirmation bias to create a fake trend or change public opinion. We analyze bot detection problems based on sentiment features inspired by the work by Micheal Workman [1] and create new features based on textual information of online comments. We offer a quantitative approach to create new features and compare machine learning models for bot detection. This work is based on psychological and social effects inherent in tweets' text content based on the work by [1]. The new set of sentiment features are extracted from a tweet's text and used to train bot detection models. Also, we implement the new model for the Dutch language and achieve more than 87% accuracy for the Dutch tweets based on new sentiment features. Considering new sentiment features based on psychological and social factors for a tweet's text will open a potential research area for social media bot detection.**

***Index Terms*—Social media bot, Deep learning, Bot detection, Social factors**

I. Introduction

Bots spread disinformation which can be hard to detect just based on content [2] [3] [4] [5], but advanced methods can detect bot with high accuracy [6] [7] [8]. Social media bot detection can use the offensive language detection [9] [10] or other text characteristic to detect bots. Social media bots can target various audiences by creating fake trends [11], [12]. In the study conducted by Cresci et al. [13], the authors identified multiple types of spam bots, including promoter bots, URL spam bots, and fake followers. URL spam bots spread scam URL links by embedding these malicious links in retweets of legitimate users [14]. Based on the studies by Howard et al. [15], URL sharing bots are used for constant tweet duplication of legitimate users in a certain time to spread malicious URLs. One popular bot detection service is "Botmeter", which is a supervised learning approach to detect social bots [16]. Botmeter uses metadata related to each Twitter account, such as network features, user features, and temporal features, to feed a Random Forest classifier algorithm. Network features show how information diffusion happens among multiple groups of users. User features include a user name, screen name, the creation time of account and geographic location, and temporal features show patterns in a tweet's timeline. Graph-based approaches for bot detection uses fully connected nodes among a group of Twitter accounts to detect bots [17].Machine learning models have different applications in health, cyber security and business [18]. Transfer learning models also can be used in bot detection models [19]–[22].

The idea of extraction of new sentiment features for bot detection in this work inspired by the work [1] and the effect on confirmation bias and backfire effect on online users. Micheal et at [1] in his work said, "People have different ways of cognitively formulating concepts and processing information, referred to as cognitive styles. When considering a problem or an issue, some people are more self-reflective and self-reliant in terms of these cognitive processes, known as internal focused, compared to others who tend to rely on the formulation using group interaction, known as external-focused . The effects of this can be observed in the differences between people who need quiet solitude and concentration for idea generation and those who find group processes (such as group brainstorming) a means of cognitively priming ideas ." So in this work also we consider a sentiment analysis related to confirmation bias and backfire effect from the External focus based on his work [1]. This work is a preliminary report on using sentiment features for social media bots from a psychological perspective based on theoretical formulation provided by [1] about these factors. We next discuss the social effects used in this work. One famous social effect is the "backfire effect" [23] which is a widespread phenomenon in social media. The backfire effect occurs when one side of an argument provides many facts to change the audience's mind, but the effort has the reverse effect, creating more resistance in the opposing person's mind [9]. For example, when a Twitter user encounters comments that support more opposing views for an extended period, a person decides not to change his or her original beliefs, and thus the reverse effect occurs. Providing more facts creates more resistance to accept the facts rather than transferring the truth behind events. So the target of the argument decides not to change their mind regardless of what the truth is. Another crucial social effect is "confirmation bias." This occurs when people try to interpret every event based on their existing beliefs. In social media and Twitter, tweets that support people's ideas are more popular than tweets from an opposing view. Some trends and positions apparent in social media are created using the backfire effect and confirmation bias.

Social media bots can use confirmation bias or backfire effect to create fake trends, fake news, and sell products. These types of bots try to infuse fake events by creating psychological effects on users' emotions. In this research, we

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

TABLE I
CRESCI 2017 DATASET DESCRIPTION

user type	tweet count	user count
genuine	2839361	3474
social spam bot #1	1610034	991
social spam bot #2	428542	3457
social spam bot #3	1418557	464
traditional spam bot	145094	999
fake followers	196027	3351

do not analyze the backfire effect and confirmation bias for social Media bot detection directly on a tweet's text; instead, we use the sentiment features introduced by [1] and make a new feature set to improve machine learning models for bot detection. These extracted features are then used to find the best machine learning model for social bot detection in Twitter. All methods in this work are evaluated based on accuracy, F1 score, and MCC for bot detection. Also, Our method provides high accuracy for bot detection in Dutch tweets as well as English tweets. We address three main questions in this work:

1) What are new sentiment features that discriminate between human accounts and social spambots? (These features are inspired by the studies conducted by Workman [1] about Confirmation bias and Backfire effect)
2) Does the new sentiment analysis improve the accuracy of machine learning models for bot detection?
3) Is the new method applicable just to English Tweets?

II. DATASET

In this work, we use Cresci 2017 data set [13], a labeled data set of bots and human users on Twitter. There are five categories of bots: Social Spam bot #1, #2, #3, fake followers, and traditional spambots. Social Spam bot #1 are automated accounts from a 2014 election in Rome. Social spam bot #2 are promoter bots that spend several months promoting specific hashtags on Twitter. Social spam bot #3 is Amazon accounts that share spam URLs on Amazon pointing to their products. Traditional spam bots are Twitter spammer accounts that are collected from the Cresci 2013 data set [24]. The Cresci authors bought fake followers from different websites [13]. Table I shows the statistics of the Cresci 2017 data set. In this data set, each account includes the following attributes: follower-count, friends-count, retweet-count, reply-count, number of hashtags, number of shared URL, tweet's text, screen name, and user ID.

III. METHOD

In this section we identify new features and compare their effect on the machine learning models for social media bot detection. At first we answer the following questions in this experiment.

A. New features

1.What are new sentiment features that discriminate between human accounts and social spambots?

Each Twitter account has different features, such as network features, user features, and user's text content information, as discussed earlier. In this research, based on the work Michael et al. [1] we believe that one way to detect confirmation bias or backfire effect characteristics in the user account is to find a very biased opinion in the sentiment of tweet's text which is posted by a specific Twitter account. Extraction of sentiment from the tweet's text can detect potential confirmation bias and backfire effect in a user's online posting behavior [1]. We first examine tweets which are posted by an individual Twitter account. If the number of tweets posted by an account shows a significant concentration in the number of positive, negative, or neutral tweets, it could indicate a biased opinion or intensity in idea [1] that has a potential create confirmation bias or a backfire effect. So, our model flags these types of accounts for further investigation.

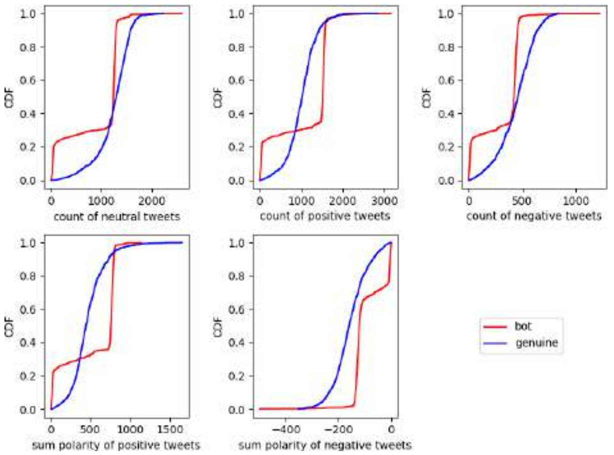

Fig. 1. Cumulative distribution function(CDF)

We provide quantitative analysis, but first, we bring a real-life example to show a clearer picture of the problem. For example, a human account on social media posts her idea about different topics in various ways. Her idea about a movie she saw last night is positive, but her opinion could be negative about the product she bought today. A human user would not post only positive comments, negative comments, or only neutral comments about all aspects of her life. When we examine tweets posted by bot accounts, the variety in the number of positive, negative, and neutral comments is very low, the user posts tweets only about a specific event, and the posts are typically skewed to extreme opinions [1]. In the following section, we apply quantitative analysis to show that the variation of tweet sentiment in each positive, negative, and neutral category is significantly different between a human and a bot account on Twitter.

Figure 1 shows a cumulative distribution function (CDF) for distinguishable characteristics of positive and negative tweets between a human account and a bot account. It can be seen that there is a significant difference in the number of positive, negative, and neutral tweets between a human and a bot account. So sentiment is a discriminating feature for a bot detection model.

We consider creating a new attribute set for each Twitter

TABLE II
NEW ATTRIBUTES

New Features	Description
Count-Neutral	Count of neutral tweets for a user
Count-Positive	Count of positive tweets for a user
Count-Negative	Count of negative tweets for a user
Sum-Positive	Sum polarity scores of positive tweets which are posted by a user
Sum-Negative	Sum polarity scores of negative tweets which are posted by a user
Average-Positive	*Sum-Positive/Count-Positive*
Average-Negative	*Sum-Negative/Count-Negative*

account based on the CDF values for positive and negative tweets. The first new attribute calculated based on the sentiment of a specific user's tweets is a polarity score for each tweet. Polarity score classifies each tweet's text into three different categories, positive, negative, and neutral. Polarity is assigned to each tweet's text by using TextBlob[1]. The polarity assigns a score X for each tweet's text such that $1 < X < 1$. The polarity score of zero means the tweet's text is a neutral comment, $0 < X$ means a positive comment, and $X < 0$ means a negative comment. Table II shows how we apply our new sentiment analysis method to extract new attributes from a tweet's text to differentiate a human account from bot accounts based on Figure 1.

B. The effect of new features in Machine learning models for bot detection

Does the new sentiment analysis improve the accuracy of machine learning models for bot detection?

In this section, we examine machine learning models based on new sentiment features. We evaluate machine learning models such as Random Forest, Support Vector Machine, Logistic Regression, and feed-forward neural network. We run bot detection classifiers with and without new features to show their effect on algorithm performance. First, the original data set attributes(previous mode of operation), and second, with the vector of new sentiment features extracted for each user(New mode). Original features for each account in Cresci 2017 include follower-count, friends-count, retweet-count, reply-count, number of hashtags, and shared URLs.

C. Random Forest

In this section, we use the Random Forest algorithm used for bot detection. This method was previously used in the study by Battur and Yaligar [25]. First, we apply the random forest on the original feature set for each Twitter account provided by Cresci 2017 [13]. Secondly, we apply the new features for each account. In both experiments, 10 fold cross-validation is used, and 20 trees are created. We determined the number of trees based on Grid search. The only difference between the two experiments is the attribute set. Table III shows that the accuracy, F1 score, and MCC are improved based on news sentiment features.

TABLE III
RANDOM FOREST PERFORMANCE

algorithm	accuracy	f1 score	mcc
random forest previous mode	0.887	0.874	0.843
random forest new mode	0.923	0.912	0.887

TABLE IV
ALGORITHM PERFORMANCE

algorithm	accuracy	f1 score	mcc
Random Forest	0.923	0.912	0.887
ANN	0.910	0.927	0.874
SVM(SVC)	0.914	0.922	0.889
SVM(SVR)	0.899	0.930	0.860
Logistic Regression	0.874	0.888	0.685

D. SVM and Logistic Regression

We first run the SVM based on original attributes, then with the new extracted features from a tweet's text for each Twitter account. Two variations of the SVM algorithm are used from the SciKit-learn library in python[2]. For the SVM kernel, we use nonlinear hyper-plane 'poly' with a degree of 7, which provides us with the best results. The data is split into 70% for the training set, 10% devset, and 20% for the test set. The input space is a set of $(x_1..x_i)$ where x_i is the attribute related to each Twitter account. . In the new sentiment analysis, we use the new extracted sentiment features. The result for SVM classification with new parameters is shown in Table IV.Based on Table IV, the F1 score and MCC value show that how the new set of features can detect bots with an accuracy of 90%, F1score nearly 91%, and MMC more than 85%. The result for SVC is better than the SVR with an MCC of 89% and accuracy of 92%.

In this research, we run logistic regression based on the new extracted attributes from a tweet's text. Table IV shows the result for logistic regression. The result shows F1score and prediction accuracy but very low MCC and so this is not a strong algorithm for bot detection based on tweet's text.

E. Neural Network

In this section, we examine the Neural Network model based on the new proposed sentiment analysis. A study by Chen et al. [26] shows how features as input space play an important role in classification results. In this research, sentiment analysis on tweet text has been done to create a new vector of features for a feed-forward neural network. As before, the model is evaluated based on two different attribute sets, original data set features and then based on new sentiment features. The neural network for proposed bot detection in this work is shown in figure 2. The Neural Network model has two hidden layers in this experiment.

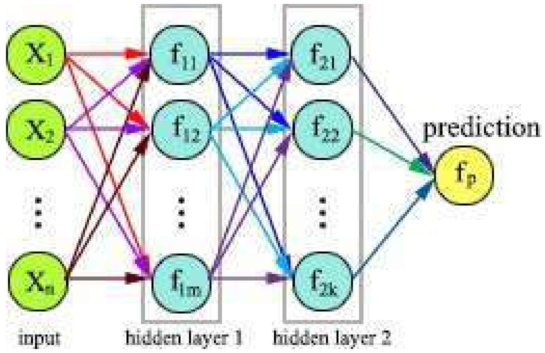

Fig. 2. ANN model for tweet bot detection

TABLE V
NEURAL NETWORK PERFORMANCE

algorithm	accuracy	f1 score	mcc
Neural network previous attribute set	0.899	0.906	0.793
Neural network new attribute set(new sentiment features)	0.910	0.927	0.874

$$y_i = \sigma(w_1 x_1 + ... + w_m x_m)$$
$$y = \begin{pmatrix} \sigma(w_{1,1}x_1 + ... + w_{1,m}x_m) \\ \vdots \\ \sigma(w_{n,1}x_1 + ... + w_{n,m}x_m) \end{pmatrix} \qquad (1)$$

In this research, based on formula 1, Twitter account feature xi where $xi \in (X_1..X_n)$ is one characteristic of user account such as retweet-count, number of followers. X shows the input to the fully connected layer where the output space is $Y \in \{Bot, \neg Bot\}$ and w_i is the weight parameter related to each feature of the Twitter account. Adding a new drop-out layer improves the prediction accuracy in comparison with a fully connected FFNN model in this experiment. The final results for two modes of operation of the fully connected neural network model are shown in TableV.

IV. Results and Algorithm Evaluation

This section provides a comparative analysis of machine learning models for bot detection. Table IV shows the results for all models. As it can be seen, new sentiment features improve Accuracy, F1 score, and MCC. The Logistic regression model has a low value for MCC in comparison with other classifiers. Regarding the prediction accuracy and F1 score, Random Forest and SVM (SVC) provide the best values. However, logistic regression has the least value for F1 score, Accuracy, and MCC. The Random Forest provides the highest value for MCC. SVM and FFNN have similar values for MCC. Based on Accuracy, F1 score, and MCC metrics and with respect to adding new sentiment features, this experiment identifies Random Forest and FFNN as powerful models for social media bot detection.

TABLE VI
DUTCH PERFORMANCE

algorithm	accuracy	f1 score	mcc
ANN	0.861	0.857	0.767
Random Forest	0.891	0.901	0.847

V. Language Dependency

In this section, we answer the third question: Can we use new sentiment features to detect bots for tweets that are not in the English language? We evaluate the effect of new sentiment features in Dutch tweets from Cresci 2017. In Table VI it can be seen that the new sentiment features provide good results for bot detection in Dutch as well. Based on new sentiment analysis, FFNN and Random Forest can detect bots in Dutch tweets with a prediction accuracy and F1 score of nearly 90%. Random Forest provides the best performance to detect bots in Dutch tweets as well as English tweets.

VI. Conclusion and future works

In this research, we evaluate the role of sentiment features on social media bot detection models and their potential role on confirmation bias and backfire effect based on a study by Michael [1]. A new set of sentiment features based on online user's posts improves model accuracy in detecting social bots. Also, applying a new set of attributes is not limited to English tweets but also shows impressive results for Dutch tweets. In our method, we consider both an account level(new set of sentiment features)and a group level approach(previous network features) for Twitter bot detection. For future work, the new method of feature engineering will be improved to extract more features from the online user comments.

***Abstract*— Disability is defined as a condition of the human body that limits the execution of a task or activity. According to the World Health Organization (WHO), 15% of the world's population suffers from it, recent studies indicate that the growing prevalence are a significant problem and that, consequently, the demand for rehabilitation services is rising considerably. For this reason, different authors propose the use of exoskeletons in rehabilitation therapies as an alternative solution. Thanks to the progress of this kind of technology, it is possible to create robotic systems that help people with disabilities to recover, totally or partially, the original movement of their affected limbs. This Innovative Review Article presents an exhaustive review of the main features of upper-limb exoskeletons such as Degrees of Freedom (DoF), mechanism type, rehabilitation mode, movements allowed, applications and Technology Readiness Level (TRL). Firstly, the study provides a brief description of the biomechanics of the upper limbs of the human body. Next, the material, the rehabilitation modes and the Technology Readiness Level (TRL) of each of these devices are analyzed. As a result, it was observed that aluminum and PLA are the most used materials for exoskeletons' manufacturing. In addition, it was noticed that most of these exoskeletons perform passive rehabilitation. Besides, it was identified that the most common applications are the assistance and rehabilitation in the affected limb of patients who have suffered a stroke. Finally, using TLR scale, it was determined that these mechatronic systems are between TRL5 and TRL8.**

Keywords—Biomechanics, biomechatronic, elbow, exoskeletons, rehabilitation, shoulder, upper-limbs, wrist

I. Introduction

Over the years, the incidence of disabilities in the world population has increased significantly, becoming an alarming social problem. According to the World Health Organization (WHO), a person with a disability is someone who has “any problem with the function or the structure of the body, a limitation of activity, a difficulty in the execution of a task or action, with a participation restriction” [1]. It should be noted that a considerable percentage of people suffer from this condition around the world.

In 2011, the World Health Organization (WHO) reported 1,636,800 people with disabilities [2]. That is, approximately 15% of the world's population [3]. For example, in Canada, 13.7% of the population over 15 years of age suffered this reality and in 2018, the percentage attained 22.3% [4]. Furthermore, in Latin America and the Caribbean, from 2000 to 2010, more than 66 million people lived with a type of disease; representing 12.4% and 5.4% of the of Latin American and Caribbean population, respectively [5]. From 2010 to 2012, there was an increase of more than 4.5 million, raising the number from 66 121 596 to 70 666 206 people [6]. In 2011, the first report on disability in Peru was published. The study determined that 5.2% of the Peruvian population suffered from some kind of disability [7]. It is important to mention that several countries do not have updated statistical information.

The demand for physiotherapy and rehabilitation services is increasing. Therefore, meeting this need properly becomes a challenge. Rehabilitation exoskeletons emerge as a possible solution to this problem [8], [9]; awakening the interest of the scientific community in proposing improved designs for these robotic systems.

One of the most prominent applications in exoskeletons is robot-assisted rehabilitation, due to the promising advantages they offer to the patient [10]. Since the device must imitate the natural movement of the patient’s affected limb, without causing complications that threaten the user’s safety [11], these mechatronic systems are very complex: imitating the movement of the patient's internal joints while retaining the same number of degrees of freedom (DoF) is a complex endeavor.

On the other hand, understanding the biomechanics of the upper limb allows researchers to easily analyze the processes and forces that affect the human body. The kinematics and the additional weight, generated by the patient's upper limb, are additional features that are considered in its design [12]. Finally, exoskeletons are classified according to the NASA Technology Readiness Level (TRL) scale.

A. *Applications*

Nowadays, exoskeletons make it possible to perfect the techniques used in rehabilitation; achieving better results compared to the traditional techniques. In this section, the application of the upper limb exoskeletons detailed in Table I are presented.

Some exoskeletons in Table I were designed for the treatment of patients that had suffered strokes, which the WHO describes as a phenomenon that interrupts blood flow through the arteries [13]. An example of these devices is AGB-Exo [14], a gravity balanced motorized mechatronic system focused on shoulder and elbow rehabilitation. This device features four active DoF and one passive DoF that offers an active rehabilitation training mode. This device performs movements such as extension-flexion, pronation-supination, abduction-adduction and internal-external rotation in the patient's upper limb. Other examples are ETS-MARSE [15], CLEVER ARM [16], among others.

However, most of the exoskeletons in Table I. were designed to rehabilitate and / or assist the upper limb, that is, the shoulder, the elbow and the wrist, without considering the hands. They are oriented to the treatment of patients with disabilities who have difficulties performing joint movements, without specifying the pathology that caused it. An example is ChARMin [17], a robotic device with 6 DoF. This system provides active and passive rehabilitation modes. It performs movements such as extension-flexion, abduction-adduction, pronation-supination, and internal-external rotation in the user's upper limb. Other examples of this type of devices are ANYexo [18] and CAREX-7 [19].

As well, most of the exoskeletons in Table I were designed to rehabilitate and / or assist a specific part of the upper limb, focused on pathologies such as myopathy, Duchenne Muscular Dystrophy (DMD), among other injuries. External agents such as exoskeletons support rehabilitation of the patients through therapeutic techniques that stimulate motor skills and functions. For example, Armeo®Power [20] is an exoskeleton of 6 DoF with the purpose of rehabilitating patients who have suffered a stroke, Parkinson's disease, cerebral palsy, among others. Likewise, InMotion ARM [20] is an exoskeleton system developed by the Massachusetts Institute of Technology (MIT), whose structure provides 3 DoF. Other examples are Higuma *et.al* [17], ETS-MARSE [21], ReHab-Arm [22], seen in Fig 1.

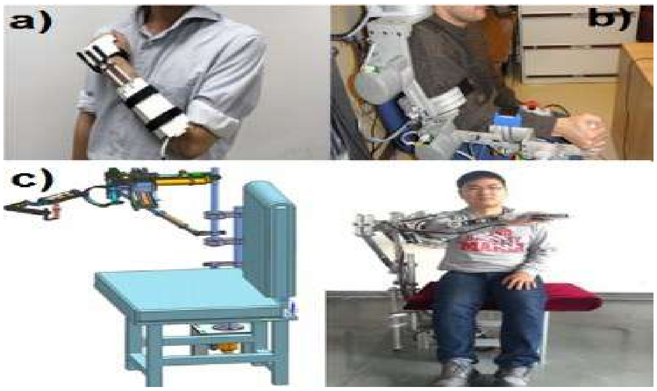

Fig. 1. Upper-Limb Exoskeletons. a) ETS-MARSE [15]. b) Rehab-Arm [22] c) Higuma *et.al* [40].

II. Biomechanics of Upper Limbs

Upper extremity exoskeletons are designed to accurately mimic the natural movement of the human body. So, biomechanical concepts are important in their design.

A. *Biomechanics of the Shoulder*

The human shoulder is a structure made up of joints with the most significant range of motion (ROM). It has three bones which are the clavicle, the scapula and the humerus. In addition, it has three independent joints. The shoulder includes the sternoclavicular, acromioclavicular, and glenohumeral joints as seen in Fig 2. The three joints form the closed kinematic chain of the shoulder girdle [23]. When exploring its range of motion (ROM), the scapulothoracic mobility (movement of the scapula over the chest wall) and the shoulder mobility should be considered [23]. Although the initial 30° of abduction are performed without movement of the scapula, the joint movement for full arm lift occurs at a ratio of 2:1 for every 3° of lift. The shoulder joint confers approximately a second physiologic thoracic scapular junction [23]. That is, when the limb has been raised, and the arm remains in a vertical position next to the head (180° of abduction or flexion of the arm), the shoulder joint has participated in 120° and the scapulothoracic junction in 60° [23]. The important movements of the shoulder girdle are those of the scapula: elevation and descent, prolongation, retraction and rotation.

The sternoclavicular joint is a saddle synovial joint, but it works like a spheroid joint. It is divided into two compartments by an articular disc. This disc is firmly attached to the anterior and posterior sternoclavicular ligaments and the interclavicular ligament. The sternoclavicular joint is stable and provides significant mobility to the shoulder girdle and upper limb. In full limb elevation, the clavicle is elevated to an angle of approximately 60° [23]. When lifting is performed by flexion, the rotation of the clavicle is followed around its longitudinal axis. The acromioclavicular joint is a flat synovial joint located 2-3 cm from the highest point of the shoulder formed by the lateral part of the acromion. The acromion of the scapula rotates on the acromial extremity of the clavicle [23]. There is no muscle that connects the bones that make the joint and move them, but it is the axioappendicular muscles that are inserted into the scapula and move it displacing the acromion over the clavicle [23].

The shoulder joint (glenohumeral) is synovial and spheroid. It allows a wide variety of movements, making it relatively unstable. The proximal area of the humerus articulates with the glenoid cavity of the scapula, and although it is relatively shallow, it is slightly enlarged by the ring of the glenoid border [23]. The glenoid cavity houses approximately one third of the proximal area of the humerus, which is held in position by the musculotendinous rotator cuff (supraspinatus, infraspinatus, teres minor, and subscapularis muscles) [23]. The shoulder joint allows movements in the three axes: flexion-extension, abduction-adduction, medial and lateral rotation of the humerus, and circumduction. Lateral rotation of the humerus increases the range of abduction. When the arm is abducted without rotation, the available articular surface is exhausted and the greater tubercle meets the coracoacromial arch, preventing further abduction. If the arm rotates laterally

180°, the tubercles rotate backwards and more articular surface is available for continued elevation [23].

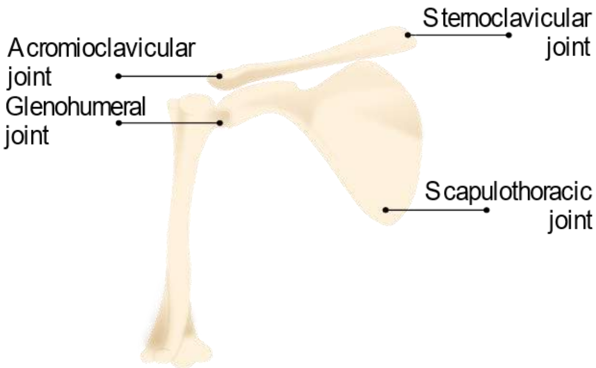

Fig. 2. Joints located at the shoulder

B. *Biomechanics of the Elbow*

The elbow joint, as seen in Fig 3., is a hinge-type synovial joint located 2–3 cm below the epicondyles of the humerus [23]. The pulley-shaped trochlea and the spheroidal condyle of the humerus articulate the trochlear incision of the ulna and the slightly concave upper face of the head of the radius. Consequently, there is a humeroulnar and humeroradial joint. The articular surfaces, covered with hyaline cartilage, are almost completely congruent when the forearm is positioned midway between pronation and supination, and the elbow is flexed at a right angle [23]. The elbow joint allows flexion and extension movements. The long axis of the ulna in full extension forms an angle of about 170° with the long axis of the humerus [23]. This angle is called the angle of transport, because of how the forearm moves away from the body. The obliquity of the ulna, and consequently the angle of transport, are more pronounced in women than in men [23]. It is believed that this allows the upper extremities to avoid hitting the wide female pelvis when swaying while walking. In anatomical position, the elbow is in front of the waist, the angle of transport disappears when the forearm is in pronation [23].

The proximal radioulnar joint is a trochoid-type synovial joint that allows movement of the head of the radius over the ulna. The proximal end of the radius articulates with the radial incision of the ulna and is held in position by the annular ligament of the radius [23]. During pronation and supination of the forearm, the head of the radius rotates within the annulus formed by the annular ligament and the radial incisions of the ulna. Supination rotates the palm anteriorly, or superiorly if the forearm is flexed. Pronation turns the palm posteriorly, or inferiorly if the forearm is flexed. The axis of these movements passes proximally through the center of the radial head and distally through the insertion of the vertex of the articular disc of the ulna [23]. During pronation and supination, it is the radius that rotates: its head rotates within the cup-shaped ring formed by the annular ligament and the radial incision of the ulna. Supination and pronation are almost always accompanied by synergistic movements of the shoulder joint and the elbow that produce simultaneous movements of the ulna, except when the elbow is flexed [23].

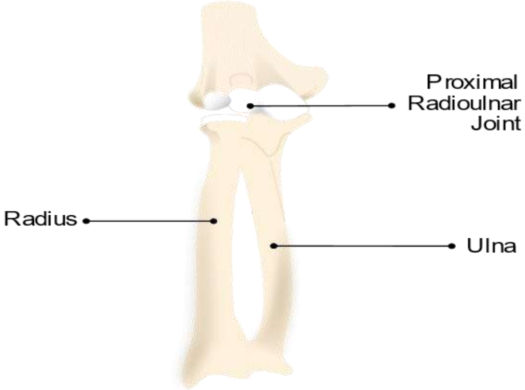

Fig. 3. Joints located at the elbow

C. *Biomechanics of the Wrist*

The radiocarpal joint is an ellipsoid-type synovial joint. The position of this joint is indicated approximately by a line joining the styloid process of the radius with the one of the ulna or by the proximal groove of the carpus [23]. The carpus (wrist seen in Fig 4.) is the proximal segment of the hand. It is made up of a group of eight carpal bones, it articulates proximally with the forearm through the radiocarpal joint and distally with the five metacarpals. The radiocarpal joint can increase its range of motion (ROM) by additional small displacements of the intercarpal and midcarpal joints. The movements that the wrist joint allows to perform them and are flexion-extension, abduction-adduction and circumduction. The degree of flexion of the hand on the forearm is greater than the one of extension; these movements are followed by similar movements in the midcarpal joint [23]. The degree of adduction of the hand is greater than that of abduction. Most of the adduction occurs at the radiocarpal joint. Circumduction of the hand consists of a successive series of flexion, extension, adduction, and abduction movements.

As mentioned in this article, biomechanics concepts are applied in the development of exoskeletons oriented to the rehabilitation of the upper limb. Within the biomechanical analysis, the researchers proceed to kinematic and dynamic modeling. Kinematic modeling is the geometric formulation of a system to obtain the values of the joints and the location of the final element (position and orientation) with respect to a reference system. Dynamic modeling consists of the physical equations of motion in a three-dimensional space and considering the forces acting on the joints. Destarac *et al.* [24], for example, performs the kinematic and dynamic modeling of the ORTE robot, obtaining the values that determine the workspace and the forces that affect it.

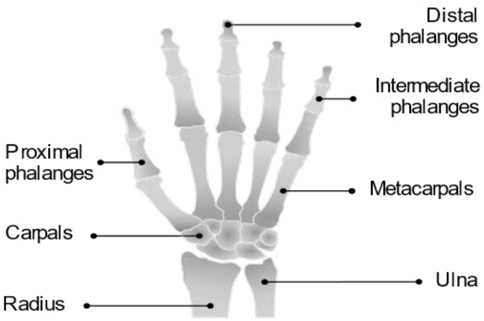

Fig. 4. Joints and bones located at the wrist

III. Mechatronic Exoskeletons

There is a wide variety of rehabilitation exoskeletons, each at a different development stage. The analyzed upper limb exoskeletons were classified according to NASA's Technology Readiness Level (TRL) scale, which is used to indicate the development status of technology projects, where TRL 1 is the lowest and TRL 9 is the highest [25], [87 – 91].

The upper limb exoskeletons shown in Table I were classified using the TRL scale. The analyzed exoskeletons were found to be between TRL5 and TRL8. Each level has a different meaning: an exoskeleton in TRL 5 is considered a full-scale development, while in TRL 6, it has already been validated in a simulated environment. In TRL 7, the system/prototype has been validated in a real environment, in TRL 8, the first prototype/system is available for commercialization, and in TRL 9, the exoskeleton is officially commercial [26].

In Table I, the most common levels observed for the exoskeletons for the upper limbs were TRL 6, TRL 7, and TRL 8, while TRL 5 was the least common. It shows the exoskeleton's names or references and their classification by degrees of freedom (DoF), mechanism, rehabilitation mode, movements, application and TRL [92-94].

A. *Materials*

The exoskeletons used for rehabilitation attempt to resemble the natural anthropology of patients. That is, they try to imitate the natural movements of the users. When designing an exoskeleton, it is essential to take into account characteristics such as mechanical strength, resistance to fatigue, weight, cost, availability, etc. Thus, this section analyzes the selection of materials used for the mechanical structure of the robotic systems shown in Table I.

a) *Metallic materials*

Metallic materials are used in exoskeletal devices due to their high resistance, hardness and rigidity. Aluminum and metallic alloys are the most used materials, used by researchers for prototype development. In this section, the exoskeletons that have metallic materials in their mechanical structure are mentioned. Some examples are RETRAINER-ARM [27], EXOWRIST [28], EASoftM [29] and 4-soft-A [48], among others; seen in Fig 5.

For EXOWRIST [28], its mechanical structure is made of aluminum alloy. This upper limb exoskeleton is a prototype for patients with cerebrovascular diseases. This system has two degrees of freedom (DoF) and is oriented to the treatment of wrist. This device performs movements such as extension-flexion and urnal-radial. It has actuators integrated into the metal mechanism that are manipulated during the physiotherapy sessions. This system is useful for the evaluation of patients with the support of a therapist, who configures the type of rehabilitation exercise to be performed.

In a different manner, RETRAINER-ARM [27] is an upper extremity exoskeleton that features four degrees of freedom (DoF). It is oriented to the treatment of stroke patients. Its mechanical structure uses aluminum metal links. The ease for manufacturing and the geometric shape of the pieces stands out. This device constitutes a non-invasive exoskeleton that assists the patient during their treatment.

For example, EASoftM [29] is an upper limb exoskeleton that features four degrees of freedom (DoF). This device performs movements such as extension-flexion, pronation-supination, and internal-external rotation in the patient's upper limb, which is oriented to the treatment of patients with different injuries. This mechatronic system aims to rehabilitate the shoulder and elbow. On the other side, the researchers have selected aluminum alloys, since it is flexible, non-invasive, it has an adequate mechanical resistance and a proportional weight. These characteristics were observed during the follow-up of the rehabilitation process of a patient.

The aluminum is one of the materials that stands out for its high availability, low cost, high manufacturability (cutting process) and preferred for the mechanical structure of exoskeletons.

b) *Plastic materials*

The use of plastic materials in robotic devices is common mainly due to their lightness. These materials are used as hybrid elements that make up the structures of robotic systems. That is, they are used together with other materials. Their elastic properties and tensile stress make them the most suitable material for deformation. In this section, some of the exoskeletons, listed in Table I, whose mechanical structure is built based on plastic materials are described. Some examples are ChARMin [17], ARMin III [55] and RETRAINER - ARM [27], among others.

For ARMin III [55], materials are selected considering design complexity. It performs movements such as extension-flexion, abduction-adduction, internal-external rotation and protraction-retraction. In this way, designers ensure that they are capable of resisting weight, resistance and fatigue. In order to design complex mechanisms, 3D printing is also used. This exoskeleton has 10% lactic polyacid to facilitate the attachment with actuators and their fixation.

On the other hand, RETRAINER-ARM [27] is a system that aims to rehabilitate the shoulder and elbow. This apparatus performs movements such as extension-flexion, elevation and rotation in the patient's upper limb. It uses flexible plastics to adapt to the anthropology of the patient, considering that the patient will use this hybrid mechanism with actuators.

For example, ChARMin [17] uses Acrylonitrile Butadiene Styrene (ABS) for manufactured parts whose geometry is complicated and requires a too complex design to support structures such as actuators. This device is made of aluminum and has joints, fixing elements, and accessories with lactic polyacid. Given the demands of the design, it is a hybrid mechanism. 3D printing is used to manufacture parts such as joints, screws, fasteners or connecting pins in order to obtain a hybrid exoskeleton that meets the fatigue and deformation requirements. This technology provides the easiest way to produce the parts, since it allows the manufacturing of highly complex designs. Acrylonitrile Butadiene Styrene (ABS) is one of the most used plastic materials for the mechanical structure of the exoskeletons listed in Table I.

Plastic materials are selected because their characteristics allow to solve several design challenges. They are resistant, they support fatigue stress, they are non-corrodible, easy to maintain and resistant to running or testing.

B. Rehabilitation mode

Currently, using exoskeletons for rehabilitation provide a high-quality option to regain movement thanks to their precision in repetitive movements. Rehabilitation is the treatment that a patient receives with the aim of recovering, maintaining or improving the physical or mental skills necessary for daily life, and thus improve their quality of life. In this case, we will focus on physical abilities, which can be totally or partially reduced due to illnesses or injuries. Rehabilitation modes can be passive, active, and assisted [87] In this section, the rehabilitation modes offered by the exoskeletons in Table I are mentioned.

a) Passive rehabilitation

The use of exoskeletons with passive rehabilitation modes allows treating patients effortlessly: the robotic system helps the patient move the muscles and joints throughout his/her ROM. This is commonly used when the user suffers from a disability caused by hemiplegia and other common injuries. Although passive exercise does not require any effort from the patient, following this kind of rehabilitation has many benefits, such as helping them to prevent joint stiffness. These benefits are most effective when used consistently over a long period of time.

An example of this rehabilitation mode is provided by EASoftM [29]. Patients during rehabilitation can perform exercises without additional effort. The succession of exercises that the patient must follow is monitored by the therapist. Passive rehabilitation is a great way to improve blood flow to affected areas and provide sensory stimulation to the affected limb. Another benefit is shown by EXOWRIST [28], where the use of this rehabilitation mode helps prevent the worsening of spasticity of the upper limbs in patients.

In ULEL [33],[34] this mode helps patients interact with the rehabilitation professional to perform exercises. This exoskeleton focuses on passive movements to provide the patient with routines that include massages, chiropractic, and physical therapy. Similarly, the RETRAINER-ARM [27] exoskeleton aims to rehabilitate the patient through the passive mode making the shoulder and elbow move using an external force which is generated by the exoskeletal device.

b) Active rehabilitation

The active rehabilitation mode with exoskeletons implies that patients make a physical effort to move, that is, they perform the exercises and the exoskeletons offer resistance to movement in a way that helps them to strengthen the muscles. In general, physical rehabilitation stimulates the brain to reconnect through neuroplasticity, improving the ability to send signals to the muscles. Neuroplasticity occurs with both passive and active exercise but is enhanced with active exercise. One of the benefits of active rehabilitation is that it helps to strengthen muscles, being beneficial if muscle atrophy has occurred due to a reduced daily movement.

ARMin III exoskeleton [55] focuses on the rehabilitation of patients with cerebrovascular accidents (CVA). The active mode is used in order to help them regain mobility of the shoulder. Using this mode is excellent for patients suffering from hemiparesis and strokes. Another example is the AGB-Exo exoskeleton [14], since the patient makes a succession of physical effort exerted on the muscular activity of the upper limbs, active movements such as self-stretching or other movements of the muscles are performed through repetitive tasks.

NESM [36], on the other hand, has a structure focused on passive rehabilitation because it is incorporated into the spine, which generates a passive self-aligning kinematic chain. The NTUH-ARM exoskeleton [39], uses the Lyapunov theory to improve stability in the controller design, allowing gravity compensation in assisted training. It presents a ROM considered in its 7 DoF, which allows a complete rehabilitation in each section of the arm. On the other hand, the ChARMin [17] exoskeleton is focused on the rehabilitation of children with defects in the motor function of the arm, cerebral palsy, and others. In addition, the rehabilitation process has a computational interface (Unity Technology) that allows the child to train through a video game.

c) Assisted Rehabilitation

In this rehabilitation mode, robotic support is provided only when the patient cannot follow the training proposed by the therapist. This means, it helps patients to exercise their limbs to the best of their ability. This type of rehabilitation is based on swinging against an object; turning the body back until the patient feels that the shoulders are stretched avoiding spasticity. Assisted rehabilitation using exoskeletons is advantageous since it provides important benefits in relation to muscle strength, it reduces motion recovery time, achieving functional independence faster.

Many authors prefer to build exoskeletons that offer the three rehabilitation modes, as seen in Fig 6. For example, Rehab-Arm [22] performs passive, active and assisted rehabilitation. This mechatronic system with 7 DoF is aimed at rehabilitation in patients that have suffered strokes and hemiplegia. RehabRoby [41], Ye *et al.* [44],[45], ETS-MARSE [15] and Wu *et al.* [46] devices also offer these modes for stroke patients, focusing on shoulder-elbow-wrist rehabilitation, with 7, 5, 7 and 6 DoF, respectively.

Finally, the robotic systems used for the rehabilitation of upper limbs shown in Table I do not offer only one type of assisted rehabilitation, but they offer assisted, active and passive modes or a combination of these.

IV. Conclusion

In conclusion, a brief review of the most recent exoskeletons for the rehabilitation of upper limbs damaged by diseases such as strokes, hemiplegia, Duchenne muscular dystrophy, among others, has been carried out. The latter are the most common disabilities for which exoskeletons are designed. Exoskeletons focus on passive and active rehabilitation or a combination of both. The passive rehabilitation mode was the most observed. This mode is used when the patient does not offer resistance to the effort of muscle movement.

In addition, the concept of TRL was defined and the indexed exoskeletons were categorized based on these. As a result, it was observed that the various exoskeleton projects analyzed are between TRL 5 and TRL 8. The most common category was TRL 6, which means that most of the exoskeletons shown are prototypes that have not yet passed the validation process in a group of patients. However, these devices show important advances which result in further progress for the development and manufacturing of exoskeletons for rehabilitation.

It was also mentioned that the choice of material is key for exoskeletons, since the objective of these robotic systems is to imitate the natural movements of the users. It is important to note that only a few research articles mention the materials used in the design of the exoskeletons. Nevertheless, it was observed that the most used materials were metals and plastic. Aluminum and ABS stand out among them for their interesting properties such as weight, strength, low cost, and commercial availability, while metallic titanium and PETG plastic are the least used due to their higher costs.

Acknowledgment

This research was supported by the IEEE Engineering in Medicine and Biology Society at the Universidad Tecnológica del Perú (UTP), the IEEE Student Branch at UTP and the Research Group on Biomedical Engineering and Related Careers (GIIBCA). In addition, the authors would like to thank the Bioastronautics and Space Mechatronics Research Group (https://orcid.org/0000-0002-7173-3960) for supporting Latin American exponential innovation carried out by entrepreneurs and new technologies. Finally, thanks to Research Direction of Universidad Tecnológica del Perú – UTP, filial Arequipa for the support and translation.

***Abstract*—The Covid-19 pandemic growth has led to a large desire for safety restrictions among citizens near or in Covid-19 affected areas. This includes requiring the use of masks when outdoors and an occupancy limit being placed when indoors. Some of these restrictions have been enforced by the government and can lead to infraction charges on those who choose to ignore them, but some restrictions are up to the decision of the respective individuals. This has led to varying levels of safety being applied when outside. This is especially concerning when some businesses may not be taking proper precautions to avoid the spread of Covid-19. To counterbalance this issue while also spreading awareness of the businesses that are careful enough to follow such precautions, the app My-Covid-Safe-Town (MCST) is created. MCST allows for individuals (i.e., patrons) to find businesses that fit the standard of safety and to specifically point out the steps being taken by each business to avoid the spread of the pandemic.**

Keywords—Covid-19, IoT applications, software engineering, HCI, mobile computing, multimedia technology

I. Introduction

With the end of the Covid-19 pandemic still unclear, businesses and patrons are being forced to adapt to the new environment. For patrons specifically, this includes worrying about safety precautions that are being taken by local businesses and ascertaining whether these businesses are open at hours desirable to the patron. Businesses, especially small ones, are also facing challenges such as operating with less staff and working for fewer hours. These businesses are not simply limited to small "mom and pop" shops since mid-sized businesses such as hotels that do not belong to a chain brand have struggled to stay afloat as well [1]. Large businesses would have enough stored income to continue operating while searching for methods to adapt. Small businesses, however, face problems. In a study conducted by Bartik, it has been reported that 75% of businesses participating in a usability test only had enough income stored to last a maximum of two months [2]. It is important that these businesses continue to get a steady flow of patrons because the failure to do so would imply closure.

Patrons, having been in lockdown for months, would like to frequent businesses again. This does not mean that they are willing to risk their lives or the lives of their families simply so that they can visit a shop. If a patron enters a business that does not take anti-COVID-19 precautions (e.g., requiring face masks inside the shop, sterilizing all frequently touched items, and dining outside to allow proper airflow) then that business is putting the lives of their patrons at risk. In addition, if patrons do not know the policies a business is using to protect its patrons, then it is the equivalent of blindly placing their lives in the hands of the business owners. Fear plays an important role in deciding whether visiting a business is worth the risk. Thus, informing patrons about the businesses that are including anti-COVID-19 practices and thereby reducing apprehension is important. This raises the question of how such information will be spread.

In response to this, a mobile application (i.e., app) called My-Covid-Safe-Town (MCST) is developed with the intention of informing the patron of Covid-19 related information and the manner in which small businesses are changing to accommodate to the new normal. If a patron wants to check whether a business is open or observe the precautions the concerned business is taking, MCST can present that information to the patron in a ubiquitous manner with easy access. In addition, should a patron want to ask questions (e.g., Asking if a certain item is in stock, or if the business takes reservations). MCST allows for this through email and phone calls. MCST provides patrons with the information they require by connecting them with the small businesses that lack the advertisement funds needed to convey that information. Ultimately the goal of the app is to display the shops that are open near the patron and showcase the manner in which it is keeping its patrons safe from the pandemic.

II. Related Works

Using apps to solve pandemic related problems is a common practice in recent times. A paper discussing an app tracking influenza infection mentions using similar methods as app developers are using today [3]. This particular app has used a data donation method which involves app users manually adding their information and location into the app based upon which the app analyzes that data for future use. The app has been designed around obtaining important information rapidly by using modern technology rather than using traditional methods that some government bodies might use. Ultimately the app has received about 10,000 volunteers who have collected data such as the age and date of last infection in real time. In addition, the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

data has correlated with existing basic information on influenza thereby making the concerned app a very interesting study [3].

Apps regarding Covid-19 are steadily surfacing on the Apple App Store and Google Play Store while more are being developed and released through online access. Apps for social distancing and contact tracing are highly significant today. For example, *Covid-Alert-NY* [4] and *Aarogya Setu* [5] are popular contact tracing apps in New York and India respectively, the latter having surpassed over 100 million installations in 40 days. A recent food donation app called *SeVa* [6] addresses hunger and food waste by connecting food suppliers and consumers with up-to-date information about good quality leftover food in restaurants, grocery stores and other such places in their vicinity. This is particularly helpful during Covid-19 though it has a generic usefulness as well. An app called *MDLive* [7] assists with telemedicine that is much needed during recent times since many patients prefer to make doctor visits from home. Another app called *Covid Control* [8] developed at Johns Hopkins University, a premier medical institution in the United States, is beneficial in terms of guiding the research related to this pandemic in order to address aspects such as prevention and cure. Many apps are being used by individuals on a daily basis to help prevent the spread of the disease, however there are drawbacks. According to paper by Kaspar [9], though people are taking steps to avoid Covid-19 by installing these types of apps, the overall ability to avoid Covid-19 is determined by the individual's motivation rather than the app's support. In addition, even though people want to avoid spreading the pandemic does not imply that they will always be motivated to follow proper safety procedures.

While several apps exist to help combat problems associated with Covid-19 and its aftermath, to the best of our knowledge none of these specifically provide a platform for local small business users to showcase their functionality and provide patrons ubiquitous, convenient access to adequate safety related information on these businesses for fostering better interaction. This is precisely where MCST makes a contribution. It goes beyond the "yellow pages" for information since it is more interactive. Yellow pages are static while MCST entails user-generated content and is more dynamic. Moreover, using MCST during Covid-19 recovery, stores can quickly populate additional fields and add new entries that could occur in a very short time span, e.g. "all employees are Covid-19 vaccinated". Information such as this could be highly relevant to safety precautions. Our work is thus orthogonal to the literature and makes specific contributions.

III. Methods

Prior to the creation of the app, its major requirements and design must be outlined, as sound requirements engineering is vital for software quality [24-28]. In our work, this involves developing a wireframe for the app. A wireframe is a mock-up design of the appearance and functionality of the app once it is developed [10][11]. This allows us to see how the pages will look and reduces the need to make drastic changes to the design later at the implementation stage of development. It is important to ascertain that the users have the visual clarity to see the app's functions while also having the tools they might need for using the app.

A. Wireframe Design Outline

The design of the wireframes constitutes the initial step of the app development. An example of the planning of visual clarity is presented in Fig. 1 where the "landing page" of the app is observed. The landing page is the first page the users would see when they open the app. This is also the page with the maximum paths available for navigation. It is thus important to ensure that the users can see all of these paths to understand the role of each button easily, i.e. within just a few clicks. If the users do not understand how to operate any page of this wireframe, then the design has not truly succeeded in assisting the user. However, that is because this is a wireframe on which further improvements can be made.

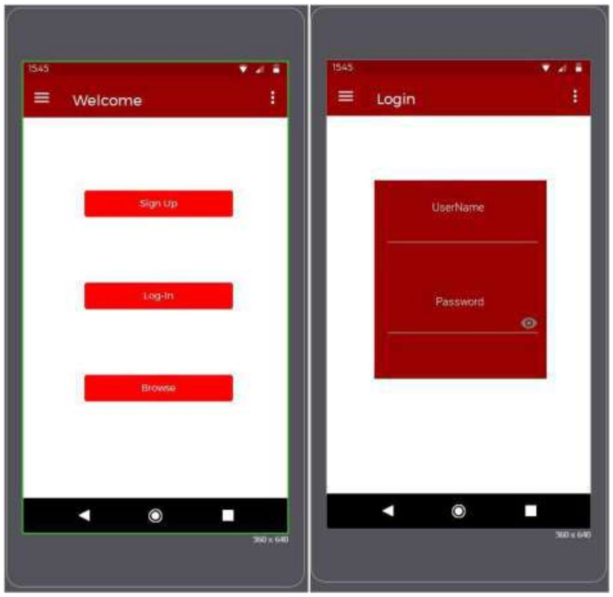

Fig. 1. Wireframe of the welcome page and login page for the MCST app

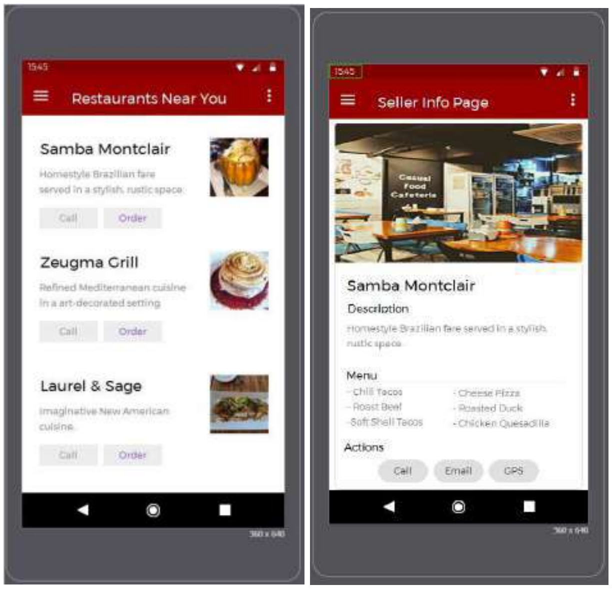

Fig. 2. Wireframe versions of pages for browsing (left) and displaying shops of small businesses (right)

Based on the figures above, we see Fig. 1 (left panel) which is the starting page through which the user can login, register, and browse the app. Fig. 1 (right panel) is an at-a-glance view of the display that appears in the pages of the small businesses. All these pages have a menu bar near the top of the screen which allows for additional options. Fig. 2 (left panel) showcases how users would find a shop that interests them. Once they click on a shop of their choice, they are directed to Fig. 2 (right panel). This is a business page that includes hours of operation and Covid-19 precautions. Likewise, after having constructed the wireframe, it is imperative to conduct usability tests in order to gauge how the targeted audience would react to the app.

B. *Wireframe Usability Testing*

Usability tests by stakeholders are an important part of developing an app. In HCI (human computer interaction) with respect to app development, stakeholders are people, groups or organizations impacted by the success or failure of the app, i.e. those who have a stake in the app [12]. In other words the stakeholders would represent the targeted users, by being the users themselves or having a clear idea of the users' needs. Without usability tests there would not be a reliable way to gauge stakeholder interest in the app. The app might seem perfect from the developers' end and have absolutely no bugs, but if there is no interest in it from the stakeholder perspective, it will not be used. It is for this reason that usability tests are conducted for this app after the outline of the wireframe that constitutes the initial app design. These are analogous to such tests conducted in the development of mid to large scale software systems in Software Engineering.

Since our study in this paper targets mainly patrons, i.e., the prospective customers of small businesses, *our sample population for usability tests focuses on patrons*, not business owners. In other words, our fundamental stakeholders for the current study's purpose are patrons. The following figures, Figs. 3 and 4, are the usability testing results achieved after showcasing the wireframe of the app to the patrons.

The results from Fig. 3 showed that our wireframes got a positive response overall. Overall, 80% responders said that they found our user interface designs easy to use (i.e., responders agree that our designs will ensure high-quality user-experience).

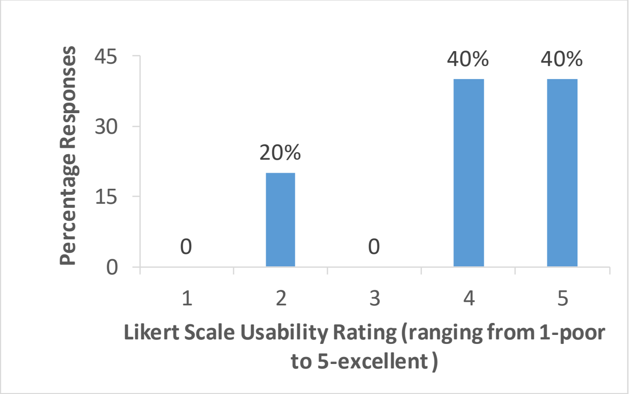

Fig. 3. Wireframe usability testing (quality): App design quality question ratings indicate that that it is well-received as evident from overall scores

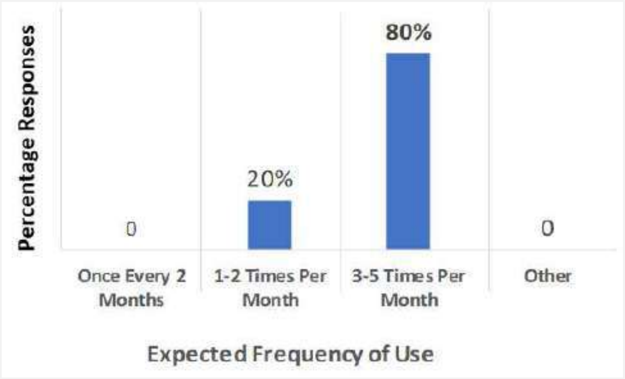

Fig. 4. Wireframe usability testing (frequency): The usage frequency question shows average use a few times a month by patrons which seems quite reasonable

The analysis presented in Fig. 4 indicates that a majority of the responders feel they will use the MCST app at least 3 to 5 times per month, and indicate this accordingly.

Observing the results of wirefame usability testing as displayed in these figures, we notice that there is interest in the app, however its design needs some improvements. We would not have been able to improve upon the app design without the help of these wireframe testing participants. Having discussed these figures it now becomes apparent that being able to navigate through each of the pages is just as important as the appearance of the pages individually. We incorporate such feedback including subjective comments from the wireframe usability tests in order to guide the final user interface design of the MCST app. A main piece of feedback is in regards to not fully understanding the app functionality; and hence this is taken into account based on which several menus are then upgraded. Another piece of feedback is in regards to the app's simplicity; and therefore we avoid adding too many complex buttons and functions in the app.

IV. Models

While wireframes are suitable for testing the appearance and visual clarity of the app, they are not feasible for perceiving the actual structure of the app. In order to accomplish this, we rely on models such as sitemaps and other Unified Modeling Language (UML) Diagrams [13]. UML Diagrams are general

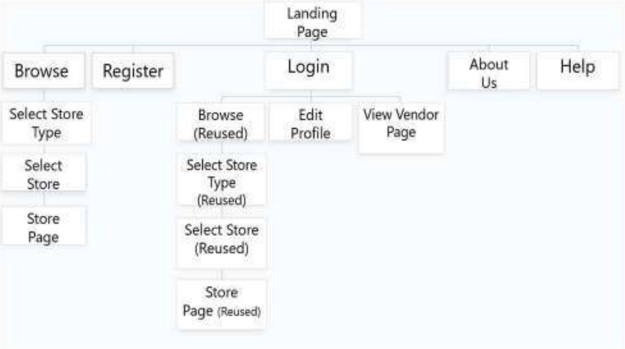

Fig. 5. Sitemap depicting the blueprint of the MCST app

purpose diagrams with the intention of allowing the developers and users of the app to easily see the app's workflow.

Considering the sitemap presented in Fig. 5, the flow of the app can be seen. This is indicative of the app structure and workflow while also allowing for changes to be made prior to the final product. For example, in Fig. 5 we can see a user starting on the landing page and then potentially clicking on login. Assuming the user then logs in, he/she will thereafter will have access to the "edit profile", "view vendor page", and "browse pages" in the app.

A sitemap shows the planned routes for accessing the site. It enables us to know where each page leads. In other words, this constitutes the blueprint of the app. However, this blueprint diagram alone is not sufficent, In the case of this specific app, there is a requirement for the data to be stored and then called upon frequently. In order to achieve this, database design is needed to map out the content and flow of the data. This is illustrated as an E-R (Entity-Relationship) diagram in Fig. 6. Here, we can see that the database is split into two tables with one being the "user account" for the vendors and another one for the businesses, Both of these contain several details such as the names and contact information needed when viewing the business pages in the latter portions of the app. The E-R diagram in Fig. 6 shows the appearance of the database from the back end. This enables us to know what should be stored in the database; in other words the absence of this could potentially lead to wasted space on redundant information. The relationships between the different entities in this app along with their data flow is visible in this diagram. Once the overall blueprint as well as the specific data flow has been accomplished, we can proceed further wirh the actual implementation of the app.

V. Implementation

```
Algorithm 1 Algorithm to determine filter
Input: n = 0 ≤ n ≤ 3
Output: intent
  Initialization:
first statement
  Switch Case
if n = 0
   intent = n
end if
if n = 1
   intent = n
end if
…
return P
```

```
Algorithm 2 Algorithm to apply filtering
Input: intent
Output: out
  Initialization:
first statement
  LOOP Process
for i = i++ do
   if i = intent
      add intent to P
   end if
end for
return P
```

Fig. 7. Algorithms 1 and 2: Pseudocode for the "browse page" in the MCST app

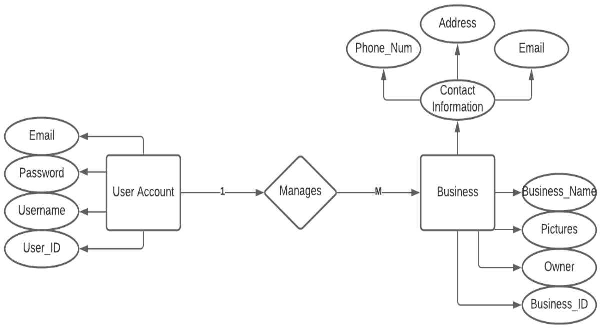

Fig. 6. E-R Diagram providing an overview of the database structure

In order to implement an app once the design is finalized, the platform and coding language must be established along with any existing programs being used. The MCST app is designed for the Android platform and therefore uses the Android Studio [14] for implementation. Android Studio encompasses both Java and eXtensible Markup Language (XML). In addition, our app development entails other software. For example, SQLite is used as a database; also calling, email, and GPS features are added. These require allowing specific permissions such as Google's API for GPS. Fortunately, since Android Studio is the main program used for developing apps it seamlessly allows for these permissions to be implemented through its program with the exception of a few API codes that needed to be transferred. The next section discusses different parts of the app with respect to their implementation details.

A. Browse Page

The "browse page", for which we present the pseudocode in Fig. 7 via Algorithms 1 and 2, portrays the toolbar used in addition to the different buttons to pass filters depending on the selection. If the user selects certain specific buttons, the search results will filter for that type of business specifically, e.g., "restaurants". These results can be seen in Fig. 10 (right panel).

B. Search Page

The "search page" is implemented with respect to the pseudocode seen in Algorithm 3 in Fig. 8. Here, we can see how the data gets sorted into a "results page" seen in Fig. 11 (left panel). Important takeaways from this pseudocode are the

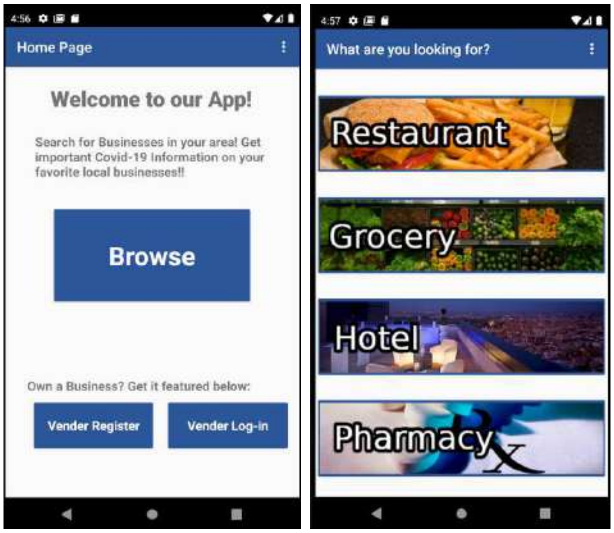
```
Algorithm 3 Display filtered results from database
Input: database results (i.e. businessName, phonenumber, etc.)
Output: intent
  Initialization:
first statement
  Declare Cursor
cursor = database results
if cursor isEmpty
   return "No data found."
end if
else while cursor moveToNext
   cursor getString (columnIndex 1)
   cursor getString (columnIndex 2)
   …
end else while
return P
```

Fig. 8. Pseudocode for the "search page"

```
Algorithm 4 Establish Email, GPS, and Phone Number
Input: intent (i.e. phonenumber, address, email)
Output: out
  Initialization:
first statement
  Call intent
intent = intent.ACTION(DIAL/VIEW/SENDTO)
third statement
  Format intent (i.e. Phone number = tel: xxx-xxx-xxxx)
startActivity (intent)
```

Fig. 9. Pseudocode for the "seller info page": Shows how the GPS, email, and call buttons operate

retrieval of the data from the database and the storage it into multiple arrays. These arrays are called at Index 1, Index 2… (entered as columnIndex1, columnIndex2 in the pseudocode shown in Algorithm 3). Hence, the piece of pseudocode shown in Algorithm 3 summarizes the manner in which the information from the database is stored and accessed.



Search for Businesses in your area! Get important Covid-19 Information on your favorite local businesses!!

Own a Business? Get it featured below:

Description:

We at Francis' Grill offer nothing but the best prime rib.

Covid-19 Precautions:

-Outdoor Dining

Hours: 9-5pm Everyday

Owners: Jim Stevenson

Fig. 11. Example of search page and the seller-info page

C. Seller Info Page

The final "seller info page", i.e., the information display page for small businesses, is primarily a collection of different buttons and text. Its functionality is summarized herewith in Algorithm 4 in Fig. 9. Note that in Fig. 10 the landing page and browse page of the app are presented. The right panel of Fig. 11 shows the seller info page. This page is certainly important since it has the numerous features useful for the patron. This is because it can call, email, and issue a GPS command to the business of a patron's choosing. In addition, it also contains any information a patron might potentially need.

VI. Experimental Evaluation

A. App Results

In the figures herewith, i.e. Figs. 10 and 11, we can visualize the front-end patron side of the app. The patron side does not have access to editing any businesses; the patrons can only search and view the shops that might interest them. They can, however, call the business from the app, email the business, and connect the GPS to the business they select.

Overall, via this implementation the aim is that the user should be able to acquire much of the information they might require through this MCST app. Any additional information can be found by contacting the business per se. Likewise, the app results have been displayed to our targeted users for their evaluations for user acceptance testing as described next.

B. User Acceptance Testing

The current version of the MCST app has been subjected to user acceptance testing in order to assess its effectiveness. Questionnaires were provided to a sample set of potential app users along with Likert scale responses [15]. This helps us to gauge how the users perceived the app. We have circulated the questionnaires among 31 users and received the following responses as illustrated in the figures next.

From Fig. 12 it seems that though most people would only use the MCST app once or twice a month while some people

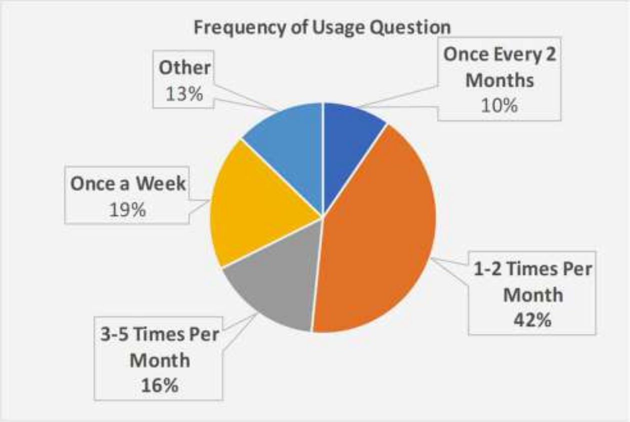

Fig. 12. Frequency of app usage estimated by the responders

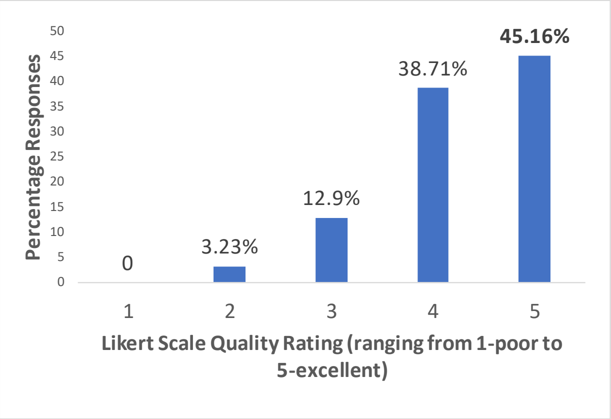

Fig. 13. User ratings for the overall quality of the app

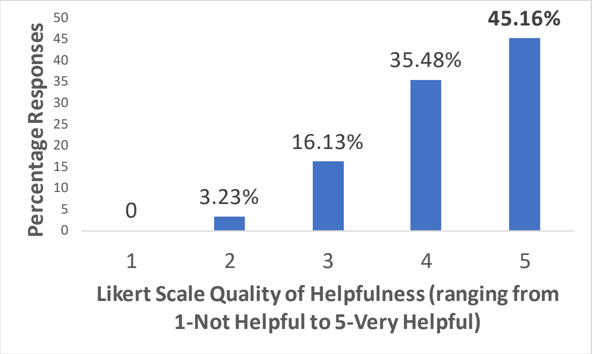

Fig. 14. Users' perceived usefulness of the app in a Covid-19 world

would use it weekly. On the whole, the results indicate that the app attracts interest. As per Fig. 13 we can infer that the app quality is well-received and it thus can be useful in a real environment. Based on Fig. 14 we can observe that the app is considered helpful by most people in Covid-19 environment. In addition to Likert scale evaluation, our user acceptance testing has also leveraged subjective assessment in order to gauge the general response to the MCST app. A snapshot of the comments from subjective assessment appears in Fig. 15. Based on this, we find that the users have well comprehended the intention of the app and have appreciated it on the whole. Some of them have provided recommendations on improving the app for an even better user experience in the future.

Hence, we can conclude that the targeted users (i.e., patrons), in general, have assessed the app as helpful and worthy of usage. It also appears as though in the current Covid-19 world, there is no such specific app identical to MCST that has already been implemented (to the best of our knowledge) and thus our MCST app would be used quite frequently. The user acceptance testing results seem promising. They also offer encouragement for any potential further enhancements to be made within future versions of the app.

VII. Conclusions and Future Works

The MCST (My-Covid-Safe-Town) app has been designed with the intention of informing users of how small businesses are taking steps to protect their patrons while also informing the patrons of any changes made to small businesses that have been impacted by Covid-19. This work falls in the general paradigm of AI in Software Engineering, in the broad realm of other such works, e.g. [16] [17] [18] addressing aspects such as software quality and requirements. The MCST app includes aspects such as: being able to find out whether a small business is closed or whether its operating hours have changed (instead of a patron walking to the shop and viewing its hours posted on the front door only to realize that it is closing early and will open the following day or worse still finding that it is temporarily shut down). Although the MCST app is still missing advanced features that require additional time investment, the fundamental features are provided and hence the core intention of the app is achieved. After having viewed the usability tests, it can be inferred that the participants comprising the potential clientele recognize the intention of the app and its goal. The app per se is designed to start on a small-scale basis and has the backbone to grow further as it becomes more popular. This app primarily covers the Montclair region in NJ, USA and it can also be used on a nationwide level; any browsing limitations can easily be implemented and updated. This app truly has the potential to grow further. It can help several people who fear leaving their homes during this Covid-19 pandemic and its aftermath. Our work on the MCST app development here is supplementary to other apps contributing to aspects of smart cities such as smart environment [19] [20], smart government [21] and smart living [4] [5] [6]. This MCST app thus makes broader impacts on smart cities, analogous to other works in the literature [22] [23] [29]. This indicates a broader perspective of the work herein besides its immediate impact on helping to combat the adverse effects Covid-19 pandemic and its aftermath.

- *"Password recovery would be useful. This is a well-designed app and a great idea."*
- *"I would very much like to see this app put to use"*
- *"Can you add something for other healthcare businesses besides pharmacies? What about therapy, rehab, counseling etc. Much needed in COVID."*
- *"It's very good work. Such apps should be designed for topics in environmental studies too."*
- *"Nice work! You should keep track of the number of real users of your app if you release this."*
- *"The app is a great idea. It has the potential to connect small business owners and patrons. This will greatly help in the cause of COVID recovery."*

Fig. 15. Comments of usability test responders (responders are asked to give general comments about the MCST app in an open-ended question)

As regards further work, after reviewing the usability tests and reflecting back on additional features that have not been implemented thus far, the MCST app does have room for improvement. There are participants in the usability test who have noticed issues such as the categories being quite limited, however those features can be added quite easily. A few mentions include minor UI (User Interface) improvements to enhance navigation on the vendor side as well as adding analytics to track the type of users that visit the app and the shops they view. A big concern that requires additional improvements is checking whether the vendor is truthful when entering his or her business information on the app. This is because false vendors could pose fake shops or enter existing shops with false or malicious information. A potential solution to this would be to either have moderators to verify each individual shop and check for validity or have the app be community-operated. In the case of the latter, the community itself would need to check whether the individual shop's claims are valid. Accordingly, a "report function" will be needed to acknowledge these claims. This constitutes some aspects of future work.

In addition to this veracity of information that can be addressed in further enhancements, other future work includes: augmentation of the functionality with respect to adding more categories of businesses such as healthcare related services; enhancement of the UI features; and publicity aspects to gain more visibility for the app. Some of these issues would be addressed as we envisage releasing the MCST app that is on our roadmap. *The MCST app can be found at the following link* [30]*:* https://dx.doi.org/10.13140/RG.2.2.12191.48802/2*.* The details of this app along with its code, data and other relevant files are available on the GitHub pages of the developers and can be provided to some interested users upon request. The ownership of the MCST app rests with its designers and developers who are the authors of this paper.

Abstract— **The Covid-19 pandemic has dramatically affected the tourism industry's development; however, the demand for traveling increases in the young people, significantly, the Generation Z, who was born in 1996. A bright outlook awaits the tourism industry in the post-Covid-19 period. The study aims to determine the relationship between the economic perspective, social perspective, user-generated content trust, and inbound travel intention of Generation Z travelers. The mixed-method research was done to archive the research objectives. The research results pointed out that there were positive impacts of economic and social perspectives on user-generated content trust; moreover, user-generated content trust positively affected the inbound travel intention. Some managerial implications were proposed for the tourism business managers to increase their business performance.**

Keywords— *economic perspective, social perspective, user-generated content trust, and inbound travel intention, Z traveler.*

I. Introduction

In global integration, tourism is an economic sector that brings significant benefits to the country. In recent years, the trends of travel have noticeably emerged on the Internet. Social media marketing of websites, representing various forms of consumer-generated content such as blogs, virtual communities, wikis, social networks, collaborative tagging, and media files shared on sites like YouTube and Flickr, have gained substantial popularity in online travelers' use of the Internet [1]. For example, users, who use social media, can share their travel experience on TripAdvisor or Booking.com. Social media users (e.g., influencers) can also serve as endorsers to promote travel destinations on social media such as Facebook, TikTok, YouTube, Instagram [2]. Simultaneously, when visitors use social networking platforms to portray, recreate, and relive the journeys, the Internet rapidly mediates tourism experiences [3]. Young people today are also more interested in advertised and well-rated places on social media.

Given the tourism product's intangible service nature, the social network is an excellent resource for travelers seeking knowledge [4, 5]. Social advertisement is more and more popular to enhance the customer experience [6]. It is widely accepted in both academia and business that social media has become an important advertising venue for marketers [7]. In line with the industry's enthusiasm for social media advertisements, the number of academic, social media advertising studies has risen dramatically in recent years [8]. Along with the influence of the media, customer confidence in the tourist destination is also crucial. Many factors that help with the tourism industry's growth increase trust, such as creating good services and taking care of tourism security create a safe and friendly environment for travelers guests when receiving related services while going travel. Tourists often travel to a familiar place and a country with crime rates and political unrest low [9]. Tourists will have a right impression of a tourist destination when that place is not reflected by social media and guaranteed by the local government's calendar [3].

Furthermore, it discussed the economic perspective of travel time, i.e., the idea that travel time is wasted time, by examining how journeys are encountered, especially on trips that are often repeated as commuting; or along specific routes with highway driving [10]. Opportunities for co-present meetings with friends and family are minimal due to the geographic distribution of social networks, the availability of a vehicle, and free time constraints. As a result, the possibility of 'teleportation' for some people suggested that there could be more possibilities for co-present experiences.

Budgets for travel time may also be strained due to more spatially compact social networking where access to or provision of public transportation is restricted. An individual's travel intention by young people plays an essential role in the traveling destination choosing process. Tourists' attitudes and preferences toward a specific tourist destination are often used to determine travel intentions [11]. Travel intention is habitually based on the tourists' attitude and preference toward a particular tourist destination. Rational and practical conditions are seen as critical measures of tourists' behavior, particularly their attitude and preference [12]. To put it another way, functional and psychological factors frequently affect one's desire to travel, which leads to actual travel behavior. For that reason, tours should promote marketing more to attract more young visitors.

The following parts of this study included the literature review, research method, result and discussion, and the conclusion.

II. LITERATURE REVIEW

A new generation is making its way into the limelight, and the rest of the world is taking note. These people are Generation Z, and they were born between 1996 and 2015 [13]. According to the Digital Tourism Think Tank, by 2020, Gen Z will account for 40% of all customers. Gen Z is reaching adulthood, and they are excited to fulfill their wanderlust. Furthermore, even though Gen Zers may not have a strong influence in a particular field, they significantly impact their family vacation. Stillman of GenZGuru discovered that children schedule more than 70% of multigenerational trips. According to a 2017 Contiki survey, 98 percent of 732 Gen Z respondents agreed that travel experiences are essential in life [14]. Overall, this multicultural generation is not only socially aware but also internationally aware. They consider themselves people of the planet, unconstrained by geographical limits, and, happily for travel advisors, they want to see it all for themselves.

The Technology Acceptance Model (*hereafter* TAM) is the most widely used in analyzing people's behavior intentions [15]. TAM is an extension of reasoned action theory with perceived behavior control to improve behavioral intention to predict an individual's actual behavior. TAM expressed why a person uses the system for their daily activities through the relationship between the perceived usefulness, perceived ease of use, attitude, behavioral intention, and user behavior [16]. The blooming of Web 2.0 has changed consumer behavior. The user-generated contents, which were evaluated directly on the sellers' websites or social network pages after experiencing the products or services by customers, become reliable sources for other customers who intend to use the service or product. Therefore, if customers believe the user-generated contents, they would easily buy or use the goods or services. Trust was recommended as the positive attitude of a person towards others or somethings.

On the other hand, the prior studies pointed out that user-generated content will benefit the other users as economic benefits as functional, monetary benefits [18]; and social benefits as relational, social, and emotional benefits [17]. From the critical evaluation above and the TAM model adoption in the tourism industry, this research proposed the research model with three components, including the perceived usefulness with an economic and social perspective, the trust of the user-generated content as the consumer attitude, and the inbound travel intention of Z travelers. The conceptual model was presented in Figure 1.

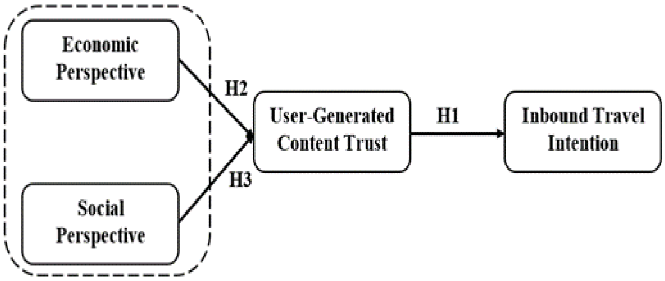

Fig. 1. The conceptual model

A. Inbound travel intention

If there is an opportunity to act, the purpose will manifest itself in actions [18]. Consequently, behavioral intention refers to the probability of engaging in a specific type of action in a given situation. As this perspective is extended to tourism, the traveler's desire or probability to visit a destination is referred to as travel purpose [19]. The greater the intention of one to travel, the higher the possibility they will travel. It is also seen as the possibility, commitment, and motivation to travel to a specific tour destination [20]. Recent studies within the field of tourism that adopt TPB's viewpoint are as follows [21]. Travel intention is habitually based on the tourists' attitude and preference toward a particular tour destination [22]. Rational and practical factors influence tourist behavior, especially attitude and preference. To put it another way, functional and psychological factors frequently affect one's desire to travel, which leads to actual travel behavior. The psychological variables were linked to the tourists' emotions, marked by extreme feelings episodes [23], whereas the functional variables were found to be related to the destination's particular qualities and atmosphere [23].

B. User-generated-content trust

The word "travel 4.0" is a modern idea that emphasizes the growing role of social media in travel and new customers in the hospitality and tourism industries [24, 25]. The growth of user-generated content is affecting travel consumer decisions. Gretzel, et al. [26] stated that almost nearly half of travel buyers said they used user-generated content in their trip planning, and nearly a third said they found the helpful knowledge. Since they can easily access travel and tourism via social media and rate tourism products and services on online online platforms, these consumers are better educated.[26]. Most readers believe that travel reviews are more likely than travel service providers to provide up-to-date, pleasant, and accurate information [25]. Peer reviews are perceived as superior by frequent travelers, who are more likely to be favorably affected. According to the above, more than half of users check online feedback while planning a vacation. The value of feedback for the accommodation product is extreme, whereas the significance for other travel products is much lower [27]. Reviews are particularly important for the accommodation product, with relevance for other travel products much smaller. Hence, the hypothesis H1 was proposed:

H1: User-generated content trust has a positive impact on the inbound travel intention Of Z Travelers

C. Economic perspective

In the last two years, the Covid-19 pandemic has made a significant impact on the global economy [28]. he Covid-19 pandemic has had a huge effect on the global economy over the past two years. The person does not benifit from the travel time (whether it be pleasure or conducting work-related tasks to reduce work time infringement on personal time). As a result, we can use the concept of travel time as a gift to refer to network involvement. In this case, the economic imperative of reducing travel time will not always be true (or be so fully applicable). People can take longer routes or agree longer travel times in some cases so that they have enough time to listen to music, rest, or think about a job problem [29]. he Covid-19 pandemic has had a huge effect on the global economy over the past two years. The person does not benifit from the travel time (whether it be pleasure or conducting work-related tasks to reduce work time infringement on personal time). As a result, we can use the concept of travel time as a gift to refer to network involvement. In this case, the economic imperative of reducing travel time will not always be true (or be so fully applicable). People can take longer routes or agree longer travel times in some cases so that they have enough time to listen to music, rest, or think about a job problem [30]. The roots of backpacker travel must be understood in the context of tourism's more enormous past. Examining historical practices such as the Grand Tours of 17th and 18th century Europe, tramping and the youth hostel movement, the idea of non-institutionalized tourism, and the meanings of terms like "drifter" tourism, youth tourism, and alternative tourism are all helpful. The travel behavior of the wealthy, well-educated youth of the late Victorian century, who set out on adventure trips to explore the secret, strange, and exotic life of faraway countries and unknown people, has impacted new backpacking. These eager explorers also readily welcomed extreme difficulties and even embraced their hosts' way of life [31]. Therefore, this study proposed the hypothesis H2 as:

H2: Economic perspective has a positive impact on user-generated content trust Of Z Travelers

D. Social perspective

Social space is physical surroundings or location, denoted social space, which can be considered at many levels. From a travel perspective, one is interested in the main life venues that individuals connect through travel. The implications of telecommuting for travel have received considerable attention [32]. As Fischer [33] hypothesized, "limitation on the potential social relations available to individuals leads to fewer communal social relations". In the age of information being transmitted in less than a second, any sentence or action becomes a trend. Especially for young people, generation Z, who like free life, exploring, and traveling is an overall experience. The most used tools are the Internet and social networks. Social networking networks are now online applications that allow individuals to socialize by sharing digital content [34]. The majority of major social media firms quickly established advertisement channels after their initial launches. According to academics and industry experts, social networking has become an important advertisement venue for advertisers [7]. Social networking networks are now online applications that allow individuals to socialize by sharing digital content. The majority of major social media firms quickly established advertisement channels after their initial launches. Social networking has become a vital advertisement venue for advertisers, according to academics and industry experts. Consequently, it is necessary to understand better the relationship between the Z generation's social contact and travel intention.

H3: Social perspective has a positive impact on user-generated content trust Of Z Travelers

III. RESEARCH METHOD

This research was conducted based on a mixed research method that combines qualitative research methods and quantitative research to increase its credibility and significance [35]. In the qualitative research method, a focus group discussion was conducted with the participation of 8 experts, including university lecturers, tourism company managers, who are the expert in research fields. Qualitative research results adjusted the scales' content for adoption in a tourism survey; simultaneously, it confirmed the research constructs were appropriate for evaluating perceived usefulness, attitude, and inbound tourism intention. All 12 items measuring six research constructs were accepted. Questionnaires for quantitative research were also established through qualitative research. Next, the study uses quantitative research methods to test the proposed model and research hypotheses. Table 1 showed the measurement scales in this study.

The study used a non-probabilistic purposive sampling method. Participants were travelers belong to Generation Z, who like to travel inbound. The total number of the collected respondent survey was 578 through the online questionnaire. After the initial cleaning phase, 12 imperfect copies were eliminated, so the amount of survey data officially used for quantitative analysis was 566. About the gender, 315 participants were male (55.65%), there were 251 female respondents (44.35%). Of 566 participants, 214 people belong from 15 to 17 years old, accounting for 37.81%; the others are from 18 to 23 years old, accounting for 62.19%.

The data is processed by Smart PLS 3.7.8 software to analyze the Partial Least Squares Structure Equation Model (PLS-SEM). The procedures to be performed evaluated the measurement model (reliability, validity) and the PLS-SEM (R^2,f^2, Q^2, VIF, path coefficient). Thereby, the study would discuss research results and propose managerial implications to enhance Generation Z's inbound travel intention.

TABLE I. MEASUREMENT SCALE

Item	***Source***
Economic perspective (*hereafter* ECP)	
I could have got the functional values (have an enjoyable trip) from the online user-generated contents (ECP1)	Chu, et al. [36]
I could have got the monetary benefits (save the money because of booking a cheaper hotel) from the online user-generated contents (ECP2)	
I could have got the sales promotions (have a discount for the room) from the online user-generated contents (ECP3)	
Social perspective (*hereafter* SOP)	
I could have got the relational benefits (have a new partner for the trips) from the online user-generated contents (SOP1)	Chu, et al. [36]
I could have got the social values (have an agreement from the others) from the online user-generated contents (SOP2)	
I could have got the emotional values (have enjoyment from reading the news) from the online user-generated contents (SOP3)	
User-generated Content Trust (*hereafter* UGCT)	
I am reliable to the online user-generated contents as traveling (UGCT1)	Chari, et al. [37]
I am affected (enjoyable/likable) in the online user-generated contents as traveling (UGCT2)	
I have the willingness to rely on the online user-generated contents as traveling (UGCT3)	
Inbound Travel Intention (*hereafter* IBTI)	
I will save time and money within 12 months for inbound traveling (IBTI1)	Park, et al. [38]
I will have at least an inbound travel with friends/family within 12 months (IBTI2)	
An inbound journey is my first choice for traveling in the future (IBTI3)	

IV. RESULT

Based on the Partial Least Squares (PLS) algorithm results, the evaluation criteria' values are calculated. Research results in Table 2 showed that the scales have reliable because Cronbach's Alpha coefficients (CA) were more significant than 0.7. Simultaneously, the outer loading coefficients were more significant than 0.708, Composite Reliability (CR) was higher than 0.7, and the Average Variance Extracted (AVE) was more significant than 0.5. Therefore, the proposed research constructs' measurement scale achieves convergent validity.

TABLE II. THE RELIABILITY AND CONVERGENT VALIDITY

Constructs	***CA***	***Outer loading***	***CR***	***AVE***
ECP	0.856	[0.746 - 0.897]	0.903	0.701
SOP	0.882	[0.949 - 0.959]	0.919	0.739
UGCT	0.836	[0.787 - 0.868]	0.913	0.701
IBTI	0.878	[0.791 - 0.871]	0.912	0.674

Besides, the study tested the discriminant validity between the research constructs, which was evaluated via Heterotrait – Monotrait (HTMT). The HTMT threshold is 0.85. The results of Table 3 showed that the enormous HTMT value was 0.735. Consequently, the constructs in the study gain discriminant validity.

TABLE III. DISCRIMINANT VALIDITY

	ECP	***SOP***	***UGCT***
SOP	0.453		
UGCT	0.612	0.276	
IBTI	0.735	0.245	0.513

Table 4 shows the Variance inflation factor (VIF) of all the independent variables less than 2 (the largest VIF is 1.27). Therefore, the research model does not have the phenomenon of multicollinearity occurred. Besides, the coefficient of R^2 of the IBTI was 0.61, which means that UGCT explained 61% of the change in IBTI. Additionally, R^2 of UGCT was 0.553; hence, 55.3% of the change in UGCT depends on the ECP and SOP. Moreover, the values of the effect coefficient f^2 of the independent variables for the dependent variable are all greater than 0.02, of which, $f^2_{SOP->UGCT} = 0.15$, so SOP had a moderate impact on the UGCT; $f^2_{ECP->UGCT} = 0.627$, so ECP had an enormous impact on the UGCT; $f^2_{UGCT->IBTI} = 1.564$, so UGCT had an enormous impact on the IBTI. The prediction coefficient Q^2 of the theoretical model is also valid at 0.474 and 0.486, which were greater than 0.

TABLE IV. THE RESULT OF THE PLS-SEM EVALUATION

	VIF		***f^2***		***R^2***	***Q^2***
	IBTI	UGCT	IBTI	UGCT		
ECP		1.27		0.627		
IBTI					0.61	0.474
SOP		1.27		0.15		
UGCT	1.00		1.564		0.553	0.486

The PLS-SEM model's analysis results in Table 5 also showed that all the path coefficients between the independent and dependent variables are significant, with 99% confidence. The results showed that all three exogenous variables have original weights greater than 0. According to the H1 hypothesis, UGCT had a positive impact on IBTI ($\beta = 0.781$; p-value < 0.001); therefore, hypothesis H1 is supported. Meanwhile, H2 is also supported when the results show a positive ECP effect on UGCT ($\beta = 0.594$; p-value < 0.001). Similar to hypothesis H3, showing positive effects of SOP on UGCT ($\beta = 0.253$; $p < 0.001$); therefore, H3 is supported.

TABLE V. THE PATH COEFFICIENT IN PLS- SEM

	Beta	***Standard Deviation***	***P Values***	***H***	***Result***
UGCT -> IBTI	0.781	0.031	0.000	H1	Accepted
ECP -> UGCT	0.594	0.056	0.000	H2	Accepted
SOP -> UGCT	0.253	0.055	0.000	H3	Accepted

V. DISCUSSION

Research results have shown a positive relationship between the factors in the research model. The research results have inherited the previous studies and have applied to the tourism industry in Vietnam.

Firstly, user-generated content trust has a positive impact on inbound travel intention. Kartajaya, et al. [39] pointed out that it usually goes through the information search phase before a customer decides. Therefore, the content shared by others has an important role and affects customer travel intention. It is difficult for young travelers, who do not have much money or time, to have a good trip if they have no authentic information source. These sharing contents can make a positive impact on customer decisions for choosing destinations. The exciting travel destinations or special foods may be the most considerable concern of Z travelers; hence, the reliable user-generated content in social media becomes the right motivation for them to decide to travel.

Secondly, the result pointed out that the economic perspective positive impact on the user-generated content trust. The economic perspective of user-generated content in travel includes functional values, monetary benefits, and sales promotions. Many Z travelers have based on the recommended websites or social network pages to evaluate or choose a beautiful destination; consequently, they have exciting or interesting trips with their friends or family. The emergence of websites offering travel services has added a channel of communication between visitors. The information exchange of room's or service's price helps travelers save money when choosing accommodations with fair prices. During the fierce competition between businesses, the dissemination of information about sale promotions programs will be a valuable weapon for businesses to create a competitive advantage. Information spreading via social networking is one solution that makes electronic word of mouth happen faster. Customers, who regularly access and follow travel-related content, will receive promotions created by service providers.

In addition to the effect of economic values on trust, social values also impact Generation Z travelers' trust when referring to user-generated content pages before and while traveling. The social perspective includes the relational benefits, social value, emotional values. The sharing of travel information on social media can receive the thousand comment or shared by people who love traveling. It can connect the strangers and satisfy the belonging needs as the Maslow's Needs Hierarchy. Young travelers can even initiate direct conversations with others after reading information about a destination written by people who have been there.

Moreover, making accurate assessments of place information also creates respect and admiration from other people. The travel community's high value to the dedicated blog owner is also an essential recognition of social value. Besides, for Generation Z who are of school age and just graduated from university, the amount of time spent traveling is not much; therefore, they can temporarily indulge themselves through reading posts written by people with real travel experience. These are posts full of pictures of tourist destinations and accurate information about services during travel, which will create confidence for travel enthusiasts. Although not comparable to authentic travel, however, this approach also creates excitement for young travelers and can be seen as a motivation for them to motivate them to take their trips soon.

VI. Conclusion

The Covid-19 pandemic has limited, even greatly affected the tourism industry's development; however, human tourism's demand has not decreased. A bright outlook awaits the tourism industry in the post-Covid-19 period. Businesses need to understand the visitors' behavior in choosing a destination or factors that influence the tourist's inbound tourism intentions to take these advantages. Hence, this study aimed to determine the relationship between the economic perspective, social perspective, user-generated content trust, and inbound travel intention of Generation Z travelers. The research results have some theoretical contributions, and some managerial implications were proposed for the tourism business managers to increase the business performance.

About the theory, there are many studies based on the TAM model in the tourism industry; however, this study is based on the TAM model and extended with the economic and social perspective to forecast the traveler intention. This research result pointed that the economic and social perspectives are the perceived usefulness in the user-generated content of tourism, and they have a positive impact on the user-generated content trust. Moreover, the measurement scales have high reliability and validity; they can be used for further studies.

Based on the research results, this study proposed some managerial implications for the tourism company's managers to enhance the inbound travel intention via user-generated content. With the vigorous development of the industrial 4.0 era, almost everyone uses social networks. Due to the pandemic COVID-19, people are restricted from going out, especially overseas travel. Therefore, inbound travel has a chance to develop. Social networking is a place to give opportunities to reach people who intend to travel based on finding tourist destinations, finding hotels, homestays. Identify the Generation Z people's target customers to help businesses identify the ideal customers, matching what businesses can offer. Stimulate travelers' excitement with beautiful landscape images, videos of trips, delicious food, scenic spots, or historic sites. Create groups on the social network to categorize travelers with similar interests to a particular tourist destination so that travelers can share experiences, photos, and videos of their trips. Create a fan page on the social network that provides information about tourist destinations, travel knowledge, advertises promotions of tours, and promotions of hotels, restaurants. Improve the tourism industry's service quality, make commitments to tourists, and reduce potential tourists' risks. Promote local brands, highlight unique local features to attract tourists. Invest in beautiful and quality images and videos to introduce exciting and unique tourist destinations to customers.

There are some limitations in this study, and they will be opportunities for further research. However, the research based on the TAM model focused on the relationship between usefulness, attitude, and behavioral intention, even though the relationship between economic, social, and inbound travel has not been exploited. The group cohort difference, i.e., Generation X, Y, X, will affect the relationship between the research model's constructs; however, this study did not reach this issue. Further studies could add more factors in the conceptual model as the perceived ease of use or external factors to fulfill the theory. Furthermore, the comparison between the group cohort should clearly understand the traveler behavior in all age groups.

***Abstract*—With the complexity and overload of IP connectivity and the variety of protocols that each technology and applications has been introducing to keep the human beings connected to the modern Internet, especially in times of COVID-19 pandemic, it is a priority for Service Providers to seek a simplification of their infrastructures to make them more scalable, efficient, simplified, and profitable. In this Proof-of-Concept (PoC) paper, Segment Routing (SR) is presented as an alternative to interconnect business networks in IPv4 and IPv6 scenarios where Headquarter-Branches connectivity is required. This paper begins by defining SR and its fundamentals. To test theory in practice, three scenarios are emulated and compared: MPLS-LDP, SR for IPv4 infrastructures, and finally, SR for IPv6 networks. The aim of the present paper is to provide a more understandable vision of Segment Routing and its operation in ISP networks.**

Keywords—Segment-Routing, MPLS-L3VPN, LDP, SRv6, IS-IS

I. Introduction

Due to the appearance of new communication protocols and technologies such as 5G, IoT [1], telepresence, Artificial Intelligence, Big Data requirements, microservices, cybersecurity concerns and Software-Defined Networking, the processing carried out by All-IP dual-stack WAN Infrastructures is becoming overloaded [2], thus not allowing to scale and being resilient in the near future. Therefore, a new ISP architecture easier to manage, operate and with automation and programmability in mind is required in the Digital Transformation era.

The use of MPLS in the ISP side has covered current market needs so far, but, with the exponential growth of information handling and processing, this business and technological model may be threatened by not being able to satisfy new information transmission requirements, which translates into non-profitable Service Providers (SP) [3].

It is, at this point, essential to describe the characteristics of Segment Routing protocol as it is conceived to be developed in an IPv6 environment with IPv4 support, and due to the simplicity of its operation, is in fact a protocol to consider, especially for ISPs that need highly qualified personnel in managing MPLS architectures.

The emulation of a Service Provider network with Segment Routing is important, because this kind of research will allow to analyze and evaluate SR as a new MPLS proposal in order to determine the behavior of this sort of network, establishing its advantages and constrains of the so called “MPLS evolution”.

Once the comparison between MPLS-LDP, SR for IPv4 and SRv6 has been made, it will be shown the improvements that SR introduces, and of course, its feasibility of implementation in the real world, thereby establishing a reference to SP operators that guarantees to carry out a gradual migration with savings in operational and economic costs (CAPEX and OPEX).

The development of this work deals with the following topics:

First, the current situation and state of the art in WAN technologies is presented, describing the evolution in terms of usage of the preferred SP infrastructures, their challenges in production environments and their evolutions with Segment Routing and SD-WAN.

Later, an analysis of Segment Routing protocol is presented as a proposal towards the simplification of a network that is going to be easier to manage and operate, presenting its advantages and disadvantages compared to the current MPLS-LDP paradigm.

Finally, the emulation of a network in an SP environment is performed to interconnect two remote sites with three different scenarios: MPLS L3VPN, SR-MPLS and SRv6. Testbeds and comparisons of these scenarios have been made to determine the feasibility of SR implementation with its different data planes.

The work finishes with the most relevant conclusions and recommendations, which are extracted from the development of this investigation.

II. State of the Art in ISP Networks

The evolution of data transport technologies has its beginnings in the development of Computing in the 60's, along with the foundations of Information Theory that have had great contributions by Claude Shannon, Harry Nyquist and Ralph Hartley at the early 20th Century [4].

From there, a series of continuous evolution in data transport technologies happened, being MPLS the turning point [5].

Multiprotocol Label Switching (MPLS) is one of the most implemented technologies used by Service Providers to send packets, mainly because of its high-performance in forwarding data from one router to another based on a set of labels instead of doing it through IP network addresses.

Label distribution is carried out thanks to LDP (Label Distribution Protocol), where LSRs (Label Switching Routers) share information in order to reach other LSRs. With

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

RSVP (Resource Reservation Protocol), resources can be reserved in the entire route of any LSP (Label Switching Path) for a specific traffic flow, this is known as MPLS-TE (Traffic Engineering).

On the other hand, unlike traditional MPLS and the complications required to operate it, Segment Routing allows to implement IP routing in a flexible and scalable manner, so the origin router chooses a route and inserts it as an ordered list of segments, not depending on LDP or RSVP-TE signaling, hence the fact that it uses segments to send in the origin.

SR can operate on an MPLS fabric or IPv6 data plane, together with its own services such as L3VPN.

The implementation of SR in current providers depends on having an adequate platform in hardware and software to allow the evolution of the network to operate with this type of packet forwarding.

Segment Routing reinforces the idea that an explicit route is an ordered set of instructions put into the packet, with routers executing these instructions as they are sent. Each instruction is called a segment, and has its own number called Segment ID (SID), encoded as a stack of labels in MPLS, with each label representing a particular segment, so the MPLS label values can carry individual segment IDs inside the Segment Routing Domain, as seen in Fig. 1

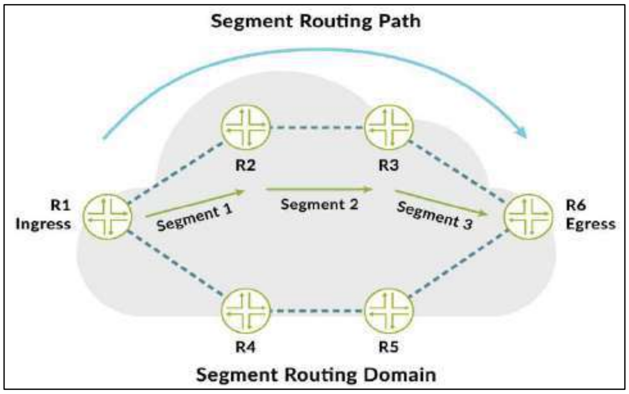

Fig. 1. Segment Routing Domain [6]

In the next section, Segment Routing operation is explained in greater detail since it is the main topic of this work.

SD-WAN bases on incorporating SDN paradigm and NFV (Network Function Virtualization) technology to a WAN network [7]; in other words, the process of creating WAN tunnels on fast and reliable manner from an API (Application Programming Interface), so the WAN network has a standardized, flexible, and scalable architecture [13].

Characteristics of SD-WAN environments are:

- Policy management: Configure and manage parameters such as QoS [8], security, access, among other policies like PBR (Policy-Based Routing [20]).
- Network by application: Where virtual networks are defined regardless of the physical part, and therefore policies can be applied for each virtual network.
- Dynamic assignment of services: Adding services in traffic flows for a given time, such as redirecting traffic to an element in the network or to a data center.
- Dual uplink: Allows to use the active and backup link according to the services or traffic flows.
- Hybrid Cloud Approach: Allows extending IT capabilities to a data center in a dynamic, simple and transparent way.
- Auto request/self-management: Through a website or Front-End API, the client can execute or request policies, changes, insights or reports.
- Monitoring and reports: As indicated, through the customer portal, information can be obtained in real time about the configuration, network topology, traffic patterns, troubleshooting, and whatever the customer deems necessary (great insights).

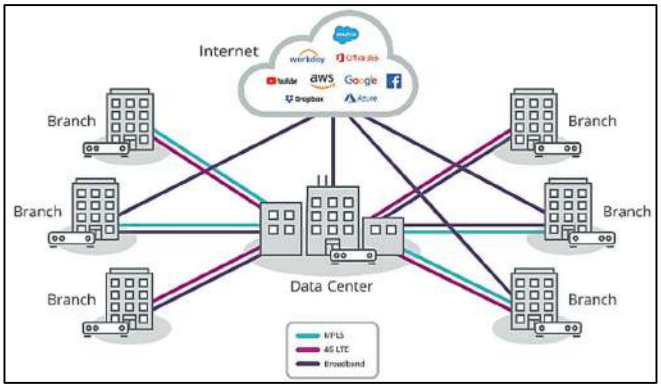

Fig. 2. SD-WAN Architecture [9]

III. Segment Routing Fundamentals

The SR's initial idea was proposed by Cisco Systems engineer Clarence Filsfils in November 2012 and IETF who formed the SPRING (Source Packet Routing in Networking) Working Group in October 2013. RFC 8402, known as Segment Routing Architecture, was developed in July 2018.

Being Segment Routing the latest technology in changing the way packets are handled in network infrastructures like Internet cores, DCs or between DCs, this protocol is a simpler way to forward packets, control networks, schedule routing, packet processing, and to implement traffic engineering policies, using the concept of source routing and bases its implementation in forwarding data plane on top of two technologies: MPLS and IPv6 as its Data Planes.

The MPLS data plane allows carry multiple labels, acting as Segment Identifiers (SIDs), IPv6 also does the same through the Segment Routing Header (SRH), carrying multiple segments as well. The MPLS data plane places the next segment represented by the tag closest to the MAC header and removes this tag after using it to determine the next hop, so the current tag and the next one will always be in the same relative place to each other.

On the other hand, SRv6 carries the current segment as a destination IPv6 address, with the rest of the segments in the SRH, the last segment being the closest to the MAC header, and the next segment in the stack is the furthest from the MAC header; since these locations vary, a pointer is used that indicates the location of the next segment, in such a way that no segment is removed from the stack, which means a great difference in speed in relation to data plane processing. This approach is represented in Fig. 3

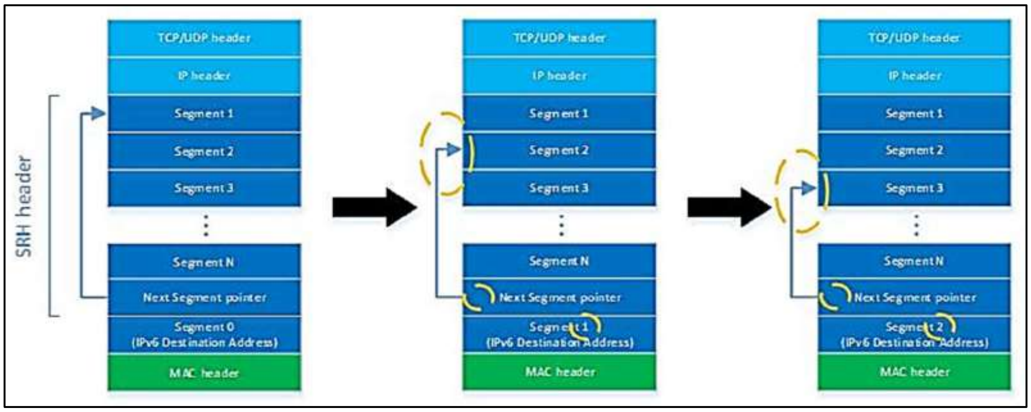

Fig. 3. SR Stack – SR Header [10]

In Segment Routing there are two main classes of segments:

- Global Segment: It is an SID-value valid throughout the entire SR domain, in such a way that each node knows this value and assigns the same action for the associated instruction in its LFIB (Label Forwarding Information Base). The range used is <16000-23999>. It is known as Segment Routing Global Block (SRGB) and this range is specific to each manufacturer.
- Local Segment: it is an SID-value that has local meaning, and only the source router can execute the associated instruction. These values are not in the SRGB range, but there are in the locally configured label range.

In a SR Topology, the LFIB (Label Forwarding Information Base) table is distributed by the Link-States IGPs like IS-IS and OSPF.

One of the differences between SR and MPLS-LDP is that the forwarding table (nodes + adjacencies) remains constant despite the number of routes in a Full-Mesh ISP topology.

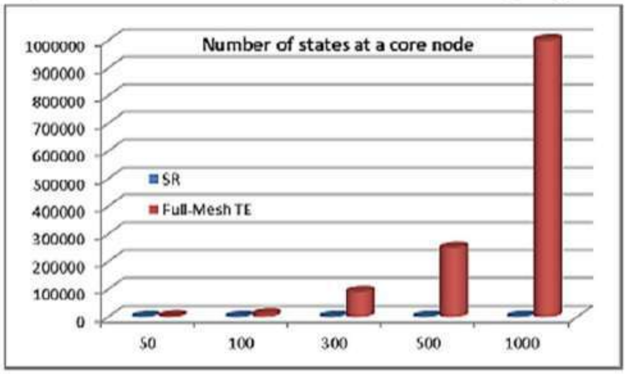

Fig. 4. SR vs MPLS-TE routing states [11]

IV. Proof-of-Concept Emulation of L3VPN in MPLS, Segment Routing amd SRv6 Networks

In this section, an emulation of a network architecture to communicate two sites by a Service Provider is presented. Three scenarios are shown to compare the feasibility and characteristics of Segment Routing IPv6 vs. MPLS-LDP.

A. MPLS L3VPN

Nowadays, it is the main model and framework deployed by SPs to establish communication between two or more client sites, but in production environments, there are different business clients managed by a single node thanks to Virtual Routing Forwarding (VRF) technology. This model consists of a client network formed by Customer Edge (CE) devices that are connected to a Service Provider through BGP routing protocol, and the Provider network formed by Provider Edge (PE) and Provider (P) devices using Level 2 Intermediate System-to-Intermediate System (IS-IS) protocol as IGP to exchange global routes, and Multiprotocol Label Switching (MPLS) to forward label-based packets. The Service Provider Cloud can forward Virtual Private Networks (VPN) traffic thanks to Multiprotocol-BGP (MP-BGP). This architecture permits PE takes part of the client routing with an optimum routing, and PE would process different routes for each client, so, it can address overlapping IPs [14].

The P devices do label switching and they do not know VPN routing at all, as well as the CE devices do not know the P device existence, so the provider network is transparent to the client.

To carry client routes from one PE to another across the MPLS domain, it is necessary to enable BGPv4 protocol through MP-BGP sessions, in which a 64-bits prefix called Route Distinguisher (RD), transforms a 32-bits address into a unique 96-bits address known as VPNv4/VPNv6 address-family. The RD are configured inside a VRF on all PEs. Route Targets (RT) permit that a VRF can participate in more than one VPN; RTs are announced as MP-BGP extended communities with the use of **import RT/export RT** commands.

To identify a remote client, the egress PE generates the 4-bytes VPN label through MP-BGP to the ingress PE which is used as an intern label at the MPLS process. The VPN label indicates to the last MPLS equipment the specific destiny of a packet for a particular VPN. This process can be observed in Fig. 5.

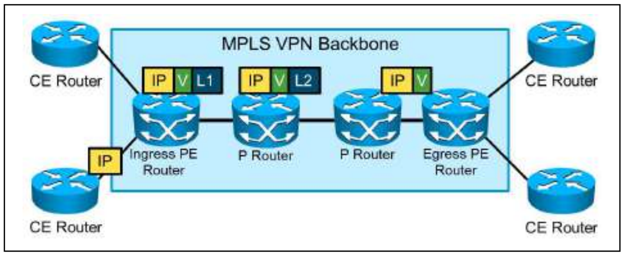

Fig. 5. VPN label operation

1) L3VPN over MPLS Architecture

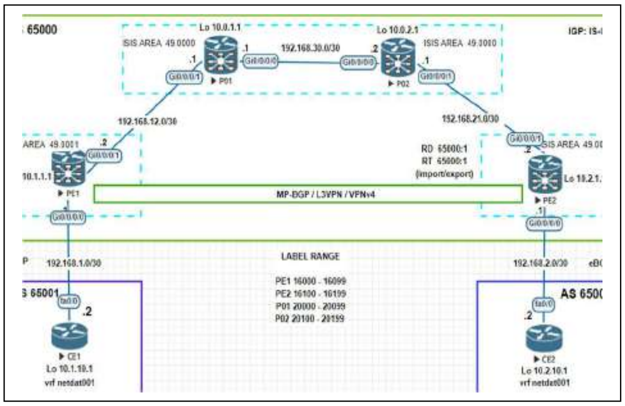

Fig. 6. MPLS L3VPN Architecture

In Fig. 6, there are two sites to be connected and one ISP Cloud acting as Transit network with the following Autonomous System (AS) numbers: 65000, 65001 and 65002, respectively. Sites are connected to the SP via eBGP. At the SP cloud there are two PEs and two Ps devices where L3VPN over MPLS is deployed. Every device has its own Loopback interface.

2) Configuring basic MPLS L3VPN

This emulation uses Cisco ASR9000 with 6.0.1 and 6.1.3 IOSXR releases and Cisco 3725 devices with 12.4(15) IOS release.

a) MPLS configuration: After configuring IS-IS, MPLS must be enable, in addition with an MPLS label range per each device (Fig. 7).

```
mpls ldp
 router-id 10.2.1.1
 interface GigabitEthernet0/0/0/1
mpls label range table 0 16100 16199
```

Fig. 7. PE1's MPLS configuration

b) eBGP configuration: This configuration lets connect a site with the Service Provider Cloud.

```
router bgp 65000
  vrf netdat001
  rd 65000:1
  address-family ipv4 unicast
  !
  neighbor 192.168.2.2
   remote-as 65002
   update-source GigabitEthernet0/0/0/0
   address-family ipv4 unicast
    route-policy PERMITE_TODO in
    route-policy PERMITE_TODO out
```

Fig. 8. PE1's eBGP configuration

c) MP-BGP configuration: Configuration to carry and exchange routes between PE devices. VPNv4 address family is used, as seen in Fig. 9

```
router bgp 65000
 address-family vpnv4 unicast
 !
 neighbor 10.1.1.1
  remote-as 65000
  update-source Loopback0
  address-family vpnv4 unicast
   next-hop-self
```

Fig. 9. PE1's MP-BGP configuration

d) VRF configuration: This step lets differentiate between more than one VRF that could exist in a PE device.

```
vrf netdat001
 address-family ipv4 unicast
  import route-target
   65000:1
  export route-target
   65000:1
interface GigabitEthernet0/0/0/0
  vrf netdat001
 ipv4 address 192.168.2.1 255.255.255.252
```

Fig. 10. PE1's VRF configuration

3) Verification of MPLS L3VPN: With the **show bgp vpnv4 unicast vrf <vrf_name>** command, prefixes that are members of the VPN are shown in Fig. 11.

```
RP/0/0/CPU0:PE1#sho bgp vpnv4 unicast vrf netdat001
Sat Feb 27 17:54:11.399 UTC
BGP router identifier 10.1.1.1, local AS number 65000

Status codes: s suppressed, d damped, h history, *
valid, > best
              i - internal, r RIB-failure, S stale, N
Nexthop-discard
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network            Next Hop   Metric LocPrf Weight

Fig. 12. MPLS-LDP WireShark Traffic Capture

B. Segment Routing MPLS

It is called SR-MPLS because it uses MPLS data plane fabric as an "underlay" infrastructure, so its operation is the same as MPLS-LDP. It is important to known that a segment equals to a label and a list of segments equals to a label stack with the advantage that LFIB table remains constant. SR-MPLS does not use Label Distribution Protocol (LDP). By default, if a device has been configured with MPLS and SR, it is going to prefer MPLS, so SR must be selected in the configuration.

Nowadays, there are many SR use cases, and real-world implementations in large ISP, such as Bell Canada, in which Segment Routing meets all its next-generation network requirements and is adopted as part of its phased Network 3.0 transformation project according to [18] [21].

Fig. 15. L

1) SR-MPLS Architecture

The scenario presented in Fig. 13 is Segment Routing over MPLS Cloud. Inside ISP Cloud, IS-IS is the cloud routing protocol; IS-IS needs an extension to keep the SID database, as well as a VRF to differentiate traffic for a specific client, and MP-BGP tunnel to establish end-to-end communication between PE devices.

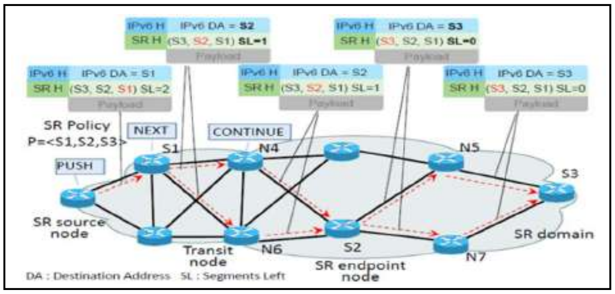

Fig. 13. L3VPN over SR-MPLS Architecture

2) Configuring SR MPLS

Because SR is built over MPLS, the operation of IS-IS, as well as the exchange of VPN through MP-BGP, are the same as in MPLS-LDP.

a) SR MPLS configuration: It is set under **router isis** instance on all SP devices, and a prefix-sid which starts at 16000, must be configured.

```
router isis 1
 net 49.0001.0100.0100.1001.00
 address-family ipv4 unicast
  metric-style wide
  segment-routing mpls
 !
 interface Loopback0
  address-family ipv4 unicast
   prefix-sid index 0
```

Fig. 14. PE1's SR MPLS configuration

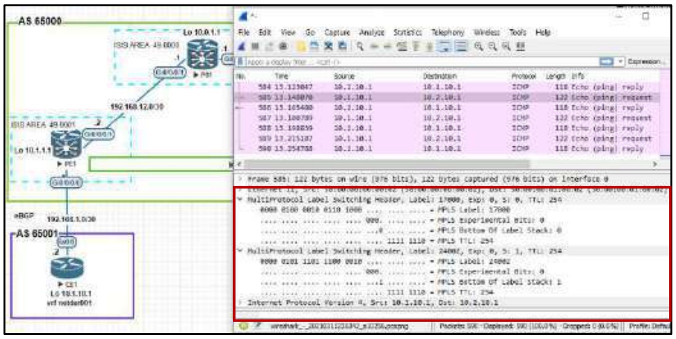
3) Verification of SR MPLS

With **show mpls interface detail** and **show cef** commands, can see the no use of LDP [15].

```
RP/0/0/CPU0:PE1#sh mpls int giga 0/0/0/1 detail
Sun Feb 28 22:52:17.405 UTC
Interface GigabitEthernet0/0/0/1:
        LDP labelling not enabled
        LSP labelling not enabled
        MPLS ISIS enabled
        MPLS enabled
```

Fig. 15. No use of LDP in SR Topology

With a ping, is possible to check segment assignment to SR MPLS and VPN label.



```
No.  Time        Source      Destination  Protocol  Length Info
584 13.123047   10.2.10.1   10.1.10.1    ICMP      118 Echo (ping) reply

Fig. 16. SR-MPLS for IPv4 WireShark Traffic Capture

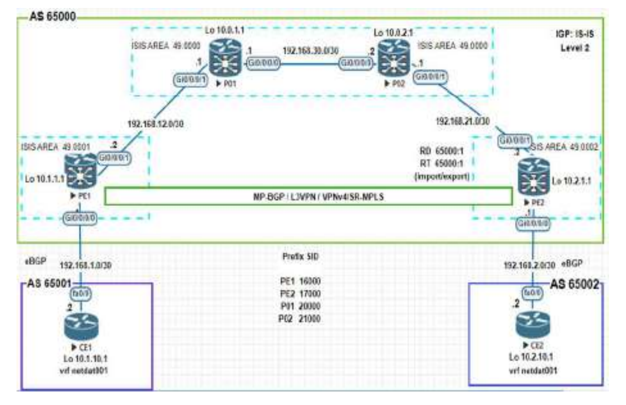

Fig. 17. SR-MPLS Topology

C. Segment Routing SRv6

An IPv6 address is used as SID, so the source router codifies the path to the destination as an ordered segment list or IPv6 addresses, which are placed in a new header called SRH. Along the path of SRv6 that a packet could take, there are nodes with different functionality, according to [16]:

- Source node and End Node: It generates IPv6 packets and place it in SRH. The End Node is the final node.
- Transit node: Appears on SRv6 path, but do not examines the SRH.

1) SRv6 Architecture

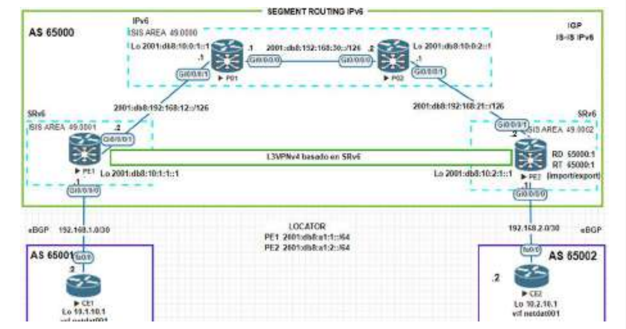

Fig. 18. L3VPN over SRv6 Architecture

To implement this scenario, at least. 6.6.1 IOS XR release is needed [16], and for this case, 6.0.1 and 6.1.3 releases have been used.

2) Configuring SRv6

a) SRv6 basic locator: It is global enabled, and a locator with its prefix must be configured, this locator is announced by IS-IS protocol.

```
RP/0/0/CPU0:PE1(config)#segment-routing srv6
RP/0/0/CPU0:PE1(config-srv6)#locators
RP/0/0/CPU0:PE1(config-srv6-locators)#locator myLoc1
RP/0/0/CPU0:PE1(config-srv6-locators)#prefix
2001:db8:a1::/64
```

Fig. 19. SRv6 locator configuration

b) SRv6 IS-IS: This protocol needs an extension to support SRv6 SID, allowing to learn local and remote locator prefixes to install it in the RIB, FIB. It is important to say that only one address-family of IS-IS can support one segment routing way, SR MPLS or SRv6[16].

c) SRv6 L3VPNv4: This configuration allows L3VPNv4 over SRv6 (Fig 20 and Fig. 21).

```
RP/0/0/CPU0:PE1(config)#router isis 1
RP/0/0/CPU0:PE1(config-isis)#address-family ipv6
unicast
RP/0/0/CPU0:PE1(config-isis-af)# segment-routing srv6
RP/0/0/CPU0:PE1(config-isis-srv6)#locator mvLoc1
```

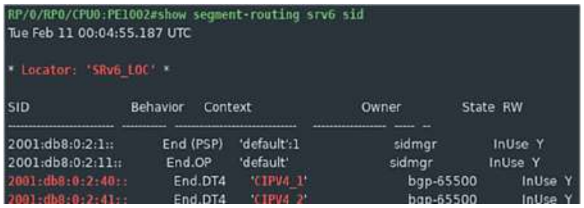
Fig. 20. ISIS Configuration in SRv6

```
RP/0/0/CPU0:PE1(config-bgp-af)#vrf netdat001
RP/0/0/CPU0:PE1(config-bgp-vrf)# rd 65000:1
RP/0/0/CPU0:PE1(config-bgp-vrf)#address-family ipv4
unicast
RP/0/0/CPU0:PE1(config-bgp-vrf-af)#segment-routing srv6
RP/0/0/CPU0:PE1(config-bgp-vrf-af-srv6)#alloc mode per-
vrf
```

Fig. 21. VRF configuration with per label allocation

3) Verification of SRv6

Once SRv6 has been enabled, the **show segment-routing srv6 sid** command verified SRv6 operation as seen in Fig. 22.



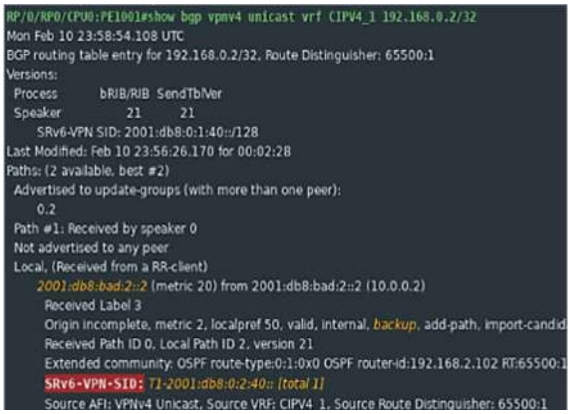
```
RP/0/RP0/CPU0:PE1002#show segment-routing srv6 sid
Tue Feb 11 00:04:55.187 UTC

* Locator: 'SRv6_LOC' *

SID                  Behavior  Context                Owner        State RW
-------------------- --------- ---------------------- ------------ ----- --
2001:db8:0:2:1::     End (PSP) 'default':1            sidmgr       InUse Y
2001:db8:0:2:11::    End.OP    'default'              sidmgr       InUse Y
2001:db8:0:2:40::    End.DT4   'CIPV4_1'              bgp-65500    InUse Y
2001:db8:0:2:41::    End.DT4   'CIPV4_2'              bgp-65500    InUse Y
```

Fig. 22. SRv6 SID verification [19]

It is possible to know the prefixes learned inside a VRF in the PE device, and the SRv6-VPN-SID assigned with the **show bgp vpnv4 unicast vrf vrf-name prefix** command.



```

V. PoC Analysis

The described scenarios show the operation of MPLS-LDP and SR architecture. The next table compares the architectures to determine the advantages of SRv6 over the other mentioned technologies.

TABLE I. MPLS vs SR MPLS vs SRv6 – Comparison

MPLS	SR MPLS	SRv6
TRAFFIC LABELING		
By Labels	By SIDs	By IPv6 address
Label Stack	SR Policy	Segment List in SRH
Topmost Label	Active Segment	IPv6 address in Dest. Address
OPERATIONS		
Push	Push	Equals SR MPLS adding IPv6 to Segment List en SRH.
Swap	Continue	Forward to IPv6 Dest. Address.
Pop	Next	Decreases Segment Left and active segment copied in IPv6 Dest. Address.
TECHNOLOGY SUPPORT		
Support by all modern devices	Requires software update, it uses MPLS data plane	Hardware changes are needed and software update to support SRv6 data plane
In operation with all technical support	SR knowledge to operate over MPLS data plane	Requires SRv6 new concept study. It is full IPv6 deployed in the backbone
MAIN CHARACTERISTICS		
Number of states increases with the number of routes	LFIB table remains constant, regardless of the routes in a Full-Mesh topology; Therefore, it considerably reduces the number of states.	
Uses LDP protocol for label distribution and route establishment, as well as	It does not use LDP, since a segment is an instruction, it uses the concept of the SID prefix, taking	It is based on the SRv6 SID, where the route is encoded in an ordered list of segments or IPv6 addresses that are placed on the SRH. It does not use RSVP or tunneling, its algorithm is

RSVP for TE optimization	advantage of the MPLS data plane	native according to source routing
Dual Stack Support	Dual Stack Support	IPv6 Support
Uses the LDP NSR (Non-Stop Routing) feature, which provides a rapid recovery mechanism in control plane from failures	50msec in prefix protection against link failures, nodes with the use of TI-LFA (Topology Independence-Loop Free Alternate). It is also supported in SR / LDP scenarios. It is calculated by the routers during the IGP process. Covers 100% of any topology	
It supports QoS in packet classification	It satisfies QoS requirements by ensuring applied bandwidth in the AB attribute of the node or adjacency segments in the SR TE route.	

VI. Conclusions

After a deep research and analysis, it was concluded that SRv6 bases its operation on the concept of source-routing, therefore, it simplifies routing and processing within the service provider's backbone by providing a simple, scalable and effective solution through network programming from the source that defines the route to the destination through IPv6 addresses in the SRH header.

With the emulation of the network architecture in the different L3VPN scenarios that connect two remote sites through a SP backbone, it has been shown that the MPLS operation is carried out through the LDP protocol with the label assignment when passing through each node; while SR-MPLS from scenario 2, takes advantage of the MPLS data plane, eliminating the need of LDP, introducing SID prefixes and writing an ordered list of instructions or SR Policy placed in the packet header; and SRv6 from scenario 3, establishes a pure IPv6 backbone on an IPv6 data plane that is based on source-routing through the registration of IPv6 addresses that are formed based on the SRv6 SIDs that are placed in the SRH header, with which the routing within the service provider becomes simple, effective and fast.

SRv6 enhances and improves latency, jitter and QoS characteristics by ensuring bandwidth that is applied to the node's attributes or adjacency segments in an SR-TE Segment Routing without using RSVP protocol, also enhances Fast Re-Route (FRR) for failovers, supports Secure VPNs, and network automation with Network Function Virtualization and Software Defined Networking.

SR-MPLS (IPv4 support), requires a software update on SR nodes, while SRv6 requires a change in hardware and software which represents an investment for ISPs, as well as training in human talent, but, the benefit of these changes will generate great interest in the operators and IT customers by supporting new network applications that demand a large amount of information processing with SDN in mind.

***Abstract*— In the nano-scale fabrication process, one of the major concerns is the impact of the process variation on the functionality of the design. At lower technology nodes, the impact from the second-order elements which were not significant is playing an important role in defining the designs. SRAM being at the forefront of every process node, it is important to assess the impact of the process in the early stages to make the required design changes. Self-time path in SRAM is crucial in defining the functionality, power, and performance. In the early stages of SRAM development, the proposed ring oscillator (RO) design helps in estimating the post-fabrication impact. This paper discusses the design and implementation of the SRAM critical path-based ring oscillator in the 7nm FinFet process and comparing the behavior with a more conventional ring oscillator. The impact from the process parameter variation is captured in the form of frequency variations. It is observed that the process tracking capability of conventional ring oscillator differs by ~17% compared with SRAM critical path behavior.**

Keywords*—** *Bitcell, Critical-Path, FinFet,* ***PMV *(Process Monitoring Vehicle),* ***RO*** *(Ring Oscillator),* ***SRAM*** *(Static Random-Access Memory)****,*** ***STP*** *(Self-Time Path),* ***SAE*** *(Sense Amplifier Enable)*

I. Introduction

Deep submicron scaling of process nodes is done to add more functional blocks on-chip by incorporating more transistors. At sub 28nm, the effects of process variations are significant. These effects are having more influence on the performance and functionality of the design in submicron nodes. Process variations are caused by the deviation of process parameters from their desired values. This is caused due to the limited controllability of a fabrication process. As device dimensions continue to scale towards ultra-deep submicron range typically less than 100 nm, manufacturing equipment’s become less reliable in controlling the design parameters. Intrinsic parameter fluctuations play an increasingly important role in submicron devices. In technology nodes 100nm and less, margins shrink due to reduction in supply voltage [1]. SRAMs are scaled aggressively to fit more bits per unit area. Scaling the transistor dimensions comes at the cost of complex process and elevated variability in the transistors [2] and hence reduces the overall yield. In FinFets, the gate of the device is elevated, hence the transistor behavior becomes more complex. This results especially in bitcells requiring new techniques to incorporate the variation of the bitcells in the ring oscillator [3]. Process monitor vehicle (PMV) block which includes ring oscillator helps to estimate the process variations in fabrication. SRAMs are more prone to variation since the bitcells dimensions are scaled more compared to logic gates. In the 7nm process, the SRAM (6T) is ~15% smaller than the smallest inverter (INV). Reduction in SRAM supply voltage reaching towards the threshold voltage makes it more vulnerable to variation [4]. The number of path delay faults observed during the first silicon debug are significantly [5] higher at high-frequency operation. Process variations of 10%-30% across wafers and 5%-20% across different die significantly affect the behavior of devices and interconnects [6].

Critical paths define the operating frequency of the block. Hence it is required to optimize the critical path and study impact from process variation at the early stages of silicon debug [7]. To capture the impact from fabrication at an early stage of SRAM development we have designed the self-suffice ring oscillator with SRAM critical path as part of the oscillator. This helps us in characterizing the SRAMs critical path which contains the STP (Self-Time Path). STP is an important part of the SRAM design. The STP design is critical and impacts the functionality, power, and speed of the memory. Speed characterization is used in many places in chip design, this will help both yield and business aspects of chip design. In 7nm Xilinx FPGA we can have several hundreds of megabytes of SRAMs. SRAMs on the mid-sized FPGA are the largest contributors to the critical path. Section II briefly discusses the conventional ring oscillator. Section III discusses the proposed design. Section IV discusses results.

II. Conventional (Ring Oscillator)RO design

Commonly used ring oscillator design comprises of inverters, nand/nor logic arranged in an odd number of stages.

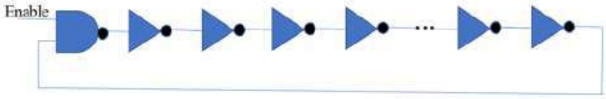

Fig. 1 Conventional design of RO.

Fig. 1 design is used for comparing the frequency response of the self-time path-based ring oscillator. The inverter-based ring oscillator is designed with the 7nm FinFet stdcell library. Ring oscillator designs are testable at the early stages of the process where the first level of metals can be used for initial process development as well as

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

process monitoring in manufacturing stages. Different configurations of ring oscillator structures are embedded inside the design itself and can be used to diagnose design and fabrication process impact on the design such as the proposed in the paper [8].

Some of the ring oscillator-based test structures are observed here [9] [10] [11] [12]. The frequency of the ring oscillator is used as a metric to quantify the process. There are different configurations of inverters that are chosen to improve their sensitivity to the process. It includes usage diode-connected configuration [13]. SRAM's critical path contains bitcell based self-timed path and many custom logic circuits which don't contain characterized standard cells. To model the SRAM's critical path behavior proposed design is embedded inside the SRAM, this will be a more accurate estimate of fabrication impact.

III. Proposed Design

The proposed design doesn't contain any chain of inverters or other gates with odd stages. Toggling here is achieved by a combination of self-time path and ring logic design. There are many methods used to characterize the process vs speed. To study the impact of the process bitcells are used while constructing the ring oscillator [14][15][16]. The proposed design includes tracking bitcells and the custom logic in the critical path.

SRAMs critical path contains tracking bitcell, which are modified bitcell used for the tracking of bitcell operation. These are an essential part of SRAMs and are very critical in compiler memories. The STP includes many custom logics along with tracking bitcells. Fig. 2 shows the self-timed path containing tracking bitcells in rows and columns. The self-time path is designed to track the worst bitcell in the bitcell array. The worst bitcell to access for the operation will be furthest from the control block. Tracking is required for word line in row and bit line in a column. The self-time path is responsible for triggering the sense signal to enable the sense amplifier in IO for the read operation. If the STP is trigger sense signal too early, then the result of the sense amplifier can resolve in an unknown state. Since sense amplifier requires certain differential voltage on bitlines to read the correct state of the bitcell. If the STP is fired too late then the bitcell will discharge too much charge from the bit line causing more power to be burned. When the word line is turned ON the entire row is activated hence any more delay than required will result in burning access power. This also results in higher cycle time since the process takes more time to complete the read/write cycle. Hence impacting the frequency of operation.

Fig. 3 shows SRAM and ring oscillator stage. SRAM output, sense amplifier enables (SAE) is taken out from the SRAM and given as input to the ring oscillator stage. By incorporating this into the oscillator structure we can accurately model SRAMs critical path behavior. The ring oscillator is responsible to generate the clock pulses depending on the input SAE signal. SAE is a pulse generated from the STP, it is processed in the ring oscillator to generate the set and reset signal for the SR latch. This generates the pulses proportional to the incoming SAE signal. The output of RO is feedback to SRAM as the clock. Fig. 4 shows the standard 2-input active low enabled SR latch which is used for the clock generation. Internally, care is taken to avoid any unwanted states which can result in functional failure. Fig. 5 shows the implemented ring oscillator and SRAM.

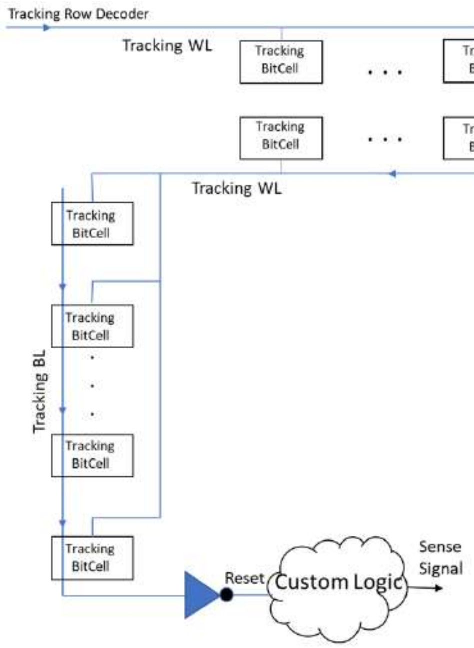

Fig. 2 Tracking bitcells used in Self-Timed Path

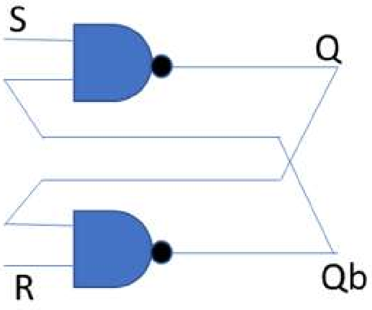

Fig. 4 Two-input NAND active low input SR latch

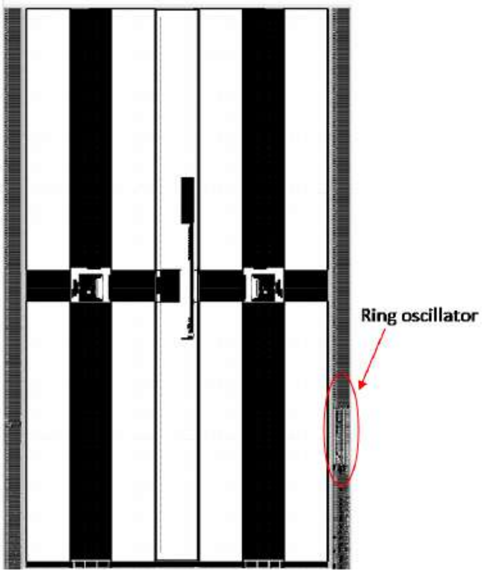

Fig. 5 Ring oscillator and SRAM layout

IV. Results

Fig. 6 and 7 show the sample frequency response of SRAM at the TT process. We can see at low voltage and high voltage there is variation in the behavior of the ring oscillator. This is due to temperature inversion caused at low voltage. SRAM RO is having a high frequency at high temperatures for low voltage and high frequency is achieved at low temperature for high voltages. This is highlighted in a red circle at two places in Fig. 6.

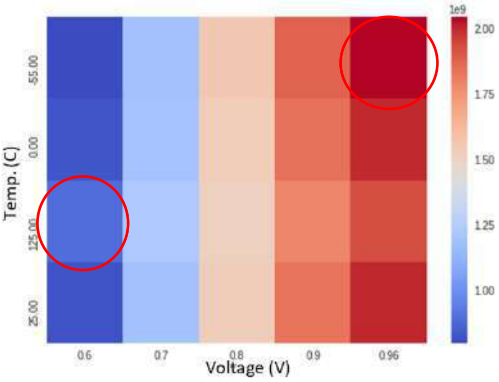

Fig. 6 SRAM PMV Frequency response at TT

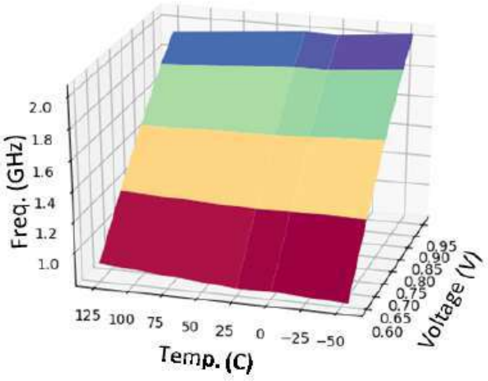

Fig. 7 SRAM PMV Temp. inversion effect at TT

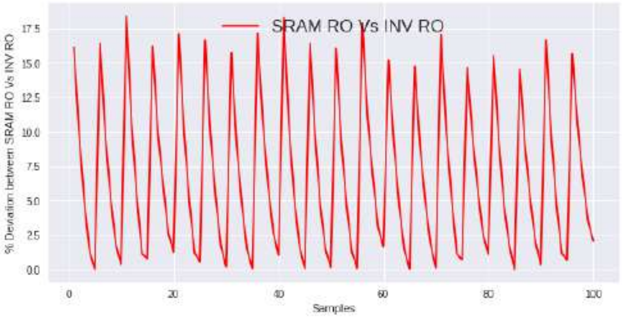

Fig. 8 100 sample points from SRAM and inverter RO with normalized frequency for comparison

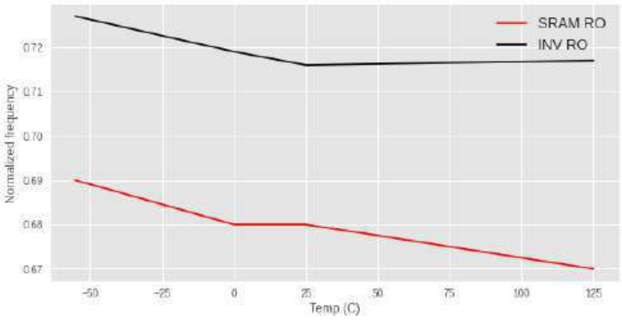

Fig. 9 Normalized SRAM and inverter RO Frequency response with temperature.

Fig. 8 contains normalized 100 samples of frequency at different processes, voltage, and temperature. 0% indicates the SRAM and inverter RO are inline and any deviation from their behavior is captured. There is a roughly ~17% variation between SRAM RO and inverter RO across process, voltage, and temperature. This gap needs to be reduced If the other ring oscillator-based design needs to be used to track the SRAM. Fig. 9 shows one of the 100 cases where the behavior of SRAM and inverter RO with temperature is not aligning with each other. This is mainly due to the presence of bitcells used in the self-time path. Bitcells behave differently compared to conventional logics since their dimensions are smaller and more prone to variations. In a compiler, it is preferred to have more variable delay and smaller fixed delay due to logic, since the STP should be able to track the bitcell for various memory configurations.

TABLE 1. σ/μ FOR DIFFERENT PROCESSES ACROSS VOLTAGE AND TEMPERATURE.

Process	*Sigma(σ)/Mean(μ)*		*% Deviation in the variation*
	SRAM RO	*INVERTER RO*	
TT	0.292	0.244	16.29
SS	0.322	0.276	14.25
SF	0.293	0.245	16.29
FS	0.289	0.244	15.31
FF	0.257	0.212	17.57

Table 1 shows the σ/μ variation of the SRAM and inverter ring oscillator. Process corners considered for the analysis are (Typical-NMOS, Typical-PMOS) TT, (Slow-NMOS, Slow-PMOS) SS, (Slow-NMOS, Fast-PMOS) SF, (Fast-NMOS, Slow-PMOS) FS, (Fast-NMOS, Fast-PMOS) FF. Variation in the σ/μ between the SRAM and inverter RO shows that these are not aligned with each other and are apart by ~17%. Embedding ring oscillator inside SRAM will yield more realistic process tracking since the ring oscillator takes the SRAM critical path into considerations.

V. Conclusion

In this paper, we have designed a self-time path-based ring oscillator incorporating the SRAM critical path. This helps in estimating the process impact on the SRAM more accurately. As nodes are shrinking beyond 7nm impact of second-order effects is becoming more prominent and it is critical to evaluate their impact early stages in the design. SRAM ring oscillator helps in tuning the design for functionality, power, and performance. Increasing the number of bits per unit area and having reduced power without compromising the reliability, performance is very critical in SRAM design. Similar more process-aware designs need to be implemented to track the process impact on design. Future work will involve updating the design to capture the effects of bias temperature instability and hot carrier injection in the ring oscillator.

***Abstract*—Online connectivity speeds are increasing rapidly on land, but are still very slow on modern ships and planes. Ships and planes depend mostly on satellite communication, which is divided up between their many passengers. This study attempts to find and overcome bottlenecks to the connectivity in ships and planes. Land-based BTS can connect to ships and planes, which can connect to other ships and planes, creating an ad hoc network. Planes can act as repeaters, overcoming the curvature of the Earth. Point-to-point microwave communication (rather than cellular concept) can link ships with ground BTS and other ships, tens of km away. Tracking antennas on ground BTS and ships, can follow planes in the air. Antenna size and movement on planes must be kept minimal, as they increase drag and fuel costs. Real-time location information can be used to point tracking antennas. There can be either moving antennas, or a large number of narrow-range antennas switching with the movement of the ship or plane. In the far oceans, submarine cable connected, solar-powered BTS can be installed for connecting to nearby ships and planes. With multiple channels available between distant ships and planes, packets of information can choose the best available path for transmission (like the internet). Point-to-point communication may be difficult between ships, and the cellular concept can be used instead. Today's technical capabilities suggest we are on the verge of a breakthrough in better connectivity of ships and planes hundreds of km from the shore. New competing technologies will emerge, of which the best will survive. Policies and rules must be established, so as to encourage competition. It is hoped that this paper will help in the research and development of the new technologies for better connectivity.**

I. Introduction

Connectivity speeds for smart phones and computers have been increasing exponentially over the last few decades, in agreement with Moore's law. Communication at up to 2 Mbps is possible with the Mars Rover hundreds of millions of miles away (20 minutes for round-trip of light). Surprisingly, in this day and age, connectivity at modern ships and planes is still very slow. Most passengers may have no connectivity or slow connectivity in the 18 hours on intercontinental flights, or for days or weeks on cruise ships. The isolation of the crew of cargo ships and oil tankers, in the seas for weeks and months, is worsened by slow connectivity with the rest of the world.

This paper attempts to identify and overcome the bottlenecks to connectivity on ships and planes. Ships and planes largely depend on dividing among passengers the already low bandwidth of satellites [1].

A. Low connectivity on Planes and Ships

Large commercial planes, such as the A380 and Boeing 777 often provide no connectivity to economy class passengers. Limited connectivity may be available upon purchase. The Wi Fi offered (free or paid) on the plane may at best allow voice communication and low-resolution picture transfer [2],[3]. Transmission of video is almost impossible. Passengers are advised to shrink pictures before sending, and to turn off background apps that refresh and synchronize. Apps such as *WhatsApp*, *Youtube* and *Netflix* are usually blocked.

Connection of planes with geostationary satellites means there is a time delay for the signals to travel 36,000 km to the satellite and back. Also, satellites do not reach planes traveling close to the poles, which happens often for inter-continental travel.

Only very recently are planes beginning to connect to ground based BTS with antenna located on the base of the plane. The plane antennas may move from BTS to BTS as they fly over the ground [4], [5], [6].

B. Low connectivity on Ships

The total number ships in the seas may be small compared to the total number of planes in the air. However, passengers and crew may spend weeks or months in isolation in the sea, which is only worsened with low connectivity.

In cruise ships, economy class passengers spend days or weeks getting slow and intermittent connectivity only with extra payment. Passengers discover that a vacation on a cruise ship also means a vacation from the internet. Even on modern liners, disconnection of internet starts from the passenger's entry into the ship, and ends upon disembarkation from the ship.

: 978-1-6654-4067-7/21/$31.00 ©2021 IEEE

C. *Ad-hoc networks*

Ad hoc networks, or temporary or changing networks, are an established technology today [7]. Ad hoc networks can be made from smart phones, or from autonomous vehicles talking to each other to prevent accidents [8],[9]. Ad-hoc networks have been proposed for interconnecting planes (Aeronautical Ad hoc Network), at least partly for the sake of safety [4] [5] [6].

This paper further develops these ideas and goes a step further in proposing an ad-hoc network from a combination of ships, planes and ground-based BTS.

Good connectivity between ships and planes means, that high demand on any ship or plane at any time, can be met by distributing the demand over a wide number of ships and planes. This means slow satellite connections to a number of ships and planes in a network can meet the temporary high connectivity demand of a single ship or plane.

D. *Potential for Improvement*

Planes flying over the ground should be made to have better connectivity with ground Base Transceiver Stations (BTS). Ships close to land should have better connectivity with shoreline BTS. Also, ships have the potential to become mobile BTS for planes and other ships.

Land-based BTS can connect to ships and planes, which can connect to other ships and planes, creating a large ad hoc network. The large number of planes on common flight paths can connect to each other, helping create such a network. Often ships travel in common shipping routes, meaning they too can help form an ad hoc network. Ships and planes can connect with each other, to form a large ad hoc network.

Point-to-point microwave antennas can link and track ships with ground BTS and other ships. Similar antennas on ground BTS and ships can follow planes real-time in the air. Real-time publicly available location information can be used to point tracking antennas. In the far oceans, BTS can be set up on islands, connected with submarine cables, and powered with solar panels

In 2008, the in-flight broadband company *Gogo* (then known as Aircell) launched its first onboard Wi-Fi service on a Virgin America plane. The 3 Mbps connection was enough for a few laptops (streaming video was prohibited). But now, this bandwidth is inadequate with every passenger having at least one device to connect to many apps and websites, *Gogo* had a monopoly on US in-flight Wi-Fi, with a network covering the whole country.

Today's technical capabilities suggest we on the verge of a Wild West of new technologies. At least for the next few years, there will be some competing technologies for enhancing connectivity of ships and planes. A major revolution in the connectivity of ships and planes may be in the near future, and it is hoped that this paper will help in the design and implementation.

II. Cellular Communication and Base Transceiver Stations

We start by comparing cellular and point-to-point communication, which will help in determining what would be appropriate for ships and planes. The cellular concept may be useful for creating a network for planes, which may be find it difficult to use point-to-point communication.

The cellular phone revolution of today was made possible by the cellular concept and the reuse of frequencies. Usually, cells are created with (a) omni-directional antennas, (b) or 120° antennas or (c) or 60° antennas

Base Transceiver Stations (BTS) may use omni-directional antennas, if the need is to cover a few cell phones over a wide area (figure below).

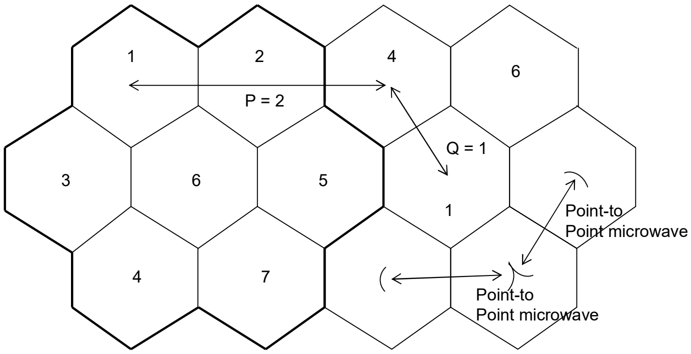

Fig. 1. Using omnidirectional antennas allows hexagonal cells and the reuse of frequencies. Number of frequencies, $N = P_2 + PQ + Q^2$. Point-to-point communication may be done between cells with microwave links or fiberoptic cable.

In the above figure, from theory, the number of frequencies required is a function of $P = 2$, and $Q = 1$, which are adjacent distances between cells.

$$N = P^2 + PQ + Q^2$$

$$= 2^2 + 2 \text{ x } 1 + 1^2 \quad = 7$$

Point to point communication between cells may be done with fiberoptic lines or point-to-point microwave links (figure above).

For higher concentrations of cell phones, three 120° antennas or six 60° antennas may be used to cover all round 360°, in effect, sectoring the cells (figure below).

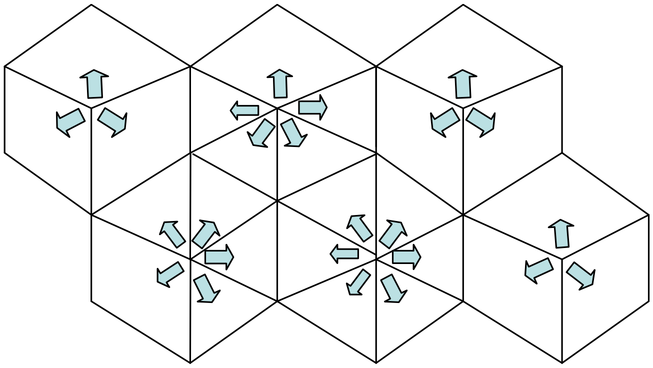

Fig. 2. The cells may be sectored with 120° antennas and 60° antennas.

BTS are often connected point-to-point with microwave towers, up to 50 - 80 km apart; a distance limited by the curvature of the Earth. Such point-to-point microwave has possibilities for connecting ships with other ships and with planes.

Owing to the tens-of-km distances between planes and between ships, the point-to-point concept may be applicable. Narrow-direction BTS antennas may have good potential for communication with planes and shoreline ships up to tens of km away (figure below).

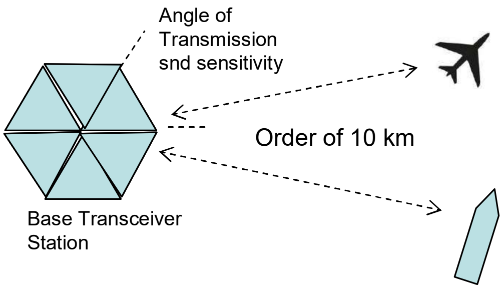

Fig. 1. Top view of a BTS shows six 60° directional antennas, covering all of 360°. Narrow-direction BTS antenna have good potential for faraway planes and shoreline ships. Advantage is planes and ships have much available power for transmission and reception (unlike cell phones)

Planes and ships have much power available for transmission and reception (unlike cell phones). Also, ships can use directional antennas (unlike cell phones).

TABLE 1. COMPARISON OF CELL PHONES, PLANES, SHIPS AND BTS ON LAND

	Power for Transmission & Reception	**Antenna**	**Tracking and Moving**	**Point to Point Commu-nication**	**Cellular communication**
Cell phone	Only battery power	Omni-directional	Unsuitable	Not suitable	Very suitable
Plane	High power available	Small size makes directional difficult	Moving and tracking difficult	Difficult, due to small antenna	Difficult because of tens of km distance
Ship	High power available	Omni-directional and /or unidirectional	Possible at top of ship	Very suitable, but need tracking antenna	Difficult because of tens of km distance
BTS on Land	High power available.	Omni direction, 60°, and uni-directional	Movement very possible	May need tracking antenna for ships and planes	Suitable for cell phones.

III. EXISTING TECHNOLOGY AND LITERATURE REVIEW

The latest aircraft (e.g. Boeing 787) already uses about 26 antenna placed around the aircraft. An antenna on top (jetwave antenna) may connect to satellites.

A. Literature Review

Considering that aircraft and ship connectivities provide great potential for growth, there are few scientific papers on the subject.

Connecting ships with each other and with shoreline BTS has been proposed [10],[11],[12].

Integrated connectivity of ground BTS, ships and planes has not been encountered in the literature.

IV. IMPROVING CONNECTIVITY OF PLANES

According to communication theory and practice, there are a number of possibilities for connecting planes.

A primary consideration is that antenna placed on planes tend to bulge out from the aircraft and produce drag, and consume extra fuel. New antennas may be difficult to install, as they may require working on the aluminum aircraft. A small sized antenna, rather than large, would be preferred. A stationary rather than moving antenna would be preferred. Large-sized moving antenna would be especially hard to install. These suggest the use of the cellular concept between planes.

The distances of planes from each other may be in the range of many tens of kilometers, meaning both microwave and RF would be possible. But the high speed and the associated Doppler shift may been a source of problems.

A. *Aircraft to Ground Connection*

There is much potential at this time, for connecting planes with ground BTS. (figure below).

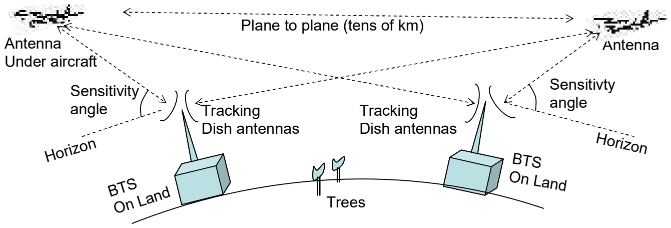

Fig 2 . Planes can connect with ground-based BTS with narrow-angle directional antennas. Moving antennas at the BTS can track and move with real-time location information. BTS antenna may point up for ships.

Planes will mostly be above the horizon of land BTS and ships, requiring their antenna to point upwards.

Connection with BTS is only possible when planes are over land. When far out at sea, planes, BTSs may not be available, but planes can still connect to ships, which can act like ground based BTS. A BTS can also be installed on isolated islands in the oceans.

B. *Moving versus Stationary Antennas*

Moving antennas have inherent problems, such as moving parts, possibility of breakage, and greater maintenance requirements [13]. In communications, moving antennas have traditionally been avoided in favor of stationary antennas.

In satellite communication, the preference is for stationary antennas connecting to geostationary satellites 36,000 km from the Earth, rather than moving antennas connecting to Low Earth Orbit (LEO) or Medium Earth Orbit (MEO) only a few hundreds or thousands of km away.

A moving antenna can be substituted by multiple stationary narrow-angle directional antennas, switching electronically from one to another (with no movement) as the plane (or ship) moves from the path of one antenna to another (figure below).

In the BTS below, there are ten 36° antennas, for all around 360° coverage. The antennas can switch from one to another, tracking the movement of the plane.

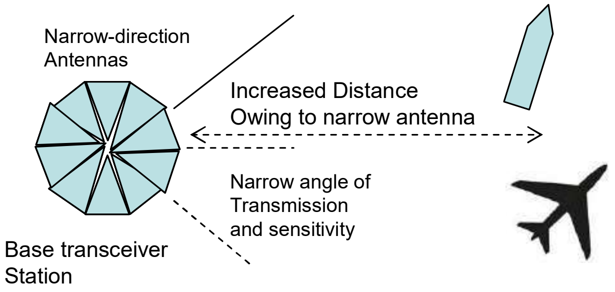

Fig. 3. Using narrow-angle directional antennas (36°) switching with movement of plane (or ship), will allow stronger transmission and greater sensitivity to signals, without movement of the antennas.

C. *Tracking with GPS and height Information*

The tracking of planes with antennas would be possible with location information from GPS. The location of the plane is also available from real time trackers [14] (figure below).

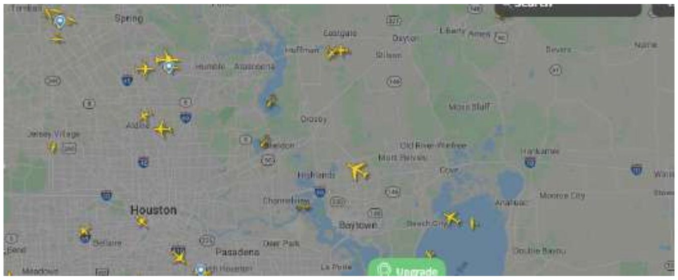

Fig 4. Planes in the Houston - Galveston area (FlightRadar24.com, April 4, 2021, 2:00 am, Dhaka time)

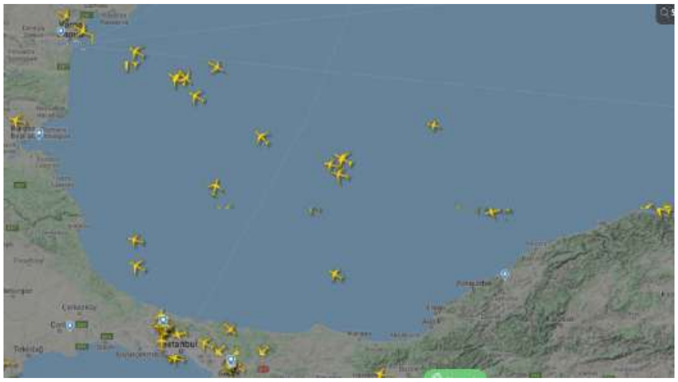

Fig 5. Plnnes over the Mediterranean, with Bulgaria on the left (flightradar24.com, on April 5, 5:00 am, Eastern time, US). Movement along common flight paths is visible.

In the above real-time location of planes near Bulgaria and the Mediterranean, planes are seen on common flight paths, indicating distances close enough for connectivity and forming an ad hoc network.

The above pictures are during the Covid pandemic, and the density of flights is much lower than during other years.

Planes can act as repeaters, overcoming the curvature of the Earth, to reach distant ships and planes (figure below).

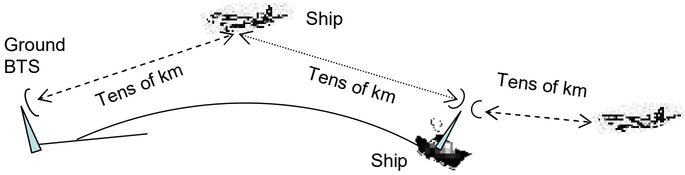

Fig. 6. A plane can act as a repeater for microwave communications, overcoming the line-of-sight requirement for microwave towers.

Using the plane as a repeater, connectivity may be possible for ships and planes about a hundred km from the shore.

V. Connectivity for Ships

The numbers of ships in the seas are far less than the number of planes in the air at any time.

When planes travel over land, they can connect to ground based BTS. But ships cannot be on the land, meaning they can connect to ground BTS only when they are close to the shore. A ship and a shoreline BTS may be connected with a point-to-point microwave dish antenna of range up to many tens of km. A ship may even act like a BTS at sea.

Ships are spacious and weighty enough to have large moving antennas. However, too high an antenna will thwart the ship's original design height specification to pass under bridges.

The roll, pitch and yaw of the ship must be compensated for:

(a) by having a wider-angle dish antenna to compensate for the movement of the ship.

(b) by having compensatory movement of the antenna along the three axes, to compensate for the movement of the ship (figure below).

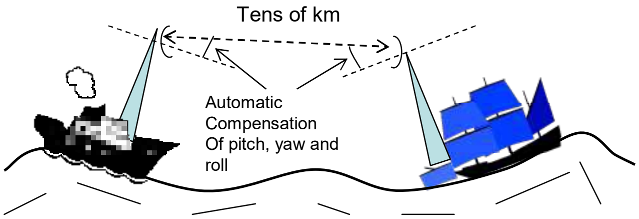

Fig. 7. Point-to-point antenna of ships may need compensation for pitch, roll, and yaw.

A problem arises far into seas and oceans, when there are no ground-based BTS to connect to. Connection to ground is not possible when passing over large bodies of water.

Many ships travel on common routes. So it is possible that ships close to the shore may interconnect with distant ships on the same route to become a network of ship-based BTSs.

The positions and velocities of ships can be seen real time in some tracking websites (figure below for Straits of Gibraltar) [15].

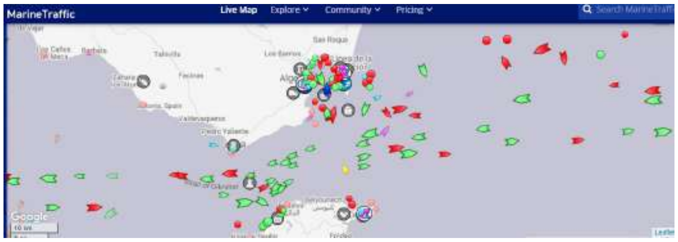

Fig 8. Ships in the Straits of Gibraltar (MarineTraffic.com, April 4, 2021, 2:00 am, Dhaka time)

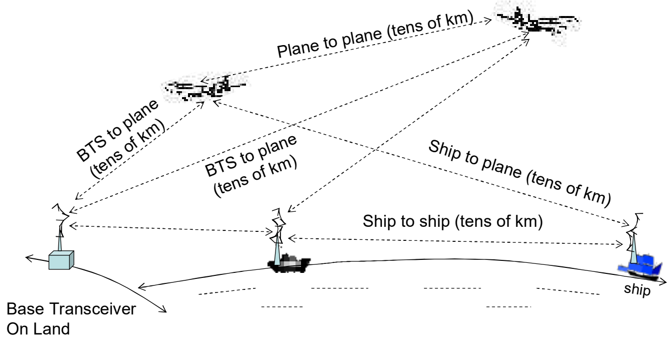
VI. Integrating Ships, Planes and Ground BTS

Having seen the interconnection of planes with each other, and ships with each other, we now look at a more integrated system involving ground BTS, ships and planes.

The high speed connectivity from land BTS can be transferred to nearby ships and planes, which can then transmit to other ships and planes.



Plane to plane (tens of km)
BTS to plane

Ship to plane (tens of km)
Ship to ship (tens of km)
Base Transceiver
On Land
ship

Fig. 9. Integrating connectivity of ground BTS, ships and planes with each other forming a large ad hoc network. The best path can be chosen for transmission, from a number of paths.

When there are a number of paths with ships and planes available for connectivity, the best path can be chosen, similar to the concept of the internet.

A. *Summary of Connections*

Summarizing the possible connections between land BTS, ships and planes;

(A) Ground BTS to aircraft connectivity. Dish antenna on ground can be large (and moving) and must point a few degrees above the horizon. Plane antenna will be small.

(B) Aircraft to aircraft connectivity. Can be narrow-direction or omni-directional. Antennas are limited in size and movability, as antennas protrude from aircraft, contributing to drag and fuel loss.

(C) Aircraft to Ship connectivity. Ship antennas must point above by a few degrees, and be compensated for yaw, pitch and roll.

(D) Ground BTS to Ship connectivity. Microwave connection can allow ship to act as new BTS. Only available when ship is a few tens of kilometers from the shoreline.

(D) Ship to Ship connectivity. Antenna must compensate for roll, pitch and yaw.

These are summarized in the table below.

TABLE 1. Tupes of connections for Ships and Planes

	Over land	**Close to land (a few tens of km)**	**Medium distance from Land (100 km)**	**Very far from land (100s of km)**
Planes	Can connect to Ground BTS with small antennas	Connection to land BTS.. Can act as repeater for BTS.	Secondary connection to ships and planes	Connect to ships. Connect to island BTS, if possible
Ship	(not applicable)	To BTS, Point to point Microwave	Secondary connection to ships, connected to land BTS	Connect to island BTS, if possible.

TABLE 2. COMPARISON OF ANTENNAS

	BTS	**Planes**	**Ships**
Antenna Features	Can be elaborate	Must be compact, as antennas increase drag	Moderately compact
Installing New Antenna	Relatively easy	Difficult	Moderately easy
Directionality angle	Can be very narrow	Wide angle	Not-so-narrow
Moving Antenna	Moving possible	Difficult	Moving possible

B. *In the Open sea, with BTS on an Island*

Connectivity becomes difficult when the ships or planes are far from land (hundreds of km) in the open seas. In this case, an available island with can be connected with a solar-powered BTS and a submarine cable. BTS connections on uninhabited island may be problematic, as salty dust may accumulate on solar panels.

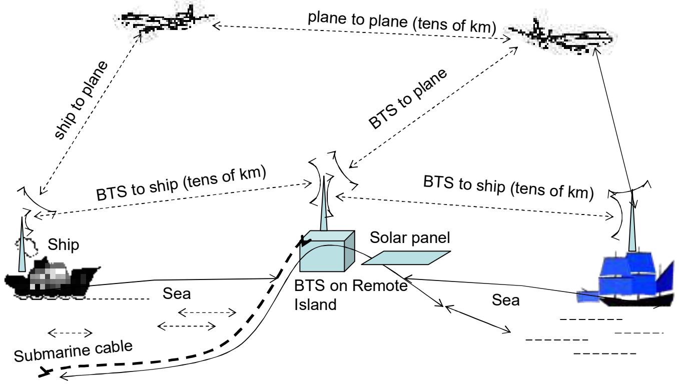

Fig. 10 . In the open sea, far from the mainland, a fiberoptic-connected solar-powered BTS can be set up on an island, for, connecting to ships and planes

With point-to-point distances between microwave at 50 - 80 km, it may be possible to extend the ad hoc network a hundreds of km into the sea (figure below).

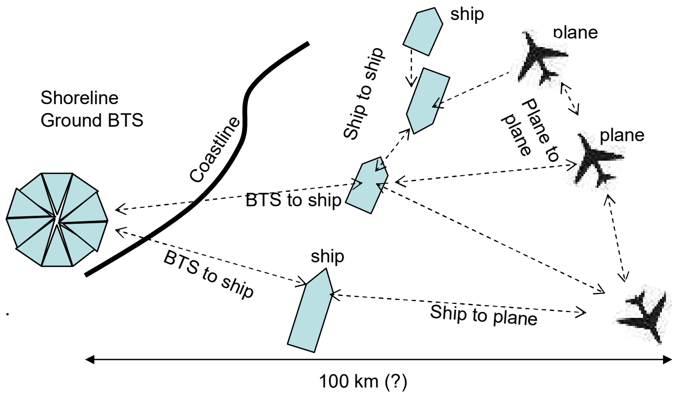

Fig. 11. Top view of a network of BTS, ships and planes, that can go perhaps a hundred km or more into the sea, depending on the connectivity of microwave.

C. *Challenges and Limitations*

As with any new technology, there are numerous challenges and limitations that must be overcome..

1. The large distances between ships and between planes may require specialized technology.

2. The proposed technology of this paper depends on the continuously tracking (or moving) narrow-angle dish antenna on ships and on ground-based BTS. Such tracking and movement may be difficult for antenna on aircraft.

3. Both ships and planes have enough power to have powerful transmitters and receivers.

4. Tracking of antennas requires moving parts and continuous movement, which could be a problem. But movement can be avoided by having numerous narrow-angle dish antennas.

5 As there may be considerable roll on ships, their antennas may have to have wider-angle dish antennas. Or there can be compensating motion of the antenna to keep it horizontal and pointing in the right direction. Rewriting, antennas must:

(a) have wider directionality to compensate for the rolling and yawing of ships.

(b) or move and compensate so as to keep connection with BTS or ships or planes.

6. The antennas on planes generate wind resistance, and may be required to be smaller and non-moving.

7. Short distances between ships and planes may allow nonmoving antennas with wide directionality. Long distances between ships and planes may require moving and tracking antennas with very narrow directionality.

8. The main problem with moving antennas is that that they must keep moving all the time, and that salty dust will lead to rapid corrosion and will require frequent maintenance.

VII. COMMERCIAL IMPLEMENTATION

With all the general strategies presented above, how are they to be implemented in practice over the next few years? Commercial airlines and passenger ships may be given an incentive not only to buy connectivity for themselves, but to act as part of a larger connectivity backbone. It is in the interest of the ships and planes to make the ad hoc networks as large as possible, because any ship or plane may be at the outer edges of this ad hoc network.

Opportunities and legislation should be provided so that a maximum number of companies can compete with each other to provide connectivity services. Rules and standards should encourage competition. Allowing multiple players would avoid monopoly and syndication, which are easy traps to fall into, considering the global backdrop.

CONCLUSION

Ships and planes today mostly rely on the very limited bandwidth of satellites, which gives slow connectivity to their many passengers.

Land BTS are connected to high-speed microwave or fiberoptics, meaning planes and ships close to the shore can connect to land BTS. Planes in proximity, especially in common flight paths can form ad-hoc networks, Ships can form ad hoc networks, especially with shoreline BTS. Ships in common routes can help in forming ad hoc networks. With multiple channels available between distant ships and planes, the best path can be chosen for transmission; which is also the principle of the internet.

Microwave communication with point-to-point antenna can be mostly used, in preference to cellular communication, Antenna on planes must be compact to reduce drag, meaning specialized compact antenna must be used. In comparison, dish antenna on BTS and on ships can be large and moving (for tracking).

Numerous narrow-angle non-moving dish antennas can switch automatically to track a moving ship or plane. Or else, an antenna can keep moving to track a ship or plane. Ships and planes have the extra power for all this communication, which a cell phone does not have.

Isolated islands far into the sea can have a BTS installed with the help of submarine cable and solar panels.

Today's technical capabilities suggest we on the verge of a Wild West of new technologies for connectivity on ships and planes. A major revolution in the connectivity may be just on the horizon, allowing connectivity hundreds of km from the shore. It is hoped that this paper will help in the design and implementation of these new technologies. A number of competing technologies are likely to emerge, followed by survival of the fittest. New policies and standards should encourage competition and discourage monopoly and syndication.

***Abstract*—Image-based applications are widely spread nowadays. Steganography is a type of data hiding methods that manage covering the presence of a confidential communication between two ends. That is obtained by concealing the secret medium into a cover medium to deliver a stego medium that ought to be unnoticeable to a third party. The contrary of steganography, image steganalysis, is about identifying the presence of stego images. Image steganography schemes are becoming more and more secure every day. Cyber criminals can utilize these schemes to conduct a secret and malicious communication. Therefore, image steganalysis is of great importance to interfere such communications. In this paper, a transform domain based steganalysis scheme is proposed that utilizes the architecture of AlexNet, which is an object classification DL scheme. Some modifications are performed on the existing AlexNet architecture to enhance the detection performance of the model. Experiments showed that FB-GAR steganography scheme was successfully detected with an accuracy of 74.72%. Also, the relationship between the capacity and the quality of stego images was studied in this paper for both FB-GAR and J-UNIWARD. Furthermore, the relationship between the correlation of the cover images and the capacity and quality of stego images was discussed.**

***Index Terms*—Steganography, Steganalysis, DCT, CNN, Accuracy.**

I. Introduction

A type of data hiding methods is steganography that manages to cover the presence of a confidential communication between two ends. In steganography, a stego medium that ought to be unnoticeable to a third party is produced by hiding the secret medium in a cover medium. Establishing this secret communication by steganography can be done by utilizing text, audio, or pictures as the cover medium [1]. The two main categories of steganography are spatial domain steganography and transform domain steganography. First, spatial steganography embeds the secret into the pixels of the cover image. Secondly, transform domain steganography embeds the secret into the frequency coefficients of the cover image. Throughout the past few years, there was a noticeable increase in the complexity of steganography schemes and therefore resulted in profoundly imperceptible stego images [2].

On the other hand, recognizing the presence of stego images and subsequently uncovering the mysterious communication between two entities is called image steganalysis, which is the contrary of steganography [3]. Spatial and transform steganalysis are the types of image steganalysis. With the expanding utilization of steganography by cyber criminals, image steganalysis is also advancing to prevent their malicious actions. A type of Neural Networks (NN) called Convolutional Neural Networks (CNNs) is being used recently in image steganalysis. Nevertheless, research in spatial domain steganalysis has commanded more notice than transform domain steganalysis [3].

Recognizing the utilization of steganography schemes that use Discrete Cosine Transform (DCT), Discrete Fourier Transform (DFT), or Discrete Wavelet Transform (DWT) in the hiding procedure is the main goal of Transform domain steganalysis. DCT steganalysis has a well-known sub-classification called JPEG steganalysis. In addition, the quantized DCT coefficients of a cover image is where the embedding of secret data in JPEG image steganography happens. Besides, spatial domain steganalysis distinguishes embedding changes made to the pixels directly.

The odds of image steganography being utilized increment considerably more than other media because images are broadly utilized in the current communication. Many different cover image formats like BMP, GIF, JPEG and so forth can be used in image steganography. JPEG format is used by a lot of image capturing tools. A well-known JPEG image Steganographic scheme that is publicly available is J-UNIWARD [4].

The aim of this paper is to utilize the architecture of an existing CNN that was designed for a certain purpose and use it for image steganalysis and evaluate its performance. There-

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

fore, this paper presents a transform domain based steganalysis scheme that utilizes the architecture of Alexnet [5], which is an object classification DL scheme that classifies objects into 1000 classes. Some modifications are performed on the Alexnet architecture to enhance the detection performance of the model. The model aims to detect two steganography schemes, J-UNIWARD [4] and FB-GAR [6] namely.

The rest of this paper is arranged as follows: the background information is discussed in Section II, while Section III presents the steganalysis scheme and discusses the experimental results and setup. Finally, concluding remarks are found in Section IV.

II. Background

Iin image and signal processing, a broadly used transformation is the Discrete Cosine Transform (DCT), because of its “energy compaction” property. Most of the image data is located in the top-left area of the domain, that is the low-frequency coefficients region [7]. An extension of the 1D-DCT is widely used in image processing, the 2-dimensional DCT (2D-DCT), since images are two-dimensional signals. 2D-DCT is useful in steganalysis since it seperates the low frequency from the high frequency content in an image.

Artificial Intelligence (AI) has shown significant advancement in the course of recent many years. It has significantly decreased the gap between the tasks that ought to be performed by people and machines. Deep Learning (DL) is a subcategory of AI algorithms [8]. One class of DL algorithms is CNN. The input of a CNN is an image, and then it specifies adaptable weights to specific characteristics of the image to differentiate between different input images. Orthodox classification algorithms utilize hand-engineered filters. On the other hand, CNNs are capable of learning these features. Furthermore, CNNs need less pre-processing in comparison with other classification algorithms. The CNN used throughout this paper is AlexNet.

XuNet, a 20-layer CNN for JPEG steganalysis was proposed in [9]. The pre-processing of the input images was done using a fixed high-pass DCT filter. The shortcut connection in [10] was utilized to attain a deep structure, while instead of pooling layers, (3x3) convolutions with a stride of two were used. Chen et al. in [11] presented a CNN for JPEG steganalysis that is phase-aware. They divided the feature maps into 64 parallel channels, and used a few high-pass filters including KV filter, a point filter, and two Gabor filters. BOSSbase [12] and BOWS2 [13] databases were used in the experiments that showed improved detection performance.

Two designs were presented by Yang et al [14]; the first design is 32-layer CNN architecture whereas the second design is an ensemble architecture (CNN-SCA-GFR). The 32-layer CNN module reuses features by concatenating all features from the preceding layers to improve the flow of gradient and data as well as reduce the amount of parameters used. The CNN-SCA-GFR model is a combination of their proposed deep CNN and the traditional SCA-GFR technique [15]. BOSSbase [12], BOWS2 [13], and ImageNet [16] databases were used and J-UNIWARD [4] and UERD [17] steganography techniques. The ensemble design obtained better performance than the 32-layer CNN because of the directional features from the SCA-GFR technique with Gabor filtering also from the CNN model, the non-directional feature maps.

III. Experiments

Alexnet [5] is an eight layer deep convolutional neural network that was designed for object classification. The network was trained using more than one million image from the ImageNet database. A pretrained version can be found online that can classify input images of size of (227x227) into 1000 classes. These classes include keyboards, pencils, and a lot of animals. Details on the architecture can be found in [5].

In this paper, the AlexNet layer layout was used as the basis model to detect the use of steganography. The layers contain convolutional layers, max pooling layers, ReLU layers, and cross channel normalization layers. The layers were trained on the BOSSbase and BOWS2 datasets as displayed in section III-B. The first layer was modified to an image input size of (256x256) and only one channel as opposed to the original size which was (227x227) and 3 channels. Another modification was done in the fully connected layer since it obtained 1000 classes, therefore it was changed to classify into two classes (stego and cover). In addition, DCT was used to pre-process the data before training and testing the network. The reason behind using DCT is because it distinguishes between the high frequency content of the image and the low frequency content, which helps the netwrok in classifying the images and detecting the use of steganography. The definition of the 2D-DCT for an input image A and output image B is [18] [19]:

$$B_{pq} = \alpha_p \alpha_q \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} A_{mn} cos \frac{\pi(2m+1)p}{2M} cos \frac{\pi(2n+1)q}{2N}$$

$$where\ \ 0 \le p \le M-1\ \ and\ \ 0 \le q \le N-1$$

$$where\ \ \alpha_p = \begin{cases} \frac{1}{\sqrt{(M)}} & p = 0 \\ \sqrt{(\frac{2}{M})} & 1 \le p \le M-1 \end{cases}$$

$$and\ \ \alpha_q = \begin{cases} \frac{1}{\sqrt{(N)}} & q = 0 \\ \sqrt{(\frac{2}{N})} & 1 \le q \le N-1 \end{cases}$$

M and N are the row and column size of A, respectively. (1)

All experiments were done using MATLAB. The training parameters used were: stochastic gradient descent as the solver with 0.9 momentum, initial learn rate of 0.001, mini batch size of 32, and 15 training epochs. The training data is 70% of the total data.

A. Evaluation Metrics

One of the parameters that is controlled and changed throughout this work is the capacity. The capacity of a steganographic technique is how much hidden data is in the stego image. Naturally, the higher the capacity, the easier it

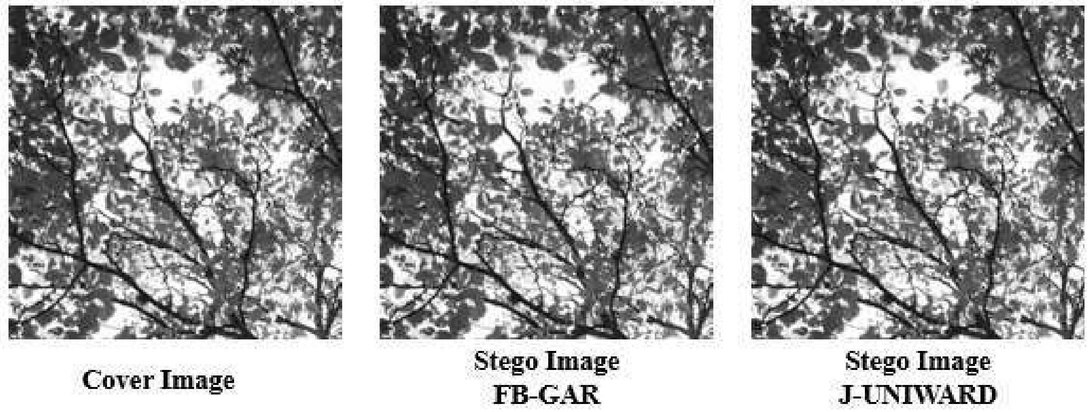

Fig. 1: An example of the stego images generated by FB-GAR and J-UNIWARD steganography schemes for a capacity of 1 bpp.

becomes to detect anomalies in the stego image. The capacity is measured in bits per pixels (bpp) as well as bits per non zero AC coefficients (bpnzAC). The formula below is used to calculate capacity if the embedding process is done in grayscale while the capacity is multiplied by three if the hiding process is done in RGB colorspace.

$$Capacity\,(Bpp) = \frac{(Secret\,width \times Secret\,height \times 8)}{(Cover\,width \times Cover\,height)} \tag{2}$$

The Peak-Signal-to-Noise-Ratio (PSNR) uses the original cover image as reference and compares it with the stego image. PSNR measures the quality of reconstruction in an image. It represents the ratio of the highest power of a signal over the power of noise. The formula for PSNR is:

$$PSNR\,(dB) = 10Log_{10}\left(\frac{255^2}{MSE}\right) \tag{3}$$

Where MSE is the mean square error of comparison between the stego and cover image.

Structural SIMilarity (SSIM) is another metric for comparison between the stego and cover images. It demonstrates whether the structure of the stego image has changed or not in comparison to the structure of the cover image.

The main performance parameter used to evaluate the efficiency of the steganalysis scheme is the detection accuracy, which is defined by equation 1.More details on the paramters can be found in [20]:

$$Detection\ Accuracy\,(\%) = \frac{(TP + TN)}{(P + N)} \tag{4}$$

The classification error probability is another metric that has been used within the steganalysis society and it is calculated as:

$$P_E = min_{P_{FA}} \frac{1}{2}(P_{FA} + P_{MD}) \tag{5}$$

Where P_{FA} represents the false-alarm (false positive) probability and P_{MD} represents missed-detection (false negative) probability.

B. Database

The databases used for the training process were modified from the BOSSBase [12] and BOWS2 [13] databases. Each of these databases consists of 10,000 images, each image was divided into four blocks using MATLAB resulting in a total of 80,000 images of size 256 x 256. The division of the images was based on two reasons: to increase the database size and to avoid losing the details in the images by resizing them to a very small size.

The created database was used to generate cover/stego pairs using two steganography techniques: J-UNIWARD [4] and FB-GAR [6]. The FB-GAR scheme was modified to work on gray-scale images as opposed to the original RGB. It was also modified to limit the capacity to ensure fair comparison between the two steganography schemes given that it was originally proposed to maximize the capacity. The fixed block size used in the FB-GAR scheme is 128 x 128. The capacity used to generate the datasets ranged from 0.1 bpp to 1.0 bpp in 0.1 intervals. Figure 1 displays an example of stego images generated by both steganography schemes.

C. Results

Experiments were done to examine the quality of stego images using both steganography techniques. Figure 2 displays the three cover images used in the experiments. These images portray a wide range of frequencies, cover 1 is highly correlated, cover 2 is medium, while cover 3 is uncorrelated.

We can conclude from Figure 3 that for highly correlated images (a) J-UNIWARD outperforms FB-GAR in both comparisons, while for uncorrelated images (c) it still outperforms FB-GAR in terms of PSNR but the gap in PSNR is less, and FB-GAR outperforms J-UNIWARD in terms of SSIM when the capacity exceeds 0.7 bpp. An important observation is that

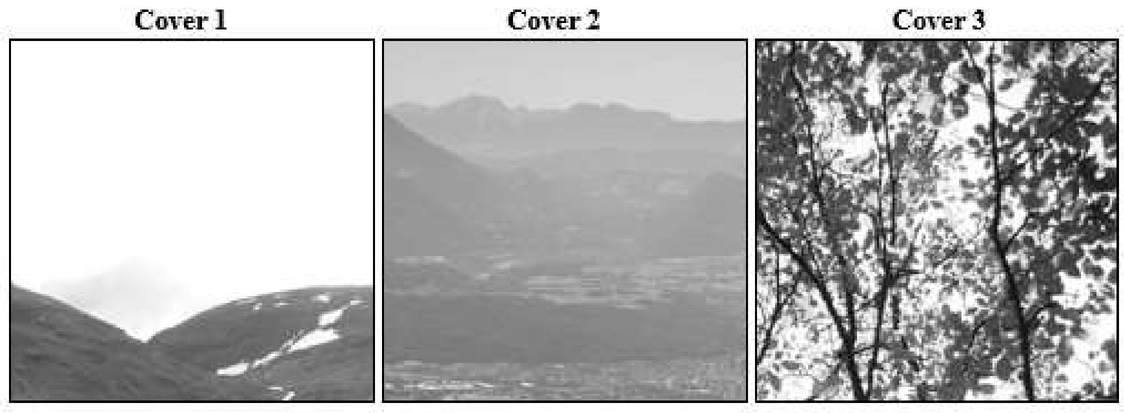

Fig. 2: The different cover images used to compare the quality of the stego images generated by J-UNIWARD and FB-GAR.

both schemes perform better with correlated cover images, since they both utilize DCT in the hiding process.

After training the network, 30% of the data was used to test the performance of the network. Figure 4 summarizes the performance in terms of detection accuracy and error vs capacity for FB-GAR. It is evident from the graphs that the higher the capacity, the higher the detection accuracy, and the lower the detection error Pe. The AlexNet layout has succeeded to detect the FB-GAR steganography scheme with accuracy of 74.72% for 1 bpp. On the other hand, J-UNIWARD was not detected throughout the experiments since it is more secure than FB-GAR. In addition, some promising experiments are being conducted to detect J-UNIWARD after modifying the AlexNet architecture.

IV. Future Work and Conclusions

Image steganography schemes are becoming more and more secure every day. Cyber criminals can utilize these schemes to conduct a secret and malicious communication. Therefore, image steganalysis is of great importance to interfere such communications. The relationship between the capacity and the quality of stego images (PSNR and SSIM) was studied in this paper for both FB-GAR and J-UNIWARD. Also, the relationship between correlation of the cover images and the capacity and quality of stego images were examined. AlexNet architecture was used to detect the use of the two mentioned steganography schemes, and FB-GAR was successfully detected with an accuracy of 74.72% for 1 bpp. For future work, some promising experiments are being conducted to detect J-UNIWARD after modifying the AlexNet architecture.

Abstract - In observational astronomy, researchers have reached a point where large datasets from sky surveys are regularly published. Sending probes to land on asteroids, collect material, and ship it back to Earth is one strategy for space exploration. Astronomical data is rapidly increasing in size and complexity as space and ground-based telescopes are developed and deployed. Machine learning has gained popularity among astronomers in recent years, and it is now used to solve a variety of tasks, including classification, regression, clustering, outlier detection, time series analysis, association law, and so on. The study on previous work of papers on exoplanets and their habitability show machine learning methods including Support Vector Classification, Random forest, K- Nearest Neighbor, and so on were used in the majority of the papers. Until now, only a few deep learning methods have been studied. As a result, this research work overcomes different challenges faced by astronomers dealing with large data and seeking relevant knowledge for each objective using Deep Learning techniques. Furthermore, deep learning techniques are capable of managing complex data with ease. To begin, this paper proposes ASTRONET, a deep learning architecture, to look for exoplanets that are habitable based on their planet gravity, eccentricity, mass, radius, and other characteristics. This research paper explains the entire process of finding exoplanets and categorizing them based on their habitability. Finally, to establish a knowledge base of parameters that affect the habitability of exoplanets.

Keywords – Exoplanets, Deep Learning, Astronet, Classification, Artificial Intelligence, TESS (Transiting Exoplanet Survey Satellite), Astronomy, Machine Learning, Habitability, Convolution Neural Network (CNN)

I. Introduction

Most of us wonder if there is life outside of our planet? We reside in a universe that is colossal beyond our imagination. The problem of detecting anomalies in massive, high-volume astronomical datasets is discussed in this paper, and a solution based on machine learning algorithms is studied and the most impactful and intense deep learning technique is proposed.

The NASA Astrobiology Roadmap has established an understanding of the origin and distribution of habitable planets and moons in the Galaxy as a major research theme (Des Marais et al., 2008). We require more detailed and cohesive models to determine the conditions for the habitability of planets to understand how sustainable the atmosphere and living conditions are or could be, to generate detectable biosignatures, and determine the similarities to the conditions that support life on Earth.

The habitable zone for exoplanets was first presented and modelled in detail by [14], who explained how physics and chemistry play a vital role in the exoplanet study. The immense diversity of exoplanets, as well as the estimated variation in their atmospheres in terms of mass and composition, has sparked a deep desire to rethink planetary habitability.

So, in this paper, the model gives an overview of existing machine learning techniques for assessing exoplanet habitability and suggests the ASTRONET deep learning approach to achieve our objectives.

II. Literature Survey

This paper discusses the effectiveness of various Machine Learning methods in classifying exoplanets into classes of thermal habitability and characterizing them based on possible habitability. The challenges solved are supremacy in the non-habitable planetary sample dataset using under-sampling methods (of dominant class samples) and over-sampling methods [1].

They proposed to build a Machine Learning model to automate Kepler cumulative object of interest data classification and then deploy it. KNN, Random Forest, and SVM models were used, validated, and checked for precision, accuracy, and recall to create a better model for classification. And for model Deployment- Flask API, Azure Cloud were used. It

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

has a Comprehensive ML pipeline: Engineer data, train, and test models. A robust model is required to handle errors [2].

The purpose of this project was to use the data as training data and use planetary and stellar characteristics to construct a machine learning model that can anticipate habitable planets. Data source: From the explanation of NASA Exoplanet Archive Attribute of Kepler data, 14 stellar and planetary features were discovered. Few of them are "Planetary Radius", "Isolation Flux", "Equilibrium Temperature", "Orbital Period", "Distance from parent Star", "Stellar Temperature" SVM with rbf kernel used. But a robust model needed to cope with huge and complex data [3].

In this paper, they used various supervised learning algorithms to predict the habitability of recently observed exoplanets. Used various models like CART, SVM, FNN, Random Forest, Logistic Regression, and Naïve Bayes. A Regression tree was created to anticipate the value of ESI for a planet. It was not suitable for unlabelled data and image data. Further optimization of the model is possible [4].

Applied Deep Learning algorithms to identify Kepler candidate transit cases. Used Kepler DR24, TESS. CNN models used are Astronet: Baseline Model, Exonet: Revised Model, and Exonet-XS: Decreased Model Size. Stellar parameters include metallicity, radius, mass, stellar effective temperature, surface gravity, and density. The model uses two views of phase-folded light curves as inputs, which is followed by completely connected layers that output a value between 0 and 1 that predicts whether transit is a planet or not. Astronet was prone to overfitting [5].

The model can differentiate between false positives and genuine exoplanets, with good accuracy. The training set was derived from the NASA Exoplanet Archive's Autovetter Planet Candidate List. It requires a high training period and high computational power. But it requires a high training period and high computational power [6].

The probability of an observation being an exoplanet is estimated using a number of datasets and classification models. For predicting exoplanets' existence, the proposal aims at using three classifiers. By using different classification algorithms like SVM, ANN, and Naive Bayes Classifiers can obtain different results. It is not suitable for unlabelled data [7].

It concentrates on the implementation of various algorithms of Machine Learning on NASA's Kepler data for the prediction of exoplanet habitability disposition. The proposed model will be able to operate on data generated by different ground and space observatories and classify exoplanet candidates as habitable or non-habitable. It involves the execution of supervised Machine Learning algorithms which include K Nearest Neighbor, Logistic Regression Naive Bayes, Decision Tree, and Random Forest. The binary classification of objects as "FALSE POSITIVE" or "CONFIRMED" exoplanets is taken into account by the model. The decision tree algorithm is a suitable model for predicting habitability [8].

The traditional Machine Learning models like SVM, Random Forest, Decision Tree, etc. used to predict the habitability of exoplanets had certain drawbacks like time-consuming and variation in outcomes.

So, the proposed Deep Learning model i.e "Astronet" is a modern technique backed with high computation capabilities that will provide error-free and unbiased outcomes.

III. Problem Statement

"Exoplanet Habitability" A planet outside the Solar System is known as an exoplanet or extrasolar planet. Habitability refers to an area or region where life can sustain. Every day, a large amount of astronomical data is produced. NASA is a well-known space agency that has similar data. Satellites, radio telescopes, orbital telescopes, space stations, and other instruments are used to collect this information. The instruments assist in the search for new exoplanet information. Additionally, they gather data on the physical states of the exoplanet. The characteristics of exoplanets will be studied using deep learning and machine learning. Further, the model will be able to discover what the key features of an exoplanet are that make it ideal for sustaining life.

IV. Objective

To determine the habitability of exoplanets based on different properties of exoplanets using deep learning algorithms and techniques.

V. Proposed system

There is numerous research work done in machine learning techniques for the classification of habitability of exoplanets. In this paper, the research proposes a deep learning model for the detection and classification of planets based on their habitable behavior. ASTRONET deep learning model is used to predict anomalies in astronomical bodies by classifying whether the studied newly existing planet is habitable or not. The design of the overall module including process flowchart, algorithm, detailed architecture of ASTRONET is explained.

Prediction of habitability of exoplanets using Deep Learning algorithm: Habitability here refers to the quality of having similar properties of being adequate enough to live in. Habitability can be determined using the exoplanet properties like mass, radius, eccentricity, orbital inclination, gravity, metallicity. Exoplanets are planets that do not orbit around our sun but do orbit around a star. So, we put forward the idea of predicting the habitability of exoplanets using the previous huge amount of data present with the help of deep learning techniques.

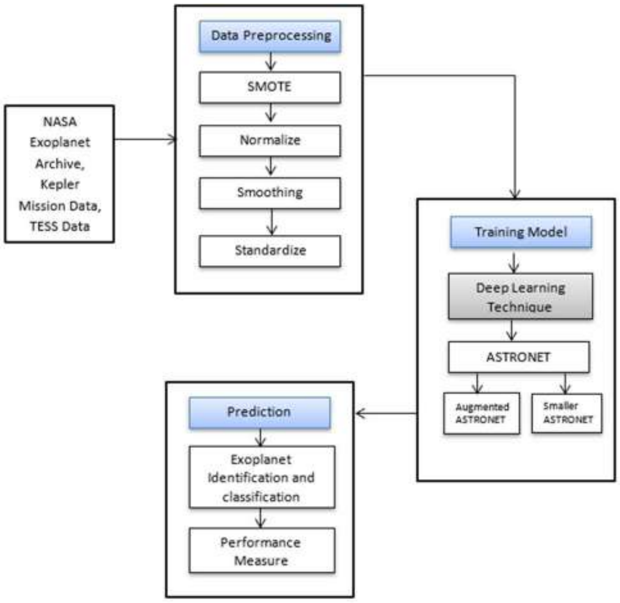

Fig 1. Flow Chart explains the total flow of Exoplanet Classification

ASTRONET:

The proposed ASTRONET architecture to identify and detect potentially habitable exoplanets that support a variety of planet and star characteristics. NASA's Exoplanet Program, NASA's Kepler mission results, and data from the Transiting Exoplanet Survey Satellite (TESS)[9].

These data must be compelled to be efficient, which means they must be reviewed for false-positive signals, such as those caused by stellar eclipses and instrumental noise, which outnumber true planet transit signals.

Let's start with the information gathered by Kepler's telescope, which was used to detect the presence of a planet. A light-weight curve is a graph that displays the brightness of a star (as determined by Kepler's photometer) over time. When a planet moves in front of a star, it blocks some of the suns, causing the measured brightness to drop and then rise again.

Now let's understand the model flowchart (Fig 1) in detail.

A. DATA GATHERING

We start with gathering information from various available data sources. We fetch the data from NASA Archive, Kepler Mission Data, and TESS (Transiting Exoplanet Survey Satellite) data.

B. DATA PREPROCESSING

It is essential to perform data preprocessing before feeding our model with data. This will result in high-quality data or valuable knowledge, which will have a direct effect on our model's ability to learn.

1.SMOTE

SMOTE stands for Synthetic Minority Oversampling. It is a method for eliminating data imbalances. It is introduced to minimize dependency on majority class values.

2.Normalization

The input dataset includes several features with varying ranges and normalization assists in getting them all to a similar scale. The values in the range [0,1] are rescaled.

3. Smoothing

Filters are used to smooth things out. Filters provide robustness in the face of noisy data. This paper aims to increase the accuracy of the data without distorting the signal tendency by averaging out neighboring data points.

4. Standardization

Standardization helps in generalizing the data. By generalizing the numerical conditions of inconsistent data, standardizing the dataset makes the training process more well behaved.

C. TRAINING MODEL

The ASTRONET is proposed which is similar to Deep Convolutional Network [10] to find exoplanets. The diagram below illustrates the Astronet Architecture briefly.

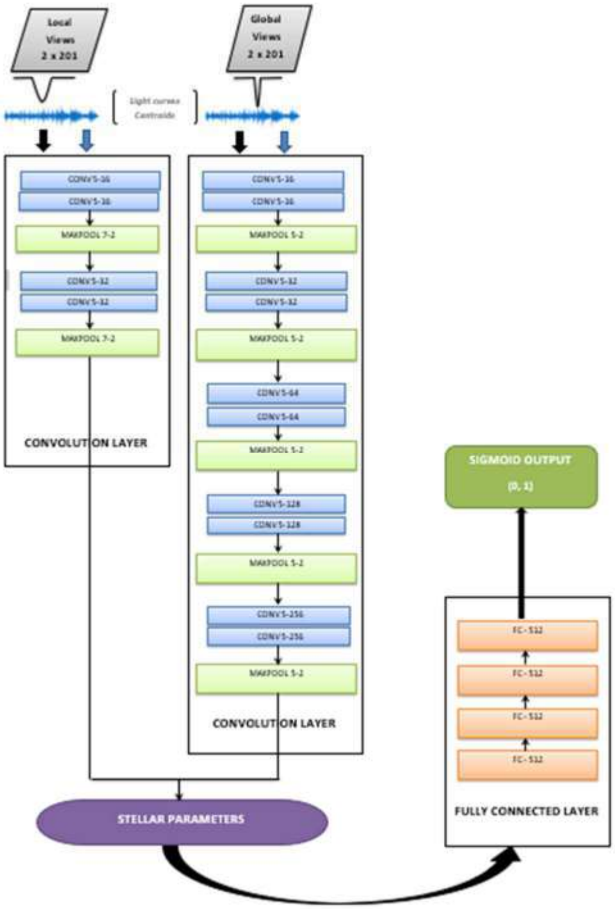

Fig 2. Astronet Model Architecture

The basic architecture is similar to the Convolutional Neural Network.

Step 1: Light Curves

The global and local views of each phase-folded TCE of Light curves [13] are used as the initial input. Each TCE represents a possible exoplanet transit with a particular period, epoch, and length.

Step 2: Convolution Layers

This section contains filters that assist in feature extraction. Every hidden layer of ASTRONET architecture uses ReLU. ReLU is a linear rectifier activation function that produces a linear graph by eliminating all negative values.

Step 3: Max Pooling

By proving an abstract form of representation, Max

Pooling reduces overfitting. It also decreases the number of parameters to learn and provides basic translation invariance to the internal representation, lowering the computational cost.

Step 4: Stellar Parameter

The performance of Max Pooling is combined and fed into stellar parameters. Stellar parameters are important concepts in science. Efficient temperature (Teff), surface gravity (log g), mass (m), density (d), metallicity, and other parameters are among them. These parameters form a set of standardized parameters for data validation.

Step 5: Fully Connected Layer

Stellar Parameter output is given as input to fully connected layers. It compiles the data extracted by previous layers to give the final output.

Step 6: Sigmoidal Output

In CNNs, the sigmoid function is the most common activation function. Finally, the astronet architecture finishes with a sigmoidal feature that generates a number of outputs (0,1). It either classifies the input as true positive exoplanet transit or as true negative exoplanet transit. The graph of the sigmoid function is in the form of an 'S,' and it has a finite limit.

$S(x) = 1 + \frac{1}{e^{-x}}$, where S(x) is the mathematical representation of a sigmoidal function.

Two Astronet variants can be designed and created during the training process.

1. *Augmented Astronet*
2. *Smaller Astronet*

These variants have fewer convolution layers and max-pooling layers. As a result, the model size is reduced, requiring less training time and computing resources.

D. PREDICTIONS

Hyperparameters: Hyperparameters are used to refine the output metrics' values. The required learning rate, epochs, and batch size are all taken into account here. The value may differ from model to model based on the amount of noise present in the dataset. In some cases, drop-out is also added to reduce model overfitting.

Once the model is built it is very important to evaluate how good the model performs. We will evaluate our model using the below matrix and then finally predict in which category the studied exoplanet belongs to i.e habitable or not habitable.

Performance Matrix or Confusion Matrix: This matrix is generated to evaluate the model performance of classification models. It shows the following values-

		PREDICTED CLASS	
		Class = Yes	Class = No
ACTUAL CLASS	Class = Yes	TP	FN
	Class = No	FP	TN

Fig 3. Confusion Matrix

True Positive (TP) - These are correctly predicted positive values that means prediction of actual class is yes and predicted class is also yes. E.g if the actual class says this exoplanet is habitable and the predicted class tells you the same thing.

True Negative (TN) - These are the correctly predicted negative values which means that the value of the actual class is no and value of predicted class is also no. E.g., if the actual class says this exoplanet is not habitable and the predicted class tells you the same thing.

False Positives (FP) – When actual class is no and predicted class is yes. E.g., if the actual class says this exoplanet is not habitable and the predicted class tells you it is habitable.

False Negatives (FN) – When actual class is yes but predicted class in no. E.g., if the actual class says this exoplanet is habitable and the predicted class tells you it is not habitable.

1. *Accuracy*—the number of accurate classifications made in a given period of time. It is the ratio of correctly predicted observations to the total observations.

Accuracy = TP+TN/TP+FP+FN+TN

2. *Recall or sensitivity* — Ratio of true planets identified correctly. Recall is the ratio of correctly predicted positive observations to all observations in actual class.

Recall = TP/TP+FN

3. *Exoplanet precision or positive predictive value*—the percentage of input TCEs identified as exoplanets that are actually planets. Precision is the ratio of correctly predicted positive observations to the total predicted positive observations.

Precision = TP/TP+FP

4. F1 score - F1 Score is the weighted average of Precision and Recall. It measures the test accuracy. It scores maximum value when it tends to reach 1 and minimum value when it tends to reach 0.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)

Optimizer: To render an algorithm's cost function as minimal as possible. The ASTRONET model recommends using Adam Optimizer (Adaptive Moment Estimation). Adam is a combination of two optimization techniques i.e RMSprop and Stochastic Gradient Descent with momentum. Adam optimizer is chosen as it has less memory requirement, more computational efficiency, easy to implement and well suited for problems with large datasets.

Mathematical approach: Adam algorithm first computes the gradient g_t w.r.t parameters Θ, then computes and stores first and second order moments of gradient, m_t and v_t respectively, as

$$mt = \beta 1 * mt + (1 - \beta 1) * gt$$

$$vt = \beta 2 * vt - 1 + (1 - \beta 2) * gt_2$$

Where β1 and β2 are hyper-parameters that ϵ [0,1], β1 = 0.9 and β2=0.999 are ideally considered. At t=1 m_0 and v_0 are zero. Since initially the values are biased towards zero, we counter it by updating it mt' and vt' as

$$mt' = mt/(1 - \beta t1)$$

$$vt' = vt/(1 - \beta t2)$$

Finally, the parameters updated are computed as

$$\theta t = \theta t - 1 - \alpha * mt'/(\sqrt{vt'} + \epsilon)$$

where is a small stability constant, with standard value of $\epsilon = 10^{-8.}$

Classification: Finally, the model would classify whether the studied planet is a habitable exoplanet or not.

Conclusion

Our ASTRONET model would be an automatic approach to examine catalogs of interplanetary objects. By learning to recognize abnormalities in these bodies in any set, you will be able to recognize anomalies in any set. This model will save researchers a lot of time by supplying them with useful knowledge in just a few seconds. Our mission is to dig deep into planetary bodies in order to discover factors that will enable life to sustain on those planets, as well as to collect a vast amount of data for research purposes.

The approach of deep learning has been accomplished to obtain the major objectives of Exoplanet classification and detection. Firstly, a complex deep learning model is proposed that will give accurate predictions. Secondly, Temperature, humidity, eccentricity, radius, weight, metallic materials, transit signals, and a number of other characteristics can all be used to determine whether or not an exoplanet is habitable and lastly, various performance measures are stated to evaluate the model predictions. To achieve these goals, a comprehensive ASTRONET will be developed and implemented.

***Abstract*— In this paper, a digitally controlled second-generation current conveyor (DC-CCII) and a transimpedance amplifier (TIA) will be employed to implement CMOS temperature sensor interface. The light emitting diode (LED) is used in optogenetic devices for optical stimulation. One of the major concerns of these devices is overheating that can cause cell damage. This work will utilize the LED used for optical stimulation as its own temperature sensor, in order to overcome the overheating concerns in optogenetics. LED reverses current represent temperature-sensitive parameter (TSP) and it can be used to sense the junction temperature. Therefore, the junction temperature can be used to measure the surface temperature. To ensure stable LED biasing and measure the LED reverse current, the CCII circuit will be utilized. In addition, the CMOS temperature sensor interface is operating under a ±0.75 V voltage supply. The standby power consumption of the circuit ranges between 240 µW at a gain for the DC-CCII equals to 0 dB and 700 µW at a gain for the DC-CCII equals to 16.9 dB. The proposed sensor interface has been implemented using LTspice with 0.25-µm CMOS technology.**

Keywords— DC-CCII, LED, optogenetics, sensor interface; TIA, TSP.

I. Introduction

Healthcare and biomedical devices have been improved as a treatment for different neurological disorders. Epilepsy is one of the neurological disorders that can be controlled by implantable optogenetic devices [1]–[3]. The optical stimulation in an optogenetic device can be achieved by human brain light exposure to light sources such as LED. Neural implantable devices are used as a treatment for a wide range of neurological disorders such as deafness, blindness, and motion disorders. For neurological motion disorders such as Parkinson disease, depression, and epilepsy deep brain stimulation (DBS) can be used for recording and stimulation [4]. Therefore, the device safety itself is equally important. The safety of those devices is represented by accidental electric discharge or overheating of the device.

Considering implantable devices overheating, the surface of an optogenetic device must remain below the threshold temperature. The optogenetic device can be used with keeping the device overheating and brain temperature within an acceptable range. In µLED-based optogenetic device, the main challenge is the dissipated heat that can damage human brain tissue. The optogenetic stimulation required acceptable power and acceptable spatial with keeping the brain tissue temperature rise below 0.5 °C. Therefore, a 2.0 °C temperature rise in the probe during stimulation leads to a 0.5 °C rise in the brain tissue [5], [6]. Consequently, to design optogenetic probes for seizures, controlling the temperature rise must be considered. In order to monitor the temperature permanently, the temperature sensor is required in implantable devices.

Several temperature sensors have been implemented using a resistance temperature detectors (RTDs) or by adding CMOS temperature sensor realizations [7]–[10]. These temperature sensors require additional surface space on implantable devices. The LED can be used as its own temperature sensor by employing reverse current (I_R) of the LED as a TSP [11], [12]. The method aimed to use the LED when it is not illuminated. The sensor interface has been developed using CCII for biasing the LED to ensure stable biasing and current sensing. The circuit is realized for an operational frequency less than 130 kHz. Therefore, the reverse current can be used to measure the junction temperature and I_R can be known as TSP [13]. The relation between temperature and reverse current can be driven as

$$I_R \alpha\, e^{\frac{1}{T}}. \qquad (1)$$

Consequently, the additional temperature sensor is not required for the device sensing.

The CCII circuit has been employed in different types of application, Such as wideband waveform generator, filters, oscillators and other instrumentation systems such as different types of sensor interfaces [14]–[18]. In this work, a digitally controllable temperature sensor interface has been implemented using a digitally controllable second-generation current conveyor (DC-CCII) and a transimpedance amplifier (TIA). The reverse current of the LED is nonlinearly and strongly sensitive to the biasing voltage. Therefore, the CCII is used to bias the LED with constant voltage and the TIA is utilized to convert the CCII output current to voltage and amplify the voltage to be suitable for ADC input dynamic range. The sensor interface is designed to be suitable with different optogenetic implantable devices using the current summing network (CSN) at terminal Z of the CCII.

The rest of the paper is organized as follows. The sensor interface circuit and CMOS realization of the self-sensing temperature sensor is firstly covered in Section II. The simulation and results of the proposed circuit using 0.25-µm CMOS technology is then explained in Section III. In Section IV, the paper conclusion has been proposed.

II. Proposed CMOS Self-sensing Temperature Sensor

As mentioned in the introduction, the sensor interface could be realized using DC-CCII cascaded with a TIA. The proposed temperature sensor interface CMOS realization is shown in Fig. 1.The DC-CCII receives the biasing voltage at terminal Y, then it buffers the voltage to terminal X to bias the LED. The current of terminal Z follows the input current received at terminal X which is digitally controlled for gain greater than one. The TIA is used to convert and amplify the Z terminal output current to match the dynamic range of the analog-digital convertor (ADC) block.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

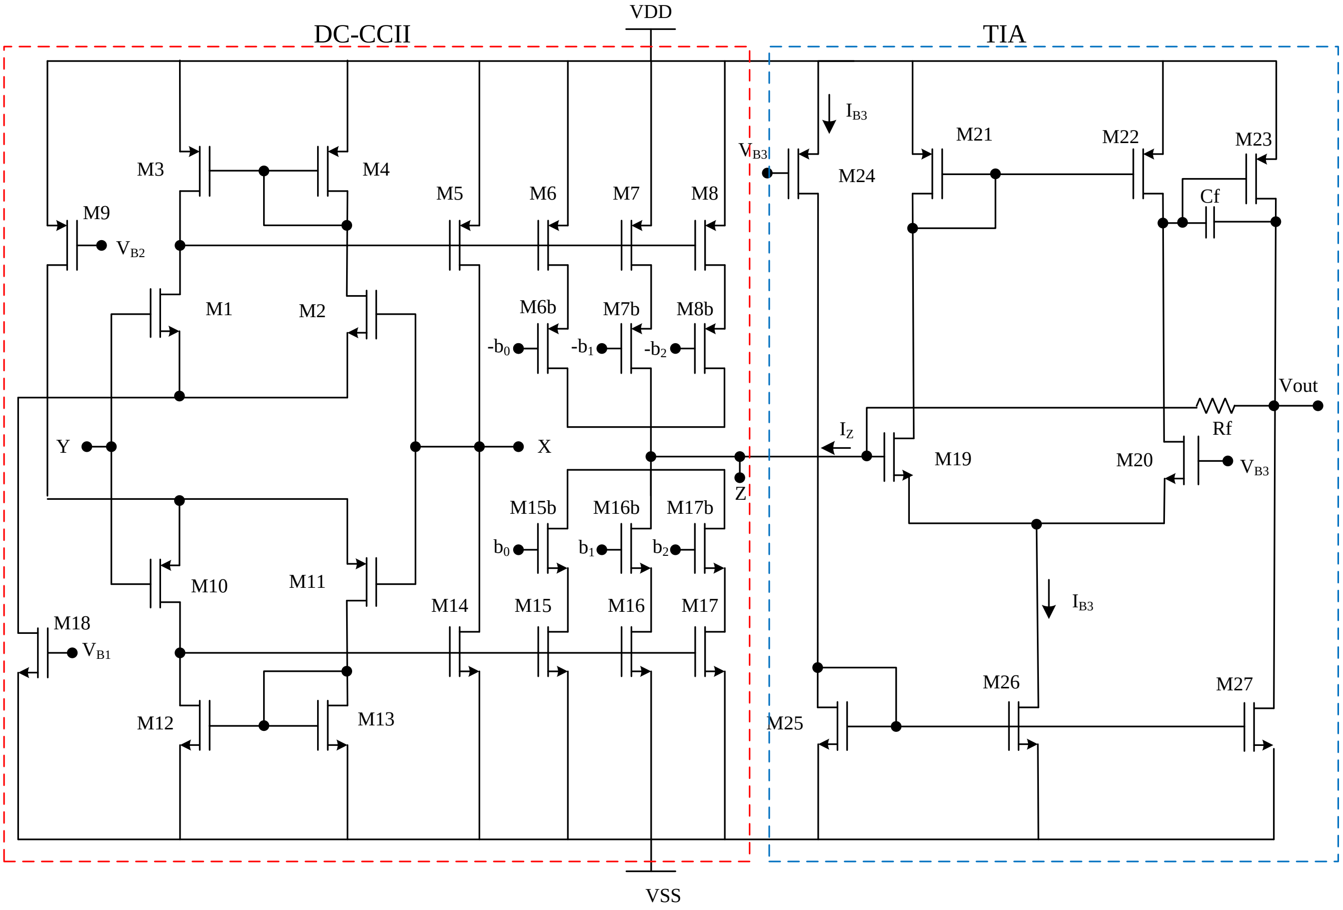

Fig. 1. Proposed CMOS sensor interface.

Based on the CCII introduced by [19], the CCII circuit's input stage has been realized using two complementary differential pairs. It consists of NMOS matched differential pair (M1, M2) and PMOS matched differential pair (M10, M11). These matched differential pair are used to provide voltage follower between terminal X and terminal Y. The biasing currents for the differential pairs are provided by transistors (M9, M18).

Two current mirrors consist of (M3, M4) and (M12, M13) provides constant tail current biasing in order to ensure the rail-to-rail operation. High Y terminal impedance has been provided and the current is equals zero. The matched transistors' pair (M5, M14) and digitally controllable transistors (M6, M15), (M7, M16), and (M8, M17) are used to convey the X terminal current to the Z terminal. The push-pull output stage at the X terminal has been formed using transistors (M5, M14) and it reduce the power consumption.

The DC-CCII realization provides gain greater than and equal to one. The following matric equation describes the DC-CCII with current gain α:

$$\begin{bmatrix} I_Y \\ V_X \\ I_Z \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & \alpha & 0 \end{bmatrix} \begin{bmatrix} V_Y \\ I_X \\ V_Z \end{bmatrix}. \qquad (2)$$

By replacing the Z terminal transistors in the CCII with transistor arrays using CSN, the current transfer gain α can be controlled in the DC-CCII circuit. The current gain is expressed as:

$$\frac{I_Z}{I_X} = \sum_{i=0}^{n-1} b_i 2^i, \qquad (3)$$

where b_i indicates the digital control bit and n is equal to 3. Therefore, the proposed circuit is digitally controlled using 3-bits control words.

The output current of the CCII is the input of the TIA. The TIA implemented using two-stage CMOS transconductance operational amplifier (OTA) [20]. The TIA circuit was implemented with differential pair (M19, M20). Transistor M21 mirrors the current to M22 to get single output. Transistors M24, M25, and M26 are used as a current source of the differential pair transistors. The third stage is consisting of transistors (M23, M27) represent the output stage of the TIA. The output stage of the TIA is class A where the current of M27 is constant. The overall transimpedance $\frac{V_{out}}{I_Z}$. All transistors are operating in saturation region.

III. Simulation Results

The proposed CMOS DC-CCII circuit and sensor interface circuit performance was tested and verified by performing LTspice simulations under ±0.75 V voltage supply using 0.25-μm CMOS technology parameters and transistor aspect ratios given in TABLE I.

TABLE I. SENSOR INTERFACE'S TRANSISTORS ASPECT RATIOS

Transistor	Width (µm)	Length (µm)
M1, M2, M10, M11	15	1
M3, M4, M12, M13	0.5	0.25
M9	1	0.5
M18	10	0.5
M5, M6, M14, M15	25	0.25
M7, M16	50	0.25
M8, M17	100	0.25
M19, M20	14	0.6
M21, M22	8.5	0.6
M23	37.5	0.6
M24	9	1.2
M25, M26	7	0.6
M27	33	0.6

The differential pairs (M1, M2) and (M10, M11) are biased through transistors (M9, M18) by setting M9 and M18 biasing voltage -219 mV and 105 mV, respectively. Fig. 2 shows the output voltage at terminal X versus the input voltage at terminal Y where terminal X is terminated with 10 kΩ. Fig. 3 shows the X terminal offset voltage variation versus X terminal input current when Y terminal voltage is equal to zero. The DC-CCII circuit offset voltage is below 12.5 mV and the X terminal input resistance (R_X) is below 18.5 Ω. The bandwidth of the voltage transfer gain is 8.07 MHz 3-dB. The circuit provides total harmonic distortion (THD) for low frequencies around 0.091%.

By including all combinations of 3-bits control word excepting zero, the DC-CCII realization with gains greater than and equal to one is examined. Fig. 4 represents the DC transfer characteristics for an input range of ±10 µA. For the gain equal to one, the X terminal and Z terminal currents are equal. Then, the current of the Z terminal increases with gain α. The magnitude frequency response of the DC-CCII with gain α is shown in Fig. 5.

Considering temperature dependency, the circuit has been tested for different temperatures. In the optical stimulation phase the temperature increases, then in the second phase which is the sensing phase the temperature decreases as shown in Fig. 6. The Z terminal current of the DC-CCII represents the output current of the circuit and the input current of the TIA circuit. The output current for different gains is shown in Fig. 7. The TIA convert and amplify the CCII output current to match the dynamic range of the ADC block. The output voltage is amplified by gain of 200×10^3 V/A. The output voltage of the sensor interface by applying current with temperature variation is shown in Fig. 8. The sensor interface has a 3-dB bandwidth around 291.6 kHz. The input referred noise spectral density of the sensor interface is less than 39 $\mathrm{pA}/\sqrt{Hz}$. The standby power consumption of the circuit ranges between 240 µW and 700 µW. For DC-CCII gain α equal to one, the power consumption is 240 µW. While for gain α equal to 7, the power consumption is 700 µW. The proposed sensor interface simulated results summary is given in TABLE II.

TABLE II. SENSOR INTERFACE SPECIFICATIONS

Parameters	Proposed Sensor Interface
CMOS technology (µm)	0.25
Power supply (V)	±0.75
Transimpedance gain (V/A)	1.4×10^6
3-dB BW (kHz)	291.6
Power consumption (µw)	240-700
Current driving capability (µA)	±1.23
Input referred noise (below 3 MHz)	39 pA/$\sqrt{Hz}$

IV. CONCLUSION

A CMOS temperature sensor interface has been implemented in 0.25-µm CMOS technology under supply voltage ±0.75 V in order to measure the implanted LED's temperature in optogenetic devices. The reverse current of the LED has been used as a TSP to measure the temperature variation. Therefore, the LED used for optical stimulation has been employed as a self-sensing element. This method is used to reduce the implantable optogenetic device's area by using the LED in stimulation and sensing phases. The CMOS sensor interface has been designed using a digitally controllable CCII to bias the LED and convey the reverse current received from the LED after controlling the current by 3-bits digital word. The circuit used to convey the digitally controlled current to a high gain TIA which is used to convert and amplify the signal. The output of the proposed DC-CCII has a 10 nA offset and the total standby power consumption is less than 700 µW. The achieved circuit characterization results show the CMOS sensor interface is suitable for implantable optogenetic devices which requires low voltage and accurate current conveyor. Future work may include the reduction of the offset current and modification of the digital control circuit. This can be obtained by increasing number of bits and reducing the power consumption.

Abstract— **Humans can use informed visual perception to generate sentences by bridging the gap between the recognition of visual features (images) and linguistic expression (words) describing these images. Videos are an example of visual perception; humans can describe the content of the video in meaningful sentences based on understanding their contents as a caption for the video. However, automating the video caption process is a challenging task as it confronts the model with two problems are: object detection and generating a sentence.**

This research aims to develop a model that automates video captioning based on Encoder-Decoder using a deep learning algorithm following these two steps. Firstly, using the KATNA model to select the most significant frames from the video and remove redundant ones. Secondly, combining the two deep learning algorithms YOLO and LSTM. The You Only Look Once (YOLO) algorithm recognizes objects in the video frames and the Long Short-Term Memory (LSTM) algorithm generates the video caption.

The proposed model describes the video's content in a meaningful sentence and it shows good accuracy and efficiency, it applies YOLO on the MSVD dataset unlike other video captions using other deep learning techniques.

Keywords—(Deep Learning, Natural Language Processing (NLP), Video captioning, You Only Look Once (YOLO)).

I. INTRODUCTION

The information over the internet is growing exponentially hour by hour, and visual content understanding becomes an interesting search area in computer vision, and video captioning is one of its applications. There are a huge number of videos uploaded around the world from different areas at one second through the Internet; these videos need to be arranged and classify based on their captions to facilitate reaching them. It is a challenging task to automate the video caption process; tasks related to video captioning are still considered a challenging research topic. The way video stream is structured and how they are dependent on temporal sequencing, multiple frames, varied objects, and actions and generating accurate sentence complicate the captioning process. Deep learning has currently shown up its efficiency in different areas and it has currently transformed computer vision studies and applications, video caption is one of its applications. Research experimenting with video caption using deep learning techniques develop various language models using LSTM (Long short-term memory), RNN (recurrent neural network), CNN (convolutional neural network), GRU (Gated Recurrent Unit), and TPGN (Tensor Product Generation Network).Recently, deep learning showed up its capability to deal with visual and text contents. Based on that, we propose a deep learning model constructs of encoder-decoder architecture; we compare the performance and the accuracy of using YOLO on the MSVD dataset and other deep learning techniques on the MSVD dataset. Our main objective is to develop an Encoder-Decoder video caption that utilizes YOLO as an encoder, unlike other models that use other deep learning techniques. , and compare final results with previous models using other deep learning techniques.

II. LITERATURE REVIEWS

Video captioning is a process for describing video content using one or more sentences [1]; It translates visual contents to natural language explanation. It starts by recognizing objects and relates them in sentences [2]. Figure1 shows the general process of video captions using Encoder-Decoder. An overview is given in what follows:

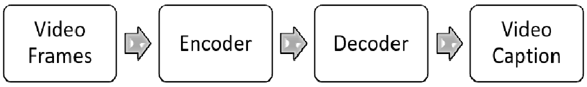

Figure 1. General Structure of Encoder-Decoder Video Caption.

Researchers informed by DL techniques; currently, adapt RNN models, such as LSTM[3] and GRU[4], to act as a decoder of the video clip and learned to generate natural language sentences instead of using a specified template.

In [5], the researchers proposed a RESNET-50 CNN-LSTM Encoder-Decoder for video captioning and an LSTM Encoder-Decoder for sentence generation. There are a different number of video frames; they take samples of each 10 frames to reach an average of 40 processed video frames. In the beginning, the researchers changed the layers' structure of the (CNN) by using the residual function F(x) to enhance performance, and they used it to produce feature vectors of each video frame. A stacked LSTM used for encoding the visual features, and another for decoding the feature output of the CNN to natural language. They used LSTM on both sides of the model as Encoder and decoder; unlike our model, we use it as Decoder and YOLO as Encoder to enhance performance. Besides, it processes a huge number of frames, which consumes time.

In [3], the researcher proposes to enhance the accuracy of video captioning by including Temporal Deformable Convolutional in both Encoder-Decoder. The Temporal Deformable Convolutional (TDConvED) supports combining information of features for a long time by adding fully convolutional to each Encoder-Decoder. In the Encoder, the CNN extracts a feature of video frames to be

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

fed into (TDConvED), model uniformly samples 25 frames of each video. This results in video intervals within context. Mean pooling is used to represent these contexts and send them to the decoder. In the Decoder, stacked shifted convolutional blocks are used to produce a word for each representation. It uses a temporal attention mechanism to help the decoder focus on selected frames based on their weights to produce video captions. It is feed-forward, which means the result from the current layer does not depend on results from previous layers; it affects the accuracy of the final result (caption) in the opposite of using RNN techniques such as LSTM in our model which is back-forward.

In[6], researchers propose a Multimodal Memory Model (M3) for video captions, they proposed a shared memory for both visual (frames) and textual (sentences) and they guide visual attention on described elements to solve visual-textual alignments. The researchers experimented with two datasets: MSVD and MSR-VTT, they uniformly sample 98 video frames to 28, and 149 video frames to 40. Findings demonstrated that their method, when evaluated using BLEU and METEOR, did outperform most of the previously reported methods. It takes a huge number of frames which consume time and there are no specific criteria to choose process frames.

In [2], the Model generates captions based on spatial-temporal attention (STAT); which focuses on some important frames and regions within the video, not whole video frames. Firstly, the encoder network extracts global feature (frame level) using 2d CNN, motion features (frame level) using 3D CNN, and local features (object level (actions)) using faster RCNN from each video frame. Then, the spatial attention mechanism detects the most relevant objects in video frames based on increasing attention weights (sum of global, local, and motion features). After that, the temporal mechanism tracks trajectories of objects detected by spatial and frames; they select frames and regions and send them to the decoder. Finally, LSTM generates sentences with high probabilities of words using beam search. It uses MSVD and MSRVTT-10 datasets, and models evaluated by BLEU, METEOR, and CIDEr.They used RNN techniques on both sides of a model as Encoder and decoder; unlike our model, we use it as a Decoder and YOLO as Encoder to enhance performance.

In [7], they were the first to pick informative frames to be processed by Encoder-Decoder based on Pick Net (two-layer feed-forward neural network) mechanism. Firstly, it transforms each color frame to grayscale and resizes to a small size to produce a "glance" version of frames. Then, subtract the current glance from the previous one (the first frame took to compare with it), results in a flat to fixed-size vector to produce binomial distribution to decide to drop it or keep it. Secondly, kept frames are access to CNN encoder to extract features from them. After that, they use a gated Recurrent Unit (GRU) decoder to generate sentences; effective and performance of generating caption is affected by several selected frames. The model uses Microsoft Video Description (MSVD) and the MSR Video-to-Text (MSRVTT) datasets and researchers evaluated using BLEU, ROUGE, METEOR, and CIDEr. It reduces processing time; it takes between 6 to 8 frames, but other factors should be considered in selecting frames for accuracy.

Many types of research applied deep learning to the MSVD dataset; but they did not apply with YOLO, they use other deep learning techniques as mentioned. Therefore, the researchers in this paper compare their results with the result of the proposed model that YOLO applies to MSVD.

III. Methodology

The proposed model has four main elements: dataset, keyframe extraction, object detection, and sentence generation process. These elements join a sequential process to generate a video caption (Figure 2).

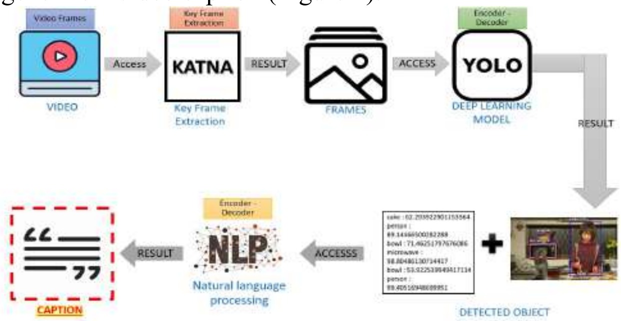

Figure 2: Architecture of Proposed Model.

For the dataset, we choose MSVD; it contains 1970 open muted videos collected from YouTube. The average duration of each video is 5 -25 seconds and it is about one action. There are 41 captions for each video on average. Researchers mostly use it for video captioning, and it is divided into training, testing, and validation sets[9]. Video caption based MSVD is done through the next three processes:

A. Key Frames Extraction (using KATNA):

keyframe extraction is a technical process for capturing meaningful frames from videos. Videos contain heavy contents and there are repeated frames; instead of processing all of them and consuming time, it considers only frames show changes in the video; it is helpful and solves heavy processing problem [10] Model uses KATNA as keyframe extraction; it is open-source code written by python, and it does video extracting frames; it provides summary frames' of video content based on five elements are: LUV color space, degree of brightness, cluster of K-Means, Entropy or contrast filter and blur detection of extracted frames. It has been tested with different types of videos format [11]. As shown in Figure 3, it captures only 3 frames from a video, its duration is 6 seconds. The number of captured frames depends on the video duration and changes that appear within frames.

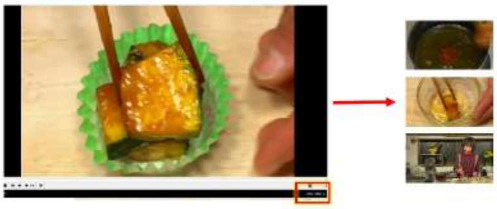

Figure 3: KATNA Result.

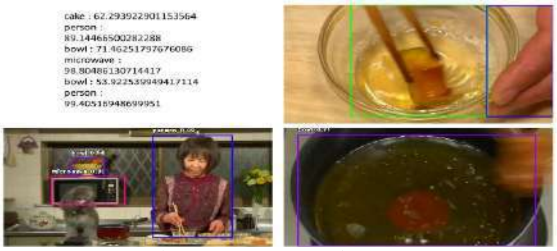
B. *Object Detection (using YOLO*

Detecting objects becomes an interesting subject in many areas; fast and accurate detecting is an important factor of any technique. The model needs it to construct sentences based on detected objects.

YOLO is one of the accurate and fast real-time detecting objects technique, it is based on predicting many objects, classifying the type of them and it shows accuracy percent. It does not slide the whole image and it is less error background detection than other deep learning techniques [12]. Figure 3 shows detected objects from YOLO in the model, it supports working with multiple images in one run and it takes 6-12 seconds to process an image based on CPU (it would run faster on GPU) [13].



```

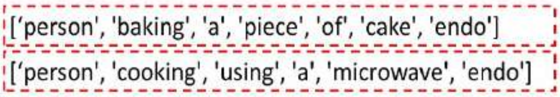
Figure 4: YOLO Result.

C. *Sentence Generation based NLP (using LSTM):*

It is a process to construct sentences based on some words. LSTM is a type of RNN, it is back- forward model; which means its current result from the current layer depends on results from previous layers[14]. LSTM tries to relate between result words in a text file; it searches in trained sentences by scanning 3 words at a time in sentences, to find detected objects words; because LSTM is backward – forward technique, every result depends on the previous one. Then, it produces sentences showing the relationship between detected objects words to choose one of them as a video caption. As shown in Figure 5:



```
['person', 'baking', 'a', 'piece', 'of', 'cake', 'endo']
['person', 'cooking', 'using', 'a', 'microwave', 'endo']
```

Figure 5: LSTM Result.

We develop a model based on tensor flow and Keras, we use the Sequential model for NLP; which means, it is plain layers and takes\produces one input\output tensor [14]. It is an unsupervised model; it has been trained on created sentences by us. It contains – sentences, it has different types of objects. The sequential model has three types of layers are embedding, LSTM, and dense; we create six Sequential models contains the same types of layers. Each model search for a given word in created sentences. Embedding is the first layer, it converts integers to fixed-size vectors[15]. LSTM is an RNN type, it is a forward-backward technique. Dense connects LSTM layers, it implements activation function, and it is softmax activation[16]. Figure 6 shows the architecture of NLP:

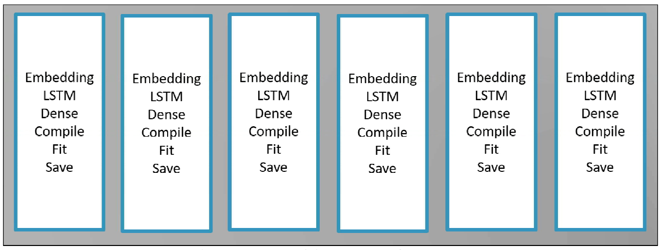


Figure 6: Architecture of LSTM.

IV. Discussion

Automatic video caption requires two important steps are: detecting objects and classifying their types (Encoder), plus step of generating sentence (Video Caption) based on detected objects as shown in Figure 1. To perform these steps, we propose model constructs of Key Frame Extraction (KATNA), object detection (YOLO), and generating sentences (LSTM).

At first, KATNA up to five frames based on video duration. It compares each consecutive two frames by KATNA elements as mentioned in the previous section, then it detects changes in frames within video and captures (frames (images)). After that, YOLO detects objects in captured frames by a surrounding box around objects with classification type plus percent accuracy; all this information is saved in a text file. Finally, LSTM reads detected objects words from the text file, then it generates an English sentence consists of subject and verb as a video caption.

V. Evaluation

Two evaluation methods implemented to measure the performance and accuracy of the model:

A. *the Metric for Evaluation of Translation with Explicit Ordering (METEOR):*

It has been used in many video captioning and description evaluation projects, especially, with short clips. It has 5 versions that calculate each hypothesis's alignment to its reference pair [17]. The proposed model has been evaluated by METEOR version 1.5, and the evaluation result of the proposed model is 0.35, it is a sufficient result. The following table shows a summary of some researchers who applied deep learning techniques to the MSVD dataset.

Table 1: Comparison with other Models.

Paper	**Percentage in METEOR on MSVD dataset**
Less Is More: Picking Informative Frames for Video Captioning [7].	0.33
M3: Multimodal Memory Modelling for Video Captioning [6].	0.2658
STAT: Spatial-Temporal Attention Mechanism for Video Captioning [2].	0.33
Temporal Deformable Convolutional Encoder-Decoder Networks for Video Captioning [3].	0.308
Proposed model	0.35

B. Human Evaluation

These criteria (Object Detection Quality, Sentence is Readable, Informativeness, Meaning preservation) have been formed in four questions and it has been sent to 20 persons for 3 different videos. Then, the average of the user's answers has been plotted.

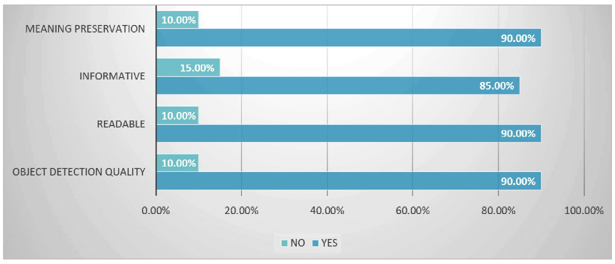

Figure 7: Human Evaluation Result.

VI. Conclusion and Future Work

In summary, video caption translates visual contents to text words sequentially (frame by frame and word by word), it is based on understanding video frames and transforms them to sentence (caption). Deep learning techniques have been greatly utilized in the field of video captioning research, which motivates researchers to develop a variety of video captioning framework which can automatically generate sentence (caption).

We develop a model using deep learning, which combines KATNA, YOLO, and LSTM. The model uses KATNA as a keyframe extraction, it chooses frames that show changes in video and remove redundant ones. The model applies YOLO on the MSVD dataset for object detection, and it generates English sentences using LSTM.

The model shows good accuracy and performance, it applies YOLO on the MSVD dataset, unlike the previous models that used other deep learning techniques. In the future, video captions will be measured by METEOR metric and human evaluation and compared with previous models using other deep learning techniques.

In the future, we think to train our model on more datasets; to be evaluated with different data. Also, we think to implement video caption-based Arabic language using (CAMeL Tools: An Open Source Python Toolkit for Arabic NLP). Finally, we think to evaluate the proposed model with different evaluation metrics such as BLEU, ROUGEL, and Diversity.

A Testbed for a three dimensional Pico–Sphere Satellite–Simulator(T3Dpilare)

Muhammad Faisal, Florian Wolz, Felix Dengel, Sergio Montenegro
Institute of Aerospace Information Technology,
Julius-Maximilians-University Würzburg,
Am Hubland D-97074 Würzburg, Germany.
muhammad.faisal@uni-wuerzburg.de

***Abstract*—This paper presents the mechanical design, assembly and construction of T3Dpilare. The principle target for this research was to design and built a three–axis floating–satellite simulator with six degree of freedom which is placed in a sphere for free movement. This three axis float–sat will be used to test the algorithms for three dimensional attitude control of satellites on earth. The simulator is named as 'T3Dpilare'. T3Dpilare is quite unique in its design, principle and mode of operation. It is a compact satellite simulator for the students and researchers. It offers a simple platform for on–ground testing of satellites and their subsystems in a quite frictionless environment to simulate the effect of zero gravity in the space.**

***Index Terms*—Aerospace, Avionics, Satellite Simulator, Attitude Determination and Control.**

I. Introduction

T3Dpilare is an air–bearing sphere, which is able to rotate freely in all three directions, internally rotation should be created by the virtue of the torque produced by the reaction wheels, same mechanism is also used in real satellites. The challenging situation for these kind of satellite simulator is the gravitational force of earth. If the centre of gravity of the sphere does not match with the physical geometric centre of the sphere then there would be a force arm which results in an unwanted torque, it is therefore required to shift the centre of the gravity of the sphere in the direction of its geometric centre. In order to full-fill this requirement there should be three moving masses in each direction (X,Y,Z), The position of the moving masses are controlled by the stepper motors. To determine the rotations a nine degree of freedom(DoF) IMU (Inertial Measurement Unit) should be used, it has a three dimensional rotation speed as well as a three dimensional acceleration sensor. The accelerometer shows us the direction of the gravitational vector and the position of the sphere, therefore it is necessary to determine the centre of of gravity of the sphere by using 6DoF IMU, where the the centre of gravity of the sphere is controlled by means of stepper motors and movable masses. The project had following requirements.

- The complete structure of T3Dpilare must reside in a hollow glass sphere of 30cm diameter.
- Structure should include three DC and three stepper motors.
- Each dc–motor should be able to rotate the float–sat in its particular axis so that the rotation in all 3–axis should be possible.
- The structure should be designed in such a manner that the stepper motor should be able to balance the centre of gravity by moving the attached masses .

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

In section two the state–of–the–art of the related projects are described. In section three the planning and the Computer Aided Design (CAD) of the simulator is presented which is followed by section four where the assembly and the integration of the different parts of the simulator are presented with explanation about the on–board electrical and electronics modules. In the last section the overall conclusion of the design and development of the T3dpilare is discussed with the recommendations for the future version of the simulator.

II. State–of–the–Art

In the field of Aerospace technology several projects are conducted to simulate the small satellites. In this section a brief description is provided about the similar efforts people have done for space research and development:

A. Floating Satellite (Float–Sat)

The Chair of Aerospace Information Technology at the University of Würzburg (Germany) has developed a Floating Satellite (Float–Sat) system. This system is used as a part of the exercises offered in the aerospace laboratory. It explains the approach for building small satellites to the students to learn and get familiar with basic satellite subsystems. It also provides a way to develop and test different control algorithms and strategies for different kind of space missions in an almost frictionless environment. The FloatSat system consists mainly of a mechanical structure that contains the basic satellite subsystems with one reaction wheel mounted at the centre of the horizontal plane of the structure. This reaction wheel is used to control the orientation of the satellite in one dimension. The detail of the FloatSat project can be found at [1].

B. Three Degree of Freedom (3DoF) test–bench for CubeSats

The University space centre of Montpellier and Nime, France has created a test–bench for CubeSats with three degree of freedom. In this test–bench a CubeSat is held in a frame with the hollow air–bearing, there is an external frame which is attached to a support and have an arm that is joined with an inner frame that contains hollow air–bearing pucks. When the sliding air–caps are attached to the bearing pucks the test-bench is able to rotate the CubeSat in all three axes [2].

C. Simsat: A Ground Based Platform For Demonstrating Satellite Attitude Dynamics And Control

A simulation satellite is developed in the joint venture of United States Air Force Academy and Air Force Institute of Technology. Simsat was based on a spherical rotor which was placed on a air pedestal.The satellite's components were attached around the surface of the spherical rotor in such a manner that whole spacecraft was balanced [3]. This idea was presented almost twenty years ago. It provides an excellent opportunity to the students to practically learn the operations of a satellite in real time in a laboratory. Although the objective of Simsat and T3Dpilare were same but the T3Dpilare is also meant to be very simple, compact and small in size.

The goals of all the simulators described above were quite same but their structure and Attitude Determination and Control System (ADCS) are different. In the paper [4] the author has described many more simulators people have invented for the simulations of an aerospace vehicle.

III. Planning

The T3Dpilare consists mainly of a mechanical structure that contains the basic satellite subsystems with three reaction wheels attached with a dc–motor mounted in alignment with the X, Y and Z axis. These reaction wheels are used to control the orientation of the satellite in three dimensions. In–line with each dc–motor there exist a stepper motor with a moving mass to adjust the centre of Mass (CoM) of the structure to balance it perfectly.

In order to facilitate a simple, compact and symmetrical design , computer aided design (CAD) tool Inventor$^{\text{TM}}$ was used to develop the structure of the T3Dpilare. The mechanical parts were designed to create the housing for three DC motors and three stepper motors, DC motors housing was created to put the motor with the reaction wheel. The housing for the stepper motor was created to put the stepper motor with the moving mass. This moving mass approach was adopted to adjust the centre of gravity during the operation of the satellite. The design was conducted so that wiring remains simple. In the following two figures some of the CAD designs of the components of T3Dpilare are presented. The housing for the batteries was designed in such a way that they can be easily charge and replace. Each battery is one cell battery. There are four housing designs to accommodate three batteries in each housing. In total there are twelve batteries in T3Dpilare. In the following figure the fully assembled design is presented. The reaction wheels were facing towards the cube and the centre housing was reserved for the stack of the controlling boards which includes the micrcontroller, dc motor driver, stepper motor controller, battery charging circuit and also an IO–expansion board.

Diameter	3.5 cm
Thickness	0.8 cm
Weight	64.8 gm

Table I: Properties of reaction wheel.

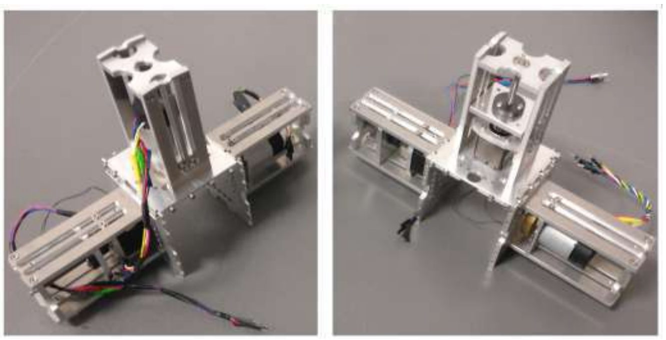

Fig. 4. Partially assembled structure of T3Dpilare

IV. Execution

After designing, all the parts of the structure were manufactured with Aluminium with the CNC machine. Aluminium was chosen because of the stability requirement. The reaction wheel that is meant to produce the torque to create angular momentum in each direction is made of brass. The density of this type of brass is 8620 $\frac{Kg}{m^3}$. This reaction wheel has following characteristics. As the design was conducted in a symmetrical fashion the assembly and the integration was also followed in the same way as shown below: The centre housing of the T3Dpilare was assigned for the microcontroller, driver boards for motors, IMU , IO–expansion and also the battery. The wiring of the components is conducted in a very careful way to avoid any loose wire that potentially creates the noise, endangers the electronics and also disturbs the operation of the T3Dpilare.

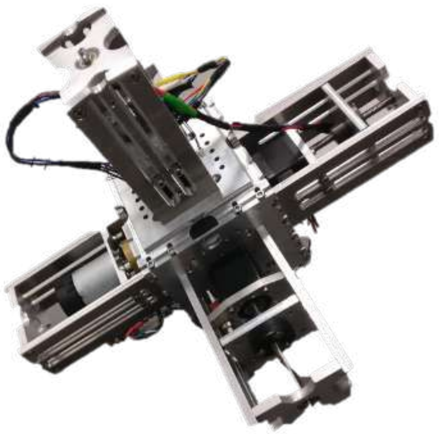

Fig. 5. Fully assembled structure of T3Dpilare

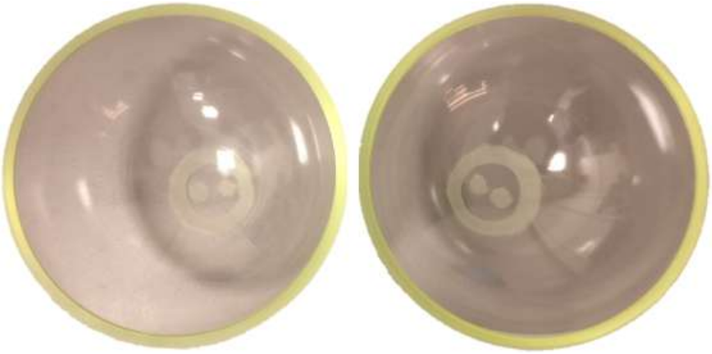

Fig. 6. Floating sphere

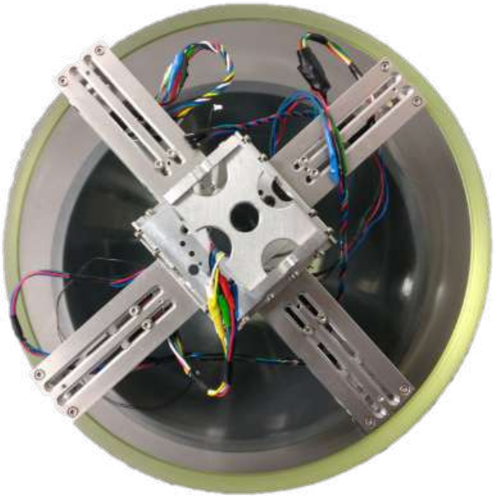

Fig. 7. Aerial view of T3Dpilare in the sphere on a floating platform

A. Floating Sphere

The T3Dpilare's structure presented in the above section is placed in a hollow sphere of the glass. The glass sphere is chosen over the plastic because the metal structure was heavy and it was not possible to properly operate with the plastic sphere. During the testing some non–uniformity was found on the surface of the glass then it was scratched to make it uniform.

Inner Diameter	30 cm
Thickness	12 cm

Table II: Properties of sphere

B. Vacuum Generation

In order to perform the proper operation of the T3Dpilare the vacuum is created in the sphere with a Deck Purge Box from the company Global Ocean Design^{TM} [5]. This box in combination with a purge port removes all the air and moisture from the sphere and creates vacuum inside to resemble the space environment around the concealed structure of T3Dpilare.

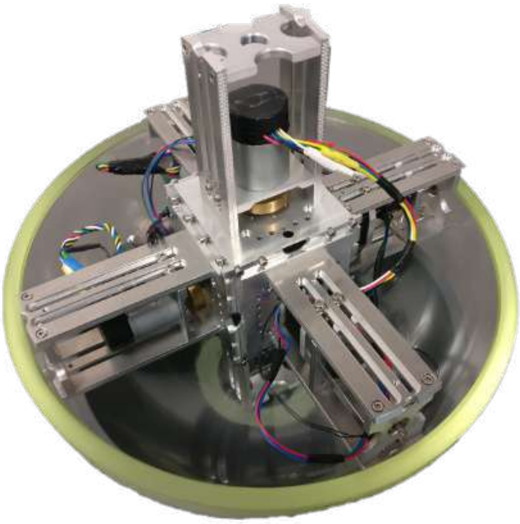

Fig. 8. Side view of T3Dpilare in the sphere on a floating platform

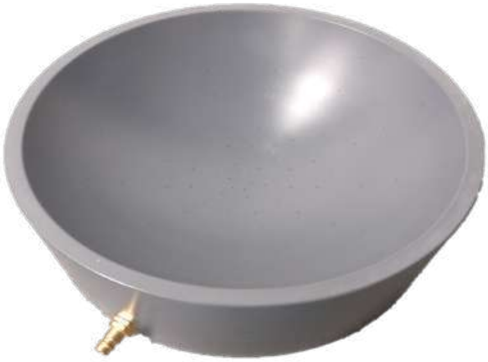

Fig. 9. Spherical Air Bearing Unit

C. Floating Platform

T3Dpilare's structure is placed into an Acrylic glass hemi–sphere shell that it is floating inside a Spherical Air Bearing Unit (SABU). The air bearing unit requires pressurized air input with a flow rate that may vary, depending on the mass of the floating unit. The pressurized air is fed in between the bearing surfaces through very small holes that are distributed on the unit's surface and discharge in the atmosphere through the edges of the bearing. This unit is made from Polyvinyl Chloride (PVC) material and it was designed to have a uniform distribution of the air flow and the pressure throughout the lubricating film between the unit and the hemisphere shell as shown in the figure 9. At the time of assembly it was observed that all the specifications of the mechanical designs were meeting the operating conditions, as shown in figure 10

D. Electrical Specification

There are four most important electrical components in the project, The dc motor interfacing, stepper motor interfacing,

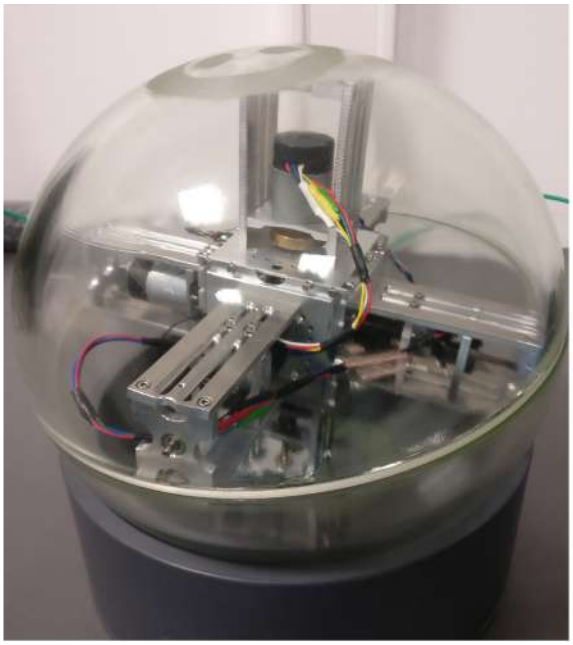

Fig. 10. T3Dpilare in operation

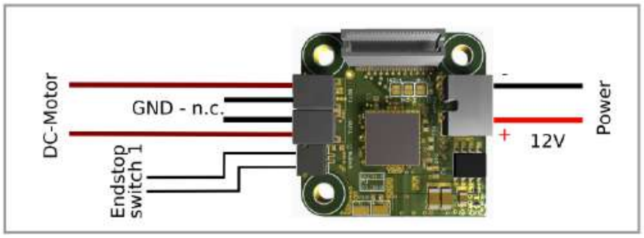

Fig. 11. DC motor driving board

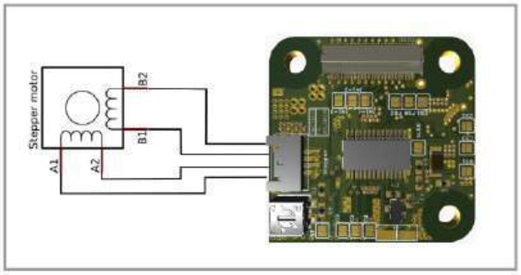

Fig. 12. Stepper motor Driving board

IMU and the power supply to the satellite. Each dc motor provides the rotation in a particular direction. These rotations are used to control the different modes of operation of the satellite. The IMU used in this project is LSM9DS1 from STMicroelectronics^{TM}, it has a 3-axis accelerometer, 3-axis gyroscope, and 3-axis magnetometer in a single chip therefore it is able to provide nine degree of freedom in motion sensing [6].

1) On–Board Computer:: The on–board computer of this T3Dpilare is based on stm32f407 micrcontroller from STMicroelectronics^{TM}, it has a Cortex–M4 core [7]. Department of Aerospace Information Technology in the University of Wuerzburg has developed a very compact and customized state–of–the–art development kit based on this microcontroller for these kind of nano and CubeSat projects. This kit is developed in the form of stack. There is a unique possibility to add several extension boards on this kit. The first module contains the main board then there is an extension board which contains the driver for stepper motor and dc motor, then comes the extension board the IMU with the WIFI module and at last there is a IO–expansion board. The distance between two boards in the stack is 5mm. The thickness of each board is 1.6 mm.

2) Battery:: Battery was selected on the basis of the power requirement as well as on the basis of the geometry of the T3Dpilare. There are twelve Lithium Ion 18650 Cell (2600mAh) Batteries.

3) DC–Motor Interface: : There are three dc–motors present in the structure therefore it was required to design a dc motor driver. The dc motor driver was based on a MC33926 full H–bridge, which can be operated in the range of 5 Volt to 28 Volt and it can provide almost 3 Ampere current(with 5A peak to peak value) [8]. Power to the dc–motor is controlled via the pulse width modulation (PWM) generated by the internal timer circuit of the microcontroller, the PWM output is passed to the H–bridge board which controls the motor operation.

4) Stepper Motor Interface:: In order to balance the structure in all three directions there is a stepper motor attached in–line with each dc motor. A moving mass is attached with each stepper motor. The control software of the T3Dpilare should be able to rotate each stepper motor such that the attached mass is moved to a specific position so that structure does not vibrate and remains stable. The stepper motor carrier board is based on L6470 dSPIN motor driver from STMicroelectronics^{TM}. It can be operated in the range of 8 to 45 V and it can provide upto 7.0 ampere of current. The driver has an SPI interface [9].

5) Circuit Diagram:: The most important part of the electrical circuit of T3Dpilare is the battery charging circuit. The battery setup of the project was providing 14.8 Volt but each board in the stack is required to be operated on 12V. Therefore a step–down voltage regulator is used to reduce the voltage from 14.8 volt to 12 volt with 15 ampere of current. A power switch is connected between the voltage regulator and the charging circuit which allows the battery to be charged in isolation i.e without being connected with the rest of the circuit. The driver boards for the dc and stepper motors, board with debugging port, IO–expansion board as well as the main board with microcontrollers are designed discretely in such a manner that they can be connected together on top of each other to form a stack. This kind of setup has improved the harness efficiency by eliminating the use of many individual wires and this stacking of boards was also necessary to place all the boards in the centre housing of the T3Dpilare.

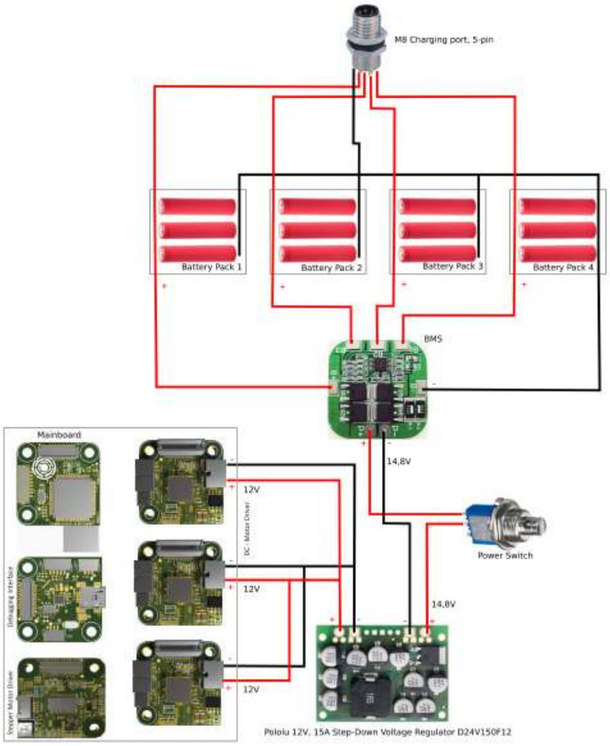

Fig. 13. Electrical Circuit diagram of T3Dpilare

V. Conclusion and Future Work

This research has produced a ground–based platform to understand the sub–systems and components of a space vehicle. It provides means to experiment, check and validate different control algorithm for the ADCS of satellites. The whole target of this project was to develop the structure of a pico–satellite with six degree of freedom . Additionally the electronics for the motors, batteries and sensors was also developed. The T3Dpilare is an state of the art satellite simulator which is designed and built to support research and education. The pitch, roll and yaw of the simulator can be controlled for the different modes of operations of the satellites. The structure is enclosed in a hollow–sphere where the vacuum is created with the vacuum generator and the structure is being floated on a hemispherical air–bearing unit which is providing a frictionless platform for the simulator to be operated in an environment which is similar to the space where the gravity is zero. The future work for this project is related to the development of the control algorithms for the autonomous operation of ADCS and also the testing of different machine learning and evolutionary algorithms for the ADCS.

***Abstract*— The application of industrial manipulators or robots is increasing annually due to its productivity, superiority, and accuracy. The manipulator-links (arms) play an important role in supporting the structure of robots and bares the various loadings such as; inertial, bending, torsional, etc. A topology optimization method is the best way to distribute the useful material in the design space; thereby, needless densities can be removed. This approach reduces the mass and makes the industrial manipulator components as energy efficient. At the same time, it also maximized the stiffness of the robotic components and helped to improve the dynamic performance and stability. In this work, a topology optimization technique is implemented on upper arm and forearm of the KUKA KR16 industrial manipulator by considering volume fraction within a range of 0.3 to 0.9. The complete robot model is designed using SOLIDWORKS 2018 software and imported into Altair Inspire software for multibody dynamic analysis and topology optimization. To make the study realistic, the complete model is operated in dynamic environments within the working range and obtained boundary conditions such as; joint forces and torques. These boundary conditions are used as load cases for topology optimization study. The objective function is chosen as maximization of stiffness or minimization of compliance. To get the better manufacturability of the final topology shape controls of the geometry applied such as; symmetry, split draw and extrusion surface, etc. The obtained topology is analyzed using post-simulation methods and obtained performance values of displacement and Von-Mises stress. Within stated range, the volume reduction of 30-50% gives better performance values compared to the before optimization.**

Keywords*— *Dynamic loading; Industrial manipulator; KUKA KR16; Robotic-arm; Stiffness; Topology optimization

I. Introduction

The usage of industrial serial robots is increasing annually in various fields such as; automobile manufacturing, medical, engineering, aerospace, product inspection, etc., due to their productivity and accuracy [1]. The industrial manipulator links play an important role in supporting structure of the robot [2]. Topology optimization is the proven method to distributes useful material in the design space; thereby, needless densities are removed, which doesn't carry a significant load in the design space [3]. Using this approach, practitioners can produce energy-efficient mechanical components, and it also improves dynamic performance and structural stability [4].

From previous research, the usage of topology optimization approach in the arena of industrial manipulators was started in 2006 [5]. Lohmeier et al. optimized the leg of humanoid topologically with the help of *Optistruc* commercial software without considering dynamic forces [6], [7]. Most researchers optimized industrial robotic arms considering static loading conditions by arranging the manipulator in maximum stretching or worst position [8]–[13]. However, when the industrial manipulator is functioning in oprating range, static loading conditions were not sufficient. To make the study realistic, consideration of dynamic loading study is a must. Rare efforts are made in design optimization of industrial robots considering dynamic loads. Albers et al. optimized one degree of freedom (DOF) manipulator-link topologically using TOSCA commercial software [14], [15]. Multi-objective topology was performed on serial manipulator considering dynamic analysis with HyperWorks or SOLIDWORKS software [16], [17]. Srinivas and Javed conducted topology optimization of 1 and 3-DOF industrial manipulator considering dynamic loading conditions [18], [19]. In this method, the dynamic loading conditions were evaluated with respect to the angle by uniform angular position. Recently, the same authors proposed a novel approach to minimize the computational time of topologies generation using non-uniform angular position based on deflection threshold values [20]. Equivalent static load method (ESLM) is proven technique used to solve the topology optimization in a dynamic environment [21], [22].

This work focused on topology optimization of the KUKA KR16 industrial manipulator considering equivalent static load method. The entire model is designed in SOLIDWORKS software and imported into Altair Inspire software for multibody simulation. Force and torque values at the upper arm and forearm of the manipulator are analyzed. This data is used as input loads for topology optimization. The objective function is chosen as maximization of stiffness. Topologies are generated for various volume fractions ranging from 0.3 to 0.9 with a step value of 0.2. The performance values are captured for various optimization links such as displacement and Von-Mises stress. The obtained results are compared with the manipulator without topology optimization.

The rest of the manuscript is organized as; the methodology of topology optimization and ESLM are presented in section 2. Dynamic analysis of the manipulator-links is provided in section 3. Simulation results are detailed in section 4.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

II. Topology Optimization Approach

Topology optimization is a well-established method in structural optimization. It is an effective and superior approach when compared to other two optimizations like shape and size [23]. It distribute the material in the design region considering applied loads, volume fraction, and density variables. In this method, the design region is discretized and every element is allocated a density value. The densities allocation is carried out using the global stiffness '$\mathbf{K_{SIMP(z)}}$' matrix using popular method, i.e., solid isotropic material with penalization (SIMP) approach as follows:

$$\mathbf{K}_{\mathbf{SIMP}(z)} = \sum_{e=1}^{n} [z_{\min} + (1 - z_{\min}) z_e^P]\mathbf{K_e} \qquad (1)$$

where '$\mathbf{K_e}$' is stiffness matrix of the element. 'z_e', and '$z_{\min}$' are the density and minimum density of the element, respectively. '*P*' is the penalization variant often selected as 3. '*n*' is a total elements in the design region. To distribute material in design space, the objective function of optimization loop is considered as maximization of stiffness or minimization of compliance (*C*). Applied loads, constraints and boundary conditions are selected as constraints as follows:

$$\left.\begin{array}{rl} \min\limits_{z} : & C(z) = \mathbf{U^T K U} \\ s.t \;\; : & V(z) = V \times f \\ & \mathbf{P} = \mathbf{KU} \\ & 0 < z_{\min} \le z_e \le 1 \end{array}\right\} \qquad (2)$$

where '*f'* is the volume fraction of design region and '**U**' is displacement of each element. '**P**' is the applied load vector. '*V(z)'* and '*V*' are targeted and stating volume of the design space.

A. Equivalent Static load Method

The ESLs are a set of static forces that produce the similar displacement effect as static study at time period for non-linear dynamic investigation [24], [25]. In ESL process, multiple load cases are calculated with respect to the time is as follows:

$$\mathbf{M}(z)\ddot{D}_N(t) + \mathbf{K_N}(z, D_N(t))D_N(t) = P(t) \qquad (3)$$

where 'M(z)' is mass matrix for design variable, '*P(t)*' is the force at time period value. '$\mathbf{K_N}$' is stiffness matrix for non-linear investigation. The displacements from non-linear study (D_N) are multiplied by stiffness matrix of linear study ($\mathbf{K_L}$) to capture the ESL at time step, as follows:

$$P_{ESL}(t_a) = \mathbf{K_L} D_N(t_a) \qquad (4)$$

where 'F_{ESL}' is the load or force at the given instance (t_a). The several loading conditions are successfully handled by structural optimization without much computational time. The optimization is conducted using ESL will update the design variables based on non-linear analysis.

B. Modeling of KUKA KR16 Industrial Manipulator

The multi-purpose industrial robot, KUKA KR16, was used for different applications such as; welding, cutting, material handling, and painting, etc. The industrial robot consist of six DOF and a pose repeatability of ± 0.04 mm. The various arms and joints of manipulator are detailed in Fig. 1. The KUKA KR16 robot can reach a maximum distance of 1612 mm .The rated payload and approximate weight are 16 kg and 245 kg, respectively.

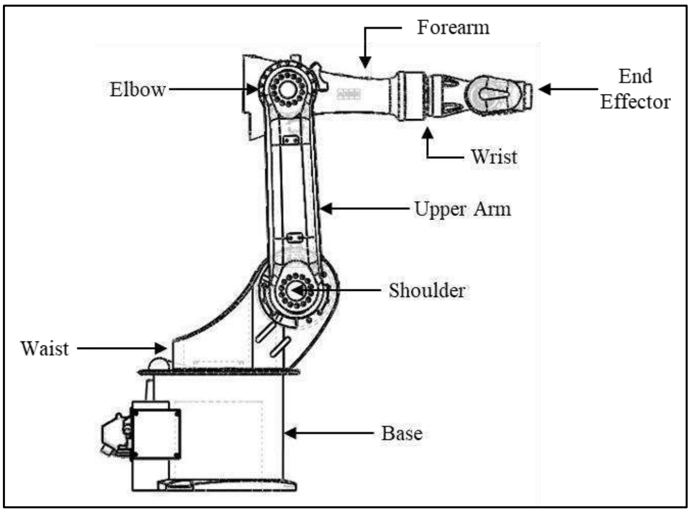

Fig. 1. The Wireframe diagram of KUKA KR16

The KUKA KR16 industrial manipulator has rotary joints and extension for end-effector at wrist. A KR C4 controller can operate the manipulator. The operating range for six DOF or axis of industrial manipulator and its maximum speeds are presented in Table 1.

TABLE I. Operating Range of Different Axis for KUKA KR16

Axis No.	Operating range (degrees)	Maximum speed
Axis 1	+185 to -185	200°/s
Axis 2	+65 to -185	175°/s
Axis 3	+175 to -138	190°/s
Axis 4	+350 to -350	430°/s
Axis 5	+130 to -130	430°/s
Axis 6	+350 to -350	630°/s

C. Dynamic analysis of Robot

The entire model of the KUKA KR16 manipulator is modeled using SOLIDWORKS 2018 software. The design is imported into ALTAIR Inspire multibody simulation software for dynamic analysis. The manipulator is considered at worst condition maximum reach point, as shown in Fig. 2. From Figure, user can also find the joint axes of the manipulator [26]. The joints are defined in the motion analysis, such as; base as fixed joint and axes are rotary joints. At center of mass, the acceleration due to gravity is applied, i.e., 9.8 m/s^2. Two servo motors are attached in the simulation at shoulder and elbow for the motion of upper arm and forearm of the manipulator.

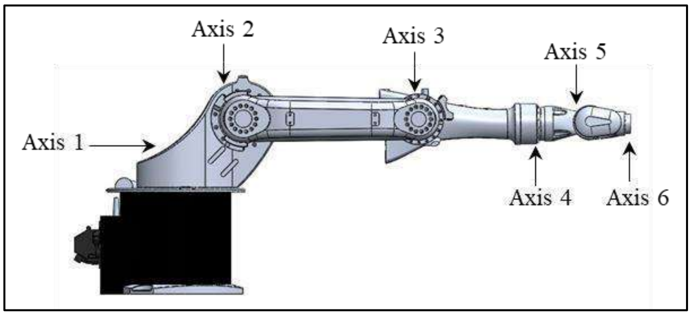

Fig. 2. Maximum stretching or worst position of a manipulator.

The ramp step velocity profile is chosen with a magnitude of 10 rpm and 8.3 rpm for upper arm and forearm, respectively. When the robotic arm is operated within working range 180^0 and 150^0, the force and torque values are captured with respect to time. The joint force values for upper arm and forearm are shown in Fig. 3.

The joint force values of shoulder and elbow for upper arm are shown in Fig. 3 (a). The joint force values of elbow and wrist for forearm are shown in Fig. 3 (b). The minimum magnitude of the force is obtained at 90^0 angular positions. This data is captured based on ESL method using Inspire simulation software. Maximum force of upper arm is recorded as 832.6 N and 464.2 N for shoulder and Elbow, respectively. The forearm maximum force is recorded as 512.6 N and 234.2 N for Elbow and wrist, respectively.

Similarly, the joint torque values are also captured for upper arm and forearm, as shown in Fig. 4. For upper arm, maximum torque is recorded as 124.5 Nm and 36.8 Nm at shoulder and Elbow, as shown in Fig. 4 (a). For forearm maximum torque is recorded as 33.6 Nm and 24.2 Nm at Elbow and wrist, as shown in Fig. 4 (b). The obtained force and torque values are used as input load cases for topology optimization. The process of obtaining topology optimization, shape controls, design space, and objective function of robotic arms are detailed in the next section.

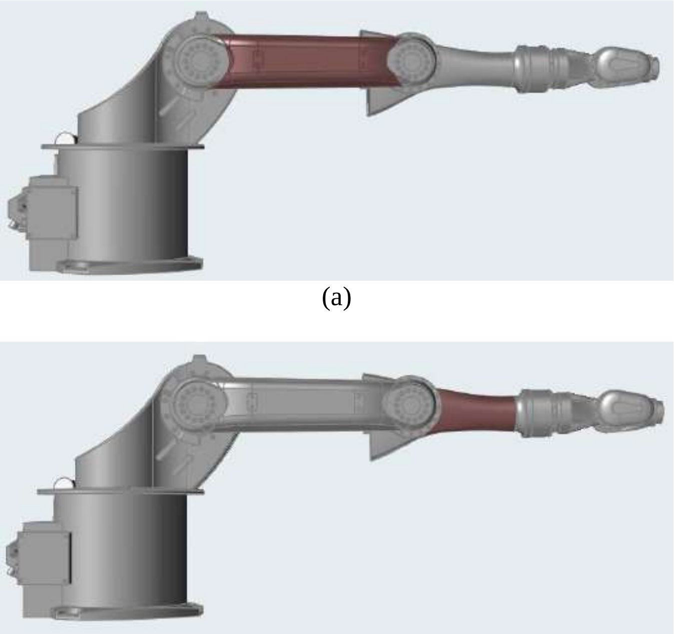
III. Topology Optimization of Robotic Arms

The implementation of dynamic loading conditions is very important in topology optimization method when the industrial manipulator is in motion. The obtained results of force and torque in motion analysis using ESL method are used as load cases for topology optimization method. The design space of the robotic components which are subjected to the topology optimization process is shown in Fig. 5.



(a)

(b)

Fig. 5. Design space of (a) Upper arm and (b) Forearm.

The robotic arms are divided into two parts such as; design space and non-design space. Only the design space is subjected to the topology optimization process remaining parts have not participated in the optimization loop. The joints are excluded from the topology optimization and come under non-design space. This feasibility is provided for assembly and placing different measuring instruments at that location. The design space for the upper arm and forearm is highlighted in the Figure. The topology optimization method distributes the useful material based on the objective function from the design space, i.e., maximization of stiffness.

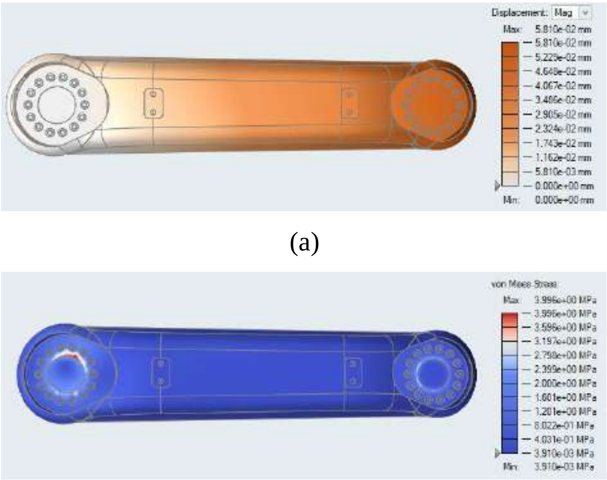
Initially, the design density elements are considered very small to avoid the singularity problem of Stress. The non-linear dynamic study is conducted to achieve linear stiffness and non-linear displacement. The boundary conditions obtained in the motion analysis are used for topology optimization and used as linear static loads w.r.t. the time. Based on the objective function, the design space is updated by useful material and eliminates needless densities. At the required volume fraction, the final manipulator-links archive the better dynamic performance. If the attained results are converged, the loop terminates, or else the design variables update and continue from the start. The results of the robotic arms are detailed in the next section.

IV. Results and Discussions

The obtained results of optimized topologies for upper arm and forearm using Altair Inspire software are provided here. The volume fraction is considered from 0.3 to 0.9 with a step value of 0.2. The displacement and Von-Mises stress values of the industrial manipulator are recorded.

A. *Before Topology optimization*

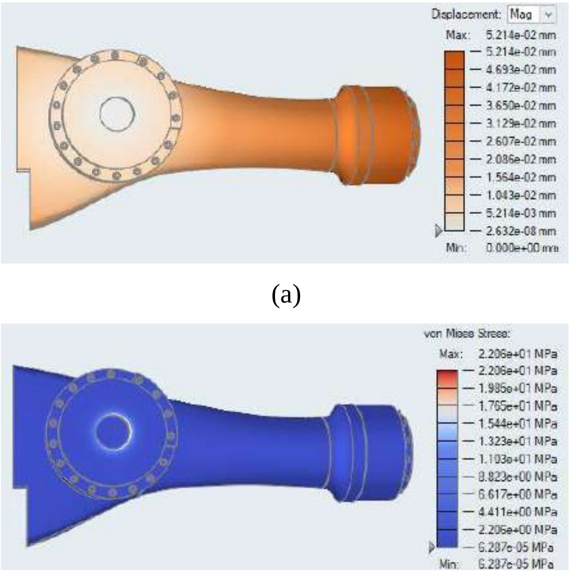
The robotic arms are dynamically analyzed and recorded the performance values before the application of topology optimization. The performance values of upper arm are shown in Fig. 6. The maximum deflection and Stress are recorded as 0.0581 mm and 3.99 MPa. Similarly, the performance values of forearm before topology optimization is shown in Fig. 7. The maximum deflection and Stress are recorded as 0.0521 mm and 22.06 MPa.



(a)

(b)

Fig. 6. Deflection and Stress of Upper arm before optimization



(a)

(b)

Fig. 7. Deflection and Stress of Forearm before optimization

B. *After Topology optimization*

As stated earlier, based on the ESL method, boundary conditions are updated at the joints for topology optimization process. The objective function was chosen as maximization of stiffness for volume fraction ranging from 0.3 to 0.9. The shape controls are applied to achieve better manufacturing conditions such as; symmetry and split draw. The obtained topologies of upper arm for various volume fractions along performance values are shown in Table 2.

TABLE II. TOPOLOGY OPTIMIZATION OF THE UPPER ARM

VF	Performance values (Displacement and Stress)
0.3	 0.5	 0.7	 0.9	 
From Table 2, at volume fraction 0.7, the performance values of displacement and Stress are 0.0573 mm and 3.95 MPa. It is provided slightly 1.3% better results compared to the solid manipulator-link, i.e., before topology, at the same time, volume reduced by 30%. Similarly, the obtained topologies of forearm for various volume fractions along performance values are shown in Table 3.

TABLE III. TOPOLOGY OPTIMIZATION OF THE FOREARM

VF	Performance values (Displacement and Stress)
0.3	 0.5	 0.7	 0.9	 
From Table 3, at volume fraction 0.7, the performance values of displacement and Stress are 0.0488 mm and 19.28 MPa. It is attained better performance with 6.2% for displacement and 14.4% for Stress compared to the solid manipulator-link. The topology obtained at volume fraction 0.5 also attained better performance. However, the performance values of displacement obtained at volume fraction 0.3 are slightly higher. Practitioners can select the required volume fraction based on the performance. From the results, user can reduce the upper arm volume by 30% and forearm volume by 50% with better performance of industrial manipulator.

V. Conclusions

This paper mainly focused on multibody topology optimization of the KUKA KR16 industrial manipulator to improve its stability and dynamic performance. The complete model was designed in SOLIDWORKS and imported to Altair Inspire software for motion and topology optimization study. The industrial manipulator initially considered at maximum stretching position, and joints were defined as fixed or rotary. The upper arm and forearm were operated in a working range of 180^0 and 150^0 with a rated speed of 10 and 8.3 rpm. The force and torque were captured at joints and used as load cases for topology optimization study. Maximization of the stiffness was considered as an objective function. The volume fraction is selected from 0.3 to 0.9 with a step value of 0.2. For better manufacturability, shape controls were incorporated, such as; symmetry and split draw. The upper arm attained the better results of 1.6% compared to the solid manipulator-link at 0.7 volume fraction. Similarly, the forearm achieved better performance results up to the reduction of the 50% volume fraction. The practitioners can reduce the volume of upper arm and forearm by 70% and 50% with better dynamic performance. Users can select the required volume fraction based on the necessary performance values. This method is also applicable for other mechanical or structural members subjected to dynamic loading conditions.

***Abstract*—Fog computing has set standards in networking and overcome complexities in cloud computing. However, despite its many benefits, the inherent distributed model of fog computing architecture introduces a new attack surface cyber-attacks. It is important to detect and prevent such attacks on the network to make the network reliable. In this paper, an overview of the various challenges and solutions proposed by many researchers is provided. This paper particularly focuses on solutions in securing networks by proposing several methods while developing an efficient intrusion detection system. Finally, observations are made based on the results of various proposed solutions and the existing research gap is also presented.**

I. INTRODUCTION

The improvement of computational and communication technologies such as cloud, edge, the fog has resulted in a smart system in many applications such as smart city, smart health, smart vehicles, etc. Deployment of these smart systems and providing IoT services are not possible by ruling out characteristics like reliability, security, and sustainability [7]. In the case of any smart system, there will be massive data collected from various sensor nodes that are requested by the user. The processing of a massive amount of data also limitation such as latency, response, and data security is the biggest challenge for cloud-only based systems.

In terms of network bandwidth scalability and latency edge computing performs better than cloud computing which prompted to design of edge-based applications over cloud-based applications in smart systems.

Due to the wide distribution of IoT networks are prone to cyber-attacks. It is key to secure the systems from this kind of attack by implementing the detection mechanisms that will detect abnormal behavior and protect sensitive data and manages the resource of the system.

In this study, we review Fog/Edge computing, its limitations/challenges and there advantage over cloud-based systems in communication and computational technologies.

Additionally, we report several methods for data confidentiality, access and authentication. However, even with this numerous mechanism, IoT networks are prone to multiple attacks in the network.

The rest of this paper is organized as follows: Section 2 provides an overview of the literature on security, latency, energy and resource utilization, and speed. Section 3 discusses the methodology and the datasets. Section 4 summarizes the findings of this survey and section 5 gives a concise conclusion.

II. LITERATURE REVIEW

Signature-based IDS detect cyber-attacks using predefined patterns which are classified as malicious that are present in the database of the system as shown in Figure 1. The method uses multiple pattern matching algorithms to detect malicious activity in the network. Proposed methods need to find all the patterns in set P. The pattern consists of alphanumeric characters that monitors flow of packets across the network.

A. Security

A summary of the highlights of this section is provided in Table 1.

Oh et al. [8] proposed a pattern for malicious detection to secure IoT networks. They significantly decreased memory usage in the process of pattern-matching by proposing a new method called auxiliary shifting and early decision scheme. Results found to be very efficient in early decision scheme of the malicious pattern. However, they were not successful in detecting and classifying other attacks like False data inject, DOS etc. Also, a malicious user may try

TABLE I
TABLE1 : SECURITY COMPARATIVE REVIEW

Citation	Methods	Metric	Result
[10]	Fat learning network (FLN), Particle swam optimization	Accuracy with nerons and classified classes	Accuracy increases as hidden layer increases
[17]	Generic algorithm, Support Vector Machine	Classification	Detection Rate 96.38, False alarm rate 0.0
[18]	Generic algorithm(GA),Whale optimization algorithm(WOA)	Sensibility, accuracy, precision	Accuracy 96 with 400 samples
[22]	Intrusion label inside decode layer	Recall,F-1 Score,False positive	Accuracy 99 percentage

patterns each time which challenges node to detect such kind of attack. Although this limitation is improved in Ali et al. [10] by proposing a fast learning network(FLN) with particle swarm optimization (PSO) which are applied in the classification parameter. Even though the results were conceiving, the system complexity applied to sensor node is high because of low computational and resource capabilities.

The above limitations were improved by combining a hybrid genetic algorithm (GA) and an SVM with PSO for feature subset selection proposed by Moukhafi et al. [17] for the Intrusion detection system. This system reported in 100 percentage accuracy in differentiating DoS attack from another attack. However, this method fails to discriminate normal behaviour from other types of attacks with a low accuracy rate. The above limitations were targeted in Vajayanand et al. [18] to improve accuracy in classification for SVM-based classifier by proposing a hybrid feature delegation module based on GA and mutual information (MI). This proved in the experimental results showing SVM-based classifier performs better than an artificial neural network(ANN). Accuracy results of 96 percentage are reported when the classifier was trained with 400 samples and this proves that using these hybrid models high accuracy is obtained. Unfortunately considering battery usage and computational cost this scheme is not suitable.

For optimum resource allocation, least-square SVM was introduced for intrusion detection systems in Kabir et al. [19]. This scheme combines datasets of training and testing. Later it determines the amount of training and testing sets. Lastly, the samples are directly selected for the classifier. Even though results obtained are satisfactory due to the missing features in the limits of the dataset training models. Soon after on the basic of automata or finite state machine, one more IDS was introduced in M. Roesch et al [26]. The characterization of the network was done based on the automata transition that was used to detect intrusion attacks. In this method three kinds of attacks were experimented i.e, jamming attack, false attack and reply attack. Few attacks like false injection and DoS were not addressed.

Another method to detect intrusion was proposed in li et al. [20] which involves two steps for efficient detection of intrusion. In the primary step, numerous binary classifiers were used to classify the sample. In the second step, using k-nearest neighbours (k-NN) algorithm the samples are classified if output obtained by the previous step is vague. Results show high accuracy at high computation and high resource utilization to deploy numerous classifier.

Further, based on feature selection, the optimized parameter of SVM and weight Tao et al. [21] presented the genetic algorithm (GA). This algorithm first selects the features set and then optimizes the parameters of the SVM. After many instances, the trained classifier is used to classify and detect anomalies in a communication network. Later M. Lopez et al. [22] based on conditional variational autoencoder (CVAE) initiates intrusion detection system. Here labels of each sample are inputted for the decoder block of VAE. Although results were efficient due to the overhead of adding the extra input the decoder block, the system is complex. To overcome these limitations another efficient IDS based on long short-term memory recurrent neural network was proposed in [23]. This technique clearly shows they are efficient and overcome other machine learning techniques which includes k-NN and SVM.

Helmer et al. [24] introduced lightweight IDS. In this technique, mobile supervisors would collect data by moving around the network and update to a mediator to get the current status of the network. Even though, this unique type of architecture is successful in limiting the major problems of centralized network it has many challenges in terms of delay while transmission of data and high response time from the mediator. Meanwhile, another lightweight IDS was implemented by Li et al. [25]. In the first phase, the SVM-based classifier algorithm selects the feature.

All the above methods perform efficiently on detecting instructions in networks but they have high resource utilizations. It is important to focus on the design that requires minimal energy, lower computational cost and uses little memory in network nodes.

Bushra Zaheer Abbasi et al. [5] surveys about the security in present IoT technology and analyse the challenges and also suggest a few solutions to mitigate the limitations. Although it proposes numerous solutions there is a drawback in energy and resource allocations. After analysing the solutions and challenges in IoT systems authors suggest Hybrid version to optimize the security systems.

T.D Dang et al. [13] approached in two ways to resolve the issues in data security. Region-Based Trust-Aware (RBTA) and Fog-based Privacy-aware Role Based Access control

(FPRBAC) are the two approaches that tracks and trace location and many also detect attack vectors like Intrusion attack, Man in the middle attack and attacks with polices and Role-based attacks. Metric used in this method is Execution time and these approaches pose Feasibility and Efficiency.

Jun Wu et al. [3] proposed FCC i.e, Fog computing content-Aware filtering in the social network applications. This technique utilizes ICN i.e, an information-centric social network that uses names instead Ip-address as addressing mechanism. This method performs an efficient security service. This is implemented in NDN i.e, Network data networking simulator. Although, it has significant results inaccuracy rate, latency, speed and control overhead the system is too complex to implement. Another technique was proposed by MD. Wazid et al. [4] for securing social networks. In this method key management and user authentication methods were implemented to protect the CIA cycle i.e, confidentiality, integrity and availability. Author targets on access control to protect the sensitive data from unauthorised users. Although this method is different from the above ICN method in terms of performance it overcomes the limitation of ICN. This method can be implemented in NS2 simulator.

Mingming Cui et al. [6] proposed an authentication scheme for safety road conditions that have real-time content transmission. Here the network can fully exchange and share information. This scheme can be used for authentication, tracking the vehicle, and for user anonymity. This scheme is implemented using Java programming language using JPBC Library in intel core processor. This scheme is evaluated using four hash functions using the user key generation. Results obtained in this scheme are in real-time with low computation. Another scheme was proposed in the area of IOV, M. Bousselham et al. [15] which points out the failure in the security of the cryptographic algorithm. For this purpose, it employs two methods Decoy technology DT and User behaviour profiling (UBP). Here UBP profiles the user data based on actions performed by vehicles in IoV and DT does on-demand generation of decoy document. Results show that UBP and DT have a greater number of false-positive and provides an unprecedented level of security in vehicular networks in VCC.

B. Latency

Nathan Wheeler [1] made a comparative survey of fog enabled and fog-less system architecture and explains problems related to latency, computational speed and energy consumption in these two architectures. The paper shows how raspberry pi can be used as an edge node. Here AWS is used as cloud and performance is evaluated. Request time and response time during service request are the metrics used to evaluate the performance. Results show there is a massive response time difference between the two architectures. Thus, the author concludes fog computing architecture is reliable and efficient also mentions response time can in the future be reduced by using SDN in the context.

C.T. Do et al. [12] targeted problems related to resource allocation in video streaming. A proximal algorithm was proposed to minimize latency in fog applications this method involves dynamic scaling at runtime that result in achieving high bandwidth and minimal resource utilization. Although this algorithm is efficient it does not address limitations of internet computational incapabilities. This limitation is focused by M. Abedi et al. [14]. Authors try to resolve the computational capabilities by using ANN which resulted in efficient results in term of delta and computational capabilities.

Moreover, Sukhpal Singh Gill et al. [9] addresses problem-related to Network bandwidth, latency, Response time and energy consumption in smart home systems. Here Resource management Technique for smart home (ROUTER) using IFogsim and iCloud tools to evaluate the performance of the system. Although results reported there is reduced network bandwidth, energy consumption and increase response time and latency. But in terms of scalability design is not suitable for huge network and are not reliable.

C. Energy Utilization and Resource Allocation

Mouro Tortonesi et al. [2] made a functionality survey on prioritizing resource allocation for data analysis to reduce computational time and resource usage in IoT applications. Paper demonstrates the usage of fog computing in the smart city. The author proposed two approaches for improving these above limitations first by implementing an information-centric server and then by prioritizing vol factors for resource allocation. This is done by OpenCV open-source library with evaluation metric vol factor and CRIOS. Significant improvement in CPU time and efficiency of the system is obtained. This approach is easy and simple although securing the system can be considered for future study [27].

Another method is presented in Adila Mebrek et al. [16]. This method uses an Evolutionary Algorithm for optimisation of memory usage and lowers energy consumption. This algorithm is choose based on the objects which are among BIP and genetic algorithm (GA) algorithms. Algorithm accesses energy, processes data and update to the cloud. Results show latency increases with the number of nodes increases.

D. Speed

C. Alippi et al. [11] proposed a re-programmable framework for Wireless sensor Networks that operate in the real-time scenario. This framework gives the advantage of programming remotely and improved computational speed.REEL framework

Citation	Methods	Metric	Result
[1]	Fog and fogless architecture	Req. and resp. time	Resp. time is high
[12]	Altering direction method	Resource usage	BW is twice cap
[14]	ANN	Process time	Reduced internet traffic
[9]	Resource management technique	Bandwidth	N/w BW reduction

is implemented in Contiki and execution time, Memory utilization was the evaluation metrics. Although results show significant low in execution time and increased efficiency in real-time computation but ROM occupation is large which results in large resource allocation.

III. METHODOLOGY

Here we will be discussing the brief overview of methods used by researchers while designing Intrusion detection system, Table 2 and Table 3 shows the comparative view of research papers in security and latency metric.

Below are the few methods proposed in the research papers.

- **Auxiliary shift**: There are two stages
  a. Pre-processing: Construct three tables i.e, Shift table, hash table, and prefix table.
  b. Pattern matching stage: It will match the pattern with the flow of the packet with a predefined malicious pattern in the database.
- **Early decision**: Here the malicious patterns are sorted in ascending alphabetical order to reduce the execution time while matching the pattern.
- **Genetic Algorithm**: This algorithm selects the fittest particle based on the fitness value evaluated based on the RBF kernel function in SVM to get the next offspring using methods like crossover and mutation.
- **Support vector machine**: It is supervised by ML which classifies two groups of problems.It uses the RBF kernel function to categories the data.
- **Particle swarm optimization**: It searches for optimal solutions in the given solutions through agents like particles.
- **Artificial Neural Network**: It consists of unit or node called artificial neurons that are used to train to classify the attack types.
- **k-NN algorithm**: Algorithm that is used to classify attack types by training the unit.

A. Data-sets

- **KDD99 and NSL-KDD**:
  a. Analysed based on number of output classes, training and testing models. b. Models can be applied are
  i. Clustering
  ii. Classification
  iii. Feature selection and reduction algorithm
  c. KDD99 is extracted from DARPA
  d. NSL-KDD obtained from KD99 by eliminating dataset.
  e. Output classes are DoS, Probe, R2L ,U2R and Normal
  f. Dataset has 24 attack and 14 attack types training and testing respectively.
  Table 3 . shows few feature selected in KDD99 algorithm.

  b. It has approximately 500k real-time network traffic data
  c. It has approximately 21k rows and over 10 workstations local IPS
  d. This data-set is monitored over three months duration. Each row consists of data, local Ip, remote asn, and count of connections in a day.
  The snap of the network dataset is shown in Figure 2.

IV. FINDINGS

Following are a summary of observations made while reviewing the paper regarding the solution w.r.t security of the

TABLE IV
TABLE 4: COMPARATIVE ANALYSIS

Paper cited	Dataset	Accuracy	Detection Rate
[1]	KDD99	96.01 percentage	96.38 percentage
[21]	KDD99 CUP	99.56 percentage	90.66 percentage
[20]	NSL-KDD	97.8 percentage	97.72 percentage

IoT.

- The detection rate of attacks is normally high with hybrid models compared to other models.
- Few models with pattern matching algorithms possess low in classifying attacks.
- Majority of the efficient proposed solution uses SVM for evaluation of fitness function.
- Performance evaluation of several proposed solutions is done by using KDD99 datasets.

V. CONCLUSION

Reviewed problems faced in IoT in various metrics such as latency, security, speed, energy, and resource allocation to understand the challenges in IoT also compared the solutions for specific problem categories. Furthermore, observations are made based on the results of efficient proposed solutions. Finally, efficient proposed solutions are studied to fill the gap and improve the performance of the system for future work.

Based on the results obtained from the proposed solutions, various enhancements in implementations can be made to produce efficient performance of the system. Firstly, by combing efficient algorithm in terms of efficient memory and execution time usage that override the limitation of memory usage and latency in few proposed solutions. Secondly, by using updated data set for efficient performance of Intrusion detection system application in real time.

***Abstract*— Security is need of the hour in today's world since the cyber physical systems are prone to malicious attacks. Advanced Encryption Standard is a cryptographic algorithm which is utilized extensively but is sensitive to dangerous attacks due to advances in technology. This paper administers Defense in Depth approach at system level on AES cryptographic core using an effective logic locking technique. AES lock block is inserted judiciously in subprocess of AES decryption algorithm. This approach achieves output corruption of 70% when incorrect password is provided at input due to which the probability of guessing the information and reverse engineering the architecture is reduced to greater extent. AES Lock block is highly efficient to secure the AES cryptographic decryption core. This work successfully shields AES cryptographic decryption core using Defense in Depth approach.**

Keywords*— *Defense in Depth, Hardware Security, Design for security, Logic locking, AES Decryption Core, AES Lock Block.

I. INTRODUCTION

Security is a major concern these days. Amidst the era of fabless companies, for the cost saved in manufacturing a significant effort has to be put in to curb variety of security threats like IP Piracy, Reverse Engineering and Hardware Trojan and a steep increase in the number of untrustworthy electronics which are encountered due to deployment of IC fabrication in the global design flow. Hardware security is an essential tool being worked upon recently to restrain the huge number of losses caused to the semiconductor industry due to the above-mentioned problems to mitigate malicious threats from attacker's end, Defense in Depth approach stands tall as it implements mechanisms in layered fashion. Design for Trust techniques (DfTr) [1] are also utilized which are broadly classified into active and passive. IC metering, Fingerprinting, Watermarking, Logic locking, IC camouflaging are examples of DfTr techniques. Out of them, logic locking is one the various active techniques which has been garnering more attention from the research world recently because of versatility, lesser limitations than others and its ability to protect against an attack in anywhere in the supply chain.

Logic locking method involves insertion of additional hardware and numerous extra key-inputs, in addition to the original inputs, into the design which are driven by an on-chip tamper proof memory. The added locking hardware makes sure that the design details cannot be recovered with the help of reverse engineering and ensures that the output is incorrect if the correct key is not provided at the input. There are various sequential and combinational logic locking techniques. The former ones' result in incorrect output since it is corrupted due to the presence of incorrect keys. Various combinational logic locking techniques implement XOR/XNOR key gates, AND/OR gates, multiplexers, or combinations of these gates [2]. Kundi et al. AES encryption core is implemented on Spartan-3 FPGA. The design includes MUX in the intermediate states to fed back data into encryption core [3]. The implementation provided fast encryption core. Santoosh et al. elaborates that AES encryption and decryption algorithm was carried out by implementing more than one round parallelly [4]. It increased throughput and offered high security.

In this work, Defense in Depth approach is administered to prevent malicious attacks like key sensitization, brute force attack and reverse engineering and secure critical data using lock locking technique on AES decryption core. Section II provides brief on the state of art technology. Section III elaborates on the AES decryption core, AES lock block core and Performance metrics. Section IV presents the results justifying all our claims. Section V presents the conclusion of this work.

II. OVERVIEW

Logic locking techniques are utilized to protect against malicious threats. Stripped functional behaviour logic locking technique is proposed by Yasin et al. which mentions that certain amount of functional behaviour is latent in form of secret key [5]. A stripped-functionality logic locking (SFLL) technique which strips the functionality of the design and hides it in the form of a secret key. The stripped functional behaviour is recovered only through on-chip restore process. There are a number

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

of ways to attack the design. SAT attack which is a recent and a fatal one which has the ability to decipher the right key of almost all logic locking techniques. Xie et al. explains one of the effective methods to counteract this is proposed in [6]. Delay locking determines functionality and time profiles. A key with incorrect timing will end up in violation of time and malfunction of the circuit. A delay key gate which is tunable is also proposed which can overshadow both functionality and timing profile of IC design. Sweeney et al. proposes Latch-based logic locking technique [7]. This method alters data flow and logic in the circuit by inserting latches. Karmakar et al. describes Logic Encryption strategy [8]. This strategy inserts key gate in such a way that quality of security improves and enhances key-interdependence due to incorporation of key-dependency module. Torrance et al. discusses Reverse engineering techniques [9]. These techniques extract design information which is confidential. Yasin et al. introduces Strong logic locking method that has been implemented in such a way that the key gates are inserted where it is non mutable. Drawback of this method is that it is laborious to find interfering key locations and does not guarantee output corruption. The study also states that existing SAT-based attacks can be averted possibly using one-way random functions. The technique of weighted logic locking [11], [12], [13] was proposed recently in which multiple key inputs are given to every control gate, usually at locations of highest fault impact, instead of the conventional technique where a single key locks the entire circuit. To gain security, Rekha et al. has implemented logic locking concept to protect the clock line of I2C protocol by securing data [14]. When loaded onto an on-chip memory, the secret keys restore the original functionality of the design and creates mismatch between the reverse- engineered netlist and original design. Baby et al. proposes a technique known as LUT based dynamic obfuscation. It ensures that the functionality is latent from untrustworthy stages of design flow [15]. Benchmark circuits were analysed related to number of cycles and hamming distance. Power consumption and area overhead is also decreased.

III. PROPOSED METHODOLOGY

The motive behind this work is to secure the critical data and prevent malicious attacks by administering the defense in depth approach at system level. This approach surges redundancies which reduces momentum of attacker resulting in enhanced reliability. This work is divided into two phases where first phase elaborates the defense in depth approach and second phase evaluates its performance using specific parameters.

A. Defense of Depth

In this work, Defense in Depth approach is applied in two stages. In the first stage, logic locking technique is used to authenticate and grant access control to implement AES algorithm and in the second stage, security is propounded by performing AES cryptographic decryption algorithm. The attacker has to obtain access in order to access the crypto primitive algorithm (AES) before key guessing resulting in high protection of the data.At gate level, in each round, the control signals from logic lock block are connected to different logic cells. This increases random behaviour and disables the attacker from differentiating the correct and incorrect output control signals. This approach adds multiple layers of security and strengths it against malicious attacks. Figure 1 depicts the Defense in Depth approach adopted in this project.

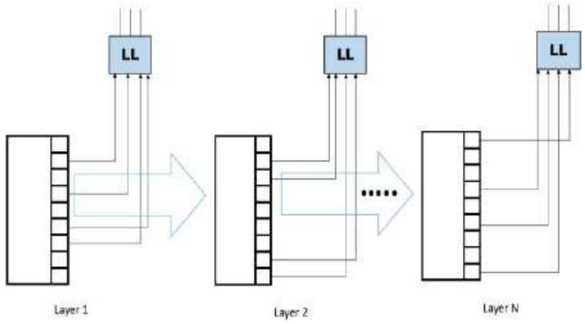

Fig. 1. Defense in Depth Approach

AES Decryption. AES algorithm is widely used symmetric cryptographic algorithm as it is more secure and has low cost for implementation. AES decryption algorithm is iterative in nature. The transformation occurs in every round of the decryption algorithm. Each round consists four subprocess. The last round is an exception as it excludes the Inverse Mix Column subprocess. AES Decryption algorithm has 4 main components. Plain text, Secret key, Cipher text and Decryption algorithm. AES Decryption algorithm consists of four subprocesses. Inverse Shift rows, Inverse Substitution Bytes, Add round key, Inverse Mix column. AES core is vulnerable to attacks. Absence of strong secure system has led to such malicious attacks and insertion of trojans. Numerous techniques are implemented to detect the presence of Trojans. But the call is for a safe and smart technique to safeguard the IC by adding extra layers of security using logic locking technique.

There are three types of AES decryption algorithms depending on key size. AES supports key size of 128, 192 and 256 bits. The number of rounds increases with respect to key size. In AES algorithm, the input text data size always remains 128 bits. The organization of AES decryption algorithms are illustrated in Table I.

TABLE I. ORGANIZATION OF AES

Type	Key Size	Data Size	Rounds
AES 128	128	128	10
AES 192	192	128	12
AES 256	256	128	14

Logic Locking. Logic Locking is an emerging technology in the sphere of Design for security. Purpose behind using logic locking technique in this work is to protect against vulnerable attacks. In this technique, the attacker is unaware of the presence of logic lock block and hence obtains corrupted text while performing attacks. This technique reduces the probability of the model being prone to attacks. Lock module is inserted to ensure that the correct output is obtained only in presence of correct password. The output is corrupted when incorrect password is provided at input.

Logic lock block is inserted in each subprocess of AES Decryption algorithm. It is inserted judiciously at system level in such a manner where the probability of differentiating it from the original circuit is minimal. The 16-bit lock key is flashed in tamper proof memory (D flash). The lock block consists of non-linear weighted hexadecimal component and a comparator. Comparator compares the weighted hexadecimal with the input password.

The naming convention of the block is in systematic form. In the naming convention, key size is mentioned first followed by B which indicates Block and then followed by numerical value which in turn indicates the subprocess as illustrated in the Table II. For example, 192-B3 indicates that the logic lock block is inserted in the AddRound Key subprocess of AES-192 algorithm. The schematic of AES algorithm with lock block using Defense in Depth is depicted in Figure 2.

TABLE II. NAMING CONVENTION

Value after B	Corresponding Sub-Process
1	Inverse Shift Row
2	Inverse Substitution Byte
3	AddRound Key
4	Inverse Mix Column

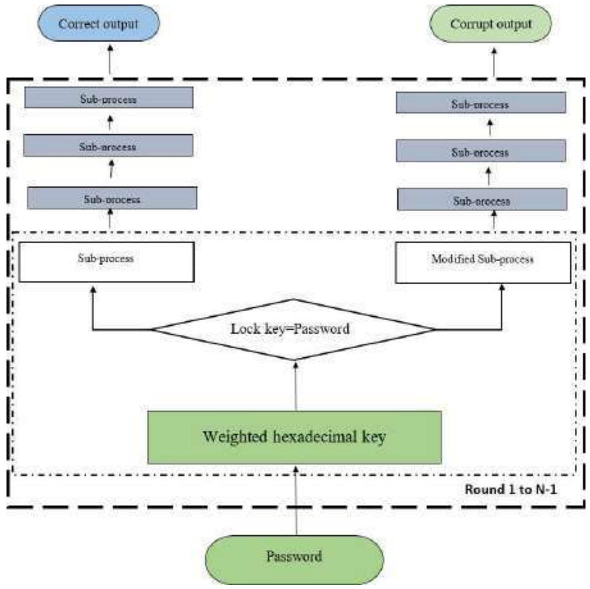

Fig. 2. AES lock block in Defense in Depth approach

1) *Insertion of Lock Block in Inverse Shift row:* The lock block accepts the password and maps the bits to weighted hexadecimal bits and compares it with the lock key in tamper proof memory. The block unlocks and executes the remaining subprocess without alteration if the password provided at input is correct. If the password provided is incorrect, the inverse shift rows sub process is altered by varying the offsets to shift the rows cyclically.

2) *Insertion of Lock Block in Inverse Substitution Byte:* The lock block accepts the password and maps the bits to weighted hexadecimal bits and compares it with the lock key in tamper proof memory. The block unlocks and executes the remaining subprocess without alteration if the password provided at input is correct. If the password provided is incorrect, the inverse substitution sub process is altered by replacing the mapping elements in the substitution box.

3) *Insertion of Lock Block in Add Round Key:* The lock block accepts the password and maps the bits to weighted hexadecimal bits and compares it with the lock key in tamper proof memory. The block unlocks and executes the remaining subprocess without alteration if the password provided at input is correct. If the password provided is incorrect, the AddRound key subprocess is altered by including additional XOR function to perform XOR operation with a random constant.

4) *Insertion of Lock Block in Inverse Mix Column*: The lock block accepts the password at input and maps the bits to weighted hexadecimal bits and compares it with the lock key in tamper proof memory. The block unlocks and executes the remaining sub process without alteration if the lock key provided at input is correct. If the password provided is incorrect, the inverse mix column sub process is altered by performing XOR operation on the resultant value of multiplicative inverse.

B. *Performance Metrics*

Performance metric such as distance metrics, power, time and Information gain are evaluated to estimate the performance of the Defense in Depth approach by examining Lock block. Distance metrics such as Hamming distance, Levenshtein distance and Jaro distance are utilized to estimate the performance of the algorithm and evaluate the extent to which the output is corrupted when incorrect password is provided at the input.

Hamming Distance. Hamming distance is the difference between the number of bits in output state matrix and input state matrix. Substitution of bits are carried out for evaluating the hamming distance.

Levenshtein Distance. Levenshtein distance is the difference between the number of bits in the input state matrix and output state matrix. Insertion, deletion and substitution operations are carried out to transform input state matrix to output state matrix for evaluating Levenshtein distance.

Jaro Distance. Jaro distance is difference between the number of bits in input state matrix and output state matrix. Transposition is carried out to transform from input state matrix to output state matrix for evaluating Jaro distance.

Power and Time. Power and time consumed is measured by performing side channel power analysis. Side channel power analysis is performed on Chip Whisperer Lite board using the measurement setup.

Information Gain. Information gain is a measure of the information obtained. Entropy is lack of order. Information gain is the difference of entropy before transformation and after transformation. The formula for Information gain is given by formula, Information Gain = [entropy(parent)] – [average entropy(children)]. Entropy is computed using the formula, Entropy = $- \sum P_i \log_2 P_{i.}$

IV. RESULTS AND ANALYSIS

This work is implemented on AES symmetric cryptographic decryption core with key size of 128,192 and 256 bits. Table III depicts the correct output and corrupted output values of AES crypto primitive for varying inputs when Lock block is inserted.

In figures 3,4 and 5, x-axis indicates the key size and subprocess where the lock block is judiciously inserted and the y-axis indicates the dissimilarity measure of input text and output text. The uncorrupted output is obtained by unlocking the lock block if correct password is provided at input whereas corrupted output is obtained when the lock block remains locked if incorrect password is provided at input.

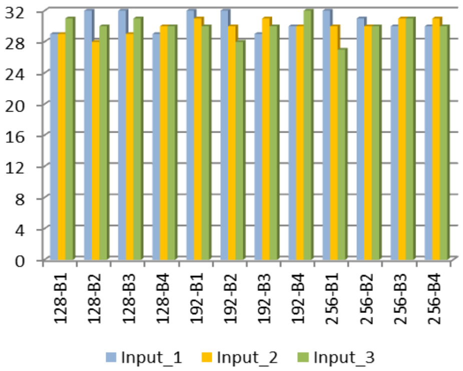

Fig. 3. Analysis of Hamming distance

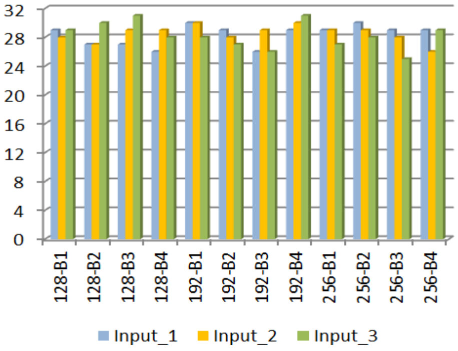

Fig. 4. Analysis of Levenshtein distance

Figure 3 depicts the analysis of Hamming distance in AES 128,192 and 256 when AES Lock block is judiciously inserted in the each of the four subprocess of AES Decryption algorithm for three different set of input cipher text and input secret key. From the figure, it can be inferred that the output text is entirely corrupted with Hamming distance greater than 80%. Figure 4 depicts the analysis of Levenshtein distance in AES 128,192 and 256 when AES Lock block is judiciously inserted in each of the four sub process of AES Decryption algorithm for three different set of input cipher text and input secret key. From the above figure, it can be inferred that the output text is entirely corrupted with Levenshtein distance greater than 80%.

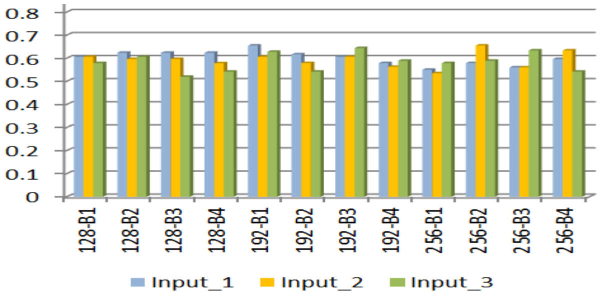

Fig. 5. Analysis of Jaro distance

Figure 5 depicts the analysis of Jaro distance in AES 128,192 and 256 when AES Lock block is judiciously inserted in each of the four subprocess of AES Decryption algorithm for three different set of input cipher text and input secret key. From the Figure, it can be inferred that the output text is entirely corrupted with Jaro distance greater than 50%.

It can be inferred that the hamming distance, Levenshtein distance and Jaro distance is above 50%. Logic locking technique is resilient to brute force attack as this technique is over shadowing the vulnerabilities due to added security control access layer. Further this technique is sturdy enough to resist key sensitization attack since the conversion of input password to non-linear weighted hexadecimal tightens the security by making it difficult for the attacker to identify correlation. between input password and weighted hexadecimal. Also, Reverse engineering is inhibited by mystifying the attacker through layered structure of defense in depth approach.

Further, power consumption and execution time are measured using ChipWhisperer Lite board. The power consumed and execution time while running conventional AES Decryption core and AES Decryption core with AES lock block is depicted in Figure 6 and Figure 7 respectively.

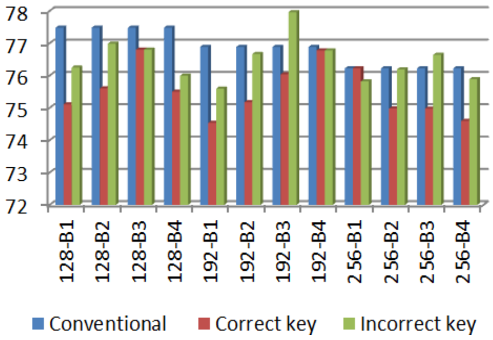

Fig. 6. Analysis of Power Measurements

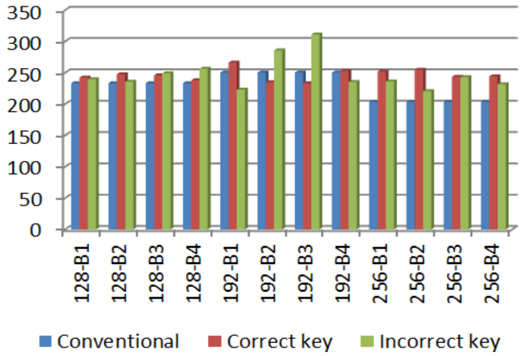

Fig. 7. Analysis of Execution time

Figure 6 depicts the analysis of Power when AES lock block is judiciously inserted in each of the four subprocess of AES 128, 192 and 256 when correct password and incorrect password are provided at input. The x-axis indicates the key length and subprocess where it is inserted and the y-axis indicates the power consumption. From the plot, it can be clearly inferred that the difference between power consumed by conventional AES core and AES core with AES lock block is less than 4 % (negligible differences of µW). Figure 7 depicts the analysis of execution time when AES lock block is judiciously inserted in each of the four subprocess of AES 128,192 and 256 when correct password and incorrect password are provided at input. The x-axis indicates the key length and subprocess where it is inserted and the y-axis indicates the execution time of the circuit.

The difference between execution time of conventional AES core is less than AES core with AES lock block core by 6% for key sizes 128 and 192, and 20% for key size of 256 (negligible differences in ms). Hence, AES core with AES lock block does not drastically increase the power consumption and execution time. So, it is a difficult task for attackers to obtain the password using side channel attacks.

Information gain has been evaluated considering the power consumption attribute. Information gain for AES 128,192 and 256 has been evaluated which has depicted in Table III. It can be inferred from the table that the information gain obtained is less. It is extremely difficult to rely on the information obtained from power consumed to differentiate the correct output and incorrect output when Lock block is inserted.

TABLE IV. INFORMATION GAIN

	Entropy	**Average Entropy**	**Information Gain**
AES 128	0.992774	0.853473	0.139301
AES 192	0.896038	0.775885	0.120153
AES 256	0.746234	0.651909	0.094326

V. CONCLUSION

In this work, the AES lock block has been successfully designed and judiciously inserted into AES cryptographic decryption core in each of the four subprocess of AES decryption algorithm. Power consumed and execution time was measured in XMEGA microcontroller with difference of less than 6% and 20% respectively. Information gain evaluated is also minimal to perform attacks. This technique achieved 80% Hamming distance, 80% Levenshtein distance and 50% Jaro distance. This technique is resilient to Key sensitization attack, reverse engineering and brute force attack. Hence, it is validated that the proposed method is an efficient defense in depth approach which uses logic locking technique. This approach is an effective security measure to avoid unauthorized access on AES Decryption core.

***Abstract*–The article discusses partially defined discrete functions and investigates the problem of logical continuation of such functions in the class of canonical normal forms. A theorem is proved on the invariant continuation of a multivalued function in the class of canonical forms, which does not depend on the adopted coding. An algorithm for constructing a set of invariant points independent of the adopted encoding and software for such an invariant continuation are constructed.**

Key words: encoding, logic, conjunction, disjunction, sets, quasi-Boolean invariant, synthesis, equivalent.

INTRODUCTION

Extension of a discrete function by the invariance principle. Let $S^n = S_1 \times S_2 \times ... \times S_n$ the Descartes product where $S_i,\ i = \overline{1, n}$ is an arbitrary collection of real numbers. Consider a formula (metric) $\rho(\alpha, \beta) = \sum_{i=1}^{n} |\alpha_i - \beta_i|$. A ball $S_R^{\tilde{\alpha}}$ with center $\tilde{\alpha}$ and radius r at S^n is the set of all $\tilde{\beta} \in S^n$ such that $\rho(\tilde{\alpha}, \tilde{\beta}) \le r$ [1-3].

Let $F(x_1, x_2, ..., x_n)$ is a discrete function, taking k values $\{0, 1, ..., k-1\}$ be defined on the set $M \subseteq S^n : F(\tilde{x}) = j,$ if $\tilde{x} \in M_j,\ (j = \overline{0, k-1}),$ $M = \bigcup_{i=0}^{m} M_i$ and $M_i \bigcap M_j = \varnothing$. Function $F'(\tilde{x})$ is called a continuation $F(\tilde{x})$, if $F'(\tilde{x}) = j$, for $\tilde{x} \in M_j,$ $M_j \subseteq M'_j,$ $M_i \bigcap M_j = \varnothing,\ \left(j = \overline{0, k-1}\right)$ for $i \ne j.$

It is easy to see that you can find different function extensions $F(\tilde{x})$, that are not equal to each other. Let us define the set of points where the continuation of the function $F(\tilde{x})$ does not depend on the adopted encoding [4-15].

Let us define an elementary function (e.f.)

$$\mathfrak{A}_{\tilde{\alpha},r}^{r}(\tilde{x}) = \begin{cases} \gamma, & \text{if } \ \tilde{x} \in S_r^{\tilde{\alpha}}, \\ 0, & \text{otherwise.} \end{cases}$$

The ball $S_r^{\tilde{\alpha}}\left(\mathfrak{A}_{\tilde{\alpha},r}^{\gamma}\right)$ is called admissible for $F(\tilde{x})$ and

$$M_j, \text{ if } S_n^{\tilde{\alpha}} \bigcap M_j \ne \varnothing, \quad S_n^{\tilde{\alpha}} \subseteq S^n \setminus \bigcup_{j=1}^{\gamma-1} M_j.$$

Further we will investigate the representation of the function $F(\tilde{x})$ in the form of the maximum of the e.f., the domain of which is chosen to be balls.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Let M_i - a ball $S_{r_i}^{\tilde{\alpha}_i}$ with radius r_i and center at $\tilde{\alpha}_i$, $i=\overline{0, n}$.

Consider a point $\tilde{\alpha}$ to preserve the encoding of the ball $S_r^{\tilde{\alpha}}$ and a point $\tilde{\delta}_j$ on a segment $(\tilde{\alpha}, \tilde{\alpha}_j)$, $j=\overline{1, n}$, $j \neq i$ such that $\rho(\tilde{\alpha}, \tilde{\delta}_j)=\rho(\tilde{\alpha}, \tilde{\alpha}_j)-r_j$. It is easy to see that, if $\rho(\tilde{\alpha}, \tilde{\delta}_j) \geq \rho(\tilde{\alpha}, \tilde{\alpha}_i)-r_i$ for any $j \neq i$, then $\tilde{\alpha}$ will be a point that preserves the code of the set M_i.

Let a set of discrete *k*-valued functions depending on *n* variables be given, i.e. the set of functions defined on the set of all vertices of the Descartes product $S^n=S_1 \times S_2 \times \ldots \times S_n$ where is S_i, $i=\overline{1, n}$ an arbitrary collection of real numbers $i=\overline{0, n}$ and taking values from the set $\{0,1, \ldots, k-1\}$. In this consideration, there is a one-to-one correspondence between multivalued discrete functions, depending on the *n* arguments and subsets $N_f \subseteq S^n$. The function $f(x_1, x_2, \ldots, x_n)$ and the subset $N_f \subseteq S^n$ have a one-to-one correspondence in the case

$$f(x)=\begin{cases}\gamma, & if \;\; x \in N_f \\ 0, & if \;\; x \in S^n \setminus N_f\end{cases},$$

here $\gamma \in E_f \subseteq\{0,1, \ldots, k-1\}$.

It is assumed that the set E_f splits the function $f(x_1, x_2, \ldots, x_n)$ into the set of subfunctions $f_{\gamma_1}(\tilde{x}), f_{\gamma_2}(\tilde{x}), \ldots, f_{\gamma_m}(\tilde{x})$, and the set N_f into pairwise disjoint subsets $N_{f_{\gamma_1}}, N_{f_{\gamma_2}}, \ldots, N_{f_{\gamma_m}}$, where $m=|E_f|$,

$$f_{\gamma_i}(\tilde{x})=\begin{cases}\gamma_i, & if \;\; f(x)=\gamma_i \\ 0, & if \;\; f(x) \neq \gamma_i\end{cases},$$

$$N_{f_{\gamma_i}}=\{\tilde{\alpha}:(\tilde{\alpha} \in S^n) \wedge(f(\tilde{\alpha})=\gamma_i)\}, \; (i=\overline{1, m}).$$

It is easy to see that

$$\mathrm{J}_{\mathrm{M}}(x)=\begin{cases}k-1, & if \;\; x \in \mathrm{M} \\ \;\;0, & if \;\; x \notin \mathrm{M}\end{cases},$$

where $\mathrm{M} \subseteq E_k=\{0,1,2, \ldots, \mathrm{k}-1\}$.

An elementary function (e.f.) is the expression [16]

$$\mathfrak{A}=\min [J_{M_1}(x_1), J_{M_2}(x_2), \ldots, J_{M_n}(x_n), \gamma],$$

where

$$\varnothing \neq \mathrm{M}_j \subseteq E_k, \; (j=\overline{1, n}).$$

In the further presentation, for the sake of convenience, the formula $\max [\mathfrak{A}_1, \mathfrak{A}_2, \ldots, \mathfrak{A}_m]$ will be conventionally denoted as $\mathfrak{A}_1 \vee \mathfrak{A}_2 \vee \ldots \vee \mathfrak{A}_m=\bigvee_{i=1}^m \mathfrak{A}_i$: if $\mathfrak{A}_i$ there is an analogue of an e.f., then the indicated formula will be called the canonical normal form (c.n.f.).

The area of truth e.f. $\mathfrak{A}$ we will call the set $N_{\mathfrak{A}}$, in which the e.f. $\mathfrak{A}$ equals γ. It is easy to see that the domain $N_{\mathfrak{A}}=\prod_{j=1}^n M_j$ is a ball (a subset of a set S^n) of a Descartes product S^n. With such a geometric consideration of the e.f. matches the ball $N_{\mathfrak{A}}$, of the Descartes product S^n.

The rank of e.f. $\mathfrak{A}$ let's call the number

$$r(\mathfrak{A})=\sum_{j=1}^n(k-|\mathrm{M}_j|)=kn-\sum_{j=1}^n|\mathrm{M}_j|.$$

The formula $\mathfrak{M}=\bigvee_{i=1}^t \mathfrak{A}_i$, where everything $\mathfrak{A}_i$, $(i=\overline{1, t})$ is e.f., will be called the canonical normal form (c.n.f.).

Note that each multivalued discrete function $f(x_1, x_2, \ldots, x_n)$ corresponds to a non-empty class of c.n.f. that implement this function. The set of all balls corresponding to the e.f. a certain c.n.f. from this class, defines the coverage N_f of balls from S^n. Whence it follows that subsets $\mathrm{M} \subseteq E_k^n$ can be specified using c.n.f [17, 18].

Let $I=\{N_{\mathfrak{A}}\}$, there be some subset of balls from S^n.

A ball $N_B \in I$ is called maximal with respect to M if it does not exist in I. the ball $N_{\mathfrak{A}}$, such that $N_{\mathfrak{A}} \neq N_B$ and $N_{\mathfrak{A}} \supseteq N_B$.

To represent the function $f(x_1, x_2, \ldots, x_n)$ in the form of c.n.f. we considered its quasi-Boolean representation: $f=f_{\gamma_1} \vee f_{\gamma_2} \vee \ldots \vee f_{\gamma_m}$ moreover $\gamma_1<\gamma_2<\ldots<\gamma_m$.

It is easy to see that for the same function $f(\tilde{x})$ can have several equal quasi-Bullian representations. Indeed,

$$\begin{aligned} f &= f_{\gamma_1} \vee f_{\gamma_2} \vee \ldots \vee f_{\gamma_m} = \\ &= f^*=f_{\gamma_1}^* \vee f_{\gamma_2}^* \vee \ldots \vee f_{\gamma_m}^*, \end{aligned}$$

where

$$N_{f_{\gamma_i}^*}=N_{f_{\gamma_i}} \bigcup Q_i,$$

$$Q_i \subseteq \bigcup_{j>i} N_{f_{\gamma_j}}, \left(i=\overline{1, m}\right).$$

We will consider only one "maximum" view

$$f' = f'_{\gamma_1} \vee f'_{\gamma_2} \vee \ldots \vee f'_{\gamma_m},$$

where

$$N_{f'_{\gamma_i}} = \bigcup_{j=1}^{n} N_{f_{\gamma_j}}, \ \left(i=\overline{1,m}\right).$$

Consider all maximal balls $N_{B_j^i}, \left(i=\overline{1, m}\right)$, included in $N_{f'_{\gamma_i}}$, intersecting with $N_{f_{\gamma_i}}$ and such that the value B_j^i is equal γ_i to $N_{B_j^i}, \left(i=\overline{1, m}\right)$.

$\mathfrak{M} = \bigvee_{i=1}^{m} \bigvee_{j=1}^{I_i} B_j^i$ will be called the reduced canonical normal form of the function $f\left(\tilde{x}\right)$.

A covering of a set N_f with the maximal balls is said to be irreducible if, after removing any of the balls included in it, it will not be a covering.

C.n.f., realizing a function f is called dead-end if it corresponds to an irreducible cover of the set N_f.

Consider a multivalued function $F\left(x_1, x_2, \ldots, x_n\right)$ defined on

$$M \subseteq S^n : F\left(\tilde{x}\right) = \gamma_j, \text{ if } \tilde{x} \in M_j, \left(j=\overline{1, m}\right),$$

$$m<k, \ \gamma_j \in E_k, \ M = \bigcup_{i=0}^{m} M_i \text{ and } M_i \bigcap M_j = \varnothing \text{ for}$$

$\left(i \neq j, i, j = \overline{0, m}\right)$. Moreover $\gamma_1 < \gamma_2 < \ldots < \gamma_m, \ \gamma_0 = 0.$

Hence $F\left(x_1, x_2, \ldots, x_n\right)$ is defined by specifying pairwise disjoint sets $\mathrm{M}_0, \mathrm{M}_1, \ldots, \mathrm{M}_{\mathrm{m}}$. The function $F\left(\tilde{x}\right)$ is partially defined on the entire set S^n. There are various extensions in the class of multivalued discrete functions $F\left(\tilde{x}\right)$ that are not equivalent to each other.

The task of this work is to find the simplest, in a sense, additional definitions.

For $F\left(\tilde{x}\right)$, select all maximal balls $N_{B_j^i}$, $\left(i=\overline{1, m}, \ j=\overline{0, I_i}\right)$, contained in $E_k^n \setminus \bigcup_{v=0}^{i-1} M_v$, intersecting with M_i such that the value B_j^i is γ_i.

C.n.f. $\mathfrak{M} = \bigvee_{i=1}^{m} \bigvee_{j=1}^{I_i} B_j^i$ will be called the abbreviated normal form for $F\left(\tilde{x}\right)$. It is easy to see that c.n.f. $\mathfrak{M}_{\Sigma\mathrm{T}F}$ is uniquely determined by the function $F\left(\tilde{x}\right)$.

Let us now indicate the points at which, when the values of the function change $F\left(\tilde{x}\right)$ (transition to $F'\left(\tilde{x}\right)$), the values change $\mathfrak{M}_{\Sigma\mathrm{T}F}$ (transition to $\mathfrak{M}_{\Sigma\mathrm{T}F'}$).

Consider a multivalued discrete function $F\left(x_1, x_2, \ldots, x_n\right)$ defined on $M \subseteq S^n$:

$$F\left(\tilde{x}\right) = \gamma_j, \text{ if } \tilde{x} \in M_j, \left(j=\overline{0, k-1}\right), \tag{2}$$

where $M = \bigcup_{i=0}^{m} M_i$ and $M_i \bigcap M_j = \varnothing \ i \neq j.$

We denote by $\left\{\pi\right\}$ the set of all permutations of the set

$$\left\{0, 1, \ldots, k-1\right\} : \pi = \left(i_0, i_1, \ldots, i_{k-1}\right).$$

The functions

$$F_\pi\left(\tilde{x}\right) = i_j, \text{ if } \tilde{x} \in M_j, \left(j=\overline{0, k-1}\right),$$

we call π is a permutation of $F\left(\tilde{x}\right)$.

We will say that a point $\tilde{\alpha} \in E_k^n \setminus \mathrm{M}$ preserves the encoding (code) of a set $M_j \subseteq M, \ j=\overline{0, k-1}$ with respect to a permutation π, if $\mathfrak{M}_{\Sigma\mathrm{TF}}\left(\tilde{\alpha}\right) = j$ and $\mathfrak{M}_{\Sigma\mathrm{TF}_\pi}\left(\tilde{\alpha}\right) = i_j$.

A point $\tilde{\alpha} \in E_k^n \setminus \mathrm{M}$ is called a point that preserves the encoding of the set M_j, if it preserves the encoding M_j with respect to any permutation $\pi \in \left\{\pi\right\}$.

Let

$$\mathfrak{M} = \bigvee_{\pi : \pi \in (\pi)} \mathfrak{M}_{\Sigma\mathrm{TF}_\pi} \ .$$

Theorem. The point $\tilde{\alpha} \in E_k^n \setminus \bigcup_{i=0}^{k-1} \mathrm{M}_i$ preserves the code of the set M_j, then and only if, when:

1) in c.n.f. $\mathfrak{M}$ there is an e.f. $\mathfrak{A}$ such that

$$N_{\mathfrak{A}} \bigcap M_j \neq \varnothing, \ \tilde{\alpha} \in N_{\mathfrak{A}}, \ N_{\mathfrak{A}} \bigcap M_i = \varnothing,$$

where $\left(i = 0, \ldots, j-1, j+1, \ldots, k-1\right)$;

2) each ball $N_{\mathfrak{A}}$ where e.f. $\mathfrak{A}$ included in c.n.f.

$\mathfrak{M}$.

Has common points with M_i, $(i \neq j)$ and contains a point M_j.

Proof. Necessity. Let the point $\tilde{\alpha}$ preserves the code of the set M_j Then for the encoding $\pi = \{i_0, i_1, \ldots, i_{j-1}, i_{k-1}\}$ of c.n.f. $\mathfrak{M}_{\Sigma TF_\pi}$ there is an e.f. $\mathfrak{A}$ such that $\mathfrak{A}(\tilde{\alpha}) = k-1$.

By definition,

$$N_{\mathfrak{A}} \subseteq E_k^n \setminus \bigcup_{\substack{i=0 \\ i \neq j}}^{k-1} \mathrm{M}_i,$$

i.e. the interval $N_{\mathfrak{A}}$ does not intersect with any set M_i, $(i \neq j)$. The first condition is proved.

Let us now consider a permutation π in which $i_j = 0$. Suppose that in the c.n.f. $\mathfrak{M}_{\Sigma TF_\pi}$ there is an e.f. $\mathfrak{A}$ such that the ball $N_{\mathfrak{A}}$ has a common point with M_l, $(l \neq j)$ and contains M_j of the point $\tilde{\alpha}$.

Let us assume that this ball contains no points of the set M_j. It is easy to see that in this case $\mathfrak{M}_{\Sigma \mathrm{TF}_\pi}(\tilde{\alpha}) \neq 0$ and the permutation π also does not preserve the code of the set M_j. We have proved the second necessary condition for the preservation of the point $\tilde{\alpha}$ of the set M_j.

Sufficiency. Suppose the conditions of the theorem are true and for each ball $N_{\mathfrak{A}}(\mathrm{M}_l, \tilde{\alpha}), (l \neq j)$, having a point $\tilde{\alpha}$, intersecting the sets M_i and M_j, e.f. $\mathfrak{A}$ - belongs to $\mathfrak{M}_{\Sigma TF_\pi}$. Moreover, in any encoding $\pi = \{i_0, i_1, \ldots, i_{k-1}\} \in \{\pi\}$ e.f. $\mathfrak{A}(\tilde{\gamma}) = i_l$, for $\tilde{\gamma} \in N_\eta(\mathrm{M}_l, \tilde{\alpha})$. We denote by N_B, the ball such that $N_B \cap \mathrm{M}_j \neq \varnothing$, $N_B \cap \mathrm{M}_l = \varnothing$, $(i \neq l)$, $\tilde{\alpha} \in N_B$ for any permutation $\pi = \{i_0, i_1, \ldots, i_{k-1}\}$ of the e.f. $\mathfrak{A}(\tilde{\gamma}) = i_j$ for $\gamma \in N_B$, $B \in \mathfrak{M}_{\Sigma TF_\pi}$.

If in some encoding π the value of the function F_π on the sets of the set M_I less than the values F_π at the M_j, that is $i_j > i_I$, then the point $\tilde{\alpha}$ will be covered by intervals $N_{\mathfrak{A}}(\mathrm{M}_l, \tilde{\alpha})$, but will also be covered by the interval N_B. Since the external operation in c.n.f. is to take a maximum, then $\mathfrak{M}_{\Sigma TF_\pi}(\tilde{\alpha}) = i_j$.

If $i_j > i_l$, then $\mathfrak{M}_{\Sigma TF_\pi}(\tilde{\delta}) = i_l$ for $\tilde{\delta} \in N_{\mathfrak{A}}(\mathrm{M}_l, \tilde{\alpha})$.

But in the interval $N_{\mathfrak{A}}(\mathrm{M}_l, \tilde{\alpha})$, there exists a point $\tilde{\gamma}$ belonging to M_j, such that $\mathfrak{M}_{\Sigma TF_\pi}(\tilde{\gamma}) = i_j$, and by hypothesis $i_j > i_l$. Consequently, the function defined by us at a point $\tilde{\gamma}$ is not equal i_j. Therefore, each such interval $N_{\mathfrak{A}}(\mathrm{M}_l, \tilde{\alpha})$, cannot participate in constructing an extension.

The sufficiency of the theorem is proved.

ALGORITHM FOR THE SYNTHESIS OF A SET INVARIANT WITH RESPECT TO ENCODING AND CONTINUATION

Based on the results of the theorem, we construct an algorithm for synthesizing a set of vertices of the Descartes product

$$S^n = S_1 \times S_2 \times \ldots \times S_n \text{ of sets } \mathrm{M}_j, \left(j = \overline{0,\, k-1}\right)$$

preserving the encoding when obtaining optimal extensions of a partially defined function $F(\tilde{x})$.

Let M_j be the set of all vertices $\tilde{\alpha} \in S^n$, of the coding-preserving set M_j, $\left(j = \overline{0,\, k-1}\right)$ and $\tilde{M} = \bigcup_{i=0}^{k-1} \tilde{M}_i$.

We consider the algorithm for the synthesis of sets M_j. We describe it as follows:

1. For any M_j we find $\{N_j\}$ the set of balls $N_{\mathfrak{A}}$ such that $N_{\mathfrak{A}} \cap \mathrm{M}_j \neq \varnothing$ and $\mathfrak{A} \in \mathfrak{M}$.
2. For $\{N_j\}$, $\left(j = \overline{0,\, k-1}\right)$, construct the set of all balls $\{N_j\}'$ whose intersection with M_i, $\left(i = \overline{0,\, k-1}\right)$ are empty.
3. If $\{N_j\} \neq \varnothing$, then in $\bigcup_{N : N \in \{N_j\}'} N$ we define points $\tilde{\alpha}$, that are not included M_j and are such that there is no ball $N_{\mathfrak{A}}$ that is contained $\tilde{\alpha} : N_{\mathfrak{A}} \cap \mathrm{M}_j \neq \varnothing$, in $\bigcup_{N : N \in \{N_j\}'} N$ and e.f. $\mathfrak{A} \in \mathfrak{M}$. It is easy to see that the multitude of all such $\tilde{\alpha}$, forms M_j, $\left(j = \overline{0,\, k-1}\right)$.
4. Combining of the sets $\tilde{\mathrm{M}}_0, \tilde{\mathrm{M}}_1, \ldots, \tilde{\mathrm{M}}_{k-1}$ we obtain the set $\tilde{\mathrm{M}}$.

DESCRIPTION OF THE PROGRAM FOR THE SYNTHESIS OF AN INVARIANT SET.

For a given set of vertices, divided into classes, the program constructs an invariant continuation for each class.

There are eight procedures in her body. A diagram of the interaction is shown in Figure 1.

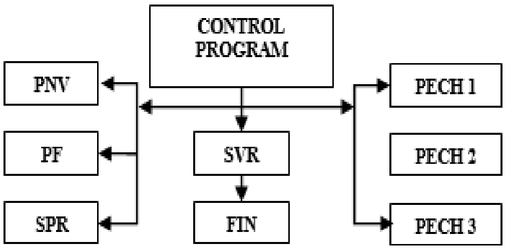

Figure 1

The SPR procedure expands the specified vertex to an interval of dimension (n-1). The PF (P) procedure is used to find the intersection of intervals; P-sign (if for one variable P = 0, then the intervals intersect; if for all variables P = 0, then the intervals intersect). The PNV procedure is used to search for such vertices that intersect with the obtained interval of dimension (n-1). The SVR procedure for a given interval synthesizes the vertices included in this interval. FIN builds index working sets. The procedures PECH 1 (A_1, A_2, PM), PECH 2 (A_1, A_2, PM), PECH 3 (A_1, A_2, PM) are used to print one-, two- and three-dimensional arrays, respectively, where A_1, A_2 are boundary values indices, PM is the array to be printed.

INSTRUCTIONS FOR THE PROGRAM

The following values are the initial values for the program: CK - number of classes; K is the significance of the function; N is the number of variables; CB is the number of vertices in all classes; R_1, R_2, R_3, R_4, R_5 - dimensions of arrays used for intermediate and final results; $R_1 = N^{R_2}$; R_2 = max (N, CB-1); R_3 is the number of extensions in MR; R_4 - number of vertices in extensions from MR; R_5 is the number of vertices in the invariant continuation; AK (CBxN) - a table, each row of which corresponds to one vertex of the cube E_k^n, the *i*-th element of the row is equal to $2^{k-\alpha-1}$, where α - is the value of the *i*-th variable; CVK (1x (CK + 1)) - vector, *i* + 1 - th element of which is equal to the number of the last vertex of the *i* - th class; Q(8x8) is the matrix used to check for intersection of intervals:

$$Q = \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 2 & 2 & 0 & 0 & 2 & 2 \\ 0 & 1 & 2 & 3 & 0 & 1 & 2 & 3 \\ 0 & 0 & 0 & 0 & 4 & 4 & 4 & 4 \\ 0 & 1 & 0 & 1 & 4 & 5 & 4 & 5 \\ 0 & 0 & 2 & 2 & 4 & 4 & 6 & 6 \\ 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \end{vmatrix}$$

The end results are arrays *IV* (1x (CK + 1)) - a vector, the (*i* + 1) th element of which is equal to the number of the last invariant vertex of the i-th class, INP (1xCIV (CK)) is a table, each row of which corresponds to an invariant top.

The block diagram is shown in Figure 2.

Test case. As an example, let's take five vertices of the cube E_3^3, divided into three classes. The initial data are the following: K = 3, N = 3, CK = 3, CB = 5, R1 = 27, R2 = 4, R3 = 100, R5 = 20,

$$A = \begin{vmatrix} 1 & 1 & 2 \\ 2 & 2 & 4 \\ 1 & 4 & 2 \\ 4 & 2 & 2 \\ 4 & 1 & 1 \end{vmatrix},$$

matrix Q and

$$CVK = \begin{vmatrix} 1 \\ 1 \\ 3 \\ 5 \end{vmatrix}.$$

The end result will be

$$CIV = \begin{vmatrix} 0 & 1 & 5 & 8 \end{vmatrix},$$

$$INP = \begin{vmatrix} 2 & 2 & 1 \\ 1 & 0 & 0 \\ 2 & 0 & 0 \\ 1 & 1 & 0 \\ 2 & 0 & 1 \\ 0 & 1 & 1 \\ 0 & 2 & 2 \\ 0 & 1 & 2 \end{vmatrix}.$$

The counting time of the test case is 15 seconds.

CONCLUSION.

The article investigates partially defined multivalued functions and the problem of logical continuation of such functions in the class of canonical normal forms. A theorem is proved on the invariant continuation of multivalued functions in the class of disjunctive norms, which does not depend on the adopted coding. An algorithm for the formation of a set of invariant points, independent of the adopted encoding, and software for such an invariant continuation are constructed.

Abstract- This paper analyzes the impact of two different electrode types from different manufacturers on the statistical lifetime models of Li-ion batteries. The analysis includes some standard goodness of fit tests and analysis of variance. It was found that batteries with a thicker electrode and different physical parameters will have different battery lifetime models.

Index Terms— accelerated life test; Li-ion battery, the goodness of fit tests; reliability; Analysis of variance (ANOVA) test; Weibull model; Lognormal model; Normal model

I. INTRODUCTION

Electrodes are the most significant components in the Li-ion battery. It affects the capacity, power density, and energy density of the battery. Mei found in [1] that the electrode's physical parameters such as thickness and volume play an important role in the heat generation rate and the energy density of the battery. Furthermore, he found that the particle size of the electrode impacts the energy density and power density.

Zhao found in [2] that thicker electrodes can increase the proportion of active materials and increase energy. However, increasing the thickness could negatively affect the thermal and electrochemical performances of Li-ion batteries. Besides, he found that batteries with a thicker electrode have more intensive and uneven temperature responses across the electrochemical cell when discharging under the same rate. This can lead to the depletion of active materials and faster capacity fading of the entire battery. Moreover, he concluded that a Li-ion battery with a thicker electrode is more sensitive to increased discharge rate. This is due to the ohmic heat generated, which led to the deterioration of the Li-ion battery's health

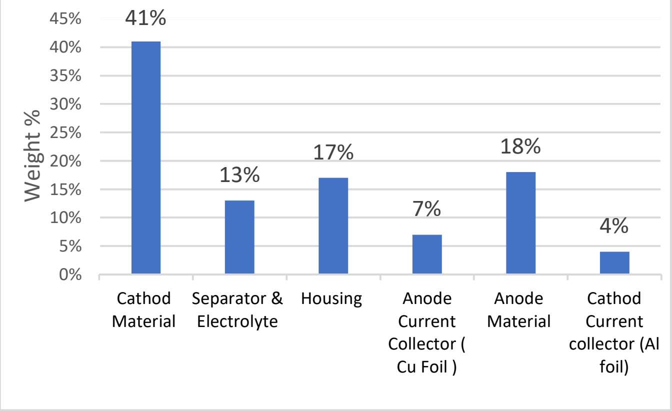

Figure 1. Show the weight percentage occupied by the component of a commercial Li-ion battery. Adapted from [3]

Figure 1 shows the breakdown of the weight percentage by the components of a commercial Li-ion battery. It is very clear from the figure that the electrodes comprise the most significant material components of the Li-ion battery.

Due to the significant impact of the electrodes on the Li-ion battery's performance, and since it comprises the largest and the heaviest material components of Li-ion battery, investigating the effects of the physical parameters of the electrodes on the lifetime models of Li-ion battery is crucial.

There are mainly three methods to model Li-ion batteries lifetime: Physics-based, statistical, and data-driven methods. This paper will focus on the statistical method due to its simplicity and convenience, which would help in further analysis. The statistical approach used in this work is based on trying to fit the experimental data of lifetimes of two types of batteries, B1 and B2, obtained from [4] by some possible parametric statistical models which might not be normally distributed as traditionally assumed in [4]. The three models examined are weibull, lognormal and normal distributions. In fact, this work favors the lognormal as the best fitting model for the B1 type but rejects all for B2. This would be achieved by implementing some standard statistical goodness of fit tests and supported by the analysis of variance technique that was investigated by [4], which will be performed in this work in more detail.

The paper is organized as follows. Section II introduces the experimental data of the two types of batteries obtained from [4]. Section III describes the statistical tools used in analyzing the experimental data. Section IV provides the results of the statistical techniques described in Section III. Lastly, the paper is concluded in section V.

II. DETAILS OF THE EXPERIMENTAL DATA

The experiment in [4] was conducted using the following two cells with the below parameters

TABLE 1: THE PARAMETERS OF THE EXPERIMENT IN [4] CONDUCTED

	B1	B2
Nominal Capacity(Ah)	1.1 Ah	1.35 Ah
Length (mm)	50	50
Width	33.8	33.8
Thickness (mm)	5.4	6.7
Weight (g)	22	28

Arbin BT-2000 was used for testing the cycle life of batteries. The number of cycles to failure for batteries B1 & B2 are in Table2.

B2_7	1.0C	747
B2_8	1.0C	724

III. METHODOLOGY AND METHODS

For the convenience of the reader, this section, as shown in Table 3, lists three of the standard goodness of fit tests that are used to check the appropriateness of the three suggested probability distributions to the experimental data. The table also shows the analysis of variance test, which is used to test the hypothesis that the homogeneity of the mean lifetime between the two types of the batteries and when changing the stress from 0.5C to 1C.

Table 3. Methods used for analyzing the data

Test	Description
Kolmogorov-Smirnov (KS)	KS test [5] is powerful nonparametric goodness of fit test that finds the maximum vertical distance between the empirical and completely specified theoretical distributions. The test is not accurate when the parameters are estimated from data, as in our case. Thus, its modified version [6], referred to as the Lilliefors test, is used instead.
Anderson Darling (AD)	AD goodness of fit test [7] for any completely specified distribution, i.e., with known or estimated parameters considering the adjustment of the test statistic or its critical values. The test applies to the three distributions.
Jarque - Bera (JB)	JB test [8] is very efficient but usually applied after taking the approval of other two tests like KS and AD. The test is only applicable to normal and lognormal, but not Weibull.
Analysis of variance (ANOVA)	ANOVA [9] is used to decide whether there is a significant difference between the means of two independent random variables, given they are sufficiently normally distributed and have similar variances.

IV. RESULTS AND DISCUSSION

The goodness of fit tests:

The goodness of fit tests was conducted using the number of cycles to failure for each battery at a different discharge rate. The tests are applied for the three probability distributions, and the results are reported in Tables 4-9.

TABLES 4: GOODNESS OF FIT TESTS FOR THE DATA SET AT B1 (0.5 C)

	Test	TS	CV	PV	Result
Weibull	KS	0.358	0.385	0.09	Accept
	AD	0.5	0.696	0.19	Accept
	JB	NA			
Lognormal	KS	0.32	0.375	0.15	Accept
	AD	0.374	0.56	0.25	Accept
	JB	0.62	0.214	0.21	Accept
Normal	KS	0.341	0.375	0.11	Accept
	AD	0.431	0.557	0.15	Accept
	JB	0.713	0.852	0.12	Accept

TABLES 5: GOODNESS OF FIT TESTS FOR THE DATA SET AT B1 (1 C)

	Test	TS	CV	PV	Result
Weibull	KS	0.28	0.385	0.47	Accept
	AD	0.348	0.696	0.49	Accept
	JB	NA			
Lognormal	KS	0.335	0.375	0.12	Accept
	AD	0.384	0.557	0.23	Accept
	JB	0.56	0.852	0.31	Accept
Normal	KS	0.32	0.375	0.15	Accept
	AD	0.347	0.557	0.31	Accept
	JB	0.474	0.852	0.5	Accept

TABLES 6: GOODNESS OF FIT TESTS FOR THE DATA SET AT B1 (1C &0.5 C)

	Test	TS	CV	PV	Result
Weibull	KS	0.178	0.29	0.5	Accept
	AD	0.291	0.72	0.65	Accept
	JB	NA			
Lognormal	KS	0.146	0.29	0.5	Accept
	AD	0.212	0.67	0.82	Accept
	JB	0.541	2.12	0.5	Accept
Normal	KS	0.1632	0.29	0.5	Accept
	AD	0.235	0.67	0.74	Accept
	JB	0.571	2.12	0.5	Accept

It can be seen from Tables (4-6) that all models are accepted to fit the data B1 (0.5 C), B1 (1 C), and B1 (1 C and 0.5 C). B1 (0.5 C) prefers lognormal, B1 (1 C) prefers its companion

Weibull [10-12], whereas B1 (1 C and 0.5 C) prefers again lognormal. This suggests that the change in the stress from 0.5 C to 1 C does not change the lifetime model of the batteries of type B1.

TABLES 7: GOODNESS OF FIT TESTS FOR THE DATA SET AT B2 (0.5C)

	Test	TS	CV	PV	Result
Weibull	KS	0.332	0.385	0.15	Accept
	AD	0.645	0.696	0.07	Accept
	JB	NA			
Lognormal	KS	0.301	0.375	0.21	Accept
	AD	0.494	0.557	0.09	Accept
	JB	0.65	0.85	0.17	Accept
Normal	KS	0.3	0.375	0.21	Accept
	AD	0.5	0.56	0.08	Accept
	JB	0.66	0.85	0.16	Accept

TABLES 8: GOODNESS OF FIT TESTS FOR THE DATA SET AT B2 (1C)

	Test	TS	CV	PV	Result
Weibull	KS	0.261	0.385	0.5	Accept
	AD	0.414	0.696	0.33	Accept
	JB	NA			
Lognormal	KS	0.298	0.375	0.22	Accept
	AD	0.419	0.557	0.17	Accept
	JB	0.704	0.852	0.13	Accept
Normal	KS	0.292	0.375	0.25	Accept
	AD	0.406	0.557	0.19	Accept
	JB	0.686	0.852	0.14	Accept

TABLES 9: GOODNESS OF FIT TESTS FOR THE DATA SET AT B2 (1C & 0.5C)

	Test	TS	CV	PV	Result
Weibull	KS	0.368	0.288	0.001	Reject
	AD	1.207	0.717	0.002	Reject
	JB	NA			
Lognormal	KS	0.343	0.288	0.007	Reject
	AD	1.059	0.667	0.003	Reject
	JB	1.608	2.116	0.080	Accept
Normal	KS	0.372	0.288	0.001	Reject
	AD	1.221	0.667	0.001	Reject
	JB	1.752	2.116	0.070	Accept

On the other hand, It can be seen from Tables (7-9) that all models are accepted to fit the data B2 (0.5 C), B2 (1 C) with preference to lognormal and Weibull, but all are rejected or weakly accepted to fit B2 (1 C and 0.5 C). This suggests that the change in the stress from 0.5 C to 1 C does change the lifetime model of the batteries of type B2.

Figures 2a, 2b, and 2c show the probability plot for Normal, Weibull, and lognormal distribution, respectively, for battery B1.

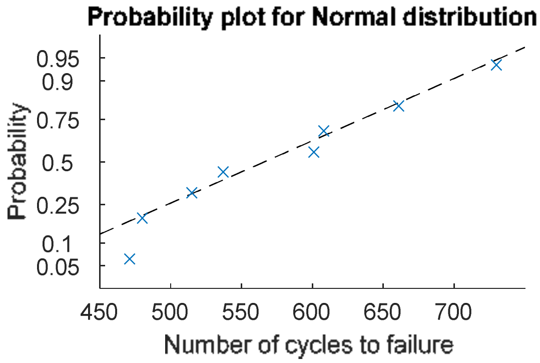

Figure 2a. Probability plot for Normal distribution for B1 at 0.5 C and 1 C.

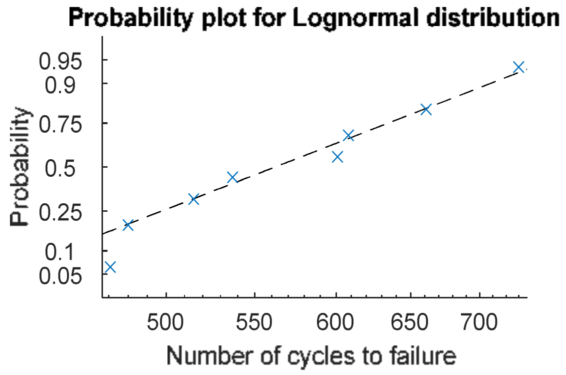

Figure 2b. Probability plot for Lognormal distribution for B1 at 0.5 C and 1 C.

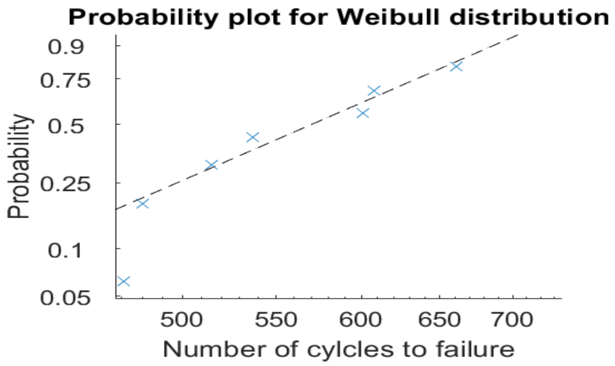

Figure 2c. Probability plot for Weibull distribution for B1 at 0.5 C and 1 C.

It is clear from Figures 2a, 2b, and 2c that almost all the data points are close or on the trend line of the three distributions. This indicates that the data fit the three models in agreement with the goodness of fit tests' results in Tables 4-6.

Figures 3a, 3b, and 3c show the probability plot for normal, Weibull, and lognormal distributions, respectively. For battery B2, where we can see that none of the three distributions is an acceptable fit to the data, which means that B2 (0.5 C) and B2 (1 C) have entirely different distributions as agreed with the goodness of fit test results shown in Tables 7-9.

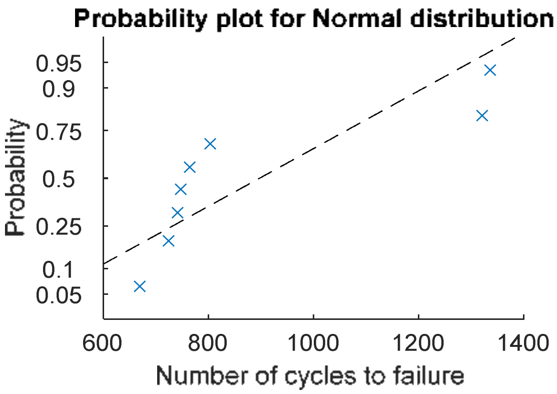

Figure 3a. Probability plot for Normal distribution for B2 at 0.5 C and 1 C.

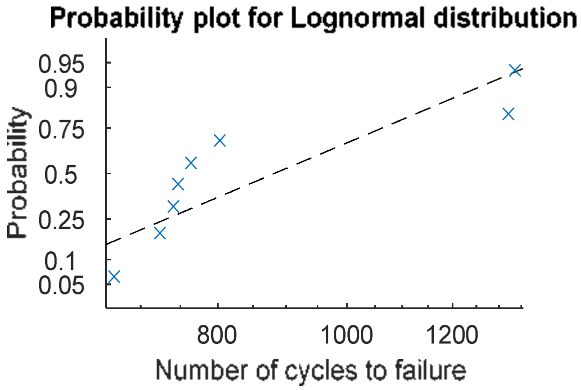

Figure 3b. Probability plot for Lognormal distribution for B2 at 0.5 C and 1 C.

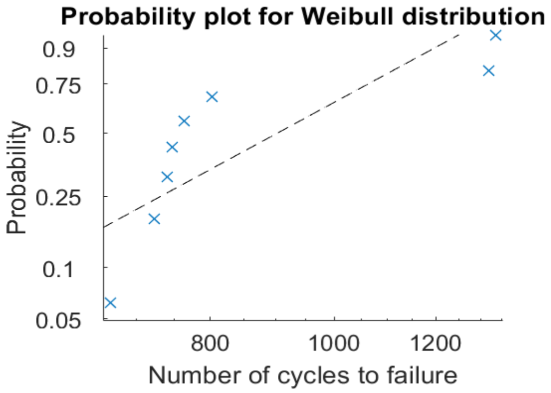

Figure 3c. Probability plot for Weibull distribution for B2 at 0.5 C and 1 C.

Analysis of variance (ANOVA) for the data:

One-way ANOVA is used to test whether two data sets have similar means at a certain appropriate level of significance; here, we choose it to be 0.05. This technique requires that the two data sets be independent, normally distributed, and acceptably similar standard deviations. B1 (0.5 C) and B1 (1 C) data sets satisfy the above assumptions because they are normally distributed as clear from Tables 4 and 5, independent, and have standard deviations of 115 and 77 cycles, which can be confirmed using Levene's test of equality of variances [13]. Indeed, it can be checked that the p-value of Levene's test for this case is equal to 0.5234. Table 10 below shows ANOVA results applied on B1 (0.5 C) and B1 (1 C).

TABLES 10: ANALYSIS OF VARIANCE (ANOVA) FOR B1 (0.5 C) AND B1 (1 C).

	SS	df	MS	F	P-value	F dist
Between Groups	1176.13	1	1176.1	0.1240	0.737	5.9873
Within Groups	56893.8	6	9482.3			
Total	58069.9	7				

Since the p-value in Table 10 is 0.7367>>0.05, where 0.05 is the level of significance, we don't reject the null hypothesis that means values are the same at different discharge rates. This indicates that the mean lifetime of B1 (0.5C) and B1 (1C) are the same. Therefore, for B1 batteries changing the stress from 0.5 to 1 does not change its mean lifetime, which entirely agrees with the goodness of fit tests in Tables 4-6.

On the other hand, for battery type B2, ANOVA is not applicable because the standard deviations are significantly different, which can be again checked by Levene's test. The p-value, in this case, is equal to 0.0054. It is easy to check that the standard deviations of B2 (0.5 C) and B2 (1 C) are equal to 315 and 36 cycles, respectively. In this case, we can look at the mean values of B2 (0.5 C) and B2 (1 C), which are 1056 and 720cycles, respectively, which are very different, whereas the mean values of B1 (0.5 C) and B1 (1 C) are very close of 563 and 588 cycles, respectively.

However, the sample size used in this study is relatively small, where obtaining complete data for the lifetime of such batteries is very difficult due to time and cost limitations. Therefore, it is necessary to increase the sample size and consider efficient censoring [14-16] and truncating [17-18] schemes to overcome this problem.

V. CONCLUSION AND FINDINGS

After conducting the statistical analysis for B1, it is found that B1 (0.5 C) better fits lognormal, and B1 (1 C) better fits Weibull, whereas B1 (0.5 C and 1 C) prefers the lognormal distribution. In fact, Levene's test of equality of variances confirms that the three data sets have similar standard deviations, and ANOVA proves that their means are also very similar. All these standard statistical evidence proves that the B1 battery for 0.5 C and 1 C has the same lifetime.

On the other hand, B2 is sensitive to a high rate of discharge due to the contribution of the ohmic heat generated. By looking at the statistical analysis of B2, it can be seen that B2 (0.5 C) better fits lognormal, and B2 (1 C) better fits Weibull, but B2 (0.5 C and 1 C) does not fit any model. Also, Levene's test shows that these two data sets have very different standard deviations as the standard deviation of B2 (0.5 C) is almost ten times that of B2 (1 C). This violates the main condition of ANOVA, yet, simple calculations for the sample means would help at this stage, which indicates that the mean lifetime significantly decreases when the stress increases from 0.5 C to 1 C.

***Abstract*— This paper presents a streetlamp control system based on the Bolt IoT platform. The aim of this project is conservation of energy by reducing electricity wastage and to minimize the manpower. The scheme utilizes Light Emitting Diodes (LED) that doesn't take huge amount of power and being directional light sources, it can radiate light in specific direction thereby improving the efficiency of the streetlamps. Using LDR with LED lights the intensity can be controlled. IR sensors utilized on one roadside send signals for the LEDs to get glowing for the next specific section of the road after sensing the density and movement of vehicles. The proposed work has achieved a better performance compared to the existing systems.**

***Keywords*— Bolt IoT platform, Internet of Things (IOT), Light intensity, Power saving, Streetlight**

I. Introduction

IOT is the interface of physical devices which permits the devices to contact with each other and make the devices sensed and controlled remotely. These advanced automation and analytics system use artificial intelligence technology to give automated and advanced products and services. IOT based systems permit better transparency, control, and great performance. [1].

IOT has different automation applications like smart parking, smart home, smart roads, smart lighting and so on. Streetlamps are the crucial requirement in present time of transportation for safety purposes and keeping away accidents during night. Despite that in the present occupied life nobody tries to turn it off/on when not needed. This project gives solution to this by reducing manpower and conserving the energy. The current manual streetlamp system has a few problems like timing problem, maintenance issues and connectivity issues. These problems can be eliminated by IOT technology [2]. This system depends on smart and weather adaptive automated street lighting and management [3]. Automation simplifies different issues on the planet economy just as in daily life [4].

The LED (Light Emitting Diode) is viewed as a next generation light source since not exclusively is it energy efficient however it has the long life needed for the illumination of outdoors, workplaces and homes. Recently, the research focus has moved to the plan of an intelligent LED lighting system on account of the fact that the LED is effortlessly combined with different electronics, for example, micro controllers, wired and/or wireless transmission devices and a variety of sensors to execute intelligent lighting system [5]. It utilizes latest innovation in LED light source to replace traditional streetlights such as HID lamps or High-Pressure Sodium lights. The LED lights are embraced in view of its different advantages over existing innovations like power saving because of increased current luminous efficiency, high colour rendering index, reduced maintenance cost, accelerated start-up, and durability [6]. These days flexibility of streetlamp system is being highly challenged. Most part of the control runs in a manual arrangement though some are automated depend on their surrounding parameters. Taking care of remote area location is the main problem. Manual mistakes can develop energy wastage and the performance of the system become low [7]. The point of this paper is to automate the streetlamps to increase the productivity and precision of the system in a practical way and also allows wireless accessibility and control over the system [8]. The main purpose of the system is the energy preservation for the fact that the assets like hydro, coal, thermal that we depend upon are not renewable energy, so presenting power saving components like LDR and LEDs can illuminate a huge region with high-intensity light whenever required [9].

The whole system is based on the Bolt IoT platform. It gives Wireless Fidelity (Wi-Fi) capabilities and cloud connectivity with the sensors in the system. One of the main purposes of connecting all devices to the web and cloud is to have wireless access of those devices. This system helps the user to control the devices from distant areas over the web, cloud or local area network (LAN). But in the LAN type connection range of the system get reduced. If the connection with the devices is over web or cloud then one can control those devices from anywhere on the planet with active internet from both system and user side. Utilizing Bolt IoT we can reduce code size about 80% and it can be run 10 times faster [10].

During daytime there is no need of street lamps so the LDR keeps the streetlamp off until the light level is low or the light frequency is low and the LDR resistance is high. This keeps current from going to the base of the transistors. Due to this reason the lights do not glow. When sufficiently high frequency light falls on the equipment, the semiconductor soak up photons and give bound electrons adequate energy to fence into the conduction band. The following free electron (and its hole partner) conduct electricity, thus dropping resistance. It supports client server operation where a single user can control the overall system [7]. It decreases heat and carbon dioxide emissions [1]. IOT based streetlamps automation is a practical and eco-friendly

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

technique which additionally take out the issues in disposal of incandescent lights and power saving [11].

II. LITERATURE SURVEY

In the present years, many efforts have been taken to automate the existing streetlamp system. For any smart streetlight system, it should work in an efficient method to maximize the quality and productivity. So, by implementing a more dependable system can remove a significant road lighting cost and reduce human effort as well. However, many methods are still operating with conventional light sources, it may reduce the human effort but the light pollution and energy wastage still exist.

F. Dheena et al. [12] in the year 2017 proposed a paper on smart streetlight management system using Arduino (ESP8266EX Wi-Fi Module), LDR, Relay, DHT11 sensor. In this system LDR detects when adequate light is not available, then with the help of relay the LED lights are turned ON or OFF. The advantage of this system is that it is simple and it can reduce manual work. It can also save energy. But the initial installation cost and maintenance are high.

The paper proposed by Jeetendra Swami et al. [13] in the year 2019 is quite same like the previous one, but here they used sensors also for vehicle detection. Still the installation cost and maintenance is high for this system.

Nabil Ouerhani et al. [14] in the year 2016 published their paper with respect to streetlamp controlling utilizing Zigbee remote module. They included microcontroller, LDR, and a transmission module. Zigbee permits wireless communication with the light module. The system consists of two LDR sensors to analyze the day-night variations and light health conditions. The outcomes from the LDR are moved to the microcontroller after processing the data and further into the transmission module. The wireless Zigbee sends the information to the control centre to monitor and operate each streetlamp. The system utilizes Zigbee network and the range of Zigbee is exceptionally short. Similar type of work also happened by M. Caroline Viola Stella Mary et al. [15] in the year 2018.

Siddaarthan Chintra Suseendran et al. [16] in the year 2018 implement a streetlamp control system using Raspberry Pi 3 model. They used python code in such a manner that intensity of light is controlled with the help of LDR. It also used Zigbee remote module. This system reduces power consumption but the design is complex.

Archibong, Ekaette Ifiok et al. [17] implemented a traffic flow-based streetlamp control system powered by solar panels. They utilized Arduino Wi-Fi module (ESP2866MOD), IOT module (Particle Electron 3G), Flying Fish infrared sensor (IR) module with adjustable distance, ULN2003 driver IC, LED array,18650 cylindrical lithium-ion batteries rated 3.7V, 2200mAh, LDR, SARODA SP09-05 model solar PV module rated 18V, 20W, wireless router and a computer and energy consumption was reduced by three times. Sensors are given at either side of the streets to recognize the vehicle movements and to instruct the microcontroller to turn on and off the lights accordingly. The installation cost is relatively high for this system due to solar panel and all other components

The paper proposed by Omkar Rudrawar et al. [18] planned a system to control street light using power electronics. In this system the light strength is controlled by TRIAC by controlling the applied voltage. As this voltage is proportionate to the light intensity. The system is automatically turned ON/OFF according to the information of sunrise or sunset from reliable internet sources. This system can be used with the existing manual system so initial cost is low but the maintenance is a problem due to not knowing which part is defective.

The paper by M. Sahithi Prasanthi et al. [19] planned a system for controlling the traffic light by image processing. The system will identify vehicles through pictures instead of utilizing electronic sensors installed in the sidewalk. A camera will be placed near by traffic signal. It will capture picture sequentially. The image sequence will at that point be analysed utilizing digital image processing for vehicle identification, and according to traffic conditions on the road, light can be controlled.

III. HARDWARE ARCHITECTURE & PROPOSED SYSTEM

The system consists of LDR, IR sensor, Bolt Wi-Fi module, Bolt cloud, LED and few basic electronic components e.g. Breadboard, Resistor, Connecting wires etc. A single system is capable of controlling four lights. The required connection for the proposed system is shown in Figure 1. The BOLT WIFI MODULE board is powered by using USB cable. Here the two sensors IR sensor and Light dependent resistor (LDR) sensor are interfaced to the board. The respective ground and VCC pin from the IR

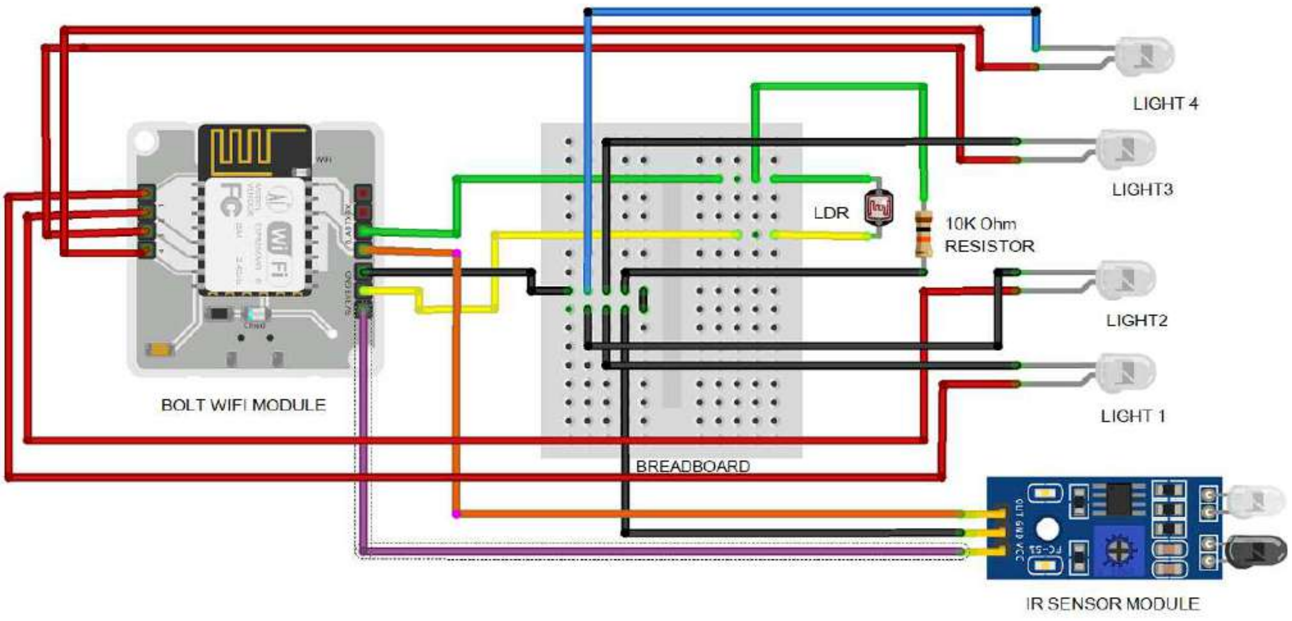

Figure 1: Circuit and connection diagram

sensor connected to GND and 5V pins of BOLT module respectively and output pin is connected to GPIO PIN 0. One of the terminals of LDR sensor is given to analog read pin A0 of BOLT module and another terminal is in 3v3 supply of bolt. A 10K resistor is connected to A0 pin with LDR and another leg of resistor is in ground. And all the positive pin of LED is connected in 1,2,3,4 GPIO pin of bolt module respectively and negative pin are connected to ground of bolt module.

For connecting bolt Wi-Fi module to bolt cloud through Message Queue Telemetry Transport (MQTT) protocol Bolt module required a local Wi-Fi Hotspot and we can access bolt cloud through mobile/tablet/laptop through HTTP & HTTPS protocols. Through cloud dashboard we can fetch data from all simultaneous systems which can control four lights individually. In Oracle Virtual Box workstation on UBUNTU server we write the python code for automatic street light controller. UBUNTU server connects bolt module through bolt cloud API key. By python coding on UBUNTU, we can control our proposed system.

The circuit and connection diagram of this system is shown in Figure.1.

A. Bolt Wi-Fi Module

The whole system is based on the Bolt IoT platform. Bolt IoT platform is an integrated IoT platform that gives Wireless Fidelity (Wi-Fi) capabilities and cloud connectivity to the sensors and actuators used in the system. This platform is based on Espressif-8266 Wi-Fi (ESP-8266 Wi-Fi) module. Machine Learning (ML) algorithms can be easily integrated with Bolt IoT projects for detecting or predicting anomalies in the sensor values. Some of the reasons to choose Bolt IoT are its ability to reduce code by about 80%- and 10-times faster time of deployment. Table I portrait the specifications of the Bolt IoT platform used [20] and Figure 2 depicts the view of Bolt IoT module.

Table I: Specifications of Bolt IoT platform

Parameters	Details
Processing/ Connectivity Module	ESP8266 (Customizable)
MCU	32-bit RISC CPU: Tensilica Xtensa LX106
Power	5V/1A DC - Micro-USB port/ 5V & GND pins
Voltage (Operating)	3.3V
Clock Frequency (CPU)	80 MHz
Internal Memory (MCU)	96KB of data RAM, 64 KB of instruction RAM
External Memory (MCU)	4 MB Flash memory [QSPI]
GPIO pins	5 Digital pins
ADC	1 pin 10-bit ADC
PWM	All 5 Digital pins capable of PWM
Dimension	35mm x 35mm
Boot Time	< 1 second

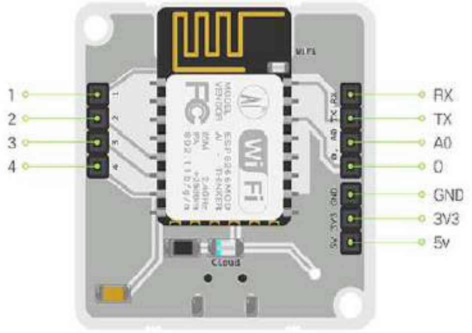

Figure 2: View of Bolt Wi-Fi Module

There are three types of connectivity in Bolt IoT. Details are given in Table II.

Table II: Types of connectivity in Bolt IoT

Wi-Fi	802.11 b/g/n Automatic AP mode when not connected to Wi-Fi WPA/WEP/WPA2 authentication 2.4 GHz Wi-Fi
UART	8-N-1 3.3V TTL UART [using GND, RX, TX pins] [2400/ 480/ 9600/ 19200 bitrates]
Cloud	Optional: Custom cloud using Bolt APIs

B. *LDR*

An LDR is a light sensitive electronics device whose resistivity is a component of the incident electromagnetic radiation. They are also known as photo conductive cells, photo conductors or simply photocells. LDRs are created with the help of semiconductor materials which have high resistance. So, when the photons fall on the gadget, the electrons in the valence band of the semiconductor material are aroused to the conduction band. LDR is used in this circuit as a darkness detector.

C. *IR Sensor*

An infrared sensor is an electronic instrument that is utilized to detect certain characteristics of its surroundings by either transmitting or detecting infrared radiation. It is additionally can measure heat of an object and detect motion. Infrared waves are not noticeable to the natural eye. In the electromagnetic range, infrared radiation is the region having frequencies longer than visible light frequencies, yet more limited than microwaves. The infrared regions roughly differentiated from 0.75 to 1000µm.

In this proposed system IR sensor is installed at the starting point of the system and then sequentially one by one four street lights are installed e.g., Light 1,2,3 & 4 as shown in Figure 3.

The LDR (Light Dependent Resistor) is used to sense the amount of light or darkness in the environment in order to switch ON/OFF the lights. In day time when sufficient light is present, street lights are OFF. The system waits for the ambient light to fall which is detected by the LDR; system gets activated and keeps all the street light (LED) at

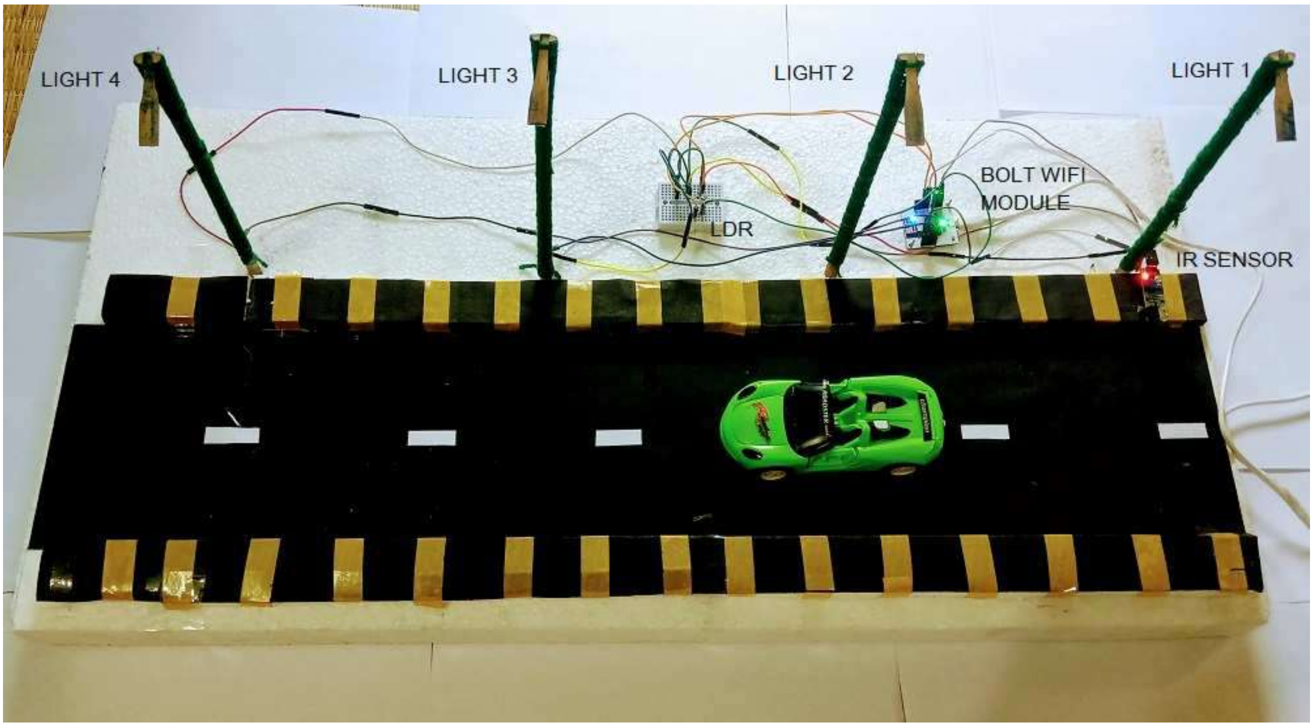

Figure 3: Prototype of the Proposed System

40% brightness and an alert SMS is sent to the authority through twilio.com [21].

Whenever the system detects an object by IR sensor, all the LEDs are powered to 100% brightness. When objects move out of the system reach all the street light are reset to 40%.

Afterwards when sufficient light is available the LDR sense and turned off LED automatically, and send an SMS to the authority that street light is turned OFF. Each of the street light can also be individually turned ON/OFF manually via login in bolt cloud dash board or using BOLT IOT mobile application.

IV. RESULT & DISCUSSION

This IOT based automated streetlamp system is extremely cost effective. The project aim is the conservation of energy. It can likewise terminate the CO2 outflows and light pollution. The method does not require manpower and frequent check rather the system status can be thoroughly monitored through updated data stored in bolt cloud. In cloud we can monitor and analyze intensity value of light over the day. The Figure 4 shows the values.

The system checks for the evening to fall which is recognized by the LDR; system gets triggered and keeps all the streetlamp (LED) at 40% of its peak brightness. And send an alert to the authority via SMS that street light is on as shown in Figure 5.

Whenever the system detects an object (human, vehicle) through IR sensor the associated LEDs are powered to its 100% brightness. After objects moves out of the system reach all the street light are reset to 40% of its peak brightness. After that when intensity value of the ambient light become high which implies day the street light are turn off automatically and send an alert to the authority via SMS that street light is OFF as shown in Figure 6.

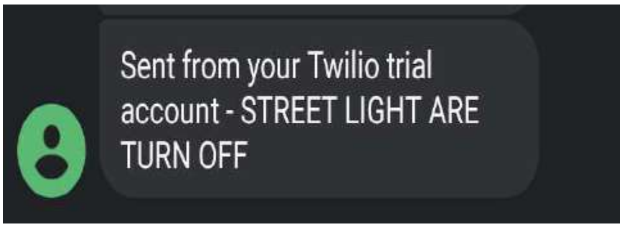
Figure 5: Street light turn ON SMS alert



Sent from your Twilio trial account - STREET LIGHT ARE TURN OFF

Figure 6: Street light turn OFF SMS alert

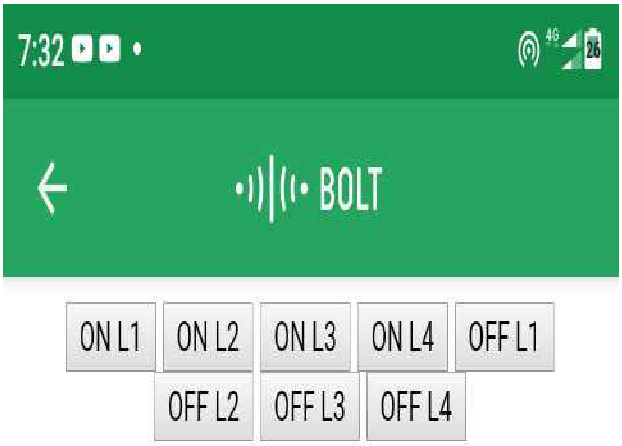


Figure 7: Manual street light control switch in Bolt IoT mobile application

The control of individual street lights is also possible through login in Bolt cloud dash board. Figure 7 shows the individual street light control switch in Bolt IoT mobile application.

V. CONCLUSION

A great portion of energy can be saved by replacing sodium vapor lamps by LED. By adding smart switching to LED streetlamps, it is turned ON/OFF automatically. Owing to the intelligence offered by this proposed system the brightness of the street lights can also be controlled through sensing the natural light or traffic flow. This prevents unnecessary wastage of electrical energy further.

The LED dimming feature is joined with the different sensors that give the distance information from any objects and the surrounding light intensity around the LED light. The intensity of the LED is automatically controlled. The LED dimming feature can operate with a wired or wireless system to realize universal LED lighting systems. It gives an effective and intelligent automatic streetlamp control system with the assistance of LDR. There is a message system to alert and communicate the status of the lights. In this proposed system the street lights send message when it will turn OFF/ON through twillo.com. By this if any day street lights are not turned off/on, system do not give an alert so authority can take measure upon it. Here one IR sensor is used for controlling four street lamps so it reduced the cost of the system. For any emergency condition we can manually operate each of the street lights through web interface or mobile application, which make the system more reliable. It can decrease the energy utilization and maintenance cost. It tends to be applied in urban as well as rural areas. The system is expandable and absolutely adaptable to the requirements of the user. It establishes a safe environment with maximum intensity light at whatever point required. This system can report street lamp failure, which make the maintenance of street lamp simpler and less formidable.

The existing bulbs or lights are also may be linked to this low-cost street light management system. The lights will make good use of the Internet of Things (IoT) connectivity to not only prevent the power wastage but also for better management and fault detection.

The need of the system is to reduce energy consumption, decrease the maintenance cost and to expand the lifespan of the system. By allowing this method the energy can be used more efficiently in smart street lightning system. This smart and relatively low cost IoT system can also reduce the CO2 emissions and help to protect the environment.

***Abstract*—Avoiding traffic congestion phenomena is an important aspect of efficient transportation infrastructure (e.g. toll roads) management. Traffic congestion phenomena can be avoided by forecasting volume traffic data. This paper aims to analyze how specific factors and parameters affect the behavior of traffic volume, like vehicle category, date, and weather data at a given timestamp and place. Moreover, the procedure of data prepossessing is presented to produce a cleaner data set that gives more fundamental information. Subsequently, spatio-temporal toll road prediction is achieved through a multi-layer perceptron. Finally, the proposed low-cost method is evaluated using real-life data from a toll plaza, while the experimental results show the efficiency of the proposed method.**

***Index Terms*—Traffic volume, spatio-temporal traffic, toll road traffic, traffic forecasting, data driven.**

I. Introduction

Traffic congestion not only leads to vehicular queuing and longer driving times but also results in waste fuel, increased carbon dioxide emissions and air pollution [1]. The first step towards solving traffic congestion is an integral approach which will enable traffic regulation through traffic volume management. Traffic management aims at safe travel and bottleneck-free roads and is part of the Intelligent Transportation Systems (ITS) [2]. A main aspect of ITS is to develop models that can be deployed to estimate, simulate and/or forecast traffic volume, traffic congestion and/or traffic density.

Especially, both the users and administrators of a toll road want to gain insight into the traffic volume at a specific toll plaza [3]. The existing literature referring to traffic forecasting is voluminous [4] and is implemented for many different aspects like travel time prediction, traffic volume prediction and waiting time in toll roads [5]. In [6] the authors state that using an artificial neural network (ANN) to predict traffic volume provides a lower error in comparison with other models (e.g. regression models). Furthermore, many of the existing models use cameras to detect traffic volume [7] and they are efficient but high-cost methods.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Moreover, a fusion of ANN method and support vector machines is used to estimate traffic using many parameters like road vehicle counts, socio-economic data, geometry of the road and other parameters [8]. These type of models use a combination of road data and economic data to predict traffic [9] and are found to be accurate enough but harvesting all this type of data may prove a thorny task. Nonetheless, there is less literature about predicting volume traffic in toll plazas. Probably, because each local toll road is affected by multi-and various parameters like the local climate, distance from big cities, socio-economic data, and pavement quality. Therefore, even if a suggested method is accurate enough, it must be rebuilt for a specific toll plaza.

As a result, this paper suggests a low-cost method to forecast the traffic volume while using the least possible data that can be effortlessly retrieved like the local weather and number of vehicles passing daily through the toll road. Moreover, an effort is made to gain awareness of how this information affects volume traffic and employ the greatest possible advantage from it. Initially, the suggested methodology, data wrangling and preprocessing is addressed in Section II. Subsequently, the results are presented in Section III. Finally, conclusions are drawn in the final section.

II. Methodology

To achieve an increased performance some additional features that may affect the traffic volume have been integrated into the traffic forecasting using the proposed model [10]. In this paper, traffic data has been enhanced with temporal features (e.g., month, hours, day, and holiday periods) and weather features (e.g. temperature, cloud coverage and weather types (e.g sunny, foggy, rainy, snowy)). Specifically, temporal features are used to capture how seasonality may affect the traffic volume.

On the other hand, weather variables may not be directly linked to traffic volume forecasting, but they can affect it indirectly. Non expected weather conditions may disrupt holiday travel plans, while extreme weather conditions may lead to unexpected delays or postponement of business truck schedules. All the aforementioned circumstances that lead to schedule cancellations or postponements affect traffic, as a result necessitating the knowledge of weather conditions for more accurate predictions.

A. Data Wrangling

To explain the process with thoroughness, some further information about the data is provided. The vehicles are classified into four categories depending on the vehicle type as follows:

$$category = \begin{cases} CAT1, & \text{Motorcycle, Tricycle Vehicles} \\ CAT2, & \text{Passenger cars} \\ CAT3, & \text{Trucks, buses with} < 4 \text{ axes} \\ CAT4, & \text{Trucks, buses with} \geq 4 \text{ axes} \end{cases} \tag{1}$$

The toll road fees correspond to the four different vehicle categories, therefore a toll system can estimate the total number of vehicles for each category directly from the daily total sum of fees. As mentioned, the data set holds traffic information in a daily time series structure.

As it may be observed in Fig. 1 the number of vehicles that belong to CAT1 and CAT2 fluctuate similarly referring to months and are characterized by a traffic increase during the summer months (June, July, August). On the other hand, the number of vehicles that belong to CAT3 and CAT4 (Fig. 2) have similar patterns, with very small variations without following a certain motif during the year. This could indicate that CAT1 and CAT2 could be grouped together, as well as CAT3 and CAT4.

As a result, the problem could be split into 2 forecasting problems, forecasting of vehicles that belong to light vehicles (CAT1 and CAT2) and prediction of vehicles that belong to heavy vehicles (CAT3 and CAT4).

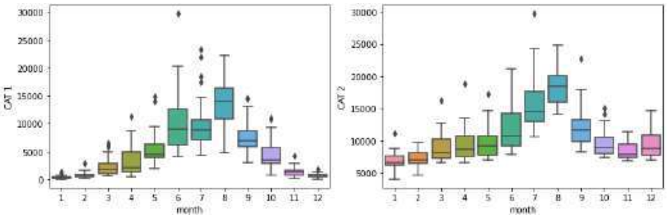

Fig. 1. CAT1, CAT2 per month

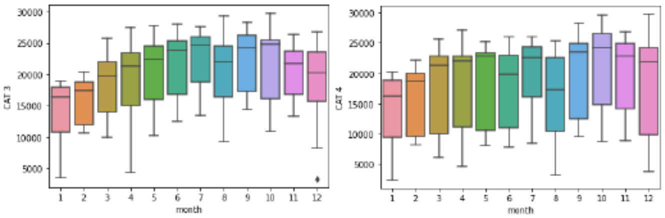

Fig. 2. CAT3, CAT4 per month

To further corroborate the previous assumption Fig. 3 and Fig. 4 reveals the same patterns in traffic volume for toll plazas for CAT1 and CAT2, and for CAT3 and CAT4. Specifically, on weekends more light vehicles seem to pass through the tolls than on weekdays, in contrast to heavy vehicles where more vehicles pass through the tolls on weekdays. Similar behaviors between the categories may also be noticed in Fig. 5 and Fig. 6.

It should be mentioned that for holiday periods the two grouped categories follow the same assumption as depicted in Fig. 7 and in Fig.8. Consequently, the problem may be split into light vehicles volume forecasting and heavy vehicles volume forecasting.

B. Data preprocessing

1) Impute missing values: The number of vehicles never have missing values as they derive from the fees. On the

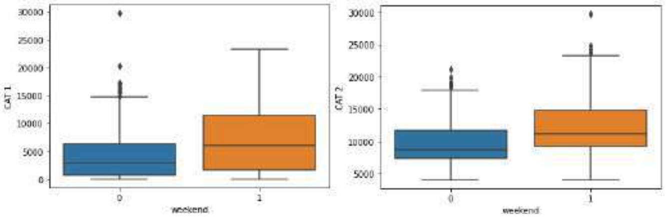

Fig. 3. CAT1, CAT2 per weekend

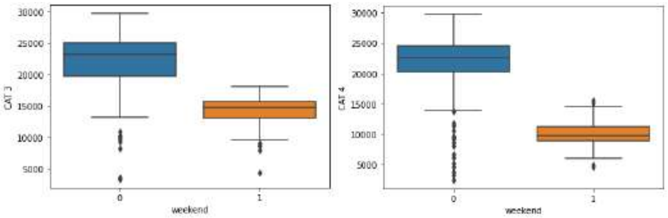

Fig. 4. CAT3, CAT4 per weekend

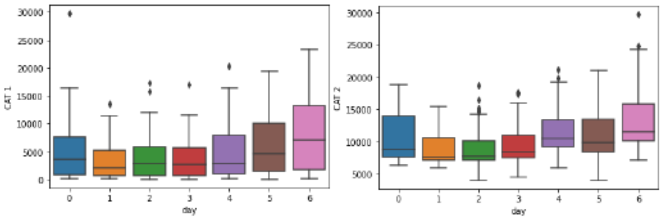

Fig. 5. CAT1, CAT2 per weekday

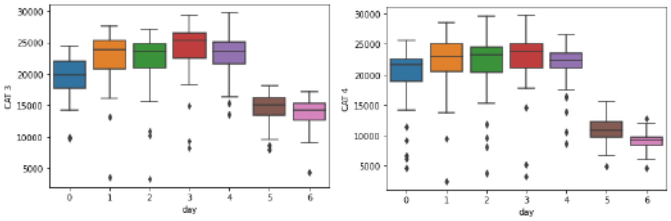

Fig. 6. CAT3, CAT4 per weekday

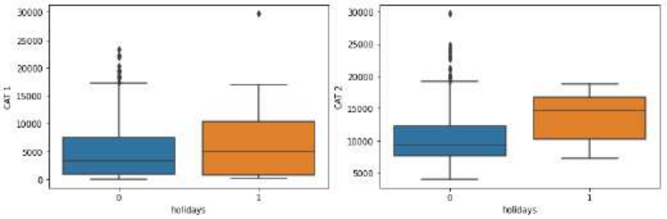

Fig. 7. CAT1, CAT2 per holidays

other hand missing data may appear in the weather variables. Every type of variable requires a different imputing method to be applied. For continuous values (e.g temperature), missing values are filled using the linear interpolation method [11], while missing data for categorical values (e.g weather state) is replaced with the most frequent values within the data set [12].

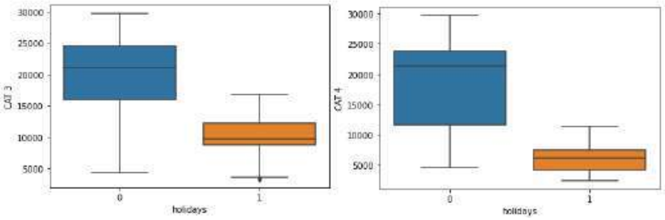

Fig. 8. CAT3, CAT4 per holidays

2) Feature Encoding: Label encoding [13] is applied to the weather state feature to convert the possible weather states into a numeric form as described below:

$$weather\ state = \begin{cases} 0, & \text{Sunny} \\ 1, & \text{Foggy} \\ 2, & \text{Rainy} \\ 3, & \text{Snowy} \end{cases} \tag{2}$$

3) Outliers: Any outliers found were replaced by the average traffic of the current month for each category. In Figures 1 to 8 some outliers are observed to appear throughout the dataset. There are various methods to detect an outlier, however, within this paper, an empirical method for outlier dection was deployed, Z-score method [14], which describes the position of a record's distance (d) from the average (μ) measured in standard deviation unit (σ) and is defined as follows [14]:

$$Z_{score}(d) = \frac{d-\mu}{\sigma} \tag{3}$$

Any data that lie beyond 3σ from the average are considered as outliers and are replaced by the average traffic of the corresponding month.

4) Data modeling: To obtain insights about future traffic volume, past traffic data, temporal and weather variables were used. In addition, to achieve a better model performance, the method proposed in this paper also uses temporal and weather data from the nested period that are retrieved from Numerical Weather Prediction (NWP) models [15]. Specifically, for every record, data from n past days from current day (t) is selected and next day temporal and weather features in order to forecast the day ahead traffic volume ($t+1$). The data modeling as described above is depicted in Fig. 9.

C. Traffic volume forecasting

Within this paper, a MLP model has been developed that implements the forecasting process, which is a conventional feed-forward Neural Network that contains more than one layer [16]. Some worth noting characteristics are that the first layer has as many nodes as the input features, while the number of the last layers' nodes depends on the machine learning task. For regression tasks, the last layer usually contains only one node. In the hidden or intermediate layers, the number of nodes may vary depending on the complexity

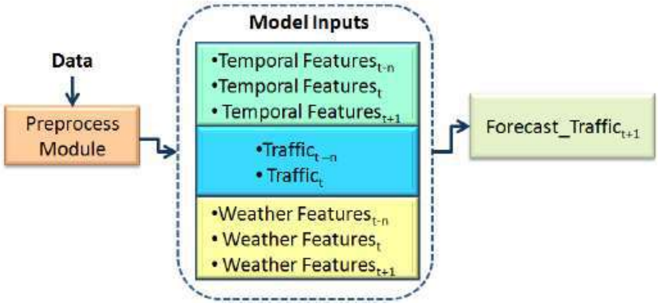

Fig. 9. Data transformation

of the problem or the source domain (e.g, images require a more complex architecture).

During training process, given a fully processed data set with N records, which can be defined as $\{(\mathbf{x}_1, y_1), \ldots, (\mathbf{x}_N, y_N)\}$, each $\mathbf{y}_i = \{y_1, \ldots, y_N\}$ is the ground truth number of vehicles and $\mathbf{x}_i = \{x_{i1}, \ldots, x_{im}\}$ represent the m input features as calculated in (4). As Fig. 9 implies traffic data from current and past n days are added as input. Temporal Features encapsulate 4 different features (month, day, weekend and holidays), while weather features contain 3 different features (temperature, cloud coverage, and weather state). For these contextual features, not only current and past n days are fed as input but also the day's ahead values that are retrieved from NPW models. To sum up, the number of input features a day's ahead prediction requires considering data from past n days can be calculated as follows:

$$\begin{aligned} Features = m = {} & (n+1) * 1[traffic\ data] \\ & + (n+2) * 4[temporal\ features] \\ & + (n+2) * 3[weather\ features] \\ & = 7 * (n+2) + n + 1 \\ & = 8 * n + 15 \end{aligned} \tag{4}$$

As the number of hidden layers and nodes per layer is increased the MLP becomes more complex and is more susceptible to overfitting. To measure the model's performance, a loss function is defined. The loss function the MLP Regressor uses to evaluate the model in each iteration is the mean squared error (MSE) [17]. The divergence between the predicted number of vehicles $\hat{y}_i$ and the actual number of vehicles y_i, calculated for N records is expressed with the following equation [17]:

$$Loss(y_i, \hat{y}_i) = \frac{1}{N} \cdot \sum_{i=1}^{N} (y_i - \hat{y}_i)^2 \tag{5}$$

Moreover, during the training procedure the weights are updated using an optimizer in order that mitigate the loss expressed by the loss function through an iterative process. In this work, Adam optimizer is used [18].

The MLP model is trained utilizing the aforementioned data. After the training phase the MLP forecasts the daily volume traffic. The retrieved data is pre-processed before fed in the MLP. Progressively, the MLP model is retrained every week with the new traffic and weather data in order to include the complete traffic volume and weather changes while improving itself through time or even capturing steep changes of the weather. A flow chart of the overall traffic forecasting model that was described is depicted in Fig. 10.

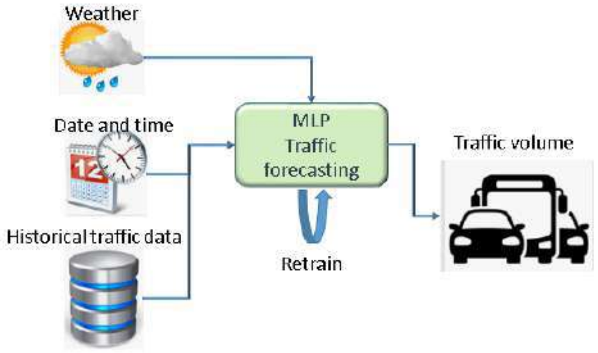

Fig. 10. Flow chart of the overall traffic forecasting model

III. Experimental Results

A. Use case

This section elaborates results obtained from the conducted experiments that took place at the toll plaza in Analipsi (Fig. 11), that is located between Kavala and Thessaloniki, Greece. The traffic data that were collected from the toll's implementation system were retrieved and used as input to the neural network that was developed within this work in order to forecast the day's ahead traffic volume. Furthermore, weather variables were retrieved based on the toll's exact location.

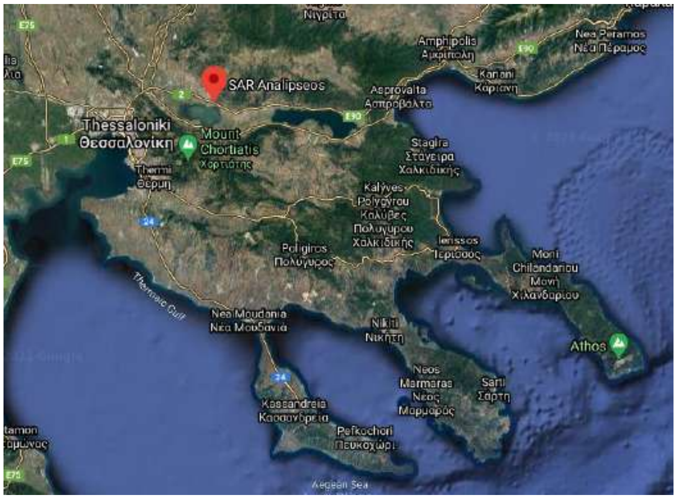

Fig. 11. Analipsi toll plaza map

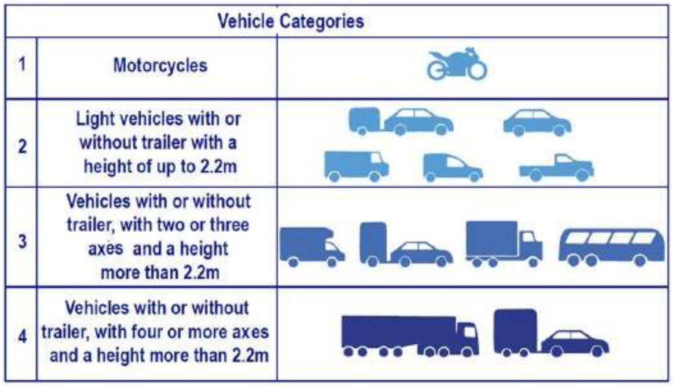
The toll rates in Greece for various vehicles are as depicted in Fig. 12. It may be observed that the categories are the same as mentioned above for the CAT1, CAT2, CAT3, and CAT4, respectively.



Vehicle Categories		
1	Motorcycles	
2	Light vehicles with or without trailer with a height of up to 2.2m	
3	Vehicles with or without trailer, with two or three axes and a height more than 2.2m	
4	Vehicles with or without trailer, with four or more axes and a height more than 2.2m	

Fig. 12. Toll rate vehicle categories

B. MLP architecture

The lack of existence of a theory-based principle in order to define the optimal topology for a neural network often leads to trial and error methods for the definition of the network architecture [19]. However some broadly accurate practise-based guides exist that suggest the number of layers and neurons for a neural network [19]. As stated by Hecht Nielsen (1987) [20], the hidden layers' neurons should contain are:

$$nodes = 2m + 1, \tag{6}$$

where m is the number of input features (input nodes).

According to Huang [21] a neural network with two hidden layers should have a specific number of neurons. In the first hidden layer, the number of neurons that are suggested are:

$$nodes = \sqrt{(m+2)N} + 2\sqrt{\frac{N}{m+2}}, \tag{7}$$

while the sufficient number of neurons for the second hidden layer should be obtained from:

$$nodes = \sqrt{(m+2)N} \tag{8}$$

It is also worth mentioning that tuning the number of neurons using the power of two increases the speed of finding a layer size for a decent performance and leads to faster computational solutions [22]. Therefore, in the current work another empirical method was used defining the number of nodes as a power of two:

$$nodes = 2^k, \tag{9}$$

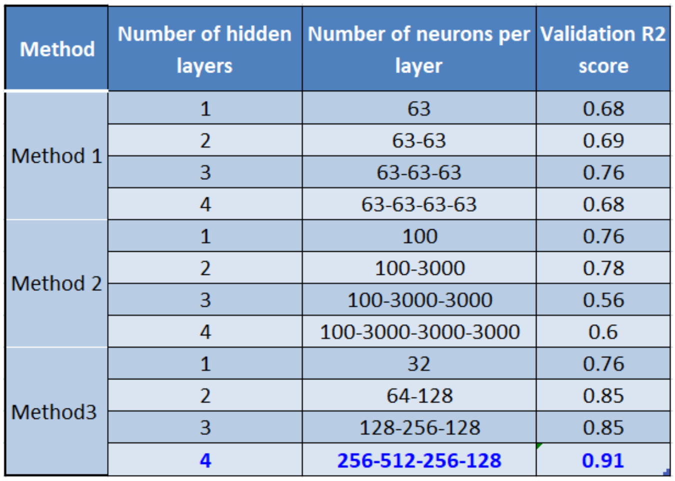
where $k \in \mathbb{N}$.

All above methods were tested for their performance through a trial and error procedure and the network with the highest performance was selected as the most appropriate. The training samples were approximately $N = 280$ while the input features considering the two previous days for the forecasting process are $m = 31$ (4).

$$m = 8 * n + 15 \overset{n=2}{=} 31 \tag{10}$$

According to Nielsen's method ([20] and (4)) each layer should contain $nodes = 63$, while using Huang's method [21] (Method 2) the first layer should contain $nodes \approx 100$, while the second layer should contain $nodes \approx 3000$.

The results obtained by the tuning procedure during the trial and error phase are presented in Fig. 13. Generally, the model seems to perform better having more than one layer, but utilizing Huang's method [21] (Method 2) the performance drastically decreases. As it may be observed in Fig. 13 Method 1 (Nielsen [20]) reveals poor results during all tests, while (9) shows better performance. Taken into account the overall performance of each network topology, method 3 (power of two [22]) with four hidden layers was selected as the most appropriate.



Method	Number of hidden layers	Number of neurons per layer	Validation R2 score
Method 1	1	63	0.68
	2	63-63	0.69
	3	63-63-63	0.76
	4	63-63-63-63	0.68
Method 2	1	100	0.76
	2	100-3000	0.78
	3	100-3000-3000	0.56
	4	100-3000-3000-3000	0.6
Method3	1	32	0.76
	2	64-128	0.85
	3	128-256-128	0.85
	4	**256-512-256-128**	**0.91**

Fig. 13. Tuning nodes per hidden layer

The overall MLP architecture that was selected is as depicted in Fig. 14.

C. MLP performance

In Fig. 15 and Fig. 16 the performance of both MLP models is depicted for heavy and light vehicles, respectively. The initial data set contains daily data during the period 2019 (January 1 - December 31) considering the total number of vehicles (for each category) that pass through the tolls. The data set was split to 75% for training and 25% for test. Specifically, the data samples that were used for training were selected by randomly getting three weeks from each month while the remaining week from each was used for testing. The metrics used to evaluate the MLP performance are Mean absolute Error (MAE) [23] and Mean Absolute Percentage Error (MAPE) [24]:

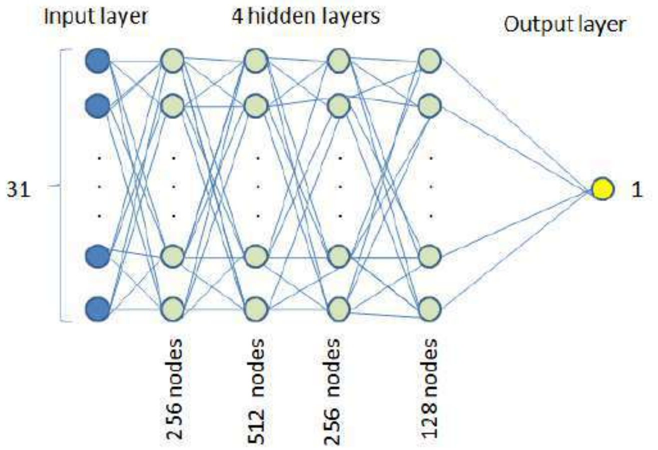


Fig. 14. MLP architecture

$$MAE = \frac{1}{N} \cdot \sum_{i=1}^{N} |y_i - \hat{y_i}| \tag{11}$$

$$MAPE = \frac{1}{N} \cdot \sum_{i=1}^{N} |\frac{y_i - \hat{y_i}}{y_i}| \tag{12}$$

An insubstantial deviation may be observed between the number of predicted and actual vehicles (Fig. 15 and Fig. 16). Furthermore, the predicted pattern seems to capture the actual fluctuations even in peak traffic volume moments. Specifically, the mean absolute percentage error in both cases is approximately 8.85%. Considering that 100 vehicles will pass through a specific toll plaza a MAPE score of this value implies that the forecasting model deviates by only 9 vehicles from the actual value.

In terms of performance, considering the nature of the data (total vehicles per day), the lack of intermediate values caused by the given time interval (aggregated daily values), is very reasonable and reveals decent credibility. To summarize, the selected architecture for the MLP proved to have an acceptable performance and is considered as appropriate for the forecasting process.

Conclusions

The proposed method is a tool for traffic volume forecasting at a specific toll plaza. Available data are analyzed revealing hidden information of the associated data, while the retrieved data is preprocessed to better fit the model. Traffic volume patterns during the experimental tests are accurate compared to the expected traffic volume.

The proposed model is a non-intrusive and low-cost traffic volume forecasting tool that informs users and administrators about the traffic volume of an exact location while indicating potential traffic congestion. Moreover, this traffic forecasting tool may be utilized in real-time traffic monitoring and management if data are retrieved real-time. Finally, it has the potential of enhancing the management of road networks while reducing traffic congestion.

***Abstract*— Harvard Business Review (HBR) reported 27% of projects were over budget, McKinsey & Company reported 66% of projects were over budget, and the Project Management Institute (PMI) reported more than 40% of projects were over budget. The causes are losing focus, execution issues, content issues, and skill issues. The failure of the software project falls into the process domain category. Undefined processes can lead to low-quality results regarding unexpected outcomes, schedule, and budget. In short, the project is poorly executed. A software development method is needed to execute the project correctly, so the quality is guaranteed, on time, and within budget. This study aims to summarize the approaches used to determine software development methods for organizations and how to use them. A systematic literature review technique was conducted and obtained 16 relevant papers. Ten approaches for determining software development methods were found. Instead of selecting a suitable software development method, the organization could create a software development method by tailoring several deemed appropriate methods to its needs.**

Keywords*— *Software Development Method, Systematic Literature Review, Approaches Selecting Software Development Methods.

I. Introduction

Harvard Business Review reports that 27% of projects usually go over budget [1]. In addition, at least one in six IT projects is 200% over-cost and 70% over-schedule [1]. IT projects performance has an average cost overrun of 66% [2]. Over 40% of projects were completed over budget [3]. The following are problem groups for most project failures: (1) Losing focus due to unclear objectives and lack of business focus [2][3]. (2) Execution issues related to unrealistic schedules and reactive planning [2]. (3) Content issues such as changing requirements and technical complexity [2]. (4) Skill issues such as unaligned teams, lack of skill, and poor communication [2][3]. The causes of project failure groups ratio can be seen in Fig 1.

According to Marchewka, that project failure issues are part of the software failure category's process domain [4]. The process domain is a set of project management and product development processes such as defining project goals and objectives and developing and implementing realistic project plans [4]. Undefined processes can lead to low-quality results in terms of not expected value, outcome, meeting schedule, budget, or quality objectives [4]. Usually, requirements that are not well-defined lead to additional work or a product, process, or system that stakeholders did not ask for or do not need [4]. In short, the project is poorly executed [4].

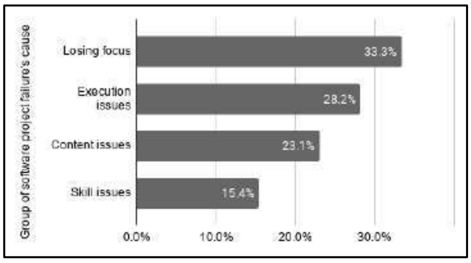

Fig. 1. Group of software project failure causes [2]

One of the project success factors is the proven methodology and tools used [2]. A software project requires a development method to control the people involved, manage the project processes, determine the technology to be prepared, and implement the organizational rules that enable developing complex software on time with quality, of course, to avoid excess budget [5]. The organization can execute software development projects without any development method, but the consequences are often more expensive and less reliable than they should be [6]. The right software development method can accommodate the needs of the project being carried out [8]. Software project needs a development methods, so that the process is structured, projects can be successful with guaranteed quality, work on time, and within budget [7].

The organization can take several approaches to determine software development methods, so the software development method complies with the organization's conditions and needs [5]. This study aims to summarize what approaches the organization can use to define software development methods and how it uses. Many previous studies have discussed how to use an approach for determining software development methods, but no research has been conducted to summarize the approach that the organization can use for its determination. This research also provides insights for determining software development methods that comply with the organization's context, conditions, and needs.

II. Literature Study

A. Software Development Method

A software development method is the approach or method used in the software development process [6].

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Sometimes software development methods can be referred as process models or software development methods [5], software development methodologies [8], software development strategies and methods [4][6]. Software development methods are divided into two classification, namely plan-driven and agile [5]. Some samples of software development methods are Waterfall, Incremental and Iterative Development, Prototype, Spiral, Extreme Programming, and Scrum [5][6][8].

B. *The criteria for determining the appropriate software development method for an organization*

The appropriate software development method for an organization is nominated based on organizational conditions, needs, and problems related to software development [5]. There are criteria and sub-criteria used to analyze conditions, needs, and problems related to application development to determine the appropriate development method [9].

TABLE I. CRITERIA AND SUB CRITERIA FOR DETERMINING SOFTWARE DEVELOPMENT METHODS

Criteria	Sample of sub-criteria
Personnel	Personnel substitutions, size of team, willingness of the team to change, team diversity, distribution team.
Requirements	Changing needs on an ongoing basis, needs that are not clear, standards of needs, necessities to meet needs.
Application	Risk level, complexity, hardware architecture, application type, application size, application performance, relationship with existing or planned systems, configuration and documentation management, development stage, products quality.
Organization	Organizational maturity, organization current practices, technical support, organization standards, commitment management, culture, organizational stability, organizational facilities, organization size.
Operational	User resistance, end user commitment, user engagement, number of users, user rotation, prerequisites to be met such as policies, regulations.
Business	Potential project losses, dependence on other projects, dependency, financial considerations, marketing activities, user satisfaction.
Technology	Availability of tools, the use of technology, development tools experience, adoption of new technologies.
Process	Process flexibility, process simplification, learning process.

III. RESEARCH METHODOLOGY

The systematic literature review (SLR) method is used to answer these research questions by comprehensively summarizing the related research that has been done before [10], and combine with existing theories. There are 3 processes carried out in the SLR method based on Kitchenham, namely planning, implementation, and reporting [10].

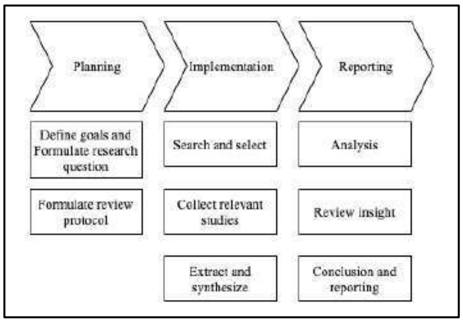

Fig. 2. SLR Methods Stages

A. *SLR Planning Stage*

The first thing to do in the SLR planning stage is to set goals and formulate research questions. Specify the research questions (RQ) was conducted to keep the review focused. It was designed by Population, Intervention, Comparison, Outcomes, and Context (PICOC) formula [11], shown in Table II.

TABLE II. RESEARCH QUESTION'S CRITERIA

Population	Software, software development, software process, software development life cycle
Intervention	Determining approach, technique, tools
Comparison	None
Outcomes	Approach, technique, or tool are used for determining software development method in organization
Context	Studies in organization and academia, software project management

The following are the research question and its motivation discussed in this literature review are shown in Table III.

TABLE III. RESEARCH QUESTIONS

ID	Questions	Motivation
RQ I	What methods can be used to determine the appropriate software development method for the organization?	Identify the most used approach for determining software development method in organization
RQ II	How to use the approach in determining software development method?	Identify how to use the approach to determine software development methods

Thereafter, protocol formulations are performed. After that, the search protocol formulation was carried out. The keywords used for the search are as follows

("software life cycle" OR "software process" OR sdlc OR "software development" OR "software development method*") AND (select* OR implement* OR determin* OR adopt* OR best OR creat* OR decision)

Filtering of literature searches is carried out so that research remains relevant. Following are the filter criteria shown in Table IV.

TABLE IV. CRITERIA OF FILTERING LITERATURE

ID	Criteria	Type
IN1	Publications in the period 2015-2021	Inclusion
IN2	Publications in English	Inclusion
IN3	Publications in the form of journals and proceedings	Inclusion
IN4	Publications must be complete and downloadable full-text version	Inclusion
EX1	Research are related studies are not opinions, books, presentations, and articles	Exclusion
EX2	The topic does not discuss other than the scope of selecting software development and modeling methods	Exclusion

B. *SLR Implementation Stage*

The second stage, namely SLR implementation, is a search and selection of relevant publications to be used as literature in this study were conducted according to the keywords that had been planned in the first stage. The databases used for searching literature are ACM Digital, IEEE, Pro Quest, Science Direct, Scopus, Springer Link, and Wiley Online Library. The SLR process is shown in Fig 3.

Firstly, a search is performed using predetermined keywords. The inclusions in this search are publications in English (IN2), and publications must be journals or proceedings (IN3). The exclusion of this search is publications in opinions, books, presentations or articles (EX1). From the results of the search and inclusion, there were 756 publications. Secondly, filtering the results by displaying publications in the range of time from 2015-2021. There are 426 publications obtained. Thirdly, conducting a review with relevant publications related to selecting software development methods and modelling (IN4) and downloadable publications (IN5). Publications that are not related to the topic of selecting software development methods and modelling will be excluded. From the third stage, 83 publications were obtained. In the fourth stage, a publication is reviewed by reading its contents. Sixteen publications can be used in this study.

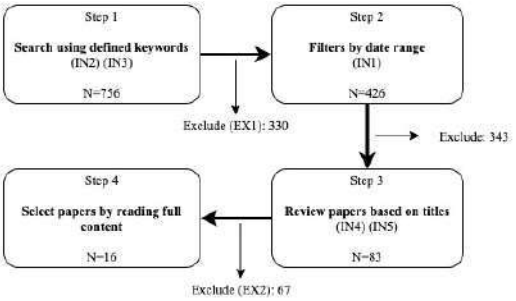

Fig. 3. SLR Process

The results from the extraction and synthesis of publications that will be used as references in this study can be seen in Table V.

TABLE V. THE RESULTS OF THE SELECTED PAPER

Database	Total Papers
ACM Digital	4
IEEE	4
ProQuest	1
Scopus	2
Science Direct	2
Springer Link	2
Wiley Online Library	1
Total	**16**

Publication quality assessment was required for further study selection after inclusion and exclusion criteria [11]. Several questions were developed to evaluate quality of studies shown in Table VI.

TABLE VI. QUALITY ASSESSMENT QUESTIONS

QA1	The discussion in publications is in the scope of software development selection and modeling methods
QA2	Population of study is adequate for data analysis
QA3	Study uses adequate methodology

Each question has following value: (1) not good, (2) adequate, and (3) good. The maximum score is 9 and the least value to pass quality value is 4.5. Table VII below show the quality assessment results.

TABLE VII. QUALITY ASSESSMENT RESULTS

Reference	Q1	Q2	Q3	Total
[12]	3	3	3	**9**
[13]	3	3	3	**9**
[14]	3	2	3	**8**
[15]	3	2	2	**7**
[16]	3	2	2	**7**
[17]	2	2	3	**7**
[18]	3	3	3	**9**
[19]	3	3	3	**9**
[20]	3	3	3	**9**
[21]	3	3	3	**9**
[22]	2	1	2	**5**
[23]	3	2	2	**7**
[24]	3	3	3	**9**
[25]	3	3	3	**9**
[26]	3	2	2	**7**
[27]	3	2	3	**8**

All the final study score was above 4.5. It means those studies eligible to be used for data extraction and data synthesizes.

C. SLR Reporting Stage

The last stage, namely SLR reporting, is selected publications as references will be analyzed comprehensively to find the approach that can be used to determine the software development method for the organization and how to use that approaches. Can be seen in Table VIII, is a list of publications used in this study.

TABLE VIII. THE PUBLICATION TO BE USED

Title	Year	Reference
Systematic Approach for Mapping Software Development Methods to the Essence Framework	2016	[12]
Analysis of software development method selection: a case of a private financial institution	2019	[13]
An Excursion to Software Development Life Cycle Models- an Old to Ever-growing Models	2016	[14]
Exploring the Use of the Cynefin Framework to Inform Software Development Approach Decisions	2015	[15]

An Approach for Systematic Planning of Project Management Methods and Project Processes in Product Development	2020	[17]
Tailoring Agile-Based Software Development Processes	2019	[18]
Agile methods tailoring – A systematic literature review	2015	[19]
Suitability of existing Software development Life Cycle (SDLC) in context of Mobile Application Development Life Cycle (MADLC)	2016	[20]
The Use of Analytic Hierarchy Process for Software Development Method Selection: A Perspective of e-Government in Indonesia	2017	[21]
Adopting scrum framework in a software development of payroll information system	2020	[22]
Decision Support Framework for the Adoption of Software Development Methodologies	2019	[23]

Title	Year	Reference
Selection of software development model using TOPSIS methodology	2018	[24]
Software process selection system based on multicriteria decision making	2020	[25]
An integrated approach to formulate a value-based software process tailoring framework	2016	[26]
SDLC Model Selection Tool and Risk Incorporation	2017	[27]

IV. Results and Discussion

The final stage of SLR is reporting. Sixteen literatures have been reviewed, a list of the approach was carried out to determine the method of software development and the determining factors in using this approach.

A. Approaches in Determining Software Development Methods

Answering the question RQ1, "what methods can be used to determine the appropriate software development method for the organization?", based on the literature review, that found 10 approaches. The explanation of these approaches are follows.

Comparative Analysis. This approach is obtained from four literatures [14][20][22][27]. Comparative analysis is carried out based on the calculation of specific situations, objectives, problems, and limitations encountered in project implementation [14][20][22][27]. After understand the conditions of the project, comparisons are made between the characteristics of the project and the existing software development methods [14]. Several criteria are used such as cost, clarity of requirements, documentation, project size, flexibility, and etc [14][20].

Multi-criteria Decision Making Technique. This approach is obtained from four literatures [13][24][25][21]. Multi-criteria decision-making (MCDM) is a sub-discipline of operations research that explicitly considers several conflicting criteria in decision-making [25]. There are several techniques found from literature studies including Analytic Hierarchy Process (AHP) [13][21], Fuzzy AHP [25], and TOPSIS [24].

Intentional Modelling Framework. This approach is obtained from one literature [16]. This framework belongs to the tailoring category of practices from agile software development methods [16]. The choice of practice based on the agile value such as customer-centered, software that works, collaboration, simplicity, communication, nature, learning, pragmatism and adaptability [16].

Goal-oriented Meta-model. This approach is obtained from one literature [16]. This framework belongs to the tailoring category of practices from software development methods [16]. The choice of practice based on the objectives of each activity. Each activity is broken down into the smallest practical parts, then the tailored practice must be understood by the development team [16].

Contingency Factors. This approach is obtained from one literature [19]. These approach deals with customizing software development methods by selecting several methods that will be available to the organization and making the selection of methods based on the development context such as degree of uncertainty, impact and structure of project. However, the development team must understand the chosen execution method [19].

Method Engineering. This approach is obtained from one literature [19]. This approach focuses on the methods of each activity in software development that occurs in the organization. This approach starts with understanding the environment and characteristics of the project, and there is a fragments repository that contains practical collections, will be combined for each project implementation [19].

Cynefin Framework. This approach is obtained from two literatures [15][17]. Cynefin is a decision framework that recognizes the causal differences that exist between different types of systems and proposes new mechanisms for understanding the level of complexity when decisions are made [15]. There are 5 classifications in the cynefin framework, namely complex, complicated, chaotic, simple, disorder [15].

Stacey Matrix. This approach is obtained from one literature [17]. The Stacey Matrix is designed to help understand the factors that contribute to complexity and select the best management action to address different levels of complexity [17]. The basis of the matrix is two dimensions: agreement and certainty [17].

Value-based Software Process Tailoring Framework. This approach is obtained from two literatures [18] [26]. The framework is a combination of value-based factors, MoSCoW rules, Quality Functional Deployment (QFD), Activity-Based Costing (ABC), Priority Map, Value Index and Value Graph [26]. The purpose of this framework is to provide a systematic method using an integrated approach that is able to reduce subjectivity in decision making and satisfy stakeholders [26], also more efficient and outcome-based [18].

Essence Framework. This approach is obtained from one literature [12]. The Essence Framework is a common ground defines the Language and Kernel for modeling software development methods [12] [28] [29]. The language is a domain-specific languages for defining the Kernel, Practices, and Method [28]. The kernel is a conceptual model of software development domain [30]. In short, this framework is a composition of practices. There are similarities, or kernels, shared between all of these methods and practices [12].

B. How to Use of The Approach in Determining Software Development Method

To answer the RQ2 question, "How to use an approach in determining software development methods?", The explanation for each approach from the previous section are as follows:

Comparative Analysis. (1) understand the organization's condition and situation from the aspects of personnel, needs, applications, organization, operations, business, technology, and processes [14]. (2) compile a list of available software development methods and their characteristics, then compare project and organizational characteristics with software development methods [14]. (3) select a software development method based on the highest compatibility level [20].

Multi-criteria Decision Making Technique. The AHP technique, the steps are taken as follows. (1) determining the criteria, sub-criteria, and alternative methods of software development. (2) selecting respondents to rank their importance using the Saaty Scale Preference. (3) calculating to get the weight of each criterion, sub-criteria, and alternative. (4) calculating the consistency ratio to ensure the consistency level of the answers. If the consistency ratio value is below 10%, repeat step number 3. (5) sort the alternatives based on the highest weight [13][21]. The Fuzzy AHP technique, the steps taken are as follows. (1) define linguistic value with corresponding fuzzy numbers. (2) defuzzification of the decision matrix. (3) define criteria, sub-criteria, and alternatives. (4) calculate matrices to get weighted numbers. (5) calculate consistency ratio. (6) sorting weight from alternatives. [25]. The TOPSIS technique, the steps are taken as follows. (1) determine the number of alternatives, criteria, and decision-makers involvement. (2) construct decision matrices. (3) standardize the decision matrix. (4) calculate weighted standardized decision matrix. (5) determine ideal solution and negative ideal solution. (6) find relative closeness to the ideal solution. (7) sorting the alternatives in descending [24].

Intentional Modelling Framework. (1) determine the goals of the project [16]. (2) determine the activities that must be done to achieve these goals [16]. (3) choose practices that are in accordance with the activities to be carried out [16]. (4) check the vulnerability of each selected practice, if there is a vulnerability, then solve the vulnerability by looking for or linking with other practices [16]. (5) apply the practice [16].

Goal-oriented Meta-model. (1) determine the objectives of each activity, then arrange or classify the elements needed [16]. (2) combine or generalize similar elements [16]. (3) do coupling process, installing independent elements with elements that are closely related to each other [16]. (4) the independent elements that have been linked are prioritized according to the appropriate criteria [16]. Ordering priorities can be done by using AHP's formal decision-making techniques [16].

Contingency Factors. (1) summarize all the methods available in the organization [19]. (2) determine the project development context to be carried out, such as the level of uncertainty, the impact of the project, and the project structure [19]. (3) prepare the criteria needed for each project [19]. (4) select the methods that are available or have been used in the organization to organize them into a series of development activities [19]. That way, the entire mechanism of the method has been understood by the team in the organization [19].

Method Engineering. (1) ensure that the organization has a repository of fragments, collection of methods, techniques, or tools used in developing software [19]. (2) understand the project environment such as goals, team, internal and external environment, and project's characteristics [19]. (3) select the fragment from the repository and validate the characteristics of the projects [19]. (4) combine the fragments for implementation in the project [19]. (5) adapt and measure the performance of the project implementation against the compiled collection of fragments [19].

Cynefin Framework. (1) mapping project criteria into Cynefin's domain to help decision makers understand the types of projects to be executed [17]. (2) mapping the criteria into the simple domain if the practice is easiest and has the least causal relationship [17]. (3) mapping criteria into a complicated domain if practices have clear relationships between explainable causes and effects [17]. (4) mapping the criteria into a complex domain if the domain causes the difficulty for process improvement [17]. (5) mapping the criteria into the chaotic domain if the criteria for the project to be carried out are the most difficult and have chaotic causes [17]. (6) mapping the criteria into disorder domain if all perspectives contradict one another [17]. (7) once the mapping is done, a software development method can be selected according to the characteristics of the project [17].

Stacey Matrix. Determining the software development method with this approach is the same as the Cynefin Framework[17]. However, the mapping is entered into a Stacey matrix with measurement parameters that are carried out by determining the level of uncertainty and agreement of a project. [17]. Once mapped, validate the characteristics of the existing software development methods for selection [17].

Value-based Software Process Tailoring Framework. (1) identify the value factors that are most appropriate for the needs of the project [18][26]. (2) do an assessment of the factors that have been determined to rank priorities is carried out using the MoSCow rules to guide the assessment process [26]. (3) assess the relationship between the identified value factors and the activities of the software development process [26]. (3) estimate the cost of each process and task in making the software to completion [26]. (4) if it is deemed unsuitable, select, eliminate, or combine related activities based on the identified value factors, then estimate the cost again until the appropriate value is obtained [26]. Experienced practitioners is needed for using this approach [18][26].

Essence Framework. (1) understand the concept of the kernel and essence language such as Alpha, Activity Space, Work Product, and Activity [12][28][30]. (3) identify the Alpha Kernel that is relevant to the activities carried out [12]. (3) outline the existing software development practices and be understood by the team [12]. (4) add a sub-alpha containing the activity derived from alpha [12]. (5) define alpha states and checkpoints for each alpha activity [12]. (6) add a work product, which contains the output of the activity or defined alpha. (7) define activities based on the expected output or work product [12][28]. (8) identify the relevant kernel activity space to put a series of activities [12][28]. (8) connect activities with kernel activity spaces [28].

TABLE IX. LIST OF APPROACHES DETERMINING SOFTWARE DEVELOPMENT METHODS

No	Classification	Approaches	References
1	Selecting	Comparative Analysis	[22], [14], [20], [27]
2		Multi-criteria Decision Making Technique	[24], [13], [21], [25]
3		Cynefin Framework	[17]
4		Stacey Matrix	[17]
5	Tailoring	Intentional Modelling Framework	[16]
6		Goal-oriented Meta-model	[16]
7		Contingency Factors	[19]
8		Method Engineering	[19]
9		Value-based Software Process Tailoring Framework	[18] [26]
10		Essence Framework	[12]

V. Conclusions

This research was conducted by a systematic literature review. In general, there are two classifications for determining software development methods for organizations, namely selecting, and tailoring. Sixteen literature reviewed, there are 10 approaches to determine software development methods including Comparative Analysis, Multi-criteria

Decision Making Techniques, Intentional Modeling Frameworks, Goals-oriented Meta-models, Contingency Factors, Method Engineering, Cynefin Framework, Stacey Matrix, Value -based Processes Tailoring Framework, and the Essence Framework. To determine the most suitable software development method for the organization, not only select an existing software development method, but also create a software development method are possible that fits the context.

VI. Future Work and Limitation

This study's limitation is the used criteria, keywords, and databases have not reached all related research that has ever existed. Furthermore, this research can be continued by evaluating the effectiveness of this approach in determining the organization's most suitable software development method.

***Abstract*—This study presents six machine learning models in the prediction of student success in a technology-mediated environment. Student behavioral attributes with a learning management environment have proven to be a significant determinant in forecasting students' performance. This study attempts to provide the model with optimum accuracy to determine students who need assistance to improve their educational performances and other learning outcomes. We examined the impacts of SMOTE data re-sampling and the effect of attribute selection in this study. The models' performances were enhanced with the re-sampling method as the imbalanced dataset was identified to have performed poorly. Attribute Selection with the top ten attributes and 10-fold cross-validation offer best performances. The six predictive models utilized in this study are Linear Discriminant Analysis, Logistic Regression, Classification and Regression Tree, K-Nearest Neighbour, Naïve Bayes Classifier, and Support Vector Machines. Classification and Regression Tree model and Linear Regression had the best accuracy score of 0.86 after 10-fold cross-validation and top ten attribute selection. This study concludes that student behavioral attributes are useful predictors of student success.**

***Keywords*—Blended-Learning, Data Re-sampling, Machine Learning Models, Information Gain, Feature Selection, SMOTE**

I. Introduction

The machine learning technique is one of the main methods used in studying student performance or success, aside from statistical analysis and data mining. Academic performance is a daunting challenge for tertiary education institutions across the globe. [1] and [2] described data analytics as a tool for identifying students who are struggling educationally and enhancing throughput in various educational institutions.

This study falls under the category of Educational Data Mining (EDM). EDM is a subdivision of data mining that specializes in designing, evaluating, and implementing various automatic tools for measuring vast amounts of data from academic environments [3]. This study investigates student success through student behavioral attributes in the learning management environment. In any learning environment, student engagement is a crucial indicator for assessing a student's success or failure [4]. The channels of education delivery include traditional classroom, online-learning, blended-learning, and others. The Learning Management System (LMS) is a learning platform that allows instructors and learners to communicate without having to meet in person [5]. The global adoption of LMS platforms in learning is increasing by the day as several factors have warranted this acceptance. The reason for the adoption of LMS include the convenience of learning at student pace, improvement of cost-efficiency for the institutions and full coverage of a large number of students [6]. The blended-learning, which is interchangeably called hybrid-learning, is an infusion of both standard classroom and technology-aided settings [7]. [8] provided objectives of blended-learning as an effective learning process, student-teacher physical contact, academic performance enhancement, and learner's freedom. However, the reported rate of failure in blended-learning in the undergraduate programs has dramatically increased in current time [9]. Research into the determinant factors for a boost in student success in this blended-learning environment will increase throughput in tertiary education across the globe as the present COVID-19 pandemic necessitated the adoption of one form of online or the other. This research provides machine learning models with optimal performance in predicting student success in undergraduate as a form detective tool in assisting students from not dropping out of the blended-learning course and increasing academic outcomes.

In this paper, Section II discusses the related work on the prediction of the success of students with the application of machine learning. Section III highlights the research design, including data collection and pre-processing, feature selection, machine learning techniques, and evaluation metrics. Section IV outlines the results. Section V concludes the paper.

II. Related Work

Student success prediction is a crucial challenge in the technology-aided settings [5]. Past researches have provided various factors that influence student success. Some the factors are the student demographic information such as gender [10], previous academic performance [11] and interactions with the learning environment [6]. Therefore, this research investigates the influencing power of the student's interaction with the Learning Management System. Most scholars proposed that

978-1-6654-4067-7/21/$31.00 © 2021 IEEE

the engagement/interaction on LMS has a positive correlation with student success [6], [12]. [13] studied student performance on final examination grade in an undergraduate program using Decision Tree, Naïve Bayes, Logistic Regression, Support Vector Machine, K-Nearest Neighbour, Sequential Minimal Optimisation and Neural Network. The Logistic Regression performance was the best among the algorithms used in the study with an accuracy value of 66%. The authors in [14] predicted student academic performance in the virtual learning environment for four categories. Artificial Neural Network outperformed Logistic Regression and Support Vector Machine algorithm with a classification accuracy of 84% to 93%. [15] used the Recurrent Neural Network (RNN) in their in-depth knowledge and engagement study. The authors achieved an accuracy value of 88.3% for RNN in their research. [5] investigated student learning performance from LMS data using Support Vector Machine, Linear Discriminant Analysis, Random Forest, K-Nearest Neighbour, and Classification and Regression Tree (CART). The result showed the performance of random forest as the best with an accuracy value of 90%. [5] further suggested the class imbalance problem's solution in future work. [16] applied the Logistic Regression predictive model in their study on variables (degree of engagement, degree of prestige, degree of visibility, student access amount, management system by subject, experience, age, and gender) and got an accuracy value of 87.53%. [12] investigated the academic success of students based on their learning management network activities. The predictive models used in the analysis were Artificial Neural Network, Decision Tree, and Naïve Bayes with bagging boosting and ensemble techniques. The highest accuracy value of 82% was obtained from the Decision Tree classifier.

Understanding data sources in prediction are essential as it lays the groundwork for future research that has yet to be pursued. It also cuts down computation times on feature extraction [17]. Many studies have used qualitative data (surveys), quantitative data (student behavioral data from online learning activities), and others used combinations of both data types in the prediction of student performance [4]. [6] in their research used publicly available data from the Open University of the United Kingdom to investigate the student's performance. Four online courses from the Moodle LMS log-file data of the undergraduate students at Tel Aviv University, Israel, were utilized by [18] used.

Captured images from videos were developed and used for engagement recognition in relation to student performance by [19]. [20] investigated the connection between student engagement and academic success in a technology-mediated platform using the LMS data from a North American university undergraduate science course. [21] explored interview questions for student engagement challenges in e-learning platforms at different Saudi universities and their relationship with student performance. [16] applied Moodle LMS data from graduate courses in public management course at the university in Brazil from 2014 to 2015. [6] used four variables to analyze student performance in online learning: initial evaluation results, the highest level of education, final test score, and clicks on the learning site. Academic achievement was strongly correlated with student clicks on nine online learning sites, final grades, and evaluation performance. Students click on forumng and oucontent were also found to be influential in predicting student performance. Student participation and final exam grade were positively impacted by forum conversation and access to course content. [20] examined the connection between student engagement and performance in a technology-mediated setting using nine engagement metrics and a cluster analysis derived through students' activity records. According to their findings, student characteristics such as frequency of logins, material read, and the number of forum read affected quiz results, resulting in a high final course score. Because of the positive association between participation and results, [20] suggested that student engagement may be a determinant of academic success.

III. Methodology

In this study, we seek to predict the success using the student behavioral patterns/activities on learning management. Six machine learning predictive models will be trained with K-fold cross-validation after feature selection using the top five and ten features after applying the information gain filter on the dataset obtained from LMS. The confusion matrix, accuracy, precision, recall, and f1-score will be used to evaluate the models' performance in this study to ascertain the model with the optimum performance.

A. Data Acquisition and Pre-processing

Students dataset containing the demographic, behavioral, and academic records were obtained from Kalboard 360 LMS. The data has 480 records of 305 male and 175 female students in an institution [12]. The data consists of 16 numerical and categorical attributes of students gathered over two semesters(first and second). The target variables are low, medium, and high represented below:

$$Grade = \begin{cases} 0-69, & \text{Low} \\ 70-89, & \text{Medium} \\ 90-100, & \text{High} \end{cases}$$

The dataset's class distribution is 127, 211, and 142 for low, medium, and high classes. To fix the class imbalanced distribution challenge, we will be employing Synthetic Minority Oversampling Technique (SMOTE) to avoid dominance from the majority class and improve the models' performance. The SMOTE works by generating new instances from the minority group prior to training the model [22].

B. Attribute Selection

To predict student success in a blended-learning environment, we explored the Information Gain evaluation filter to determine the most contributing attribute. For attribute selection, entropy is used to measure the value of attributes in descending order. We will be selecting the attributes with high entropy for dimensionality reduction and improvement in model performance [23]. Information gain value is represented mathematically as 0≤e≤1. This means that the value spans from 0 to 1.

C. Classification Models

In this study, two linear (Linear Discriminant Analysis and Logistic Regression) and four non-linear (Classification and Regression Tree, K-Nearest Neighbor, Naïve Bayes and Support Vector Machines) supervised machine learning models will be trained to predict the success of the student in a blended-learning setting.

a) Linear Discriminant Analysis: The Linear Discriminant Analysis (LDA) is a predictive model used to model the differences in classes. The discrimination is done by comparing the means of attributes. LDA is used for dimensionality reduction and the minimization of the possibility of misclassifying cases. The structure of LDA used in this paper is from [24].

b) Logistic Regression: The Logistic Regression (LR) is used for predictive exploration. LR is also used to forecast categorical dependent attributes, mostly with the support of predictor attributes. The LR is focused on the estimate of the greatest probability, and the estimate must be most likely. The architecture of the LR used in this study follows [25].

c) Classification and Regression Tree: The Classification and Regression Trees (CART) build a framework from the training set. The division points are selected rapaciously by comparing each attribute and the significance of each attribute in the training set to reduce the loss function [24]. The application of the CART model in this paper is from [24].

d) K-Nearest Neighbor: The K-Nearest Neighbor (KNN) identifies the centroid sample in the training dataset for new samples. The overall average sample is considered here as forecast from the centroid closest neighbor [5]. The distance measure used is the Euclidean distance. KNN is a simple model but very useful in prediction.

e) The Naïve Bayes Classifier: The Naïve Bayes Classifier (NBC) is the most proactive and logical learning algorithm for most classification problems. NBC is based on Bayes' theory of strong assumptions of independence within attributes using a Bayesian framework [1], [6], [24]. The execution of NBC in this study is gotten from [24]

f) Support Vector Machines: The Support Vector Machines(SVM) is an efficient, strong, and reliable predictive model that is identified by a separating hyperplane. SVM generates a decision boundary that is used for prediction. SVM works by determining the closest data dimensions called support vectors to the inference segregation in the training dataset and separates the current test variable through the use of the functional margin [26]. The implementation of the SVM used in this paper comes from [26]

D. Performance Metric

The efficiency of the six classification models used in this study will be assessed through performance metrics such as the confusion matrix, accuracy, recall, precision, and F1 score after K-fold cross-validation, where k=10. These performance metrics have been widely used in previous research.

Table I: Information Gain and Attributes Categorisation for the Set of Attributes in the Prediction of Student Success

Rank	Entropy	Attribute	Attribute Categorisation
1	0.46	Visited Resources	Behavioural
2	0.4	Student Absence Days	
3	0.37	Raised Hands	
4	0.26	Announcement View	
5	0.15	Parent Answering Survey	
6	0.13	Nationality	Demographic
7	0.13	Relation	
8	0.12	Place of Birth	
9	0.11	Discussion	Behavioural
10	0.10	Parent School Satisfaction	
11	0.07	Topic	Academic
12	0.05	Gender	Demographic
13	0.04	Grade Id	Academic
14	0.01	Semester	
15	0.01	Stage Id	
16	0.00	Section Id	

- **Confusion Matrix**: The value of the information provided by a predictive model about expected and actual class labels is held in the confusion matrix. Our models are evaluated using the information in the matrix.
- **Accuracy**: The accuracy score is a common metric for evaluating classification models. It's calculated as the number of precise predictions dependent on the total number of predictions.
- **Recall**: The number of accurate positive predictions and the ratio of the total number of positives are referred to as recall. This is also known as the true positive rate.
- **Precision**: The number of accurate positive predictions as a percentage of the total number of positive predictions is known as precision.
- **F1 score**: The F1 score represents the average of recall and precision. It serves as a red flag of incorrectly classified performance.

IV. Results and Analysis

The results of the experiments performed with the six predictive models are presented here. After applying the information gain attribute evaluation in InformationG, ten attributes were the most contributing attributes in predicting student success. The top five attributes are categorized under student behavioral attributes with the LMS, as shown in InformationG. The two separate experiments were performed using the top 5 and 10 attributes for attribute selection to reduce the dimension and improve models' performances. K-fold (5 and 10) cross-validations were utilized for training the models after resampling the data with the SMOTE technique in this study.

The Information Gain results show the order of the importance of the features in the prediction of student success in descending order. Figure 1 also gives the graphical representation of the features in order of entropy value.

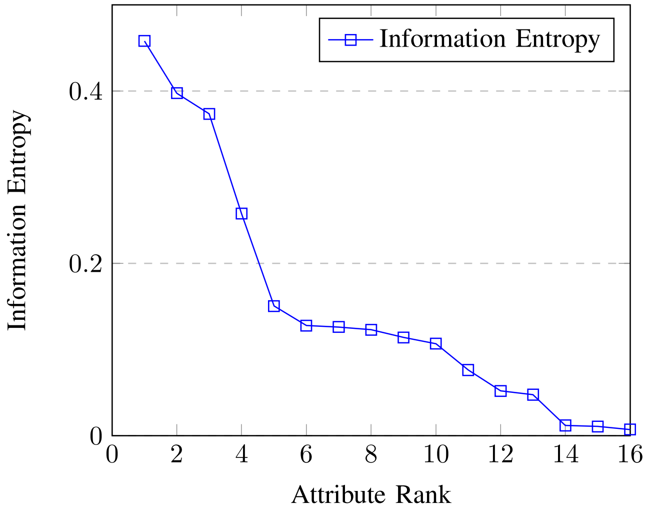

Figure 1: A Chart representation of the Information Gain for Set of Attributes to Predict Student Success

	High	0%	10%	90%

Table III: Confusion Matrix showing the performance of **Logistic Regression** Model after 10-fold cross-validation using the top 10 attributes

A. *Prediction Models*

This segment of the paper presents the results obtained from six models used in this study. The confusion matrices in Tables II, III, IV, V, VI and VII highlight the performances of the predictive models. The confusion matrices are determined from the testing dataset with the SMOTE-balanced dataset after the 10-fold cross-validation. We obtained the best model performances from the balanced dataset in contrast to the imbalanced dataset performance. tab: 10-fold comparison and tab: 5-fold comparison also compared the performances of the application of the 10 and 5 fold cross-validation on the balanced and imbalanced dataset. The performance of the 10-fold cross-validation outweighs that of 5-fold in the balanced dataset, while 10 and 5 fold cross-validate make no difference in the models' performances in the imbalanced dataset. From tab: Linear, the Linear Discriminant Analysis obtained an accuracy score of **0.84** after attribute selection of the top 10 attributes and 10-fold cross-validation. The percentage of the classification of the classes are 98, 62 and 90 for the low, medium, and high, respectively. The accuracy score for the Logistic Regression model is **0.86** and tab: Logistic shows the performance of Logistic Regression for low-class as 98%, medium as 67%, and high as 90%. tab: CART represents the Classification and Regression Tree model's performance with an accuracy score of **0.86**. The percentage of the low, medium, and high classes is 95, 72, and 88, respectively. The K-Nearest Neighbour accuracy score is **0.81** which was obtained from the confusion matrix in tab: KNeighbour with the low, medium, and high classes percentage as 92, 56, and 90. The dominant class in this classification is low-class. The Naïve Bayes Classifier performance as represented in tab: Naïve gives the accuracy score of **0.82** where the classes are rightly classified in the percentage of 88, 61, and 92 for low, medium, and high. The performance of Support Vector Machines as illustrated in tab: Support presents an accuracy score of **0.72** achieved from the classification of 90%, 36%, and 84% for low, medium, and high classes. The best accuracy were achieved from the **Logistic Regression** and **Classification and Regression Tree** with an accuracy score of **0.86**. The poorest performance was obtained from the **Support Vector Machines** with an accuracy score of **0.72**. In summary, the performances of the six models used in this study are represented in tab: Summary where the Classification and Regression Tree outperformed the five other models with an accuracy value of 0.86, precision value of 0.86, recall value of 0.86, F1-score value of 0.86 and Area Under Curve (AUC) value of 0.97. The other models in order of their performances are Logistic Regression, Linear Discriminant Analysis, Naïve Bayes Classifier, K-Nearest Neighbour, and Support Vector Machines.

V. Conclusion

This paper gives a framework for predicting student success in a blended-learning course to assist vulnerable students who are prone to fail or withdraw from the program. The result represented in InformationG shows that the behavioral and demographic attributes are the most contributing predictors in forecasting student performance. The academic attributes have no tangible contribution to attribute importance. The

SVM	0.72	0.70	0.72	0.70	0.90

Table X: The Summary of the Performance Metrics of the Predictive Models' Performances after 10-fold Cross-Validation on the SMOTE balanced dataset and top 10 Attribute Selection.

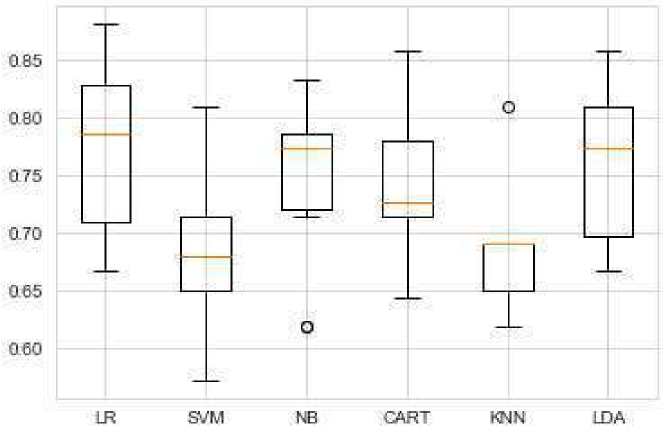

Figure 2: Algorithm Comparison Performance by Training Set

imbalanced data resulted in the models' poor performances in this study; hence, SMOTE method re-sampling technique for balancing to equal count. The application of SMOTE method and the attribute selection using the top 10 features recorded high-performances in the models' performances as expressed in tab: 10-fold comparison. The 5-fold cross-validation results in tab: 5-fold comparison were not as good as that of 10-fold cross-validation in tab: 10-fold comparison except for CART and NBC with the top 5 features. It is also important to note that the 5 or 10 fold cross-validation results are the same for the imbalanced data with 5 and 10 top attributes as shown in tab: 5-fold comparison and tab: 10-fold comparison. In fig:Algorithm Comparison, the LR and LDA performances were the best at the training phase. From tab: 10-fold comparison, the accuracy scores of CART and LR were the best, with a score of 0.86. The other accuracy scores are 0.84, 0.82, 0.81, and 0.72 for LDA, NBC, KNN, and SVM respectively. On critical analysis of the results illustrated in tab: Summary, the CART performance for classification of student success band was the best with an accuracy score of 0.86, precision score of 0.86, recall of 0.86, and an AUC of 0.97. The other models in order of performances are LR, LDA, NBC, KNN, and SVM. We observed that the class's misclassification rate in medium-class was higher than any other classes for imbalanced and SMOTE balanced data. The most rightly predicted class is low, followed by high class. In summary, the results obtained from this study show that machine learning techniques are efficient in identifying student performance on time for possible aid to prevent failure in their courses. The behavioral and demographic attributes are also essential in student performance classification. The constraint of this study is the type of data used. A more robust dataset in terms of the number of attributes would have given a holistic view of other essential attributes needed to classify the student performance. The findings of this study are solely dependent on the data utilized in the research. In the future study, we intend to investigate the reasons for the medium class's low classification for both imbalanced and balanced datasets. This study's machine learning models will also be extended to data from the university repository and not freely available dataset online used in this study. This paper's contribution is the presentation of the critical behavioral attributes for timely identification of students who are prone to withdraw from their courses for assistance by the institutions or administrators in an expeditious manner. This study concludes by highlighting that students' behavioral activities with the LMS are positive predictors to detect the students' performance.

***Abstract*— Contrary to the popular Convolutional Neural Network (CNN), which depends on the shift-invariance in the image, Capsule Networks depends on hierarchical model relations. This aspect of Capsule Networks keeps them in the machine learning domain despite their enormous size with only comparable accuracy to the CNNs. Capsules utilize an intricate algorithm to create a route by agreement, leading to their size and uniqueness. Recent developments in Capsule Networks have contributed to mitigating the problem of size and improving accuracy. We focus on modifying one of the Capsule Network, Residual Capsule Network (RCN), to a comparable size to modern CNNs, thus restating Capsule Network's importance. In this paper, Residual Capsule NeXt (RCNX) is proposed as an effective and more advanced version of RCN with a size of 1.5M parameters and an unprecedented improvement in the network's accuracy on the CIFAR-10 dataset to 89.3%. This accuracy and size exceed the famous embedded CNN model MobileNetV3.**

Keywords—Convolution Neural Networks, Capsule Network, Residual Capsule Network, ResNeXt, CIFAR-10, Residual Capsule NeXt, RCNX

I. Introduction

In recent times, CNNs are prevalently convenient for image recognition in the Machine learning domain. Before the arrival of machine learning, any signal processing for an image used convolution, which led to the intuitive development of CNNs. Recently machine learning algorithms are moving towards an approximation of human vision[2]. One of the earliest successful attempts was AlexNet. The neural arrangements of the AlexNet had similarities to the human visual pathway[2], [3]. The model replicated the interlaced Optic nerves in the human visual pathway.

Capsule Networks[1] are different in many ways when compared to CNN. Capsule Networks took a forward step in the improvement of end layers of image recognition. This network is first proposed by one of the authors of AlexNet, i.e., Geoffrey Hinton[1]. Capsule Networks implement the concept of capsules for each characteristic detected in an image. These capsules indeed required a new way of routing between nodes to bring the idea of routing by agreement. All these combined, we arrive at an excellent model to recognize handwritten digits. Furthermore, Capsule Networks can recreate the different handwritten digits in different styles, a fascinating technique known as the reconstruction[1].

Developments are brought into the Capsule network to advance its application. These advancements helped Capsule networks to improve from simple handwritten digit classification to fully functional object recognition in an image. We focus on one such model, which improved the Capsule network's application to become an excellent image recognition tool, namely, Residual Capsule Network[4].

In this paper, a new machine learning model, Residual Capsule Next (RCNX), is proposed, which aims to improve contemporary architecture Residual Capsule Network (RCN)[4]. By utilizing well-established ideas that improve model size and accuracy, we transform RCN into a machine learning model for embedded systems. The paper focuses on reducing the model size tremendously by including modifications that have been proven in different Capsule Network models while improving the model's accuracy. The complex modifications proposed in this paper include replacing initial convolutional layers, change in architecture, improvement in routing by agreement algorithm, including a complex reconstruction network, activation functions, and tuning the model to be excellent in every layer.

II. Background

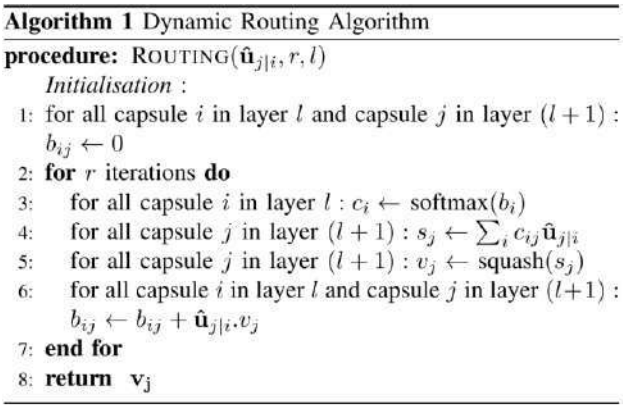
A. Convolutional Neural Networks or CNNs

Space invariant artificial neural networks, commonly known as CNNs, have their name due to the inclusion of existing convolution algorithms and their shift-invariant function[5]. CNN derives its understanding from the similarities and differences from region to region in an image. They feed these scalar-feature detectors output through multiple layers of feature detectors and pooling layers and embedded in them to reduce the complexity while capturing the assumed essential data[4].

B. Capsule Network

Acknowledging limitations of the above-mentioned scalar-feature detectors and the loss of information due to pooling layers led to Capsule Networks' invention[1]. Capsule networks substituted the shift-invariant scalar features with an equivariant vectored-feature detector that brought forth this new branch on neural networks[1], [4]. The pooling layer's loss of information is replaced with the invention of the 'routing-by-agreement' algorithm.

Capsules are a collection of neurons that singly activate based on numerous aspects of an object, such as size, position, and hue[4]. Every capsule excites depending on a single significant aspect of the object. The output of these feature detectors is vectors encoded with each aspect's probabilities that the network knows[1], [4]. Routing by agreement improves the complexity of the network while the increment in size is tolerable. By combining the probabilities vector yielded by each capsule, it is possible to estimate the network's prediction reasonably. The initial algorithm that the capsule networks used is the Dynamic Routing Algorithm[1]. The Dynamic Routing Algorithm is as per Fig. 1[1].



```
Algorithm 1 Dynamic Routing Algorithm
procedure: ROUTING($\hat{\mathbf{u}}_{j|i}, r, l$)
  Initialisation :
  for all capsule $i$ in layer $l$ and capsule $j$ in layer $(l+1)$ :
  $b_{ij} \leftarrow 0$
  for $r$ iterations do
    for all capsule $i$ in layer $l$ : $c_i \leftarrow \mathrm{softmax}(b_i)$
    for all capsule $j$ in layer $(l+1)$ : $s_j \leftarrow \sum_i c_{ij}\hat{\mathbf{u}}_{j|i}$
    for all capsule $j$ in layer $(l+1)$ : $v_j \leftarrow \mathrm{squash}(s_j)$
    for all capsule $i$ in layer $l$ and capsule $j$ in layer $(l+1)$ :
    $b_{ij} \leftarrow b_{ij} + \hat{\mathbf{u}}_{j|i}.v_j$
  end for
  return $\mathbf{v_j}$
```

Fig. 1. Algorithm 1: Dynamic Routing Algorithm[1]

The squashing function used in Algorithm 1 is [1]:

$$v_j = \frac{\|s_j\|^2}{1+\|s_j\|^2}\frac{s_j}{\|s_j\|} \qquad (1)$$

C. *Residual Capsule Network (RCN)*

RCN is cumulative of architectures of ResNet and Capsule Network[4]. The abstract of RCN architecture is a redundant intricate layer of ResNet CNN applied on the initial Capsule Networks section. These repetitive layers allow the network to create a deeper feature extraction process before passing it on to Capsules[4]. The Capsule Network consists of a light convolutional layer before the Capsules. This simple convolution is replaced with 8 layers of redundant ResNet convolutions, which improves the complexity tremendously and boosts the Capsule Network's ability, thereby increasing the model's accuracy[4].

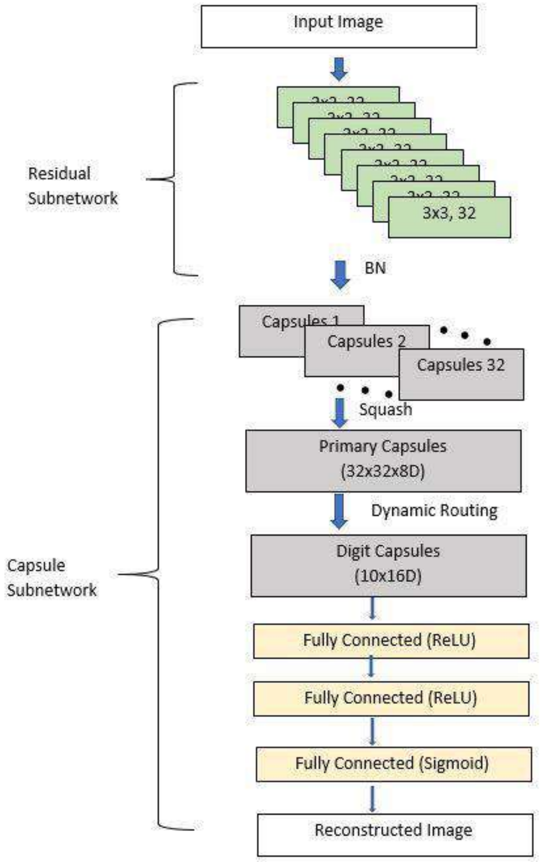


Fig. 2. Residual Capsule Network[4]

This modification is consistent with Capsule Network's view as no loss of information or embedded pooling layers. This RCN produced 84.16% accuracy with 11.86 M parameters for the CIFAR-10 dataset is significantly better than the 89.4% with the seven ensemble Capsule Network model with 101.5M parameters[4].

Considering the redundancy of the ResNet convolutions and the inefficiency of ResNet in comparison to ResNeXt[6], it is only fair to observe there is room for improvement. Although there has been an improvement in the routing-by-agreement algorithms, the RCN authors have not included any such changes to the later networks' capsules. Keeping in mind these variations, we propose changes in the initial convolutional layers and routing-by-agreement algorithm.

D. *ResNext and Cardinality*

ResNeXt is a neural network that brought improvements to ResNet. It is a homogeneous network with the ability to compress the conventional ResNet substantially[6]. "Cardinality" is the additional dimension that is provided to the network to move forward from the fundamental channels and kernels of convolutions in ResNet[6]. Cardinality delineates the extent of transformations. The implementation of Cardinality in ResNet architecture leads to ResNeXt.

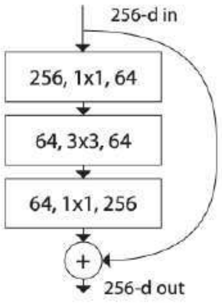

Fig. 3. ResNet convolution.

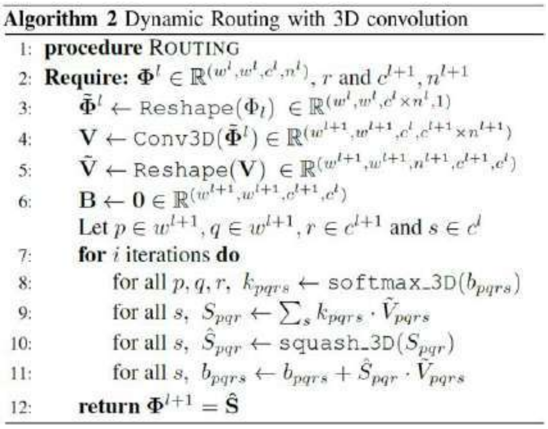
E. *DeepCaps*

Compared to various routing-by-agreement algorithms, the performance boost proved in the DeepCaps Network with the inclusion of Dynamic Routing with 3D convolution stands out. This significance to DeepCaps routing-by-agreement algorithm is due to the algorithm's simplicity in theory and its application. The following Fig. 5. contains the algorithm of Dynamic Routing with 3D convolution[7].



```
Algorithm 2 Dynamic Routing with 3D convolution
procedure ROUTING
Require: $\Phi^l \in \mathbb{R}^{(w^l,w^l,c^l,n^l)}$, $r$ and $c^{l+1}, n^{l+1}$
    $\tilde{\Phi}^l \leftarrow$ Reshape($\Phi_l$) $\in \mathbb{R}^{(w^l,w^l,c^l \times n^l,1)}$
    $\mathbf{V} \leftarrow$ Conv3D($\tilde{\Phi}^l$) $\in \mathbb{R}^{(w^{l+1},w^{l+1},c^l,c^{l+1} \times n^{l+1})}$
    $\tilde{\mathbf{V}} \leftarrow$ Reshape($\mathbf{V}$) $\in \mathbb{R}^{(w^{l+1},w^{l+1},n^{l+1},c^{l+1},c^l)}$

F. *3-Level Residual Capsule Network*

Inspired by the You Only Look Once (YOLO) network model, the RCN authors incorporated 3-staged feature detectors to bring a compound effect of various views of the image throughout the network to the RCN model[8]. This novel model, 3-Level Residual Capsule Network, is an exemplary work in utilizing Capsule Network's potential in deep stages. Nevertheless, an increase of complexity traces to an upsurge in the parameters, and as the network is a concatenation of three sets of 8-Layered ResNets. This modification increased accuracy to 86.42% while compensating for the increase in parameter via reducing intricacy in the reconstruction and maintaining a single layer output instead of RGB reconstruction[8].

From the 3-Level Residual Capsule Network, we note the contraction in the reconstruction network is deteriorating the performance. Also, the 3-Staged model is a significant factor of improved accuracy.

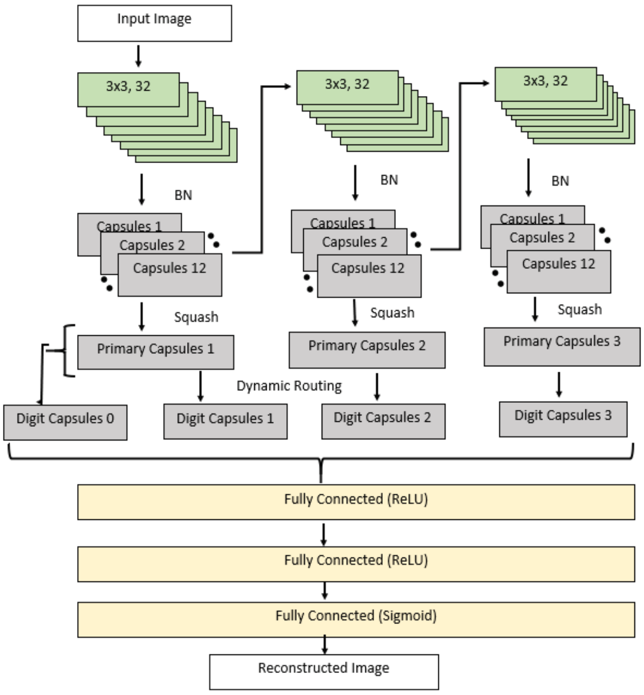

Fig. 6. 3-Level Residual Capsule Network [8]

III. PROPOSED RCNX: RESIDUAL CAPSULE NEXT

The following sections reveal the underlying enhancements included to RCN and model architecture of the proposed RCNX: Residual Capsule NeXt. Fig. 7. demonstrates the new architecture of RCNX.

A. *Primary Res Next Layers*

To accomplish superior accuracy, convolution layers of Capsule Network should be made capable of compound feature extraction. Even though Capsule Network performs based on routed capsules, the preliminary layers are convolutions dependent[8], [4]. Redundant layers of convolution in the initial stages of Capsule Network give us better multiplex feature extraction, and this provides the model with a good starting point.

The RCN considers eight layers of the residual network without any inclusion of bottleneck design or any different cardinality to improve the complexity and reduce parameters[4]. As mentioned previously, this paper proposes modifications in such features which is incomplete in the RCN network. We brought considerable compression and improvement to the RCN network. RCNX standouts with the inclusion of the new cardinality to RCN. As explained in the background, ResNeXt architecture reduced the number of parameters and, at the same time, improved the accuracy of the model's image classification properties.

With the missing structural advantages, RCN lacks the complexity to uncover a deeper understanding of the images, which can be the reason for not developing higher accuracy despite eight repetitive layers of ResNets. Since we include the required complexity using ResNeXt, we eliminated the redundant layers. ResNeXt structure embedded in the RCNX is with variable cardinality before reaching the capsules. While including the 3-level staged architecture, we also find the network improves learning of the image for different capsules to learn from various views of the image.

B. *3-Level ResNeXts before Capsule Network*

With the incorporation of various views, the proposed RCNX can learn intricate features and can do it fast. Allowing the training network to go through each level repetitively due to the intricate structure brings the best of RCNX with minimal effort.

In the 3-Level structure, the ResNeXt models with four and two cardinalities are included, with filters of the same size, i.e., 32. This varying cardinality brings variable total filter lengths for different capsules. Primary capsules receiving three different views to the image were structured to produce probability vectors of varying lengths, including flexibility in designing various features with various dimensions. We use the dimensions of 8, 24, 32, and 8 across four primary capsules.

C. *Efficient Capsules with '3D convolution-based dynamic routing.'*

Using 3D convolution-based dynamic routing, DeepCaps authors modified and improved routing by agreement algorithm for capsule networks[7]. This 3D convolution helps to trim the network in size. The convolution is considering that neighbouring neurons produce a similar pose, and this can be a cluster[7].

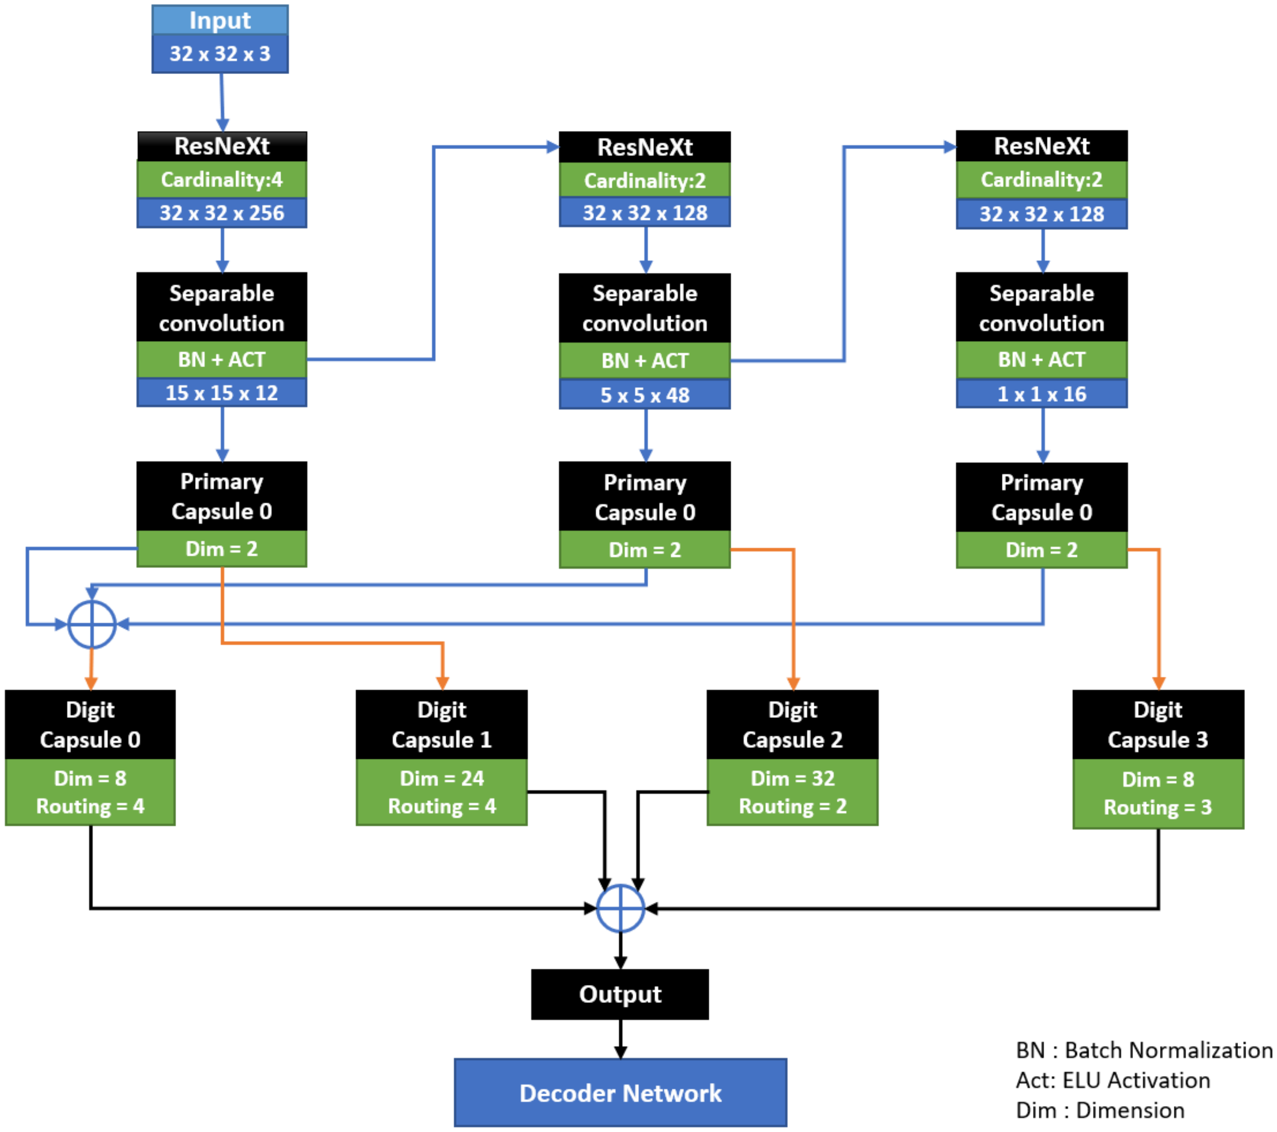

Fig. 7. Proposed RCNX: Residual Capsule NeXt Architecture

Using the 3D convolution-based dynamic routing algorithm, we tremendously reduced the repeated routing from layer ‘L’ to layer ‘L+1’. This reduction amount to a reduction factor of $c * (w^L w^{L+1})^2$ parameters in each capsule, where c represents the number of channels, and w^L represents the width of layer L[7].

The Capsule network of the RCNX is optimized to perform iterations that give the best performance and accuracy. We achieve optimization with Neural Network Intelligence (NNI)[9], and thus we use routings of 4, 4, 2, and 3 for each capsule network to be effective.

D. 3D reconstruction by decoder network

At the end of RCN, the reconstruction network does not comprise 3-dimensional inverse rendering but is limited to a 2-dimensional reconstruction. We include this 3-dimensional reconstruction as this is important for the Capsule Networks, in general, to learn quickly, and thereby creating the model to be more involved by integrating class independent decoder.

E. Elu activation function

Activation functions provide image classification models non-linearity that help them learn mapping functions, contributing to training and performance[10]. After most convolution layers, we use activation functions, and activation functions are mainly an integral part of the ResNeXt layers. The activation function in RCN is ReLU[8]. This ReLU activation is replaced by the Exponential Linear Unit (ELU) activation function as it is understood via repeated trials and NNI hyperparameter search that ELU outperforms ReLU in the case of proposed RCNX architecture[9], [10]. ELU also avoids some cons of ReLU activation. ELU activation excludes the problem of dead ReLU[10]. It also produces negative outputs, creates better optimization of biases and weights, and prevents saturation by avoiding non-zero gradient errors.

F. Summary

In summary, a 32x32x3 image travels through the proposed Residual Capsule NeXt as follows. The 3-channel image is convolved with primary ResNeXt convolutional layers, which extracts in-depth features, and creates channels of size $c * f$, where c is the cardinality and f is the filter length. These networks generate channels of 256 and 128. These pass through a separable convolution before proceeding to primary capsules, thereby creating a deeper model of RCNX architecture.

The separable convolution changes the image height and filter sizes to 15x15x12, 5x5x48, and 1x1x16, which provide the proposed RCNX with a wide range of views of the images. These views at three levels traverse through Primary capsules that have only 2-dimensional capsule vectors as output. These, in a manner of merged layers, get connected to one Digit Capsule, and others are individually connected to separate Digit Capsules.

The digit capsules are of varying sizes yet longer dimensions than Primary Capsules with optimized routing numbers of merges to form an output. Further, we decode output to form an inverse rendering effect by the decoder network to the corresponding input. This decoder network only activates during training and is removed while testing the proposed RCNX.

IV. Training Setup

Lenovo Think System compute node with Intel Xenon Gold processors, with 128GB RAM, and NVIDIA Tesla V100 is used in training and inference of RCNX[11]. CIFAR-10 Dataset is used for training and inference. The model is trained for 35 epochs, with a batch size of 32, Nadam optimizer, and LR decay of 0.9.

V. Results

The proposed RCNX model is trained and tested against the CIFAR-10 benchmark[12]. RCNX delivered an accuracy of 89.31% during the test, and the evaluation model size is 1.58M parameters.

Table I

Performance of various network models on CIFAR10

Model Name	***No. of Parameters***	***Test Accuracy***
Proposed RCNX	**1.58 M**	**89.31%**
Residual Capsule Network V2	1.95 M	85.12%
Baseline Residual Capsule Network	11.8 M	84.16%
3-Level Residual Capsule Network	10.8 M	86.42%
CapsNet	101 M	89.40%
DC Net	11.8 M	82.63%
DC Net ++	13.4 M	89.71%
MobileNet V3	1.83 M	88.93%

Comparing results of the proposed RCNX with results of other capsule network models like baseline Residual Capsule Network, Capsule Network, DCNET, DCNET++, Residual Capsule Network V2, and 3-Level Residual Capsule Network as per Table I[1], [4], [8], [12], we can easily conclude that the proposed RCNX is producing unparalled results.

CIFAR-10 benchmark dataset contains 60,000 images of 10 classes with 6000 pictures per class. 10,000 images in these are for inference and remainder for training the neural network models[12].

VI. Conclusion

Here, a new architecture, RCNX: Residual Capsule NeXt, is introduced. Using ResNeXt convolutions, 3D convolution-based dynamically routed Capsules, architecture following 3-Level RCN, full image reconstruction, ELU activation function, and hyperparameters tuned with NNI, and we achieved a model that is efficient with an accuracy of 89.31% and a reduced model size of 1.58 M parameters when tested on CIFAR-10. Thus, the proposed RCNX is better than embedded models like MobileNetV3, and RCNX is the first capsule network to achieve this in image classification tasks.

***Abstract*—In this paper, we demonstrate the implementation of our ultra-efficient deep convolutional neural network architecture: CondenseNeXt on NXP BlueBox, an autonomous driving development platform developed for self-driving vehicles. We show that CondenseNeXt is remarkably efficient in terms of FLOPs, designed for ARM-based embedded computing platforms with limited computational resources and can perform image classification without the need of a CUDA enabled GPU. CondenseNeXt utilizes the state-of-the-art depthwise separable convolution and model compression techniques to achieve a remarkable computational efficiency.**

Extensive analyses are conducted on CIFAR-10, CIFAR-100 and ImageNet datasets to verify the performance of CondenseNeXt Convolutional Neural Network (CNN) architecture. It achieves state-of-the-art image classification performance on three benchmark datasets including CIFAR-10 (4.79% top-1 error), CIFAR-100 (21.98% top-1 error) and ImageNet (7.91% single model, single crop top-5 error). CondenseNeXt achieves final trained model size improvement of 2.9+ MB and up to 59.98% reduction in forward FLOPs compared to CondenseNet and can perform image classification on ARM-Based computing platforms without needing a CUDA enabled GPU support, with outstanding efficiency.

I. Introduction

ARM processors are widely used in electronic devices such as smartphones and tablets as well as in embedded computing platforms such as the NXP BlueBox, Nvidia Jetson and Raspberry Pi for computer vision purposes. ARM is RISC (Reduced Instruction Set Computing) based architecture for computer processors which results in low costs, minimal power consumption, and lower heat generation compared to its competitor: CISC (Complex Instruction Set Computing) architecture based processors such as the Intel x86 processor family. As of 2021, over 180 billion ARM-based chips have been manufactured and shipped by Arm and its partners around the globe which makes it the most popular choice of Instruction Set Architecture (ISA) in the world [1].

The roots of ARM processors trace back to December 1981 when the first widely successful design, BBC Micro (British Broadcasting Corporation Microcomputer System), was introduced by Acorn Computers [2]. Due to the use of DRAM (Dynamic Random Access Memory) in its design, it outperformed nearly twice as that of Apple II, an 8-bit personal computer, which was world's first successfully mass-produced publicly available computer designed by Steve Wozniak, Steve Jobs and Rod Holt in June 1977 [3].

Fast forwarding to the 21st century, due to constant advances in computing and VLSI technology, ARM-based chips are found in nearly 60% of all mobile devices and computing platforms produced today. With processor performance doubling approximately every two years with a focus on parallel computing technologies such as multi-core processors, computer vision researchers can now implement sophisticated neural network algorithms to perform complex computations for OpenCV applications without a requiring a GPU support.

Convolutional Neural Networks (CNN), a class of Deep Neural Networks (DNN) first introduced by Alexey G. Ivakhnenko and V. G. Lapa in 1967 [4], have been gaining popularity in recent years as researchers focus on creating more advanced intelligent systems. CNNs are popularly used in machine (computer) vision applications such as image classification, image segmentation, object detection, etc. However, implementing a CNN on embedded systems with constrained computational resources for applications such as autonomous cars, robotics and unmanned aerial vehicle (UAV), commonly known as a drone, is a challenging task. In this paper, we present image classification performance results of CondenseNeXt CNN on NXP BlueBox, an ARM-based embedded computing platform for automotive applications.

II. Related Work

Following work has contributed to the research and implementation results presented within this paper:

CondenseNeXt: An ultra-efficient deep convolutional neural network for embedded systems, introduced by P. Kalgaonkar and M. El-Sharkawy in January 2021 [5] has been utilized to train and evaluate image classification performance on three benchmarking datasets: CIFAR-10, CIFAR-100 and ImageNet.

III. NXP BlueBox 2.0

The BlueBox 2 family developed and manufactured by NXP Semiconductors N.V, a Dutch-American semiconductor manufacturer with headquarters in Eindhoven, Netherlands and Austin, United States of America, is a Automotive High Performance Compute (AHPC) platform that provides essential performance and reliability for engineers to develop sensor fusion, automated drive and motion planning applications along with functional safety, vision acceleration and automotive interfaces for self-driving (autonomous) vehicles.

NXP BlueBox Gen1 was first introduced in May 2016 at the 2016 NXP FTF Technology Forum held in Austin, Texas, USA. This opened avenues to a host of autonomous and sensor fusion applications. Shortly after, NXP introduced BlueBox Gen2 (BlueBox 2.0), a significant improvement over Gen1, incorporating three new processors: S32V234 ARM-based automotive computer vision processor, LS2084A high performance ARM-based compute processor and S32R274 ASIL-D RADAR microcontroller.

S32V234: The S32V234 automotive computer vision processor comprises of a quad core ARM Cortex-A53 CPU running at 1.0 GHz paired with a ARM Cortex-M4 functional safety core which utilizes the ARMv8-A 64-bit instruction set developed by ARM Holdings' Cambridge design centre. It has a 4MB internal SRAM in addition to a 32bit LPDDR3 memory controller for external memory support. It is an on-chip Image Signal Processor (ISP) designed to meet ASIL-B/C automotive safety standards and optimized for obtaining maximum performance per watt efficiency.

LS2084A: The LS2084A high performance compute processor comprises of an octa core ARM Cortex-A72 CPU running at 1.8 GHz which utilizes the ARMv8-A 64-bit instruction set developed by ARM Holdings' Austin design centre. It has two 72 bytes DDR4 RAMs running at up to 28.8GB/s memory bandwidth. The LS2 provides software compatibility with next generation LayerScape LX2 family and offers AEC Q100 Grade 3 reliability with 15 years product longevity.

S32R274: The S32R274 radar micro-controller comprises of a dual core Freescale PowerPC e200z7 32-bit CPU running at 240 MHz and a dual core Freescale PowerPC e200z4 32-bit CPU running at 120 MHz with an additional checker core. It has a 2 MB Flash and 1.5 MB SRAM for radar application storage, message buffering and radar data stream handling. The S32R processor is optimized for on-chip radar signal processing to maximize performance per watt efficiency. It has been designed by NXP to meet the ASIL-D automotive applications standards.

IV. RTMaps Remote Studio Software

Figure 1. NXP BlueBox 2.0 ARM-based Automotive High Performance Compute (AHPC) embedded development platform. It delivers necessary prerequisites to help develop high-performance computing systems, analyze driving environments, assess risk factors, and then direct the car's behavior. BlueBox 2.0 also supports OpenCV applications using an external camera for real-time image classification object detection and image segmentation.

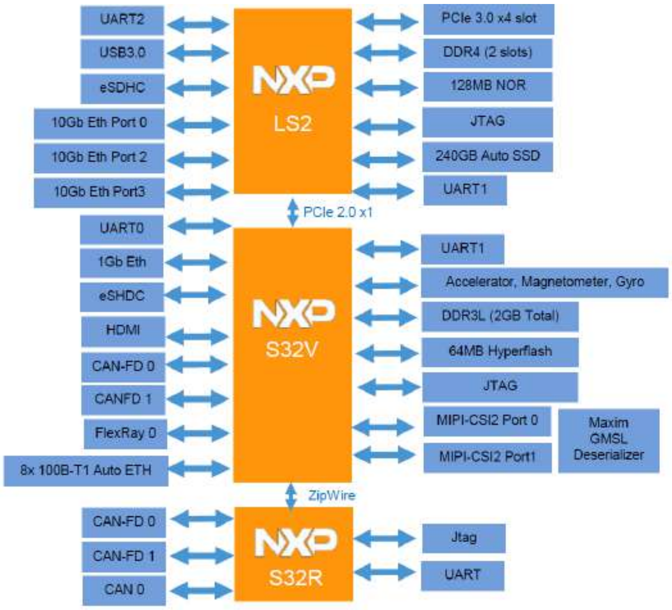

Figure 2. High-Level View of NXP Bluebox 2.0 Gen2 Architecture [6]. S32V processor utilizes two CAN-FD (Flexible Data Rate) with enhanced payload and data rate, PCIe, Ethernet, FlexRay, Zipwire, one SAR-ADCs, four SPI and one SD card connectivity. LS2 processor utilizes two DUART, four I2C, SPIO, GPIO and two USB 3.0 interfaces. S32R processor utilizes JTAG, UART, three FlexCAN and Zipwire to connect to a radar ASIC.

RTMaps (Real-Time Multisensor applications) developed by Intempora is a powerful GUI software that aids in development of applications for advanced driver assistance systems, autonomous driving and robotics. It helps in capturing, processing and viewing data from multiple sensors and offers a multi-modular development and run-time environment for ARM-based computing platforms such as the NXP BlueBox 2.0. This data can also be reviewed and play-backed at a later time for offline development and testing purposes.

RTMaps Remote Studio supports PyTorch, an open-source machine learning library based upon the Torch library, widely used for real-time computer vision (OpenCV) development. Algorithms for OpenCV can be developed using Python scripting language and by the means of block diagrams. It also facilitates the development of algorithms directly on to any supported embedded system without having to connect external user interfacing peripheral devices.

V. CondenseNeXt

CondenseNeXt is an ultra-efficient deep convolutional neural network architecture designed for embedded systems introduced by P. Kalgaonkar and M. El-Sharkawy in January 2021. CondenseNeXt refers to the *next* dimension of cardinality. In this section, we describe in detail the architecture of this neural network that has been utilized to train and evaluate image classification performance on three benchmarking datasets: CIFAR-10, CIFAR-100 and ImageNet.

A. Convolution Layers

One of the main goals of CondenseNeXt is to reduce the amount of computational resources required to train the network from scratch and for real-time inference on embedded systems with limited computational resources. Following state-of-the-art technique has been incorporated into the design of this CNN:

- Depthwise convolution layer: It acts like a filtering layer where convolution to a single input channel is applied separately instead of applying it to all input channels. Assume there is an input data of size $A \times A \times C$ and filters (kernels) K of size $F \times F \times 1$. If there are C number of channels in the input data, the output will be of size $B \times B \times C$. At this point, the spatial dimensions have shrunk. However, the depth C has remained constant and the cost of this operation will be $B^2 \times F^2 \times C$.
- Pointwise convolution layer: It acts like a combining layer where a linear combination is carried out for each of these layers. At this stage, a 1×1 convolution is applied to C number of channels in the input data. Thus, the size of filter for this operation will be $1 \times 1 \times C$ and size of the output will be $B \times B \times D$ for D such filters.

Assume a standard convolutional filter K of size $F \times F \times A \times B$ where A is the number of input channels and B is the number of output channels with an input feature map A of size $D_x \times D_x \times A$ that produces an output feature map Z of size $D_y \times D_y \times B$ can be mathematically represented as follows:

$$Z_{k,l,n} = \sum_{i,j,m} k_{i,j,m,n} \cdot A_{k+i-1,l+j-1,m} \tag{1}$$

In case of a depthwise separable convolution, (1) is factorized into two stages: the first stage applies a 3×3 depthwise convolution $\hat{K}$ with one filter for every input channel:

$$\hat{Z}_{k,l,m} = \sum_{i,j} \hat{K}_{i,j,m} \cdot A_{k+i-1,l+j-1,m} \tag{2}$$

Consequently, in the second stage, a 1×1 pointwise convolution $\tilde{K}$ is applied to carry out linear combination and combine the outputs of depthwise convolution from previous stage as follows:

$$Z_{k,l,n} = \sum_{m} \tilde{K}_{m,n} \cdot \hat{Z}_{k-1,l-1,m} \tag{3}$$

Figure 3. A 3D illustration of the overall process of depthwise separable convolution. An image is transformed 128 times whereas an image is transformed by depthwise separable convolution only once and then this transformed image is stretched to 128 channels which allows the neural network to process more data while consuming fewer FLOPs (Floating Point Operations).

This methodology splits a kernel into two discrete filters for filtering and combining stages as shown in Figure 3 above, which results in reduction of computational resources required to train the network from scratch as well for real-time inference.

A widely used model compression technique is also implemented into the design of this CNN where a further significant impact, both in computational efficiency at training time and on the final trained model size is seen.

B. Model Compression

A widely popular model compression technique called Group-wise Pruning is implemented to make CondenseNeXt neural network computationally more efficient by discarding redundant elements without influencing the overall performance of the network.

Group-wise Pruning: The purpose of group-wise pruning is to remove trivial filters for every group g during the training process which is based on the L_1-Normalization of $A^{g_{ij}}$ where for every group g, a is the input and z is the output. A pruning hyper-parameter p is established and set to 4 which allows the network to decide the number of filters to remove before the first stage of depthwise separable convolution. A class balanced focal loss function [7] is also added to assist and ease the effect of this pruning process.

Consider a group convolution comprised of G groups of size $F \times F \times C_A \times C_B$ where $C_A = \frac{A}{G}$ and $C_B = \frac{B}{G}$. The total number of trivial filters that will be pruned before the first stage of depthwise separable convolution is mathematically represented as follows:

$$G \cdot C_x = A \cdot C - p \cdot A \tag{4}$$

Cardinality: A new dimension to the network called *Cardinality* denoted by C is incorporated into the design of CondenseNeXt neural network in addition to the existing width and depth dimensions so that loss in accuracy during the pruning process is reduced. Experiments prove that increasing cardinality is a more efficacious way of accruing accuracy than going deeper or wider, especially when width and depth starts to provide diminishing returns [8].

C. Activation Function

In deep neural networks, activation functions determine the output of a neuron at particular input(s) by restricting the amplitude of the output. It aids in neural network's understanding and learning process of complex patterns of the input data. Furthermore, non-linear activation functions such as ReLU6 (Rectified Linear Units capped at 6) enable neural networks to perform complex computations using fewer neurons [9].

CondenseNeXt applies ReLU6 activation function in addition to Batch Normalization technique prior to each convolutional layer. In ReLU6, units are capped at 6 to promote an earlier learning of sparse features and to prevent a sudden blowup of positive gradients to infinity. ReLU6 activation function is defined mathematically as follows:

$$f(x) = min(max(0, x), 6) \tag{5}$$

VI. Cyberinfrastructure

A. Training Infrastructure

- Intel Xeon Gold 6126 12-core CPU with 128 GB RAM.
- NVIDIA Tesla V100 GPU.
- CUDA Toolkit 10.1.243.
- PyTorch version 1.1.0.
- Python version 3.7.9.

This cyberinfrastructure for training is provided and managed by the Research Technologies division at the Indiana University which supported our work in part by Shared University Research grants from IBM Inc. to Indiana University and Lilly Endowment Inc. through its support for the Indiana University Pervasive Technology Institute [10].

B. Testing Infrastructure

- NXP BlueBox 2.0 ARM-based autonomous embedded development platform.
- Intempora RTMaps Remote Studio version 4.8.0.
- CIFAR-10, CIFAR-100 and ImageNet Datasets.
- PyTorch version 1.1.0.
- Python version 3.7.9.

VII. Experiment and Results

Training results presented in this report are based on the evaluation of image classification performance of CondenseNeXt CNN on three benchmarking datasets: CIFAR-10, CIFAR-100 and ImageNet. CondenseNeXt was designed and developed in PyTorch framework and trained on NVIDIA's Tesla V100 GPU with standard data augmentation scheme [11], Nesterov Momentum Weight of 0.9, Stochastic Gradient Descent (SGD), cosine shape learning rate and dropout rate of 0.1 for all three datasets discussed in this section.

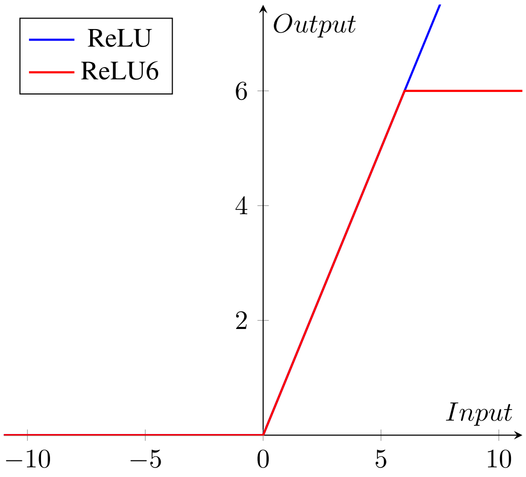

Figure 4. Difference between ReLU and ReLU6 activation functions.

A. CIFAR-10 Classification

CIFAR-10 dataset [9], [12] was first introduced by Alex Krizhevsky in [13]. It is one of the most widely used datasets for evaluating a CNN in the field of deep learning research. There are 60,000 RGB images of 10 different classes of size 32×32 pixels divided into two sets of 50,000 for training and 10,000 for testing.

CondenseNeXt was trained with a single crop of inputs on CIFAR-10 dataset for 200 epochs, batch size of 64 and features k of 8-16-32. Using RTMaps Remote Studio, an image classification script was developed using Python scripting language and evaluated on NXP BlueBox for single image classification analysis. Table I provides a comparison of performance between CondenseNet and CondenseNeXt CNN in terms of FLOPs, parameters, and Top-1 and Top-5 error rates. Figure 5 provides a screenshot of the RTMaps console.

B. CIFAR-100 Classification

CIFAR-100 dataset was also first introduced by Alex Krizhevsky in [13] along side CIFAR-10 dataset. It is also one of the many popular choices of datasets in the field of deep learning research. Just like CIFAR-10 dataset, there are 60,000 RGB images in total. However, it has 100 different classes, where each class contains 600 images of size 32×32 pixels divided into two sets of 50,000 for training and 10,000 for testing. CIFAR-100 classes are mutually exclusive of CIFAR-10 classes. For example, CIFAR-100's baby, chimpanzee and rocket classes are not part of the CIFAR-10 classes.

CondenseNeXt was trained with a single crop of inputs on CIFAR-100 dataset for 600 epochs, batch size of 64 and features k of 8-16-32. Using RTMaps Remote Studio, an image classification script was developed using Python scripting language and evaluated on NXP BlueBox for single image classification analysis. Table I provides a comparison of performance between CondenseNet and CondenseNeXt CNN in terms of FLOPs, parameters, and Top-1 and Top-5 error rates. Figure 6 provides a screenshot of the RTMaps console.

Table I
COMPARISON OF PERFORMANCE

Dataset	CNN Architecture	FLOPs (in millions)	Parameters (in millions)	Top-1 % Error	Top-5 % Error
CIFAR-10	CondenseNet	65.81	0.52	5.31	0.24
	CondenseNeXt	**26.35**	**0.18**	**4.79**	**0.15**
CIFAR-100	CondenseNet	65.85	0.55	23.35	6.56
	CondenseNeXt	**26.38**	**0.22**	**21.98**	**6.29**
ImageNet	CondenseNet	529.36	4.81	26.2	8.30
	CondenseNeXt	**273.16**	**3.07**	**25.8**	**7.91**

Table I provides a comparison between CondenseNet (the baseline architecture) vs. CondenseNeXt (our ultra-efficient deep neural network architecture) in terms of performance each utilizing the training setup and infrastructure as outlined in section 6 and 7 in this paper.

C. ImageNet Classification

ImageNet was introduced by an AI researcher Dr. Fei-Fei Li along with a team of researchers at a 2009 IEEE Conference on Computer Vision and Pattern Recognition (CVPR) in Florida [14]. This dataset is built according to the WordNet hierarchy where each node in the hierarchy corresponds to over five hundred images. In total, there are over 14 million images in this dataset that have been hand-annotated and labelled by the team.

CondenseNeXt was trained with a single crop of inputs on the entire ImageNet dataset for 120 epochs with a Group Lasso rate of 0.00001, batch size of 256, features of 8-16-32-64-128 and four Nvidia V100 GPUs using Data Parallelism technique. An image classification script was developed in RTMaps Remote Studio and evaluated on NXP BlueBox for single image classification analysis. Table I provides a comparison of performance between CondenseNet and CondenseNeXt CNN in terms of FLOPs, parameters, and Top-1 and Top-5 error rates. Figure 7 provides a screenshot of the RTMaps console.

VIII. CONCLUSION

In this paper, we demonstrate the performance of CondenseNeXt CNN which is an ultra-efficient deep convolutional neural network architecture for ARM-based embedded computing platforms without CUDA enabled GPU(s). Extensive training from scratch and analysis have been conducted on three benchmarking datasets: CIFAR-10, CIFAR-100 and ImageNet. It achieves state-of-the-art image classification performance on CIFAR-10 dataset with a 4.79% Top-1 error rate, on CIFAR-100 dataset with a 21.98% Top-1 error rate and ImageNet dataset with a 7.91% single model and single crop Top-5 error rate. Our experiments on NXP's BlueBox further validate the effective use Depthwise Separable Convolutional layers and Model Compression techniques implemented to discard inconsequential elements and to reduce FLOPs without affecting overall performance of the neural network. In the future, we will explore different applications with CondenseNeXt such as image segmentation and object detection to better exploit different opportunities for OpenCV applications.

***Abstract*—Deep Neural Networks (DNN) are prominent in most applications today. From self-driving cars, sentiment analysis, surveillance systems, and robotics, they have been used extensively. Among DNNs, Convolutional Neural Networks (CNN) have achieved massive success in computer vision applications as the human visual system inspires their architecture. However, striving to achieve higher accuracies, CNN complexity, parameters, and layers were increased, which led to a drastic surge in their size, making their deployment challenging. Over the years, many researchers have proposed various techniques to alleviate this issue—one of them being Design Space Exploration (DSE) to minimize size and computation with little compromise to accuracy. MobileNet V3 is one such architecture designed to achieve good accuracy while being mindful of resources. It produces an accuracy of 88.93% on CIFAR-10 with a size of 15.3MB. This paper further reduces its size to 2.3MB while boosting its accuracy to 89.13% using DSE techniques. It is then deployed into NXP's i.MX RT1060 Advanced Driver Assistance System (ADAS) platform.**

Keywords—MobileNet V3, Convolution Neural Networks, Depthwise Pointwise Depthwise blocks, Compressed MobileNet V3, CIFAR-10, Design space exploration, TensorFlow, i.MX RT 1060.

I. Introduction

Convolutional neural networks have shown commendable performance in various computer vision tasks due to their compelling ability to use multiple feature description stages to grasp representations from images. They first came into the spotlight through the work of LeCun et al. 1989. Since the victory of AlexNet in the ImageNet challenge in 2012, they have gained high popularity [1]. The appealing factor of CNNs is their intelligence to extract spatial and temporal content from crude data. The design of CNN incorporates many convolutional layers, subsampling units, and nonlinear activation functions. Convolution operation guides extraction of valuable features from locally connected information points. Its output is then passed to nonlinear activations that produce diverse activations for various responses and encourage semantic contrasts in pictures. Subsampling is used in CNNs to make it invariant to the location of features. Subsequently, in this way, CNN learns pictures without the need for human involvement in feature extraction. The human visual cortex profoundly propels the building plan of CNNs. In the course of learning, CNN alters weights employing a backpropagation calculation. This ability to move towards the target is comparable to the brain's capacity to memorize based on responses. CNN's multi-layered structure helps gather low, mid, and high-level features, with high-level features being an aggregate of mid and low-level features. This dynamic learning ability of CNN emulates the neocortex in the human cerebrum and is responsible for its pervasiveness.

Over the years, there have been many advances in their architectures, activation functions, regularization, and parameter tuning. In a race to achieve higher accuracy, CNN model complexity and parameters have escalated [2] [3] [4] [5]. This has led to increased demand for resources needed for their storage and computation. Many small-sized architectures were proposed to ease this problem, such as MobileNet [6], SqueezeNet [7], ShuffleNet [8], and so on.

There are various advantages to using small architectures. Firstly, they are more suitable for embedded resource-constrained applications. Due to their size, computations can be performed in place for tasks such as image recognition, semantic segmentation, etc., rather than sending it to the cloud. It reduces latency and assures the privacy of data. In autonomous driving, companies make updates to the model and load it into customer vehicles from their servers [9]. Small-size CNNs make this update more convenient. Hence, to benefit from these advantages, many techniques were developed. Some of them include knowledge distillation [10] [11], pruning, and network quantization [12][13] , low rank and sparse decomposition [14], and developing new innovative architectures[8] [15][16].In knowledge distillation, a small model learns from a large model using a teacher-student approach. In pruning, weights that are insignificant to network performance are zeroed out based on a criterion [17] [18], and in network quantization, filter kernels and weights in fully connected layers are quantized. This quantization can be achieved by various methods such as k-means, Huffman coding, etc. Sparse decomposition and low-rank approximations achieve compression by reducing the parameter dimension of the network. This paper accomplishes a similar purpose by reducing MobileNet V3 small by making architectural modifications and changing the baseline model's activation functions.

Baseline architecture is demonstrated in section 2. Section 3 illustrates changes made to MobileNet V3 small to produce CMV3. Training setup is detailed in section 4. Section 5 has implementation details. Results and conclusion are mentioned in sections 6 and 7, respectively.

II. Prior Work

A. *Baseline Architecture*

MobileNet V3 is the latest variant of MobileNets. It was designed using a platform-aware network architecture search, and net adapt algorithm. MobileNet V3 small and MobileNet V3 large are two forms of this model developed to serve

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

different resource constraints [15]. MobileNet V3 large has lesser latency than MobileNet V2 while being 3.2% more accurate on the ImageNet dataset [19].

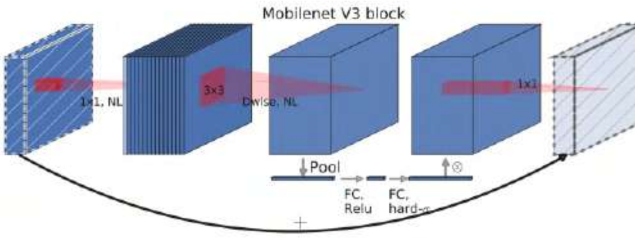

Fig. 1. MobileNet V3 Block [15].

MobileNet V3 encompasses the best practices from MobileNet V2 and Squeeze and excitation networks[20] .It is a combination of inverted residual bottlenecks and squeeze and excitation blocks. These SE blocks are added to improve networks' representational power by suppressing neurons that do not contribute to performance and enhancing those that do. The bottlenecks consist of an initial 1x1 pointwise expansion layer, a depthwise convolution layer (DWC) with a kernel of size 3x3 or 5x5, and a final 1x1 projection layer. The architecture of MobileNet V3 is shown in Fig.1. The model uses the H-swish activation function.

III. MODIFICATIONS

Modifications made to MobileNet V3 are described below. Table I summarizes CMV3 architecture.

A. *Convolution Layers*

CNN with more Depthwise convolutions than pointwise convolutions have shown better performance [21]. This fact has been exploited to make architectural changes by emphasizing spatial information rather than aggregating channel information. Depthwise Pointwise Depthwise (DPD) blocks, as shown in Fig.2, were used for the model.These blocks comprise a 3×3 Depthwise convolution, with a stride s that expands the number of channels and performs down-sampling. They also consist of a 1×1 pointwise convolution that collects information along channels, merges them, and finally, a 3×3 Depthwise separable convolution layer. All DPD blocks were followed by batch normalization and RELU.As more Depthwise convolutions are used than pointwise, good compression is achieved. The ratio of number of parameters in Pointwise to Depthwise convolutions is displayed below:

$$\frac{W \times H \times C \times mC}{W \times H \times k \times k \times mC} = \frac{C}{k^2} \tag{1}$$

(W × H) is the input dimension, C is the number of channels, m is the channel multiplier, and (k × k) is the filter size. Since the number of channels is much higher than the filter size, the ratio to be greater than 1.

B. *Mish Activation Function*

Mish possesses the self-regularizing capacity and lessens overfitting. It outruns other activation functions in performance. It also keeps negative gradients, has better generalization and eliminates saturation due to near-zero gradients [22]. The formula below can describe it:

$$f(x) \ = x \cdot \tanh(softplus(x)) \tag{2}$$

$$softplus(x) = \ln(1 + e^x) \tag{3}$$

The Mish activation function followed DPD blocks in the new architecture. It improved the accuracy from 88.14% to 89.13%. Fig.3 depicts the graph of Mish.

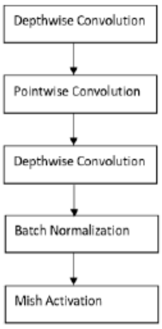

Fig. 2. DPD Blocks

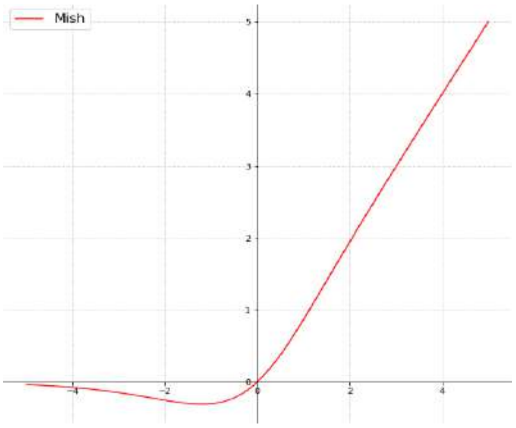

Fig. 3. Mish Activation Function [23].

C. *Expansion filters*

Mobilenet V3 uses expansion filters to extend to a high dimensional feature space to intensify non-linear transformation on channels [15]. This technique is used on CMV3 as well. Expansion filters in a few layers are increased. It boosted accuracy from 84.56% to 88.14%.

IV. TRAINING SETUP

The modified model was trained with Intel Xenon Gold 6126 processor with 32GB RAM and NVIDIA Tesla P100 GPU. An l2 weight decay of 1e-5 was used. A dropout of 0.8 and a cosine decay type scheduler were added. A width multiplier of 0.5 was selected to reduce overfitting and maintain a good trade-off between accuracy and size.

V. Deployment

NXP eIQ is a software platform comprising resources and tools to help machine learning deployment on NXP hardware. It has Neural Network (NN) compilers, libraries, inference engines, Hardware Abstraction Layers (HAL) to support TensorFlow lite (TFLite), ARM NN, glow, Cortex Microcontroller Software Interface Standard (CMSIS)-NN, and OpenCV [24].

The model used TFLite for deployment into iMX RT1060. It is available in both yocto and MCUXpresso environments. It is faster and consumes less memory than TensorFlow, making it suitable for use in low-resource devices. We used MCUXpresso IDE and built the SDK for iMX RT 1060 using eIQ middlewares. This middleware comes with a lot of demo examples. CIFAR-10 label image example was used. This example uses a DL model to classify images captured by the camera attached on board. CMV3 was then included in the header files, and many images were tested to decipher model accuracy and inference after deployment. Fig 4. shows the results observed on the console. Fig 5. shows the block diagram for eIQ inference procedure for TensorFlow Lite.

VI. Results

MobileNet V3 small was modified to give rise to CMV3 with no compromise to accuracy. The revised model has a size of 2.3 MB with an accuracy of 89.13%. Its parameter count has been reduced from 1,846,930 in baseline to 171,946 after compression. It was then deployed onto iMX RT 1060 for inference. It gave an average inference time of 720ms. A plot of proposed model accuracy vs the number of epochs using the Tensorboard visualization tool is shown in Fig. 6.

Various Scaling factors for CMV3.		
Width Multiplier	***Model Accuracy***	***Model size***
1.5	91.39%	10.5 MB
1.0	90.64%	5.2 MB
0.75	90.10%	3.6 MB
0.5	89.13%	2.3 MB
0.35	87.36	1.9 MB

TABLE II

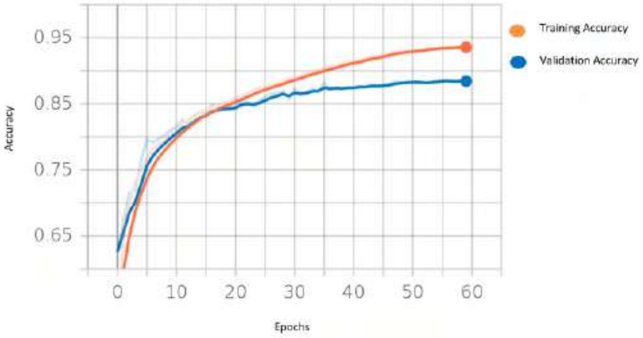

Fig. 6. Compressed MobileNet V3

VII. Conclusion

In this paper, using DPD blocks, mish activation function, and increase in expansion filters, an architecture that is 84.96% smaller in size and 0.2% more accurate than baseline is accomplished. It can be successfully used in various embedded vision platforms. Table II shows different width scaling factors that can be used with the model. Based on the application, a suitable configuration can be used to achieve optimal trade-off.

***Abstract*— There is a high demand for research into innovation and development of miniaturized electronic devices for biomedical applications such as lab on a chip device, implantable medical devices (IMD), and wireless biosensor systems (WBS), etc. These electronic systems must be wireless as wires penetrating through human skin increase the risk of infections as they act as conduits for viruses and bacteria and they also limit the flexibility of movement for patients. Ultra-low power transceivers are essential because wireless communication subsystems consume most of the power in wireless biomedical implants and implanted batteries are undesirable due to their limited lifespan and the risk of infection they pose. Also, a limited amount of power can be transferred through the wireless power link system. The design requirements for wireless communication and power source subsystems for wireless biomedical implants can be determined based on the specific application of the wireless biomedical implants. Practical limits and challenges in low power and low voltage design of wireless systems in lab-on-a-chip devices and implantable biomedical devices need to be considered for investigating various techniques for low power design with the advantages and the trade-offs of each design technique. This paper outlines the practical limits and challenges for powering wireless systems in implantable and lab-on-a-chip biomedical devices and reviews low power design techniques.**

Keywords*— body sensor networks, wireless, phase noise, ultra-low power, implantable medical sensors, medical Implant Communication Service (MICS) frequency band.

I. Introduction

Lab on a chip and implantable biomedical devices have become an increased research focus. These devices have various applications such as chronic monitoring implants, nervous system stimulating implants, brain-machine interface systems and temporary implants like intelligent pills and wireless capsule endoscopy (WCE) systems. Most of these devices have sensing, signal processing, wireless communication, and power source subsystems [1].

Wireless communication subsystems consume most of the power in wireless biomedical implants [3], and because of the limited available power in miniaturized energy sources and battery-less operating systems [2], designing a power efficient wireless communication and power source subsystem is very challenging.

The design requirements for wireless communication and power source subsystems for wireless biomedical implants can be determined based on the specific application of the wireless biomedical implants.

Chronic monitoring and nervous system stimulating implants need to operate for several years after insertion in the body through a surgical procedure. These implants transmit and receive data with different bit rates for different applications. For example, chronic monitoring implants have higher data transmission and so for the higher sample rate and resolution, they require higher bit rates [3].

Nervous system stimulating implants have higher bit rates for receiving data depending on the required stimulation cycle rate and the number of stimulating channels.

Brain-machine interfaces (BMI) have a high number of channels for monitoring and stimulating and require high bit rates for both transmitting and receiving data. Designing a power efficient wireless communication subsystem for these devices is very challenging.

Temporary implants like intelligent pills and wireless capsule endoscopy (WCE) systems have a limited operation lifetime inside the body, and there are more available options for designing the power source subsystem of these temporary implants.

II. Available Power Sources for Wireless Biomedical Implants

Two important factors for power sources are the capability to deliver instantaneous power and the ability of integrated power delivery. For nervous system stimulating application, the power source has to have the capability for instantaneous power and integrated power delivery, but for chronic monitoring application, the ability of integrated power delivery is more critical.

Supercapacitors have a high capability of instantaneous power delivery, but their ability for integrated power delivery is limited. Alternatively, power harvester systems like solar, thermal and glucose fuel cells that gather energy from the implant surrounding area and convert it to electrical power have a higher ability for integrated power delivery, but reduced capability of instantaneous power delivery. Rechargeable batteries have a moderate capability for instantaneous and integrated power delivery and are suitable options for applications where the power source needs the capability for instantaneous and integrated power delivery and their operation lifetime is matched with that of a battery’s lifetime.

Battery-less operation systems are a suitable option for applications with an operational lifetime longer than that of a battery. For battery-less operation systems where the power source has to have the capability for instantaneous power and integrated power delivery, power harvester systems can be combined with supercapacitor systems through implementing extra circuitry for sleep and active mode control. However, available energy needs to be allocated to the extra circuitry for the sleep and active mode controls but having power-efficient design for this extra circuit is very challenging. For backup supplies of these systems, rechargeable batteries can be used.

A. *Rechargeable batteries*

Rechargeable batteries have moderate capability of instantaneous power delivery and integrated power delivery. Thin film batteries with mechanical flexibility are a cost-effective and attractive option for biomedical implants and lab-on-a-chip devices [4]. The challenge, however, of using rechargeable batteries in wireless lab-on-a-chip and biomedical implants is finding ways to decrease their recharge capacity over recharge cycles because currently expensive surgical procedures for battery replacement are required. Also, these batteries require special packaging to eliminate the risk of poisonous chemicals leaking. This naturally increases the device costs.

For power harvester systems, electromagnetic field power transfer systems and ultrasound power transfer systems, rechargeable batteries can be used as a backup supply.

B. *Electromagnetic field power transfer systems*

Wireless biomedical implants and lab-on-a-chip devices can be powered by an electromagnetic field generated by an external device. This system can be used in combination with a rechargeable battery as a backup [5].

One of the challenges for implementing electromagnetic field power transfer systems is designing an optimal external antenna size that fits with the implant size and still receives maximum power from the external electromagnetic field. Matching the external antenna size with the implant size creates some limitations in using compact external antennas and selecting an external electromagnetic field frequency. To minimize energy absorption in the tissue, electromagnetic field frequencies less than 30MHz are used in most commercial devices. However, for an efficient power transfer system in low frequency, the size of the implanted antenna has to be tens of centimetres, which is an unacceptable size for an implant [7][37]. In recent designs, to maximize power transfer efficiency and maintain a small sized implanted antenna, the implant size has been optimized to operate with a high electromagnetic field frequency in the range of 100MHz to 5GHz [6][36]. Human tissue absorbs some part of the transmitted power because of finite tissue conductivity and the maximum radiated power from the external electromagnetic field is limited.

One limiting factor of maximum radiated power from the external electromagnetic field is the operating life of the power source of the external electromagnetic field system. For example, if a battery is used as the power source of the external electromagnetic field system, the maximum radiated power is limited by the operating lifetime of the battery.

Another limiting factor for the maximum radiated power from the external electromagnetic field is IEEE standard for maximum allowable specific absorption rate (SAR) on chronic exposure [8]. This standard applies a limit on the maximum allowable radiated power, based on the carrier frequency and antenna size.

C. *Ultrasound power transfer systems*

The wireless biomedical implants and lab-on-a-chip devices can be powered by an external ultrasound transducer that transfers power through generating pressure waves and an implanted piezoelectric transducer inside the body absorbs and converts incoming pressure waves into electrical energy [7, 9]. A rechargeable battery can be used as a backup source in combination with ultrasound power transfer systems.

Designing a miniaturized ultrasound transducer and solving the mismatch issue between air acoustic impedance and tissue acoustic impedance is a challenge for using ultrasound power transfer systems as power sources for wireless biomedical implants.

D. *Power harvester systems*

Power harvester systems (ambient power) that gather energy from the implant’s surrounding area and convert it to electrical power can be a power source option for wireless biomedical implants [10, 11].

One power harvester system is solar cells which are the topic of significant commercial and academic research [12, 13].

Piezoelectric in some power harvester systems absorbs and converts incoming pressure waves into electrical energy. Electromagnetic and capacitive power harvesting systems absorb and convert electromagnetic and inductive waves into electrical energy [14].

One of the challenges of using these systems is the requirement for larger device volume size to generate more output power. Another challenge for designers in implementing these systems is the need to match excitation frequency with the size of these devices which is sometimes impracticable. Another challenge using these systems is the additional circuitry needed to rectify the generated AC output voltage which reduces their efficiency.

Power harvesting systems that use electrochemical [11] and glucose fuel cells [10] can produce power by implanting in specific locations of the human body with higher densities of energy. The challenge here is their large size and limited ability to integrate power delivery.

Power harvester systems that use thermoelectric generators can be used as power sources for implants under the skin as the temperature inside the human body does not vary significantly [15]. The amount of generated power in thermoelectric generators is related to the surface area of the device.

III. Wireless communication subsystem for wireless biomedical implants and lab-on-a-chip devices

Selection of correct system and architecture level design is critical for designing low power systems. One of the critical steps in system and architecture level design is selecting the modulation technique.

Modulation techniques such as on-off keying (OOK), amplitude shift keying (ASK), binary frequency shift keying (BFSK) and binary phase shift keying (BPSK) are the most popular digital modulation techniques for low power applications.

Design and implementing of OOK and ASK modulation techniques are more straightforward than BFSK and BPSK, but their reliability to the noise is less than BFSK and BPSK modulation techniques. BFSK modulation technique has better spectrum efficiency, and BER performance compares with OOK modulation technique [20].

Wireless biomedical implants and lab-on-a-chip devices can have either a remote power source or a local power source and can communicate via the back-scattering transmitter method or up-conversion transmitter method.

A. *Wireless biomedical implants with the local power source*

Wireless biomedical implants and lab-on-a-chip devices with local power and up-conversion transmitters are the most popular systems that can be powered by local power harvester systems and rechargeable batteries as backup. They are compatible with MICS technology and use broadband or narrow-band modulation techniques like BFSK, BPSK, MSK and ASK. These devices have good frequency selection capability, are reliable against noise and can be adopted by other systems easily [16].

The challenge for wireless lab-on-a-chip devices and biomedical implants with local power and up-conversion transmitters is the high-power consumption in transmit mode.

Ultra-wideband systems like on-off keying (OOK) or pulse position modulation (PPM) have simpler transmitter designs and lower power consumption in transmit mode, but require more complex receiver architecture and have higher power consumption in receive mode. There is a trade-off between the complexity of the transmitter and the receiver. Ultra-wideband systems are the preferred design for applications with more transmit cycles whereas narrowband systems are the preferred design for more receive cycles.

The back-scattering technique can be implemented in wireless biomedical implants and lab-on-a-chip devices with a local power source to decrease power consumption in transmit mode. The complexity of the architecture design in this technique is transferred to the receiver side and external carrier emitter device which has more power consumption for generating the carrier frequency. Implanted transmitter systems with no carrier generation and power amplification remain simple and power efficient.

B. *Wireless biomedical implants with the remote power source*

The back-scattering technique can be implemented in wireless biomedical implants and lab-on-a-chip devices with a remote power source to decrease power consumption in transmit mode. The remote power source for these devices can be electromagnetic field power transfer systems or ultrasound power transfer systems.

In the back-scattering technique, the external carrier emitter device generates the carrier signal. The back-scattering transmitter in the implant modulates the carrier signal which is picked up by the antenna through changing the impedance loading of the data. This modulated signal will be detected by the external receiver/reader which has more complex architecture and sensitivity, and higher power consumption. Implanted back-scattering transmitters remain simple and power efficient with no carrier generation and power amplification [17]. Single compact antennas for both wireless power transfer and data communication are the preferred option in recent back-scattering implant designs. The challenge for designers is to optimize the antenna size for both carrier frequency and wireless power transfer systems. Other issues with backscattering systems is their requirement for an external carrier signal emitter system, their limited capability for calibration and their performance changing with variations in environmental factors [18].

Wireless biomedical implants and lab-on-a-chip devices with a remote power source can be used in combination with the up-conversion transmitter [19]. Up-conversion transmitters use mixer circuits to modulate the baseband data signal and they require two separate (or multi-mode) antennae for data communication and the power transfer system. The issue using up-conversion transmitters in wireless biomedical implants is the higher noise bandwidth and power consumption, compared with backscattering transmitters.

IV. Low power design techniques

In order to significantly save power, consideration of a low power design for the system and architecture level are critical. Applying low-power methodology from system-level to device-level is essential for optimizing the power dissipation. Based on the system requirements and architecture proposal, the required process technology can be determined. The detailed circuits and device requirements are other critical factors. Also, the selection for types of architecture, circuit, and device can be limited by selected process technology. For analogue blocks such as amplifiers, oscillators, and filters, the fundamental minimum power consumption can be defined as [30]:

$$P_{min} = 8kTf(S/N) \qquad (1)$$

where f is the operating frequency, the S/N ratio (SNR) is the signal to noise power ratio, and k is the Boltzmann's constant.

Fundamental minimum power consumption is calculated based on the operation frequency and signal to noise power ratio (SNR), and only has an asymptotic limit realistic restrictions such as voltage swing, circuit topology, and nonlinearity are not considered in this calculation. The power consumption for typical analogue circuits is several orders of magnitude larger than the fundamental minimum power consumption.

For designing low power analogue circuits, finding the best trade-off among the basic analogue design parameters such as bandwidth, linearity, gain, noise, and accuracy is essential. The first step in the design process can be selecting the circuit topology, then the supply voltage based on specifications such as voltage swing and dynamic range. The selection of the operating region of transistors such as subthreshold operation is another important step.

CMOS technology has become the technology of choice for radio frequency (RF) and integrated circuit (IC) designers because of its low fabrication cost and the potential to integrate with accompanying digital circuits. Various low power design techniques for radio frequency (RF) and integrated circuits (IC) are available with modern CMOS technology, such as subthreshold operation of CMOS field-effect transistor (FET) devices, which are popular in low power designs.

A. *Low supply voltage and subthreshold operation*

Subthreshold or weak inversion (WI) operating regions for transistors are used in many biomedical electronic circuit implant applications as they are considered the most power efficient region. The transconductance is higher in a subthreshold device operation for a given bias current which is a desirable property for low power circuits design, but is let down by lower transit frequency (f_T). Therefore, the subthreshold operation has been associated with low frequency applications. In new MOS technology, with each generation of scaling, f_T increases by more than 75% in all regions of operation which provides the possibility of using subthreshold operation regions for low to mid-range frequency applications.

Most of the biomedical signals are in the low to mid-range frequency. Therefore, the subthreshold operation region is a practical option for these biomedical devices. The roadmap for CMOS, technology scaling report for submicron processes, shows that the device gate length and supply voltage decrease, thereby reducing power consumption and enabling a smaller chip size [21]. Total power consumption in electronic circuits is divided into dynamic power and static power. The dynamic power consumption relation to the supply voltage (V_{dd}), the load capacitance C_L, the clock frequency (f_{clk}), and α is as follows:

$$P_{Dynamic} = \alpha \,.\, C_L \,.\, (V_{dd})^2 \,.\, f_{Clk} \qquad (2)$$

Decreasing the supply voltage may reduce power consumption, but it creates a longer propagation delay, which is proportional to the square of the difference between the supply voltage and the threshold voltage as follows:

$$T_{pd} \propto V_{dd}/(V_{dd} - V_{TH})^2 \qquad (3)$$

Therefore, decreasing the supply voltage without decreasing the threshold voltage, increases the propagation delay and slows the circuit. The threshold voltage has to be scaled down to minimize the propagation delay. The static power consumption increases by reducing the threshold voltage because of leakage current. Static power has a direct relationship to leakage current and the supply voltage source as follows:

$$P_{Static} = I_{Leakage} \text{-} V_{dd} \qquad (4)$$

The total power is expressed as follows:

$$P_{Total} = P_{Dynamic} + P_{Static} \qquad (5)$$

Subthreshold or weak inversion operation is a suitable technique for low power design for low to mid-range frequency applications but the leakage current has to be minimised to decrease the static power specifically for devices with a long standby mode. There are several techniques for reducing the leakage current, such as variable-threshold CMOS (VTMOS), multi-threshold voltage CMOS (MTCMOS) [22], super-cut-off CMOS (SCCMOS), double-gate-dynamic-threshold CMOS (DGDTMOS), and multiple supply voltage and transistor stacks [23].

B. Important leakage current sources in MOS transistors

1) Gate-induced drain leakage current (I_{GIDL}): Gate-induced drain leakage current (I_{GIDL}) is caused by the gate-field influence on the depletion region of the drain. Increasing gate voltage makes the depletion layer thinner, causing overlap between the gate field and the depletion layer. This overlap makes band-to-band-tunnelling (BTBT) and increases the gate induced drain leakage current [23].
2) Gate leakage current (I_G): The thickness of CMOS oxide in recent technology is just a few nanometers, which allows electrons from the gate tunnel through the SiO2 layer to the substrate or in the reverse direction, thereby creating gate leakage current (I_G). Increasing the gate voltage makes the electric field stronger and helps the holes in the gate to overcome the potential barrier at the interface. Direct hot carrier injection is possible through three mechanisms: electron conduction band (ECB) tunnelling, electron valance band (EVB) tunnelling, and hole valance band (HVB) tunnelling. The gate leakage is produced more by electrons than holes because of the lower effective mass and barrier height (3.1 eV) in electrons holes have a higher barrier height (4.5 eV) [23]. Therefore, the hole valance band (HVB) tunnelling current is smaller, and the gate leakage current in the p-channel device is lower. The contribution of gate leakage to the static power is important because it increases by a factor of 4000 when changing technology from 90 nm to 50 nm, but the subthreshold current increases by a factor of 25 at the same time [24]. New gate material such as metal gate and high-k dielectric is being used in nanometers technology to keep the gate leakage under control [25].
3) Leakage current from the reverse-bias p-n junction (I_{rev}): Reverse-bias p-n junction leakage current (I_{rev}) is produced from the p-n junction diodes of the source and drain to the substrate in a reverse-biased situation. The generation of the electron-hole pair inside the depletion region and minority carrier diffusion/drift produce the reverse bias leakage current. The magnitude of the p-n junction leakage current is directly related to the doping concentration and the junction area when the high electric field is applied across the p-n junction. In this state, the BTBT current increases because of electrons from the p-side's valance band tunnel to the n-side's conduction band [23].
4) Channel punch-through leakage current: Two depletion regions of the source and drain in a CMOS device merge by applying the voltage to the drain in nanometre technology because of the very small channel length. Channel punch-through leakage current occurs when these two depletion regions merge. Most of the source carriers overcome the energy barrier in this condition and are either collected by the drain or enter the substrate.
5) Subthreshold leakage current (I_{sub}): As shown in (6), an equation for the drain current in the subthreshold region; the leakage current increases exponentially by scaling of the threshold voltage.
$$I_{DSub} = I_0 e^{\frac{V_{GS} - V_{TH} + \eta V_{DS}}{n \cdot V_T}} \left[1 - e^{\frac{-V_{DS}}{V_T}}\right] \;\; ; V_{GS} \leq V_{TH}$$
(6)
Where V_T is thermal voltage, n is subthreshold slop factor, V_{GS} is gate – source voltage, I_0 is reference static current, η is DIBL coefficient and V_{DS} is drain – source voltage.

V. THRESHOLD VOLTAGE MODIFICATION

Variations in the threshold voltage effect the leakage current leakage current reduces by increasing the threshold voltage. The width of the transistor has an effect on the threshold voltage and leakage current. Reducing the width of the transistor causes short channel effects (SCE) such as narrow width effect [26]. Local oxidation of silicon (LOCOS) or the shallow trench isolation is used in MOS transistors from isolating transistors from each other [26].

Because of the two-dimensional oxidation effect, the gate oxide can sometimes be thicker near the edges of the channel which increases the threshold voltage by enlarging the total depletion charge of the substrate.

Oxide thinning near the edges or fringing fields can sometimes reduce the thickness of the effective oxide near the edges of the device in shallow trench isolation (STI) devices. In this condition, reverse-narrow-width-effect occurs, and the threshold voltage decreases because a higher voltage is required to invert the channel [26].

A. Threshold voltage variation because of the body effect

The threshold voltage changes between the body and source of the transistor (V_{BS}). The relationship between the threshold voltage and V_{BS} is expressed in (7):

$$V_{TH} = V_{THo} - \eta V_{DS} - \gamma\left(\sqrt{2\varphi_B - V_{BS}} - \sqrt{2\varphi_B}\right) \qquad (7)$$

Where V_{TH0} is zero threshold voltage, V_{BS} is voltage between body and source, γ is body bias coefficient, η is DIBL coefficient and Φ_B is Fermi potential. The depletion region in the body increases by applying the voltage to the bulk of the transistor. In this state, the threshold voltage increases because of the reverse bias.

B. Threshold voltage variation because of drain-source voltage

Increasing the drain-source voltage decreases the threshold voltage which is called drain induced barrier lowering (DIBL). Depending on the channel length in SCE, the depletion regions around the drain and source junctions can be large, and these depletion regions increase with the drain-source voltage, causing channel inversion with lower gate-to-source voltage (V_{GS}). In fact, the threshold voltage is modulated by reducing the barrier potential. The DIBL effect has no effect on the subthreshold slope. Applying a high surface and channel doping or selecting shallow source and drain junction depth, can reduce the DIBL effect [27]. As expressed in (8), in minimum length devices, the DIBL effect decreases early voltage and the intrinsic voltage gain of the device.

$$A_v = g_m \,.\, r_{ds} = (g_m / I_D) \,.\, V_A \qquad (8)$$

Where A_V is intrinsic voltage gain, g_m is transconductance of the device, r_{ds} is output resistor, I_D is drain current and V_A is early voltage. The minimum length should be selected with caution where the gain of the circuit is important to the weak inversion region [32].

VI. CIRCUIT TECHNIQUES FOR REDUCING THE LEAKAGE CURRENT TO REDUCE THE STATIC POWER CONSUMPTION

One circuit technique for reducing leakage current is the dual-threshold CMOS (DTCMOS) method. The DTCMOS is an effective method to reduce static power consumption. The circuit in the DTCMOS method has low threshold voltage devices on the critical path and high threshold voltage devices off the critical path. The leakage current reduces because of the high threshold devices, but the delay of the critical path increases because of the high threshold devices [23]. In active mode, high threshold devices footer/or header from the power rails are able to enable regular circuit operation and turn off in standby mode to reduce the leakage current. There are several other techniques for reducing the leakage current such as variable-threshold CMOS (VTMOS), multi-threshold voltage CMOS (MTCMOS) [22], super-cut-off CMOS (SCCMOS), double-gate-dynamic-threshold CMOS (DGDTMOS), multiple supply voltage and transistor stacks [23].

VII. CIRCUIT TECHNIQUES FOR REDUCING THE LEAKAGE CURRENT TO REDUCE THE DYNAMIC POWER CONSUMPTION

Pass transistor logic (PTL) is one technique to reduce the leakage current to lower the dynamic power consumption [31]. The drain and source of the transistors in the pass transistor network are not connected to the ground and supply voltage, thus significantly decreasing the number of leakage paths. The pass transistor logic (PTL) is an interface between the drivers which generate the signal and the receiver circuits which recover the voltage swing and signal and therefore the leakage current is confined to the transistors for the drivers and receiver circuits. Increasing the delay, the effective channel length and number of sneak paths in the circuit, which allow the leakage current to flow, are the main drawbacks for pass transistor logic (PTL). The sense amplifier-based pass-transistor logic (SAPTL) method is offered to overcome the limitations of the PTL method. The SAPTL circuit consists of the stack, which is the pass transistor network and computes the logic; the node driver, which injects the signal to the stack section; and the sense amplifier, which recovers the voltage swing and performance. Considering the bidirectional operation of the pass transistors, an inverted pass transistor tree is utilized as the stack to mitigate the sneak path limitations of the pass transistor logic (PTL). The drain and source of the transistors in the stack are not connected to the supply rail and have delay paths. The stack has two pseudo-differential outputs, where a signal is present in one of the two stack outputs at the same time. The sneak path limitations are mitigated in the stack because the input signal can only pass from the root to the output of the stack. Therefore, reducing V_{TH} to near zero is possible. The reduction of the threshold voltage reduces the resistance and the propagation delay without increasing the leakage current [31]. The first transistor in the chain needs voltage drop to maintain the drive current flow, and therefore the maximum voltage that can appear at the output of the stack could be ($V_{dd} - V_{TH}$). The time it takes for the input signal to reach the stack output is dependent on the number of transistors in the series in the stack loop from the root node to the output of the stack. A sense amplifier (SA) which consists of the pre-amplifier and cross-coupled latch is added to the output of the stack to recover the voltage degradation of the signal, to improve the performance of the SAPTL, and to provide sufficient buffering for driving a reasonable load capacitance. There is a trade-off between the power consumption and sensitivity of the sense amplifier in the SAPTL.

VIII. MOS Transistor Model for Different Operation Region

The world's first industry standard model for a MOS transistor, introduced in 1997, is the UC-Berkeley short-channel insulated-gate field-effect transistor (IGFET) model (BSIM) which has become more complicated to increase accuracy as the technology geometry shrinks. Selecting the correct value of (V_{GS} – V_{TH}) and the transistor length L is essential for IC design and the design parameters are related to the threshold voltage-based model. The threshold-based model causes inconsistency because there are no unified equations covering the whole region of operation and dividing the CMOS operation region into pieces when an allocated set of equations is required. For low power (micro-power) analogue circuit design, the Enz-Krummenacher-Vittoz (EKV) model was derived to substitute the threshold voltage based-model by using the surface potential-based model or the charge-based model. The advanced compact current-based (ACM) model is based on the EKV model but avoids the use of equations for the weak and strong inversion models [28]. The availability and acceptability of the ACM model are less than the BSIM model [29]. The drain current (I_D) is expressed as the difference between the forward and the reverse current in the ACM model [28].

$$I_D = I_S\,(i_f - i_r) \qquad (9)$$

The forward normalized current (i_f) depends only on the source-gate voltage whereas the reverse normalized current ($\acute{\imath}_r$) depends only on the drain-gate voltage. I_S is the normalized coefficient or specific current [28]. The value of $\acute{\imath}_f$ and $\acute{\imath}_r$ specify different modes of transistor operation. The reverse current can be ignored in the saturation region and the forward current is roughly equal to the drain current. If $\acute{\imath}_f$ <1 and $\acute{\imath}_r$ <1, then the whole channel is only weakly inverted and the transistor is in the weak inversion region [28]. The normalized coefficient or specific current (I_S) is defined as:

$$I_S = 1/2 \,.\, n \,.\, \mu \,.\, C_{ox} \,.\, V_T{}^2 \,.\, W/L \qquad (10)$$

Where W is the width and L is the length of the transistor, V_T is the thermal voltage, C_{OX} is oxide capacitance, μ is mobility and n is the slope factor. The normalized reverse and forward current are defined as:

$$i_{f(r)} = I_{F(R)} / I_S \qquad (11)$$

The most accurate parameters for the ACM model can be obtained from the foundry, but another less accurate option is by extracting from the BSIM model.

IX. Parameter Extraction for Normalized Coefficient (I_S) and the G_M/I_D Design Methodology

The normalized coefficient or the specific current (I_S) can be extracted through a method explained in [23] but a more accurate method is by calculating transconductance efficiency to determine the normalized coefficient or the specific current (I_S). Transconductance efficiency is the ratio of the transconductance (g_m) to the drain current (I_D) [29]. The transconductance (g_m) is defined as δI_D / δV_{GS} and is equal to:

$$g_m = (2 \,.\, I_D) / (V_{GS} - V_{TH}) \rightarrow g_m / I_D = 2 / (V_{GS} - V_{TH}) \qquad (12)$$

The (V_{GS} – V_{TH}) and g_m/I_D are related. The transistor operating region can be determined by the transconductance value. The level of inversion can be determined by the normalized drain current value. The level of inversion is moderate when the normalized drain current value is equal to one. The intersection of the weak and strong inversion is the centre of moderate inversion. Based on the normalized drain current ($\acute{\imath}_S$) value, the transistor is in strong inversion when $\acute{\imath}_S$ >10, the transistor is in weak inversion when $\acute{\imath}_S < 0.1$, and the transistor is in moderate inversion when $0.1 < \acute{\imath}_S < 10$.

In order to obtain the same inversion coefficient, PFETs must have a larger aspect ratio than NFETs because of lower mobility and ($\acute{\imath}_S$) in PFETs. For most of the IC design, gm is the key design parameter and the gm/ID design methodology is a well-known and effective method of designing analogue circuits. The gm/ID ratio is plotted against the normalized inversion coefficient, which defines the operation region of the transistor. The first step for the gm/ID design methodology procedure is setting the target gm, then figuring out the required DC bias current in the targeted region and determining the transistor aspect ratio (W/L) according to the corresponding IC and also determining the channel length and width.

X. Conclusion

The characteristics and design requirements of the wireless biomedical implants and lab-on-a-chip devices for different applications were reviewed. The alternative power sources for the wireless biomedical implants and lab-on-a-chip devices were considered, and their advantages and limitations were discussed. Different architecture methods for wireless systems in lab-on-a-chip devices and implantable biomedical devices with local and remote power sources were reviewed.

Practical limits and challenges in low power and low voltage design of wireless systems in lab-on-a-chip devices and implantable biomedical devices were reviewed, and various techniques for low power design were investigated, with the advantages and the trade-offs of each design technique identified.

Subthreshold or weak inversion operation was highlighted as a suitable technique for low power design for low to mid-range frequency applications, but the leakage current has to be reduced to decrease the static power specifically for devices with a long standby mode. There are several techniques for reducing the leakage current such as variable-threshold CMOS (VTMOS), multi-threshold voltage CMOS (MTCMOS) [22], super-cut-off CMOS (SCCMOS), double-gate-dynamic-threshold CMOS (DGDTMOS), multiple supply voltage and transistor stacks [23].

However, a combination of low power techniques can be used for designing different modules to achieve the best performance for individual sections. Investigating the whole system functionality before selecting a modular design for each section may be more efficient. For example, different biomedical implants and lab-on-a-chip devices require different levels of efficiency even when performing the same tasks such as monitoring, stimulation or wireless transmission. Therefore, considering the required level of efficiency for the whole system functionality is critical for designing low power biomedical implanted devices.

***Abstract*— Agile project management has been widely applied, especially in software development projects, but there are still very few implementations in IT Infrastructure projects. This study aims to improve knowledge about the implementation of agile project management on IT Infrastructure. This paper uses case studies and Design Science Research Methodology on a pharmaceutical company that transforms the IT network infrastructure for branch offices from conventional WAN topology to SD-WAN topology, managed by agile project management Lean and Kanban. As a contribution, this study proposes a project management model for IT Infrastructure agile adoption inspired by Kanban and Lean agile project management frameworks for implementing network transformation.**

Keywords*— *Agile Project Management, Design Science Research, IT Infrastructure, Kanban, Lean, Network Transformation, SD-WAN

I. Introduction

In a growing digital economy, the increasing and changing demands of internal consumers for infrastructure services, technological developments, and high technology will need to face formidable challenges as digitization changes the industrial landscape [1]. Information Technology (IT) Infrastructure has an essential role in business resources for competitive advantage because it is enabled cross-functional initiatives and processes for the business. Previous studies discussed in a dynamic and ever-changing environment characterized by complexity and uncertainty, new infrastructure services developed on top of existing infrastructure services [2].

This paper uses a case study on a pharmaceutical company among 100 branch offices in Indonesia. The entire network for branch offices managed by the Corporate IT (CIT) team. The IT team's challenge is to manage the complex network, and there is a network Service Level Agreement (SLA) target to be fulfilled every month as a part of the commitment to the company's services. The SLA Network Availability report in 2019 shows the average SLA has not achieved 98.17% from the SLA target of 98.80% see Fig 1. The impact of this condition is decreasing branch productivity. High network branch utilization in 2020 because of pandemic conditions prompted companies to implement a new standard office. From the network utilization report in 2020, 29% of branch offices reach the maximum throughput. This condition has made the branch performance decrease since delays in the branch administration and operational processes can affect the branch office's sales activities and productivity. Another challenge for the IT team is the enormous investment costs for the procurement of network equipment, and the impact is network operating costs increase every year. The pandemic conditions in 2020 require significant changes to IT infrastructure to improve immediately. The operational processes can run according to business needs, as discussed with IT Infrastructure Head, especially for network transformation. The research question is about how to transform IT Infrastructure agile.

This study aims to learn adaptations of agile project management in IT infrastructure transformation, limitations on the Software-Defined Wide Area Network (SD-WAN) implementation project on the research object. This research's novelty is the implementation of agile using Kanban- Lean, which has been implemented in the company and custom to transform IT Infrastructure—using the research science design methodology (DSRM), through six stages, problem identification, the objective definition for solutions, design, and development, demonstration, evaluation, and communication [3]. Three expert judgments help the author formulated an agile adoption model, Lean and Kanban. As an academic contribution, this study proposes a project management model for IT Infrastructure inspired by Kanban and Lean agile project management frameworks for implementing network transformation SD-WAN. Simultaneously, the organization can apply agile methods to project management to be more efficient, effective and answer business needs or requirements more quickly for IT Infrastructure transformation.

II. LITERATURE STUDY

A. Agile IT Infrastructure

IT Infrastructure is the arrangement of IT stocks' technical components and services necessary for its IT environment's existence, operation, and management [1]. Three companies took a unique approach to agile transformation based on principles tailored to business needs in the previous research. Agile transformation helps organizations modernize their IT infrastructure while increasing performance significantly. The processes by which companies provide infrastructure services have grown to be more complex and labor-intensive as the company grows, so it can take months to bring new products and features to the market [1]. Previous studies have shown that agile IT Infrastructure transformation practices at team level IT combine close dialogue with stakeholders and an agile method. The scalable approach requires investment in automation, the key to a more agile delivery infrastructure. In this way, the end-to-end sending process can be better developed, and infrastructure needs should be better understood and implemented appropriately. From the above explanation, here is an example of Agile IT Infrastructure transformation inspiration from Scrum's agile framework, Kanban, and SAFe [2].

B. Agile Project Management

The agile project management approach is currently widely practiced in software development [4]. An agile project is better to adapt to changing business requirements. To increase visibility, customer collaboration, and limited-time iteration delivery provides an opportunity to re-evaluate priorities regularly [5]. Agile project management represents the management approach, and a productivity framework supports incremental progress on work priorities and continuous, even in the face of changes [6]. Agile project management is iterative, incremental, self-organizing, and emergent. The Agile Manifesto inspires the agile methodology, created by a group of software practitioners in response to this growth IT-related project failures [7]. Based on previous research, the authors conclude agile project management is a group of project management methodologies based on an agile mindset and principles.

C. IT Infrastructure

IT Infrastructure is a platform technology hardware and operating systems, network and communication technologies, data, and critical software applications [8]. IT Infrastructure collects various components can be individualized hardware entity or Infrastructure Group comprised of the server cluster infrastructure components[9]. IT Infrastructure is a technical and human device managed to provide the foundation for specific IT applications. IT technical Infrastructure includes computing platforms, hardware, operating systems, communication networks, data, and IT applications [10].

D. Kanban

Previous research explained Kanban in Japanese means signboard developed by Toyota in the 1940s to enhance its manufacturing process. Kanban is now a popular Agile methodology visualizing and controls work progress through the Kanban board. Kanban helps improve transparency, planning, and efficiency. Kanban boards can be physical or virtual and can vary in complexity [1]. Here are three principles of how the team can run the Kanban process [11]:

1. Visualize the workflow.

Divide the work into sections. Write the card's tasks and place them on the wall either physically or on a virtual computer system. Making work visible is believed as increased communication and collaboration.

2. Limit Work-in-Process (WIP)

Limit WIP focuses on WIP and designation, limiting total items in each workflow state. By limiting unfinished work in progress, the team can reduce the time it takes for an item to travel through a Kanban pipe. Limit WIP can avoid problems caused by task shifting and provide agility by activating new tasks prioritized effectively.

3. Focus on Flow

Using WIP constraints and growing team-driven policies, the team can smooth the workflow and complete the team job. Kanban works in an organization. From small to big companies and a personal level. This technique's advantage is the old practices do not have to be removed entirely but adapted to the new rules. Next to the principles, Kanban comes in six ways to implement this new working method in a team [12].

E. Lean

Lean is Kanban principles and practices based on a management philosophy, which Toyota also developed and concentrated on understanding things generate additional costs and human resources and elements in the production [11]. Lean is an effort to eliminate waste. The principle relies on improvements in administration, strategies, production [13]. Using Lean and Kanban at research object in all manufacturing processes, and Lean is also an excellent method there is no waste in all available resources during the project. This study, the agile management project approach by Lean-Kanban.

F. SD-WAN

SD-WAN has also understood the application of SDN (Software Defined Network) in WAN to integrate software-defined network technology and WAN. Besides the development of SD-WAN, various technology architectures emerge endlessly [14].

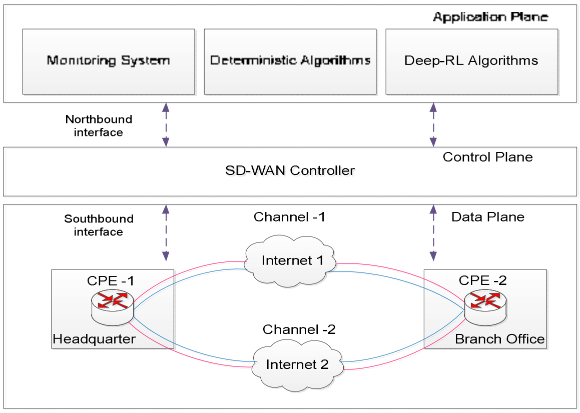

Fig. 2. SD-WAN Network Architecture [15].

SD-WAN relies on a Software Defined Network. It simplifies network control, network management and enabling innovation through network programmability. SD-WAN separates physical forwarding elements from the data field, from the network control logic, called control-plane is implemented in a logically centralized controller [15]. This control logic is what differentiates SD-WAN from VPN. SD-WAN is possible to provide good QoS. Control of the network from centrally, which continually monitors the network conditions and, consequently, adjusts the connection options [16]. SD-WAN has been implemented only on the edge of the overlay network, inside the Residing Customer Premises Edge (CPE) device at branches, head office, and the company's main office.

G. Related Research About IT Infrastructure Transformation

The related study performed agile techniques in three other infrastructure-related projects. A unique infrastructure point of view indicates that the term agile infrastructure consists of several layers. We need to address each layer [17]. The Agile methodology, adapted and applied for the Information Technology (IT) team, has also been discussed in previous studies. The research methodology practices for managing change as well as running managerial practices smoothly. The method development procedure uses a design science research approach, including problem identification, designing the proposed methodology, and evaluating case studies to show a strong relationship between the application of agile methods and IT staff members' performance [18]. IT technology models the development of infrastructure operations and the scope of agile management. It aims to analyze changes and the contribution of operational processes within the agility scope in traditional methods. An agile transformation contributes to the process's corporate structure within the system infrastructure's operational scope [19].

H. Theoretical Framework

The theoretical framework is a framework formed from related theories, previous studies, and appropriate methods in a study [20]. This paper's theoretical framework uses the theory and previous study agile project management, IT Infrastructure agile, and transformation. Designed to build agile adoption model solutions in case studies See Fig.3.

IT Infrastructure Agile Adoption for SD-WAN Project Implementation in Pharmaceutical Industry: Case Study of an Indonesian Company

Fig. 3. Theoretical Framework

III. RESEARCH METHODOLOGY

Based on research questions and the theoretical framework formulated, this research is a case study by design science research (DSR). Design science research combines the necessary principles, practices, and procedures [21]. Through the following six stages of DSR [3], (1) Identification of problems and motivation based on the business needs and operational issue, (2) defining the objective of the solution, determining the goals of the projects, and measurable organizational value (MOV), provide the business case thru three option solutions, (3) design and development project planning, design project management model agile Lean and Kanban, design proof of concept (POC) for SD-WAN topology, (4) implementation the project execution stage SD-WAN using Kanban and Lean in Indonesian pharmaceutical company, (5) Evaluation is carried out during the SD-WAN project stage, on this project using two evaluation, weekly for IT project team, and monthly for all stakeholder review, conduct with three expert judgments from the internal and external company (6) this communication during the SD project -WAN to all IT project member, stakeholder, and publish the journal model adoption in international conference IEEE.

IV. RESULT AND DISCUSSION

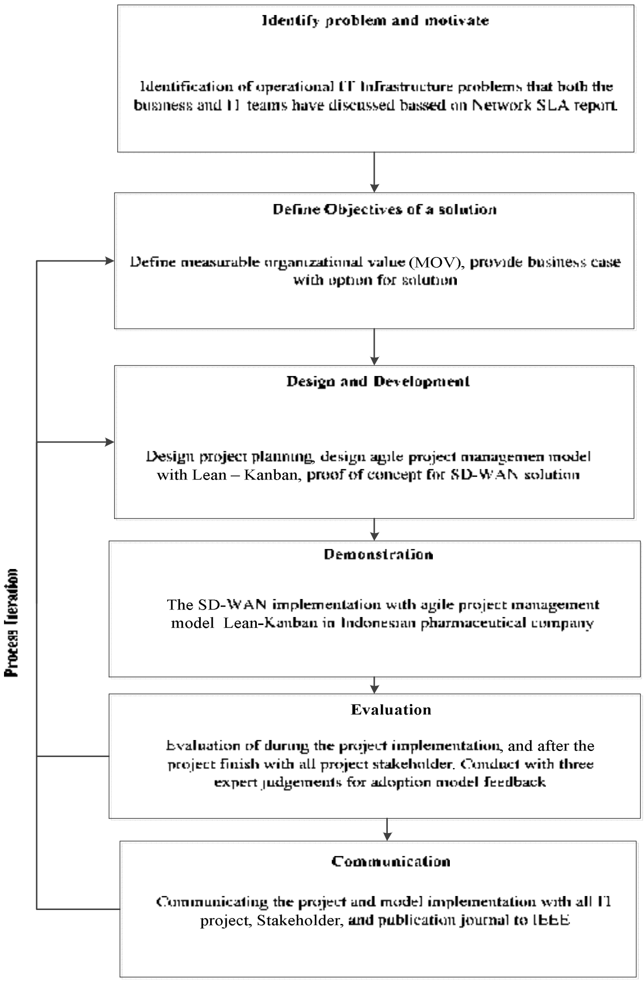
This section contains the result from the DSR methodology and a discussion of the research results.

A. Identify Problem and Motivate

Conducted a discussion on current conditions attended by the IT Project Team, Stakeholder, and Branch Subsidiary IT. The result is the organization's needs. The result of this stage is a business case agreed upon by all parties involved in the project. The option agreed on in this project is to improve the branch office network services SD-WAN.

B. Define Objectives of a solution

The measurable organizational value (MOV) is determined to be achieved after understanding the business needs. The IT Project Team collects approximate options from the solutions that can help as solutions.



Identify problem and motivate
Identification of operational IT Infrastructure problems that both the business and IT teams have discussed bassed on Network SLA report.
Define Objectives of a solution
Define measurable organizational value (MOV), provide business case with option for solution
Design and Development
Design project planning, design agile project managemen model with Lean – Kanban, proof of concept for SD-WAN solution
Demonstration
The SD-WAN implementation with agile project management model Lean-Kanban in Indonesian pharmaceutical company
Evaluation
Evaluation of during the project implementation, and after the project finish with all project stakeholder. Conduct with three expert judgements for adoption model feedback
Communication
Communicating the project and model implementation with all IT project, Stakeholder, and publication journal to IEEE
Process Iteration

Fig. 4. Design Science Research Methodology

TABLE I. MOV PROJECT

Potential Area	Desire Objectives	Change Factor	Time
Financial	the efficiency of network operating costs	10%	Two years
	investment cost efficiency of network equipment	100%	Two years
Operational	improve network service performance	98%	Two years
Customer	increase the productivity of branch offices	Meet SLA	Two years

C. Design and Development

Design and development project plan, define the project implementation methods, SD-WAN implementation concept. In this stage, a selected SD-WAN model developed, and a proof of concept (POC) with several internet service providers to choose the best suits your needs. The results of this stage are the project implementation model, project plan, and POC.

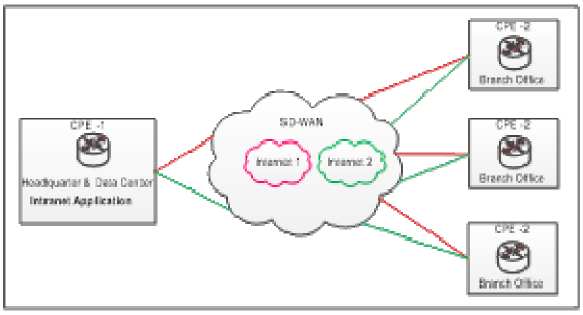


Fig. 5. Proposed Design Topology SD-WAN

D. Demonstration

The stage is the implementation of the SD-WAN project using the Lean-Kanban method. Kanban board to monitoring

all processes and project tasks until SD-WAN project complete. In this stage, the model for adopting Kanban and Lean for the SD-WAN project was implement in the Indonesian pharmaceutical company. The demonstration stage does inspect and adapts from agile to speed up feedback from all project members and stakeholders. During the implementation, Kanban helps to monitor the project task to eliminate the stopper.

E. Evaluation

The SD-WAN implementation project uses the agile Lean-Kanban method, so the evaluation process at the end of the project, but the evaluation in each period is by the IT project team every week. Moreover, at the end of each month, an evaluation is by the project team, stakeholders, and IT SBU. This evaluation aims for all teams to have the same perception and update of the ongoing project. The kanban board helps to evaluate the process that is inhibiting and must be accelerated more quickly. This evaluation also further accelerates decision-making if there is a need for changes related to ongoing projects.

To ensure the method used is correct, the researcher conducts expert judgment. It is from an internal company IT head Infrastructure and two people from external companies experts for agile and Kanban. Expert judgment with semi-structural interviews and presentation of the agile adoption model designed for the SD-WAN project. Three experts gave different input. According to business objectives, the first internal expert provided lean input as the project's main principle. The second expert provides process input to Kanban and must be detailed, and there is a "Done" in each process to make it easier to see the stopper project task. The third expert provides input to add an expedite in Kanban as a unique path if there is an urgent request, such as a VIP request. The final adoption model sees Figure 6.

F. Communication

Communication to ensure the project is going well. This stage generates inspection and adoption reports for improvements during the project. This stage's result is an update report for the project until it is done and accepted by all project teams and stakeholders. The author communicated the SD-WAN model implementation to all the project members and stakeholders and published the journal adoption model to the international conference IEEE.

G. Discussion

This study produces an agile adoption model for IT infrastructure projects, as shown in Figure 6. This agile adoption model suitable for current business needs. It was created a business case and project plan by the IT project team. The adoption of Lean in this project embodies one of the business goals with network operating costs' efficiency. Project implementation is carried out by monitoring tasks using Kanban, consisting of a task list, project processes, and a WIP 3 process limit. Each process has a done column to facilitate the complete task in the project stage.

Moreover, the completed column is for the project complete in all phases. This model has an expedite thru the provisions of WIP + 1. Expedite is used for exceptional cases if urgent conditions must be processed immediately without considering the WIP is currently running. This model evaluation and communication in each project process to ensure changes can be adapted quickly.

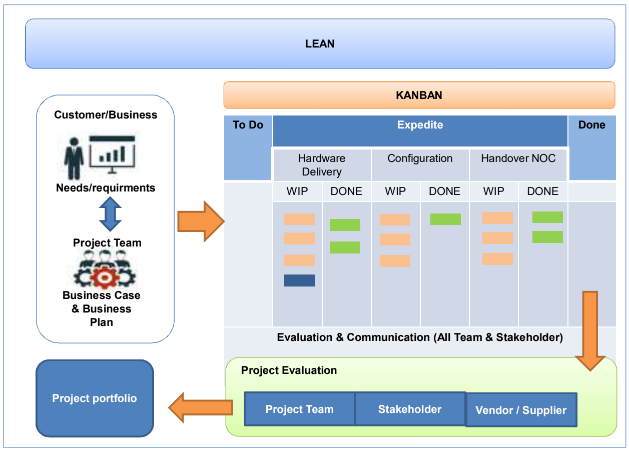

Fig. 6. Agile Adoption Model Lean-Kanban.

The project evaluation of the whole team and then a project portfolio is compiled and archived for the following project implementation.

The IT infrastructure transformation results in the branch office's SD-WAN implementation project see Figure 5. From the results of the project team's report on the performance of the SD-WAN implementation project, it has a good value, reaching 100% for the following project components, namely (1) project scope, (2) delivery increments, (3) and human resources. (4) While costs reach 98%, (5) the project implementation schedule gets 96% due to delays in completing four cities those experience problems in setting up network infrastructure from ISPs.

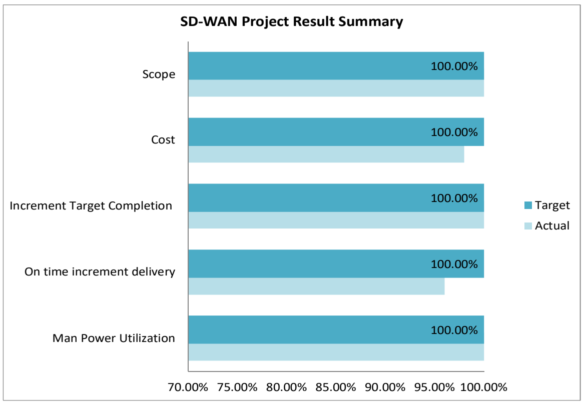

Fig. 7. Project Performance Result

The advantages of adopting an agile project management model lean and Kanban are as follows:

1. Lean by efficiency network operational, and investment cost practice SD-WAN solution.
2. Kanban board helps Project task monitoring, so all project teams and stakeholders can give feedback sooner.
3. It is facilitating project implementation has been accepted by users and stakeholders.
4. It minimizes waste for all resources in the project, costs, time, and human resources.
5. Assist in the implementation of projects more very flexible and need various adjustments.

Based on the results and discussions in this study, the agile adoption model in IT Infrastructure projects, especially the SD-WAN implementation, has a very effective and efficient impact on the organization. The IT project team's report shows with Kanban and Lean that completing the project for phase 1 in 2020 has reached on-time delivery 100%. All project tasks are well monitored through the Kanban board to minimize the risk of project delays. With WIP restrictions on each process, the project flow and tasks are controlled and carried out more quickly. This project had a cost-efficiency impact on network operation cost, which has decreased by 11.34% of total network expense.

Changes to the network topology with SD-WAN were carried out very well and smoothly in phase 1 of 2020 implementation due to the project risk mitigation arrange details. The changes made using the first SD-WAN installation scenario moved the old network to the new network during work breaks, making this activity not disturbing branch operations. Furthermore, with careful planning through a pilot project at the beginning of the proof of concept with the vendor, the SD-WAN implementation process runs smoothly.

V. CONCLUSIONS AND FUTURE WORK

A. Conclusions

This research aims to implement IT infrastructure agile project management using the Lean-Kanban approach. Lean helps achieve cost efficiency for network investment and operation. Kanban helps ensure the entire team is consistent, making it easier for all teams to monitor the project and understand its goals. Kanban can also be a solution IT

Infrastructure team to maintain flow during the transformation process as they have to ensure the IT Infrastructure project runs smoothly and existing operations are not interrupted. Based on this study's implications, IT Infrastructure at pharmaceutical companies, through complexity, can implement an agile project management approach for IT infrastructure transformation projects to accelerate the delivery process to internal businesses and increase company competitiveness due to accelerated changes according to the market and business needs.

B. Limitation and Future Work

This research's limitation is the specific adoption of Agile Lean and Kanban project management in IT infrastructure projects (SD-WAN) using the DSR method. Future research can further develop IT Infrastructure project applications, other agile project management and develop more complex iterative DSR models. This case study is specifically in organizations pharmaceutical companies in Indonesia. In future research, the next adoption model can use IT Infrastructure projects in other industrial fields suitable using Kanban and Lean.

***Abstract*— In today's industrial world, renewable energy represents 16% of the total produced and consumed energy. Wind energy is gaining popularity and imposing bigger footprint in the natural sources of electricity and plays a key building block for economic recovery from the impact of COVID-19 according to the Global wind Energy Council.**

Yet, because its presence in the energy resource share is below 5%, since most of the wind farms use Doubly Fed Induction Generator (DFIG) it will suffer from grids faults such as symmetric dips. The scary part of the dips is that it will increase the currents at the back-to-back converters and even when dealing with them oscillation might destroy the turbine and generator assembly. In this paper we will review techniques used to detect the dips and override the heavy increase of the current using a crowbar, we will concentrate only on the detection and compare the resulting parameters while keeping the controllers and the value of the crowbar resistance unchanged

Keywords—DFIG, PI Controller, Voltage Dips, Crowbar, Grid Connection, Energy Conversion, Vector Control, Distributed Generation, Wind Turbines

I. Introduction

Distributed generation (DG) is the only answer to the growth of population, and the relocation of noisy industrial zones outside cities. This increased dramatically the challenges of producers of electricity in terms of cost of production, environment cost (usually emission), and reliability. The structure of the grid offers by itself a solution by itself as with DGs we can isolate regions to increase local reliability of the systems. Reliability of the system related to the adoption of wind energy is seen from two different perspective: does it offer enough energy with less cost and during the time, and weather it is immune against grid faults specially voltage dips.

In this paper we will talk about the effect of voltage dips on the Wind Turbines (WT) build around Doubly Fed Induction Generator, which is the most used machine in such field. [1,2].

Sudden drops of voltages in the grid are described as Voltage Dips, they are usually caused by faults occurring in the grid [1], there are two types of voltage dips symmetric and asymmetric voltage dips. We will be only talking about symmetric dips.

Due to the impact on the various connected DGs, several studies have been conducted to detect the dip and to limit its effect on the DFIG connected to the grid. Different scholars from diversity disciplines worked together to solve this issue mainly limit the effect on DFIG's which direct maintenance and down time cost cut. Thus, we will find people form electrical engineering working with artificial intelligence experts to predict behavior of the machine during dips and deploy necessary counter measure.

A. Stanisavljevic, et al in their work reference [4] described clearly the threat towards the DGs degenerated from voltage sags (dips), and then presented an overview of all the techniques used when the paper was published. They mainly worked on the detection of the fault by the grid administration. Once the fault is detected different generation unites are informed accordingly. These techniques are either based on analysis of harmonics, RMS value, or hybrid methods. Then they have established a Key Performance Index (KPI) to define the effectiveness of each method. Since we will not work on the grid side rather, we will deal with DFIG itself we will consider on the simplest technique base on RMS value of the nominal voltage and because it is the most used [5]

The early a voltage dips are detected the best it will be and multiple stages are always better, for large grids the dip might be seen by the grid operator (or control room) but before the DGs are notified the fault is fixed or disappeared as the cause disappeared, this justifies the need to have a at least a detection process at the DG level (DFIG in our case), this was elaborated in reference [6] a cleaver technique was used to coordinate different individual converts of each DFIG in the plant in order to regulate and voltage and respond rapidly to voltage dips.

Furthermore, work described in reference [7] finds a solution using combination of power electronics and apply crowbars in different circuits depending on the classification of the fault. The classification of the fault is achieved using "Adaptive Neuro-Fuzzy Inference System."

Other research found the solution in eliminating or reducing the fault magnitude by introducing dynamic voltage restorer (DVR) in attempt to enhance the fault ride-through of a DFIG based WT. the control is also based on "novel hybrid genetic algorithm optimized Elman neural network" [8], the cured system will help then to cure the grid.

Even though all the doors have been knocked, there would each time be some of the power electronics that needs to be called for help. To this end earlier work presented in reference [10] is revised thoroughly, we will use simple logic parameters and keep the crowbar resistance value fixed while we will be playing on the triggering parameters of the switching circuit to protect the IGBTs of the converters, while meeting the grid code of operation.

The introduction is followed by section II describing fault detection at the wind turbine level, then we describe the whole electrical configuration of the DFIG with different controllers and crowbar connection, followed by simulation and results we describe thoroughly the different control signals. Finally,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

we wrap up the findings by a description of the results versus the targeted objectives and future work.

II. Fault Detection

To achieve voltage Dips counter measure and save our DFIG from the voltage dip consequence we will need the deployment of a crowbar and a rectifier. During the voltage dip both rotor current and the dc-link voltage will increase and hence it will damage the rotor side converter components. Once the control switch CB is closed the current will be diverted towards the crowbar resistance meanwhile the RSC will have to be disabled so the current will not flow through.

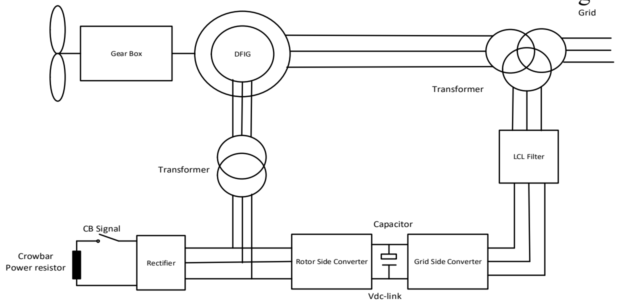

Fig. 1. DFIG with crowbar, RSC, GSC and power rectifier

We need also to detect the fault to decide when to apply a supportive reactive power from both Grid side converter and rotor side converter. We choose a simple method based on threshold RMS value of the nominal value of V_s we will consider anything below 90% as a voltage dip [5] this is considered as adequate choice as we will be dealing only with symmetric voltage dips. To increase the freedom of the fault detection and to simulate the possible delays of the other systems we can insert a delay after the fault is detected and another delay after the fault is cleared.

III. Electrical configuration of a DFIM based wind generation

We will consider a DFIG connected directly to the grid while the rotor is fed from rotor side converter, the last is also fed by grid side converter generating necessary dc-link.

This justified by its simplicity and its ability to deal with generated power as explained deeply on reference [1] [2]

We will be using PI controllers we will not go through the justification of such technique as it is well described in almost all previous work and we will not add anything extra to it. Yet we will have to find what are the limits of the crowbar, and what are limits of the dc-link and the rotor current to set our simulation to work within accepted operation range.

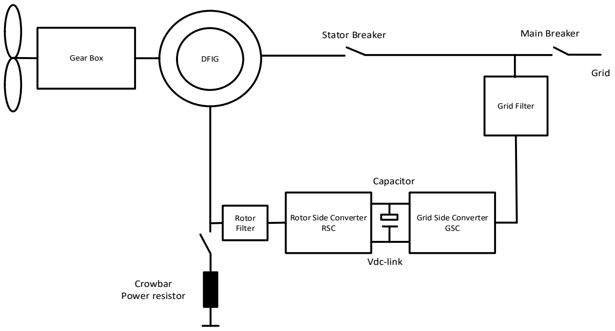

Fig. 2. DFIG Electrical configuration [2]

During a voltage dip the GSC will keep controlling the current, while the stator disturbance will be carried out to the rotor causing an overcurrent and overvoltage observed at the dc-link capacitor, this is due to the RSC currents control lose. This means that the rotor converter now cannot control the generator and has been restricted [2]

The aim of the crowbar is to short circuit the rotor at the right time with right duration to achieve a full protection to the system. Its minimum and maximum values are well developed in reference [10]

$$R_{cbmin} = \frac{\omega_r}{I_{safe}} \sqrt{\left(\frac{V_s}{\omega_1}\right)^2 - (L_\sigma I_{safe})^2} \qquad (1)$$

Where ω_1 , ω_r are synchronous and rotor angular frequencies, V_s is the stator voltage, R_{cb} crowbar resistor, I_{safe} is the upper extreme current at the rotor converter that will not damage it , finally L_σ is the sum of the leakage inductance of rotor and stator.

$$R_{cbmax} = \frac{V_{dc\_safe}\omega_r L_\sigma}{\sqrt{3(V_s\omega_r/\omega_1)^2 - V_{dc\_safe}^2}} \qquad (1)$$

$V_{dc_safe}$is the highest safe DC-link

IV. Simulation and Results

In this work we have adopted all justifications described in the literature to give renaissance to simple logic described in flow chart figure 3.

Case1:

We will use hysteresis compare described in paper of Y. Ling and X. Cai.

We built logical blocks to generate the different control signals as follows:

- CB: is the control signal for the crowbar.
- CE: is the control signal for the RSC enable or disable
- ED: is to enable the I_{dr} component to generate the supportive reactive power from the RCS as recommended by most of early references and literature.
- DI: is set the reference torque and the Pref (found by the MPPT) to zero to avoid saturating the PI feedback loop.
- EQ: is the control for the supportive reactive power on the GSC, it is mainly “true” during all the time on which the fault is detected.

The flow chart on figure 3 explains all connections with different control signals and how each one is active, again this just an interpretation of the logical sequence presented in most of the papers and books referenced here.

Case 2:

In the second experiment we have only 3 main control signals the remaining 2 are just a replay of the other two signals:

- CB: is the control signal for the crowbar.

- CE: is the control signal for the RSC enable or disable
- ED: is to enable the I_{dr} component to generate the supportive reactive power from the RCS as per earlier work and it is set to be identical to CB signal
- DI: is set the reference torque and the Pref (found by the MPPT) to zero to avoid saturating the PI feedback loop it equals the CE signal
- EQ: is the control for the supportive reactive power on the GSC, it is mainly "true" during all the time on which the fault is detected.

Fig. 4. Flow chart of propoused logical controls-case2 during voltage dips

Figure 5 shows the current flowing from the RSC, it shows that both techniques limit the current

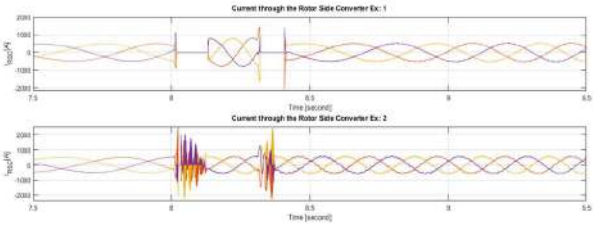

Fig. 5. Current flowing from or to the rotor convert side expirment 2 is done without fault detection

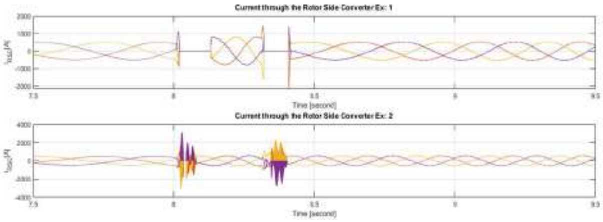

Fig. 6. Current flowing from or to the rotor convert side expirment 2 is done with fault detection

Figure 7 shows the Simulink® model created on the simulation software MATLAB® where the different values of the machine are shown in Table 1.

The different measured parameters on the machine for both cases are presented in figure 8. 1st method shows better control in terms of currents, Torque and represent less oscillation and better timing for stability of the machine after the fault, yet the power inserted to the grid remains higher than the one generated by the comparison technique on case 2

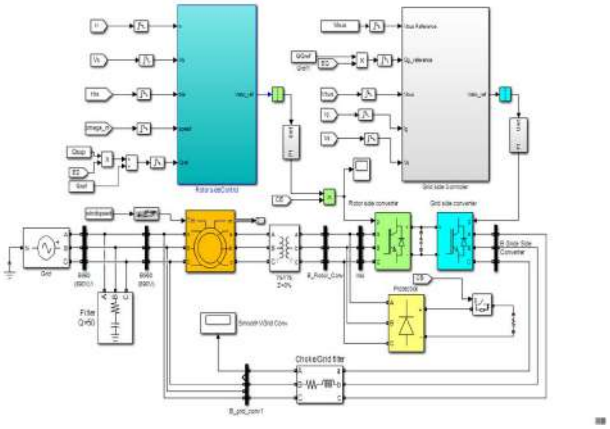

Fig. 7. Simulation model on MATLAB®

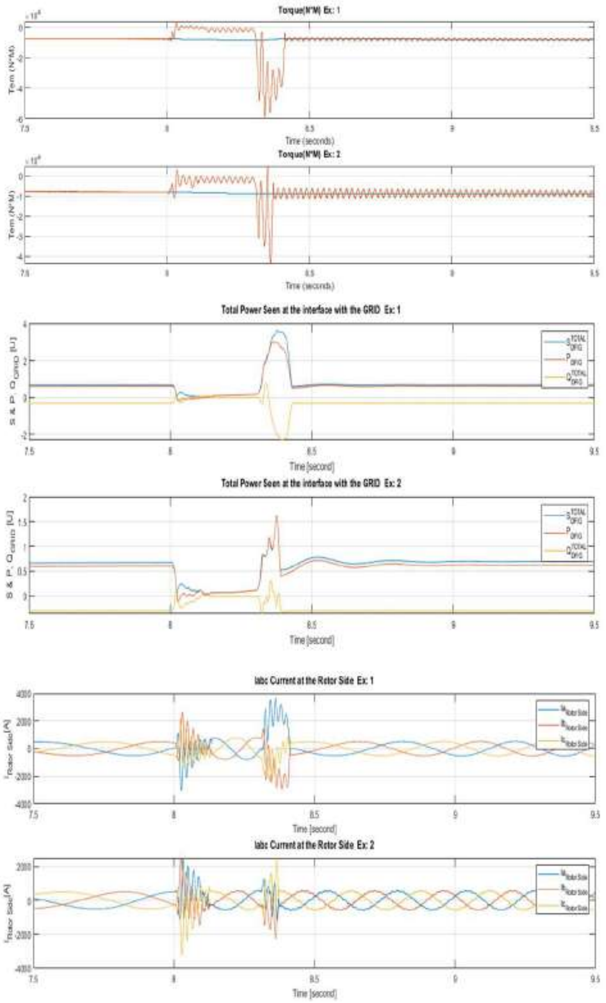

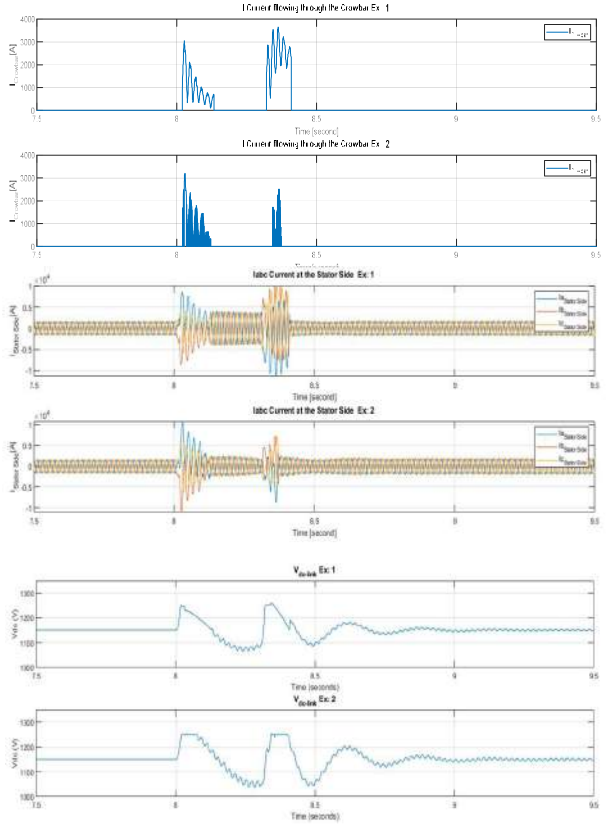

Fig. 8. Results of the simulation

V. Conclusion

The voltage dips are major issue that might kill the electricity production based on DFIG and wind turbines. Scientists tried to solve the issue using techniques that are far from power electronics or at least ignore the effect of power electronics in the whole system design, in our work we tried to polish legacy power electronics and bring it back using only simple logical methods and introducing different control signals we counted 5 in our proposed revision of crowbar technique. Essentially the Dc-link is better controlled in case 2, and might happen to go little bit beyond the upper limit in the first method or case 1, yet the first method is better in terms it offers the possibility to invest in simple logic as it offers lot of parameters that can reduce the power or increase it depending on the KPI required by the grid operator, it opens also the door for applying optimization algorithms to enhance it according to the requirements or constraints of the operator. Each of the graphs shared in this work can be shaped by this parameters and fair resolution between all the requirements is always possible.

Another side finding occurred when generating a reactive power from the GSC in the first experiment shows less current flowing in the inverter compared to the one flowing when running case 2 with the same requirement that is providing supportive reactive power from the GSC while the RSC is off (disabled and restricted)

We believe that the rig up of case 2 is much easier to implement but we doubt that such high frequency switching will not cause issue in real live converters. Also, we simulated the action of IBGTs but we did not simulate the heat dissipation.

The rig up of the whole system is much closer to the real-world system as we are not using average model to replace the PWM and the converters instead we are using a model of IBGTs and the closest possible model of PWM.

TABLE I. MACHINE PARAMETERS

Parameter	***Value***
Rated stator voltage Vs	690 V
Rated stator power Ps	2 MW
Rated stator current Is	1760 A
Stator frequency f	50 Hz
Rated torque Tem	12732 N.M
Rated rotor voltage	2070 V

***Abstract*—In the dairy industry, road milk tankers transport milk from one location to another. The milk inside the tanker needs to be kept between 3-5 °C to ensure that the quality of milk is always preserved. The tanker needs to be kept running at all time with the case of sufficient energy being continuously supplied to the cooling unit. The source of energy normally used for this application is a typical generator which needs fuel to operate. This is expensive and is not environmentally friendly. To address this problem, generator as a source of energy needs to be replaced by solar energy to lower the costs associated with cooling of the tanker. In this research a small scale solar powered intelligent cooling system was developed. This system was designed to make use of thermoelectric cooler as a viable cooling unit and operating it intelligently with a programmable logic controller. The system was designed in a way that it can also display the volume of milk inside the tanker and the system power consumption.**

Keywords—PLC, thermoelectric cooler, milk tanker, milk cooling, TECM

I. Introduction

Road milk tankers, transport raw milk from dairy farms to dairy processing factories where the milk is processed and utilized to produce dairy products like cheese, yoghurt etc. [1]. To ensure that the quality of the milk from milked cows is maintained during transportation, the temperature of the milk is kept between 3-5 °C [2]. This implies that the milk tank, during transportation, needs to be kept running by ensuring that sufficient charge is provided to the cooling unit of the tank. Road milk tank trucks make use of fuel-based energy sources like DC generator to cool down and control the temperature of the milk during transportation. The fuel-based energy machine is usually kept always running to provide sufficient charge to the cooling unit. The process to maintain the temperature of the milk is costly due to the fuel being used as a source of energy [3].

Rapid increase in price for fuel can have devastating effects on the freight management companies, particularly, road milk trucks. The fuel price increase can also decrease the profit that dairy processing plants make [4]. The use of renewable energy sources could help reduce the high fuel costs associated with cooling of the milk tank. The petrol cost associated with the cooling of the milk tank is high and this causes milk trucking/logistics companies not to make maximum profit due to petrol expenses. The fluctuation of petrol price constantly has evolving effects on the milk price rates [5]. The petrol as a source of energy is not environmentally free, and it contributes to global warming. Environmentally friendly and renewable energy powered intelligent milk tanks need to be developed in this case to lower the fuel costs and fuel related global warming effects, associated with cooling of the milk tank [6].

Heat pumps are very efficient for heating and cooling systems, they can significantly reduce the energy cost. They keep energy cost as low as possible which is the most important thing for any industry. The performance of the heat pump can also be described by COP. This method of cooling uses the refrigeration evaporator pipes or specially designed flat pillow-shaped plates that are attached to the bottom outer side of the tank containing milk. The heat of the milk is transferred through the walls of the tank to the refrigerant. The refrigerant then absorbs the heat of the milk inside the tank. The milk cooling process takes place inside the tank and normally an agitator is used to continuously mix the milk to prevent it from mixing at the bottom of the tank. Ice water cooling is another method used for the cooling of liquids in bulk tanks. The small compressors are normally used to build up a reserve of 'coolth' in the form of ice over a long period of time. The ice is normally formed on the copper pipes through which the refrigerant passes and the ice is surrounded by the water close to freezing point [7]. The water generally surrounds the outside of the tank while agitator is used to mix the milk inside the tank. The advantage of this method is that the ice can be made anytime and not only during the time when content must be cooled. This method is not as effective as a direct expansion method because the heat must be transferred several times (from ice, to water, to the milk). The other disadvantage of this method is if the ice has melted, it must be made all over resulting in high electricity usage.

In this research a smart cooling system is proposed based on the thermoelectric cooling module (TECM). A similar approach has been proposed in [8]. TECM, also known as Peltier cooler, because it is based on the Peltier effect is a semiconductor-based electronic component that functions by removing the heat from one side to the other when a low DC power source (12 V) is applied. One side of the module is cooled while the opposite side is heated [9]. The working principle of the TECM is shown in [10]. The heat flow out of the module has a significant impact on the overall system performance. The larger temperature difference that the module must work against, the smaller the quantity of the heat removed for the cold side. The performance of TECM and any other cooling device can be compared by determining their coefficient of performance (COP) [11]. The advantage that a TECM has over a compressor is that they have no moving parts and do not require the use of chlorofluorocarbons. This makes them

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

perfect for application since they are environmentally friendly [12].

II. Proposed Design

Fig. 1 shows the overview and operational analysis of the proposed system which describes the actions that the end-user will have to perform in order to operate and monitor the system.

The end user will at first, must switch the system on and check the alarm indications - whether all the components of the system are connected and functional. If the alarm system indicates certain components of the system are disconnected or malfunctioning, the end user will have to replace or connect them to the system and monitor the alarm system again to verify that they all connected. When the alarm system indicates positive results, the end user will have to operate the controller with the aim to check/ monitor the temperature and the level of the milk. The end user will also monitor the power being consumed by the system. After the process of operating the system, the end-user will then have to deliver the cooled milk inside the tanker to respective dairy processing plants. The control unit will have the buttons and screen through which the end-user will operate to view the status (level and temperature) of the milk inside the tanker.

The TECM from laird technology/TE technology Inc., usually comes with heat sink and fan already assembled, depending on the application for which they are needed. The cooling capacity of the thermoelectric cooling system is dependent on the operating temperature of the content desired for cooling, quantity of thermoelectric modules used, the type of thermoelectric module used and the applied power. The Marlow guide [13], will be used in this case to select the applicable TECM which will be compatible for the research. Firstly, the heat load capacity of the milk needs to be determined to select the applicable TECM which will be able to provide cooling capabilities. As such, the selected TECM must be able to handle the temperature difference of 34 °C. The cooling capacity of the milk, in this case, is determined to select the right TECM for the application. Equation (1) can be used to estimate the heat load/capacity of liquids [14].

$$Q_C = mC\Delta T\Delta t = \rho VC\Delta T \qquad (1)$$

Where, m is cooled substance mass (kg), C is cooled substance specific heat capacity (J/(kgK)), ΔT is cooling temperature difference (K), ρ is cooled substance density (kg/L), V is Volume of the cooled substance (dm^3) and Δt is cooling time (s). Although our research was based on milk cooling, water was used as a viable substance to cool.

Fig. 1. Operational flow diagram of proposed system.

The density of the water was 1 kg/L, its heat capacity was 4.2 KJ/(kg*K). The heat load capacity of 50 L of water is: 661.1 W. Considering the safety factor of 20%, cooling capacity of 50 L of water/milk is: 1.2 *661.1 = 793.3 W. The TECMs chosen, must be able to pump this amount of energy to cool 50 L of milk to 4 °C within the estimated time of 3 hours.

Table I, shows the heat load for different levels of water. It is evident that the heat load doubles whenever the quantity of the milk doubles. The heat loads calculated using Equation (1) is only an estimate and something to work on regarding choosing the right TECM for the research. The liquid cooled TECM (Laird Technologies LA-115-24-02-0710) that was used is shown in Fig. 2.

This module has the voltage rating of 24 V, current rating of 5.8 A and power rating of 139 W. This Single Assembly, from our heat load capacity calculation of the water/milk, would be able to cool 8 L of milk/water to a temperature of 4 °C within the period of 3 hours. Approximately 7 of these TECM assemblies will be able to cool 50 L of water/milk. These approximations are only theoretical, and they do not account for the shape of the tanker and all other factors which might affect cooling process of the tanker.

Simulation was done later in SolidWorks® to estimate the cooling capacity that is needed for 50 L of milk. Simulation results provided more accurate approximations because in this case other factors which can influence the cooling process were considered. The eTape liquid level sensor from the Milone Technologies Inc was selected for this research. This sensor output was used by the controller to calculate/determine the actual capacity of milk inside the tanker in L. The controller also used eTape results to determine the temperature sensors that must be activated and considered to calculate and ensure that accurate temperature results of the milk are displayed. eTape was placed in a vertical position inside the tanker and was in contact with the liquid. The eTape used the radius/diameter measurement of the tanker which was then used altogether with the tanker dimensions to determine and display the liters of the liquid inside the tanker.

Table I. Heat Loads for Different Quantities of Water

Liters (L)	Q_c heat load (W)

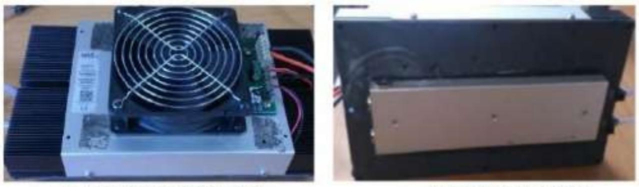
30.0	476.00
40.0	634.67
50.0	793.33



a) Heat disposal side of Available TECM

b) Liquid cooling assembly side

Fig. 2.Utilized liquid cooled TECM.

A thermocouple was selected as the temperature sensor to be used for the research. Three thermocouples were placed at different levels inside the tanker and their output was connected to the controller. The controller was programmed to only display the average temperature sensed by the thermocouples in contact with the liquid. One thermocouple was used to sense the temperature surrounding the tanker. Four thermocouples were needed for this for the research. The thermocouple sensor had the requirement of being able to measure the minimum temperature of -5 °C and maximum of 40 °C, as the temperature ranges of the liquid sensed were within this range. The controller also used the imbalance of 10% (within the sensors placed inside the tanker) to activate the mixer to ensure that temperature of the milk was distributed and accurately displayed. Type K thermocouple sensor from RS-pro was used. This industrial manufactured sensor has a temperature range of -50 to +400 °C [54], which was viable for the research.

The alarm system for the research consisted of light emitting diodes (LEDs) which indicated the status of the system components such as photovoltaic (PV) (1st Power Supply), the battery (2nd power supply) and the state of the mixing unit. The green LED was used for indicating the connection of the PV panel to the system, yellow LED was used for indicating the presence of the battery in the system and lastly the blue LED and red LEDs were used for indicating the status of the mixing unit. The blue LED was activated when the mixing unit was in operation and the red LED was used to indicate the off state of the mixing unit. The operator (driver) was able to view the status of the components and able to make informed decisions thereafter. The alarm system also indicated whether the control system was supplied through the PV or the battery and this was indicated by means of green and yellow LEDs, respectively.

This controller was used to implement the temperature control unit and energy management unit of the system. The PLC read the information, gathered through the sensors discussed, and took control steps to meet the specifications of the research, such as maintaining temperature of the liquid between 3-4 °C. In the temperature control unit, the PLC used the temperature sensors in contact with the fluid and displayed their average sensed results. The PLC required level measurements from eTape to decide which temperature sensor to consider. In the energy management unit, the PLC decided on the energy source that needed to be used depending on weather conditions. The PV was the primary source while the battery was the secondary source. The battery was utilized when there was insufficient energy from the PV due to weather conditions. The PV charged the battery and supplied the system when there was sufficient energy during sunny days. The PLC also managed the alarm system of the research by sending the switching instructions to the LEDs depending on the input information it received from the system's components.

Fig. 3 shows the suggested control flow diagram that was implemented. In this flow diagram, the system first determines the amount of milk that is inside the tanker. The system uses the minimum level (L_1) as the level at which the cooling occurs, as to avoid wasting energy during the time when the tanker was empty. TECM started to be activated when the water level was above the minimum level.

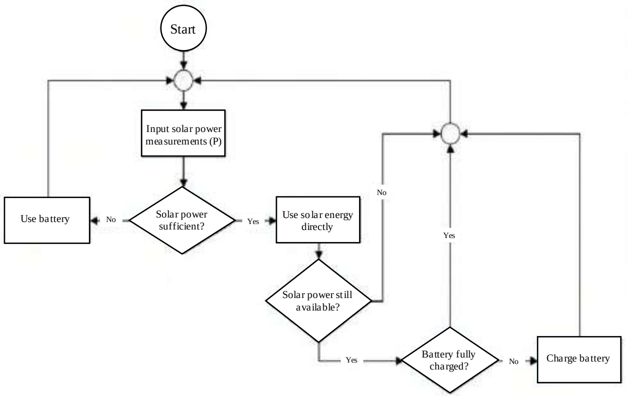


Fig. 3. Implemented control flow diagram.

When the measured liquid level was between the minimum level and the median level (L_2), only the first thermocouple (T_1) measurement was considered. T_1 and T_2 were considered when the water level was between L_2 and L_3 (maximum level).

T_3 together with T_1 and T_2 were considered when the liquid level was above L_3. The average temperature (T_{avg}) sensed by the thermocouples, was calculated together with their temperature deviation (T_{dev}). When the average temperature of the liquid was greater than 4 °C, the cooling units continued to be in activation state until the average temperature was less than 4 °C. The mixer was activated when the temperature deviation was greater than 10% and deactivated when the temperature deviation was less than 10%.

The energy management control flow (shown in Fig. 4) was implemented on the PLC controller. Table II summarizes the abbreviations used in Fig. 4.

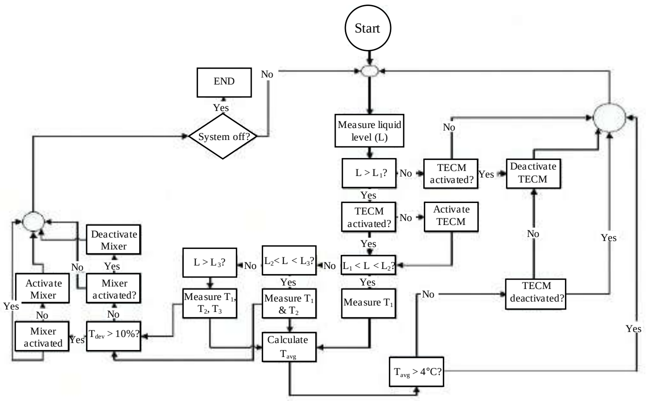

Fig. 4. Energy management control flow diagram.

TABLE II. SUMMARY OF ABBREVIATIONS USED IN FIG.4

Abbreviation	Description
L	Measured liquid level
L_1	Minimum liquid level of the tanker
L_2	Medium liquid level of the tanker
L_3	Upper Liquid level of the tanker
T_1	Temperature sensor placed at minimum liquid level
T_2	Temperature sensor placed at medium liquid level sensor
T_3	Temperature sensor placed at the upper liquid level
TECM	Thermoelectric cooling unit
Mixer	Agitator
T_{avg} & T_{dev}	Average temperature and temperature deviation

In the flow diagram, it is seen that the energy of the PV was first determined/measured and decided if it's enough to power the system. This required both the voltage sensor and current sensor be implemented to determine and monitor the power from the PV. During sunny days, the energy of the PV is likely to be enough to power the system and simultaneously charge the battery. During the night or bad weather conditions, the energy from PV is likely insufficient to power the system directly, hence a battery was needed as a backup source. The power measurement from the PV allowed the controller to determine which power source to use between the PV and the battery. The voltage sensor (voltage divider) was also used to sense the voltage capacity of the battery to determine or monitor its energy capability. This sensor was connected to the analog input of the PLC to allow the implementation of flow diagram shown in Fig. 3. Since there three sensors were used to implement the energy management unit, three analog inputs of the PLC were used for this purpose.

For current sensing measurements, the shunt resistor, together with the current sense amplifier, was used to take the current measurements from the PV. The power of the PV was then determined from the current and voltage measurement of the PV. This power calculation was then used to determine if the PV is able to supply sufficient power or not. Fig. 7. Temperature analysis with TECMs placed parallel to bottom of tanker.

The TECM was operated outside the tanker with copper coils placed inside, for direct contact with the milk/water. The purpose thereof, was to see how the temperature was distributed within the milk upon the placement of the copper coil to the relevant place inside the tanker. Only one TECM was available for the research and the SolidWorks® simulation was done to investigate the effect of this module inside the tanker. The minimum temperature of the provided cooling module was -10 °C. Ethanol was chosen as the circulating liquid which will flowed through the heat exchanger of the TECM. In the simulation, the temperature of the ethanol entering the copper coil was set at -10 °C. Fig. 5 shows the temperature results of our analysis. It was considered that the coils were placed at the minimum level of the tanker to allow cooling when the liquid level is at that point.

The surrounding temperature of the tanker was set at 25 °C since this was the temperature regarded as room temperature and the water was used as a liquid to be cooled with an initial temperature of 38 °C. In Fig. 5, the copper coil only managed to cool the liquid near it and as such, the agitator was needed to mix the liquid and ensure that the temperature of the liquid was well distributed. This setup of the tanker required that the agitator be placed in the parallel position to the tanker to allow the movement of the cooled liquid to mix with the hot liquid as seen in Fig. 5(a).

The thermocouples for this scenario, had to be placed at different levels of the tanker. One thermocouple was placed at the bottom level of tanker, the second thermocouple was placed in the middle of the tanker and the third thermocouple in the top level of the tanker. The fourth thermocouple sensor was placed outside of the tanker to read the outside temperature. This setup in Fig. 5, was implemented as there was only one available TECM. The tests on the tanker were conducted to evaluate the cooling capability of this cooling module.

Fig. 6 shows the thermal analysis of the tanker when there is multiple liquid cooled thermoelectric cooling modules. The position placement of three TECMs was investigated in this regard, to determine how the liquid was cooled in these scenarios. In Fig. 6, the tanker was connected to three TECMs whose coils are placed perpendicular to each other. This set up of coil placements is not proper since the temperature at the top is not cooled. The liquid at the bottom of the tank will also freeze due to high concentration of cooling happening at the bottom. Hence the choice of placing the cooling coils in this manner is not proper. In Fig. 7, the three TECM copper coils are placed in a parallel in accordance with the levels of the tank. The cooling in this case happens much better that in Fig. 6. The temperature of the water in Fig. 7 is mostly seen to be around 3-7 °C. This proves the setup in Fig. 7 is better than the setup in Fig. 6.

III. Results

The subsystems discussed above were all integrated to realize the intelligent solar powered TECM road milk tanker shown in Fig. 8. This figure shows the setup of the research where 8.91 L of water was inside the tanker as indicate on the LCD screen. The LCD screen also displays power consumption. The PLC recorded the temperature to be 7℃ inside the tanker and the surrounding temperature was 18 °C.

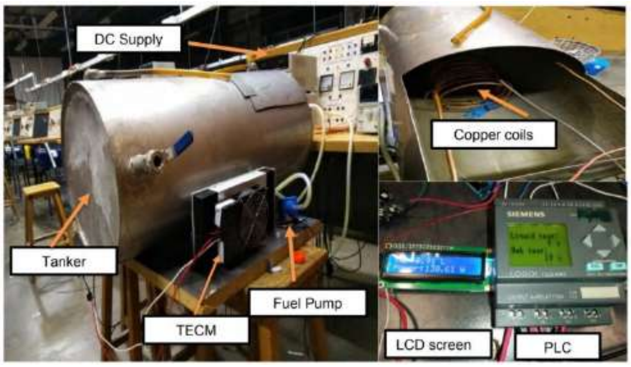

Fig. 8. Integrated intelligent solar powered TECM road milk tanker.

Two tests were performed in order to evaluate the system performance and determine the efficiency of the system. The results were used in order to draw a conclusion on how, on the big scale, the system performed. The ability of TECM as a cooling unit was evaluated and tested as to predict how many TECMs were needed to ensure that the system becomes more efficient in terms of cooling. The ability of the tank to preserve and maintain the cooled temperature will be discussed. The critical tests that were conducted were the cooling ability and the temperature control.

A. *Test 1: Cooling ability*

This test determined the ability of the tanker to cool the milk. Water was used as a viable liquid that was cooled and tested even though the objective of this research was to design the tanker which will be able to cool the temperature of the milk from 38°C to 4 °C within a time period of 3 hours to ensure that the quality of the milk is preserved. 7 L and 21 L of water were externally heated up to a temperature of 38 °C. 7 L of this hot water was filled inside the tanker first and the test was performed. 21 L of hot water was filled secondly, and the cooling test was conducted. The temperature measurements of the critical sensors were recorded and noted while the system was being operative for 3 hours for both cases of 7 L and 21 L. Fig. 9 shows the cooling test results for both the cases. The system managed to cool down 21 L of water from a temperature of 33 °C to a temperature of 19°C within the period of 3 hours. On the other hand, the system only managed to cool down the temperature of 7 L of water from the temperature of 30 °C to the final temperature of 13 °C.

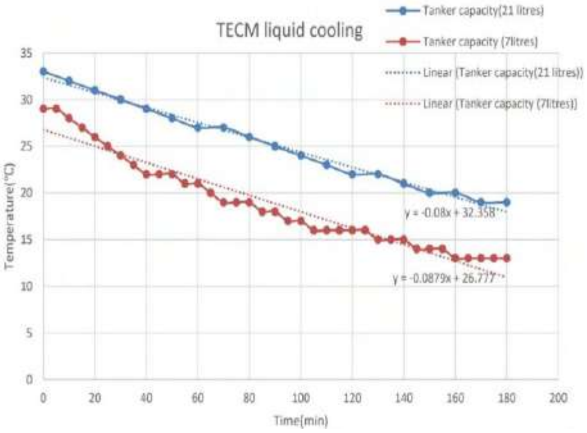

Fig. 9. Liquid cooling test results for 7 L and 21 L, repsectively.

The cooling test results from Fig. 9 indicate linearity hence the trend line was drawn. With these results, we were able to estimate after how long the system will be able to cool the liquid to the temperature of 4°C. These results shows us that the cooling unit (TECM) had insufficient cooling capacity for this tanker. The TECM that was used in this research has a cooling capacity of 113 W which is insufficient to ensure that the temperature of the liquid is cooled and maintained up to the temperature of 4°C within the period of 3 hours. The heat load for specific amounts of water were calculated and estimated in Table I. From this table, this cooling unit was to cool 7 L content to 4 °C within 3 hours. Because of the surrounding factors which dissipate heat, like the electric fuel pump, this was not realized. From Fig. 9, it is safe to conclude that two of these TECMs should be able to cool down 7 L of water from initial temperature of 38 °C to the final temperature of 4 °C within 3 hours.

B. *Test 2: Temperature control*

The objective of this test was to determine the ability of the tanker to maintain the temperature of the liquid between 3 and 5 °C. The ice cubes were filled inside the tanker so that the temperature of water can initially be below 4 °C. Ice cubes were added to the 7 L of water that was tested for cooling. The water capacity after the ice cubes were filled changed to an average water capacity of 9 L. The critical sensor, which in this case is sensor number one, initially registered a temperature of 2 °C as can be seen in Fig. 10.

The system was then off for a period of 40 minutes. The system turned on when the temperature of 4 °C was exceeded. This is indicated by the profile of current measurements plotted in Fig. 10. The temperature of water continued to rise even when the system cooling unit was activated. The temperature of 9 L of water continued to rise until it settled at 7 °C after 120 minutes. The temperature of the liquid continued to be between 6 and 7 °C for the remaining period of 1 hour. The behavior of current when this happened is shown in Fig. 10. During the time when the system was off, the temperature of liquid inside the tanker changed from 2 °C to 4 °C within the space of 40 min.

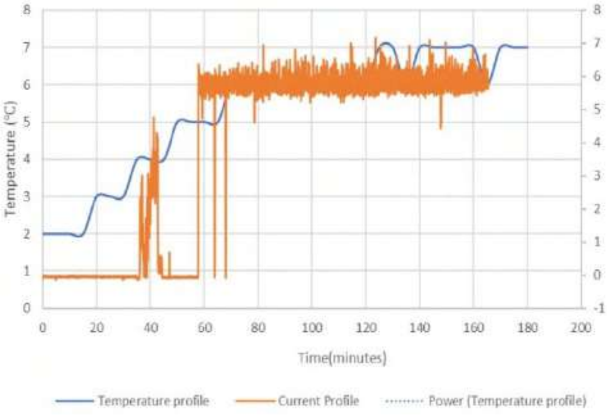

Fig. 10. Results for temperature control test.

This result proves that the tanker was not efficient enough to hold and maintain the temperature of the liquid for an extended time. This is not surprising since the tanker did not have insulation between the outside part of the tanker interacting with the environment and the inside of the tanker which interacts with the liquid. This means that insulations needs to be applied to this tanker. The tanker can store 50 L of milk, as such this required a cooling unit with minimum cooling capacity of approximately 800W according to Table I. Taking into account environmental factors, it would be safe to use a cooling unit with cooling capacity of 1200 W. Using TECM as a cooling unit, 12 will be required. For an actual tank of 8000 L, the cooling unit used shall require a cooling capacity of 192 kW. This will require 1920 TECMs.

IV. Conclusion

This research was based on designing and implementing a small scale intelligent TECM road milk tanker. The proposal was drafted and a brief background about the research was presented. The problem stated that an intelligent solar powered road milk tanker needed to be developed to lower the cost associated with cooling of the milk. Research was compiled on available solutions which can be used in order to implement the research. All the critical subsystems like liquid measuring, power monitoring and temperature control of the research were integrated and found to be working accordingly. Two types of tests were performed to determine the cooling ability of the tanker. It was found that the cooling of the tanker was not efficient as the temperature of 4 ℃ could not be reached by the minimum capacity of the tanker in a period of 3 hours. It was decided that the cooling capacity of the TECM is not sufficient to realize the objectives of cooling the liquid to temperature below 4 ℃. The temperature control of the tanker was also not efficient due to the fact that the temperature of 9 liters of water was not controlled at the required set point for the period of 1 hour. It was suggested cooling units with sufficient cooling capacity be used instead. Comment was made regarding how many of these TECMs were needed and what can be done to improve the tanker.

***Abstract*— Venous thromboembolism (VTE) is an important disease to increase the number of patients because of lacking awareness in Thailand to block the blood flow in the vein. In addition, an effective assessment model of VTE risk is the most important for medical doctors to diagnose. So, this paper represents an automatic diagnosis model by using effective machine learning to predict the important risk factors of VTE from collecting patient data of the medical ward at King Chulalongkorn Memorial Hospital. This research prepares the 83,850 raw data and investigates the missing values for transforming the data to ready import into each model and then separates the adjusted data for training and testing in the ratio of 70:30. The experimental results were compared to the effectiveness of three machine learning algorithms that consist of the decision tree, logistic regression, and neural network. From the experimental result of the decision tree, this model represents the best assessment model with an accuracy of 96.6% by adjusting the balance data with the class weight method for assisting diagnose the medical doctor.**

***Keywords*— venous thromboembolism, machine learning, automatic diagnosis**

I. Introduction

Venous thromboembolism (VTE) is an important problem to increase the number of patients because of lacking awareness in Thailand [1]. The common complication of VTE occurs during and after hospitalization for acute medical illness or surgery that 5–10% of patients die in hospital. Moreover, VTE is a long-term treatment of the post-thrombotic syndrome. So, these complications contribute to patient disease and the cost of management. VTE is the main cause of a blood clot that slowly blocks the blood flow in a vein. Deep Vein Thrombosis (DVT) occurs in a deep vein in the legs because a blood clot to the pulmonary artery can cause immediate death [2]. However, an assessment model of VTE risk only have been developed and validated in Caucasians that reports the assessment model of VTE risk for Asians by using a machine learning algorithm is lacking [3,4].

This research investigates the research of Agharezaei L. et al. [5] to propose the prediction of the risk level of pulmonary embolism in patients by using the mean of artificial neural networks. There are two types of artificial neural networks consists of Feed-Forward Back Propagation and Elman Back Propagation that were compared in this study and analysis data by using MATLAB software. The result of this study proposed the optimized artificial neural network model that represent an accuracy and risk level index of 93.23 percent. In addition, Fei Y. et al. [6,7] constructed and validated the artificial neural networks (ANN) for predicting portosplenomesenteric venous thrombosis (PSMVT) by comparing the predictive ability of ANN and logistic regression. This research represented the result of ANN that was more accurate than logistic regression in predicting the occurrence of PSMVT following acute pancreatitis. Moreover, Qatawneh et al. [8] presented a clinical decision support system that classifies the risk of venous thromboembolism using ANN. The system uses Multilayer Perceptron (MLP) feed forward neural network and uses Resilient Backpropagation algorithm (Rprop) for training. The developed system classifies the risk of VTE into five risk levels ranging from low to high. The results of the experiment show that the accuracy of the system is 81%. Furthormore, Ferroni Z.et al. [9,10] represented to use a machine learning (ML) and random optimization (OR) techniques developed for predicting the risk of venous thromboembolism to devise a web interface for VTE risk stratification in chemotherapy-treated cancer patients. This research compared the effectiveness of both techniques with the current technique which is the khorana score (KS). The result of this research shown the ML-RO to provide more performance than khorana score (KS). It is therefore suitable and useful to design a web service. In addition, Liu S. et al. [11] proposed a ML to conduct an effective assessment of peripherally inserted central venous catheter (PICC) related thrombosis. It uses five models: Seely, Seely-RF, Seely-LASSO-RF, RF and LASSO-RF to compare the model performance. The result shown machine learning model provides better performance to help prevent disease decision and effectively reduce the rate of thromboembolism in cancer patients with PICC catheters. Moreover, Nafee T. et al. [12] evaluated the performance of super model (sML) and reduced model (rML) compared by using International Medical Prevention Registry on Venous Thromboembolism (IMPROVE) score for predicting occurrence venous thromboembolism. The result shown sML method has c-statistic result highest for predicted venous thromboembolism.

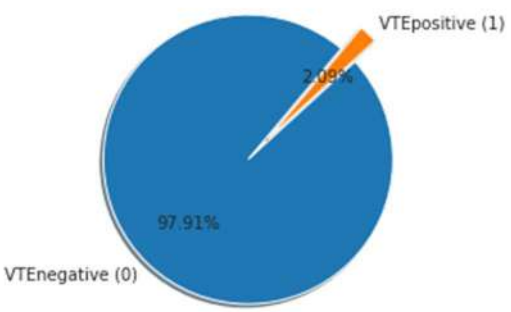

Fig. 1. The percentage of VTE positive and VTE negative was derived

Therefore, this research will find an effective machine learning to predict the risk of VTE from collecting patient data of the medical ward at King Chulalongkorn Memorial Hospital to assist the medical doctors that make more accurate diagnosis and treatment decisions. The remaining of this paper is organized as follows : Section 2 presents the methodology followed to design the prediction model of machine learning. Section 4 presents the experimental result. Finally, Section 5 provides the conclusion.

II. METHODOLOGY

From the data of King Chulalongkorn Memorial Hospital, this research was used for comparing the performance of each algorithm as following in these steps. First, this research imported raw data by using the Python program and then using the Exploratory Data Analysis (EDA) for analyzing the relationship between the variables or risk factors for thromboembolism. Second, this research prepared the raw data and investigated the missing values for transforming the data to ready import into the model for further analysis. Third, this research separated the adjusted data for training and testing in the ratio of 70:30. Finally, this research created a predicting model based on machine learning by using 3 techniques including Decision tree, Logistic regression and Neural network technique for comparing and finding the best performance of prediction model.

A. Gathering Data

This research is based on the information that was collected by the doctors who researched to determine risk factor for VTE. The data were collected from patients who were admitted to internal medicine wards of Chulalongkorn hospital in 2009 and approved by the Ethical committee of the faculty of medicine, Chulalongkorn University. The data consisted of a total 1290 rows that were the number of patient's survey and 65 columns that were the risk factors of VTE. Analyze the correlation of data all risk factors for venous thromboembolism as shown in Fig.2 and Fig.3. This figure represented the relationship of each risk factor for venous thromboembolism that was related each columns variable has very little correlation with the class label because all the data collected are discrete variables.

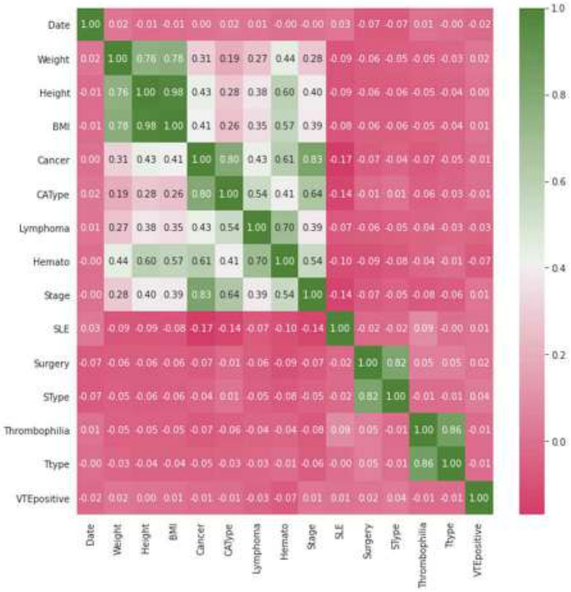

Fig. 2. The relationship between each risk factor for venous thromboembolism

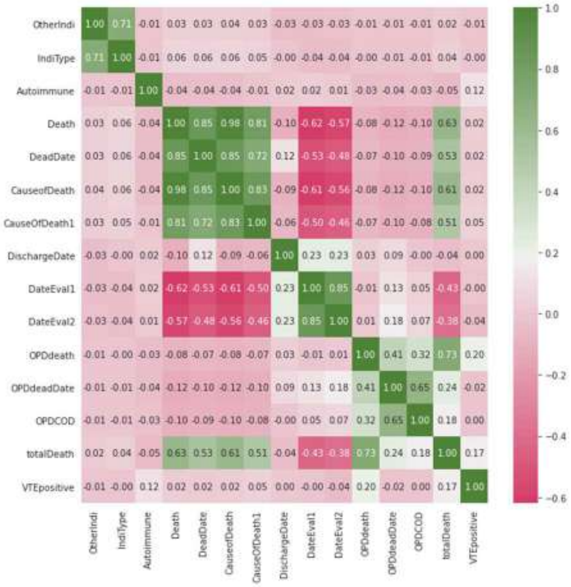

Fig .3. The relationship between each risk factor for venous thromboembolism

B. Filtering Data

This research filtered the gathering data by using a professional suggestion and a filtering algorithm, as following:

1) Filtering by a computer principle algorithm: This research filtered the data to be analyzed for risk factors for VTE as shown in Fig. 1. This figure represented the patients having venous thromboembolism (VTE positive) 2.09% and patients without venous thromboembolism (VTE negative) 97.91%. Then, we had classified it as a class label with the following: 0 is a patient without venous thromboembolism (VTE negative) and 1 is a patient with venous thromboembolism (VTE positive).

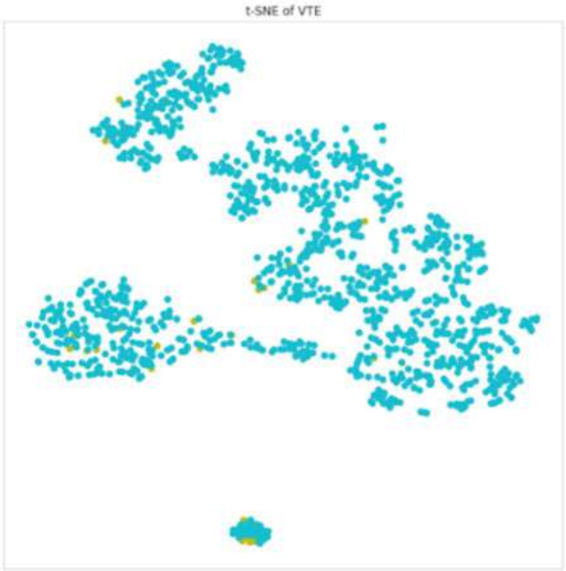

Fig. 4. The relationship between patients with venous thromboembolism and all risk factors.

Then we looked at the relationship between patients with venous thromboembolism and all risk factors represented by t-distributed Stochastic Neighbor Embedding : t-SNE method shown in Fig.4.

C. Preparing Data

1) Missing Values: The data had many missing values for considering to delete some of the columns that were not affected or analysis and manage the remaining missing values with fill missing values principle using "fill with zero" method.

2) Transform data: As a result of the exploration data, there some columns were an object type to be analyzed data must be change to numbers. Therefore the data type was transformed data with a label encoder method

3) Split data: This research splited the data for training and testing with a ratio 70:30.

4) Balance data: From the Fig. 1, it represented an imbalance data problem was more in patients VTE negative than VTE positive. It would be sensitive to a majority class data because bias on the data that would not be able to detect data in a minority class. Therefore, we managed an imbalance data problem with 5 methods include Oversampling, Undersampling, Synthetic Minority Oversampling TEchnique : SMOTE, Class weight and Ensemble sampling.

D. Model Building

This paper is proposed an automatic diagnosis model for risk of symptomatic VTE by analyzing the important risk factors of VTE data 1290 rows and 65 columns. From review the related works, we selected the 3 effective models and tunning parameters of each model to evaluate and compare the performance of the best model as follows:

1) Decision Tree model : Decision tree model would to try to divide the data into classes as clearly. Modeling principle was to choose the variables can separate the answer classes.

2) Logistic Regression model : Logistic Regression model was an extended version of linear regression used to solve binary classification problems for predicted 2 classes such as 0 with 1. The sigmoid function used to normalize the value between 0 to 1. The result from the sigmoid function was the probability that classes can be divided.

3) Neural Network model : The Neural Network model simulated the function of the human brain which consists of consists of input layer, hidden layer and output layer. neurons. In a neural network, it was divided into 3 layers

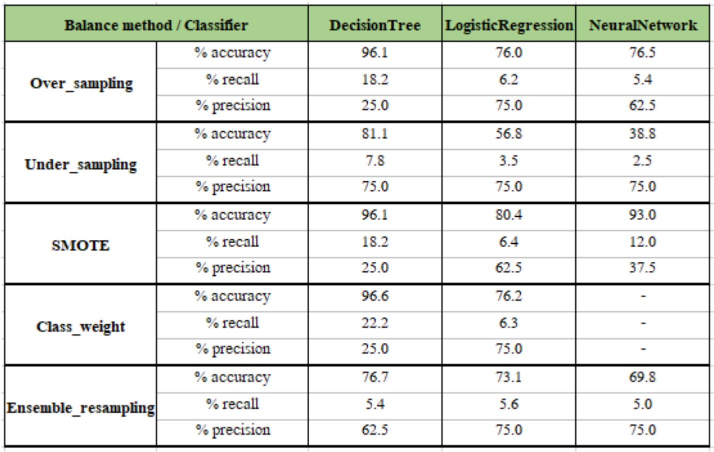
E. Evaluate Model

Each model evaluation had the different targets. This research based on classification to use a confusion matrix table for the evaluation model which was a table used to evaluate prediction results compared to the actual. The indicated accuracy was the recall and precision of models by representing to graph by using the receiver operating characteristic curve (ROC) and area under the curve (AUC).

III. EXPERIMENT RESULTS

This section presented the experimental results of each automatic diagnosis model for risk of symptomatic venous thromboembolism. After preprocessing, we divided the VTE data with ratio training data per testing data 70:30. After that, we balanced the VTE data with 5 methods include Oversampling, Undersampling, Synthetic Minority Oversampling TEchnique : SMOTE, Class weight and Ensemble sampling. Finally, we apply to create the model results as presented in Table I.

TABLE I. THE EXPERIMENTAL RESULTS OF EACH MODEL



Balance method / Classifier		DecisionTree	LogisticRegression	NeuralNetwork
Over_sampling	% accuracy	96.1	76.0	76.5
	% recall	18.2	6.2	5.4
	% precision	25.0	75.0	62.5
Under_sampling	% accuracy	81.1	56.8	38.8
	% recall	7.8	3.5	2.5
	% precision	75.0	75.0	75.0
SMOTE	% accuracy	96.1	80.4	93.0
	% recall	18.2	6.4	12.0
	% precision	25.0	62.5	37.5
Class_weight	% accuracy	96.6	76.2	-
	% recall	22.2	6.3	-
	% precision	25.0	75.0	-
Ensemble_resampling	% accuracy	76.7	73.1	69.8
	% recall	5.4	5.6	5.0
	% precision	62.5	75.0	75.0

IV. Conclusion

In this paper, we proposed to select an effective of the automatic diagnosis model for risk of symptomatic venous thromboembolism based on machine learning. This model will assist to diagnosis of professionals and medical doctor for treating patients more easily. The proposed system compared the 3 effective techniques of machine learning for evaluating multifactorial venous thromboembolism. Developing the system passed through several steps starting from collecting, preparing and stratifying the data set and choosing the most accurate system model. Decision tree model represented the best performance model with an accuracy of 96.6 percentage by adjusting the balance data with the class weight method.

Acknowledgements

We would like to thank King Chulalongkorn Memorial Hospital for providing effective data and good diagnostic information in this research. In addition, our research was funded by the master of science in data science from the department of computer science and the Graduate School of at Srinakharinwirot University of Thailand to provide the scholarship for publishing this article.

***Abstract*—The purpose of this paper is to provide descriptions of E-Commerce case situations and draw insightful conclusions from them. The document will be in a format with Ten E-Commerce Rules that are numbered here from 1 - 10 within the cases they represent. They can be applied in retrospect for discussion and in the future of new E-Commerce opportunities to help identify risk and give insight into ways to avoid it. This is a subset of available cases that will be released in a larger more detailed document for use in an academic environment for teaching about E-Commerce. Most of the SMB companies and participants have been hidden to protect those whose revelation could prove harmful.**

Keywords—E-Commerce; Risk; Shopping Cart; Payment Processing; Web Sites.

I. Introduction

My internet experience since 1998 includes a long list of E-Commerce opportunities and situations where my services were employed to make SMB on-line shopping work. In some cases, it was merely to see if it could work. From those experiences comes a list of Ten E-Commerce Rules that are time tested and true from the real-world case summaries included here. Admittedly, they are based on the internet prior to Web 2.0 but the resulting Rules are still applicable even today.

II. CASES

1. A commercial cleaning products company that was selling 55-gallon drums and 22 and 32 oz bottles of cleaning products using ShopSite [2] shopping cart installed and subsequent conversion to OpenCart [3].

In early 2003 my four-year customer, a local wholesale distributor of his and I had a meeting to discuss installing a shopping cart on their website. As the meeting began, it was clear that the distributor had an idea to sell 55-gallon drums of cleaning solutions in an online shopping cart. “Those large drums won’t fit in a shopping cart” I said, indicating that the idea was not practical at the time. Most shopping carts then were B2C with B2B only just beginning and not likely to penetrate institutional cleaning purchase agents anytime soon. The distributor insisted, however, and the owner acquiesced yet cleverly agreed to a one-year test. So, I built the shopping cart with descriptions of twenty products with product “image not available” superimposed over images of 55- gallon drums.

Image #1 – 55-Gallon Drum [1]

After one year, only one 55-gallon drum was sold. As agreed, I was called in to discuss taking the shopping cart down. Before leaving, I suggested that since the cart was operational, and the product descriptions were already there, all I had to do was add images of their 22 oz and 32 oz containers with current pricing and he could sell them in the shopping cart. The owner agreed to a new test for that concept with me managing the cart and sending the orders to his facility for processing.

Ironically, the shopping cart soon took off and within approximately 90 days, the owner asked me to build him another shopping cart with the disclaimer that it was being offered for customers that had no retail location within their local area.

~E-Commerce rule #1. Try anything with a time sensitive test. Be willing to change course as needed and if it takes off, take immediate action.

2. An independent drop ship distributor selling cleaning products in 22 and 32 oz bottles to consumers using ShopSite shopping cart.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Below is an image reflecting the sales from the shopping cart I continued after such a robust beginning. Of course, with the revenue I received from product sales commissions, it was agreed that I would complete the web site maintenance for them at no additional charge.

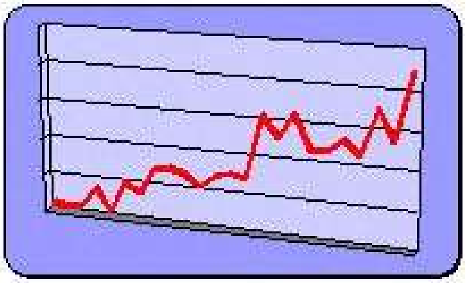

Image #2 - 3-2009 (3 years of growth) [1]

That arrangement seemed to work fine until the government dictated that the Material Safety Data Sheet (MSDS) was to be changed to Safety Data Sheet (SDS). All links between the Technical Data Sheet (TDS) for the product were linked to the product number followed by …msds. Consequently, all the MSDS file names and TDS links had to be manually changed to …sds on two websites for over 20 products to meet the compliance deadline.

Fortunately, this presented us with a good time to update the SDS's as pdf's that I could put 'inline' in the pages. Then we no longer needed to update those SDS pages in HTML detail.

~E-Commerce rule #2. When the government makes a compliance decree, waste no time in responding no matter how cumbersome it appears to be. Try to use the opportunity to your advantage to accomplish something on the 'nice to do' list simultaneously.

Finally, as their investment in IT grew, they eventually ported their website over to different servers. With that migration came the shopping cart as well. But, their financial officer wanted a less expensive alternative to the monthly charge for ShopSite. That is how both carts had been installed initially.

Because of my experience of migrating another customer from MivaMerchant [4] for the same reason, I quickly converted them to OpenCart [3], which was a proven and reliable object-oriented public domain shopping cart still in operation today. My ShopSite [2] version continued until it was mutually ended in 2019, almost 15 years after initially started as a test to see if it could work. It most certainly did!

~E-Commerce Rule #3 – There is a time for everything and if the situation dictates a change, cut your losses, make the change, and move on.

3. A spa company selling chemicals, filters and accessories on-line using MivaMerchant [4], OS Commerce [5] and OpenCart [3] shopping cart software products at different times.

I met the female half of the husband-and-wife team when she opened a new location next to one of my customers that I used to visit often. We became fast friends and when her website developer left for Texas, she turned to me to provide the local support she was looking to have.

~E-Commerce Rule #4 – Keep your technical support nearby. Even with today's collaboration, it is best they be near you.

One challenge was to learn the functions of MivaMerchant, their shopping cart product. Of course, my first objective was to get a handle on their website, but it was not long before I tackled MivaMerchant as well. They became conscious of the fees for that service and rather than suggest moving to the more familiar ShopSite with fees of its own, I looked at the Object-Oriented offerings my hosting company made available at no additional charge.

We looked at a couple of them such as OS Commerce [5], OpenCart [3] and ZenCart [6] to name a few. We landed on OS Commerce as it offered a sort/list capability that was of interest to the owner.

After a minor technical glitch with OS Commerce, we switched to OpenCart and OpenCart continued to run just fine.

Image #3 – Original Flash Template 2010 [7]

4. BBD – One of the previous customer's friends was interested in also selling Hot Tub Accessories online via a shopping cart. After completing modification of a suitable template, I built the cart and loaded up the products. But it never seemed to get off the ground. To stop the bleeding, we pulled the plug not long after it had begun.

Image #4 Online Accessory Template [8]

~E-Commerce Rule #5 – Having a retail establishment in a large market to fuel online sales of additives, supplies and accessories does not necessarily translate well to a fully online entity somewhere else without that connection.

Unfortunately, it was not allowed to be viewed as a test, and with an expectation of success, it was sad to end. If we had applied E-Commerce Rule #1 it would have worked better for all involved.

5. A wedding location listed online images for both on and off-site wedding and event planning services.

One of my earlier customers was an event facility. They performed event and wedding planning and on-site wedding ceremonies including dinners and receptions. They did very well and as I offered directory listing for customers, I even featured them on my wedding directory pages with the wedding picture of one of their staff members,

Image #5 Wedding Directory [9]

as well as an image from one of their wedding receptions.

On his site we had created images from letters of reference and added those to his site. (E-Commerce Rule #10). Also, we designed an on-line form that had drop down lists for party size and estimated budget amount in ranges.

Eventually, the owner wanted to attract some of the customers they were not able to reach because of their location. He decided to update his site with images of his site location and images of other sites in Greater Atlanta that he was able to use for events.

With the acquisition of another domain name, we created a mirror image web site and linked the images on the left of the home page to the new one.

Including directions for each location, the on-line form generated increased targeted results.

Image #6 Pictures of event locations [1]

We updated that on-line form with a location dropdown list and it worked just fine. Business was booming. Regrettably, the owner met a premature death from an accident in the Pacific Ocean not long after that.

~E-Commerce Rule #6 – Do not be limited by what your situation dictates. Expand by offering what is available per diem and limit acquisition expenses.

6. A delicatessen specializing in sandwich rolls uploaded their menu planning to sell the idea of creating a franchise.

My regional prospecting one day brought me to a very good delicatessen for lunch. I asked for the owner and upon meeting her we began to talk about a website for the restaurant and how it might be designed.

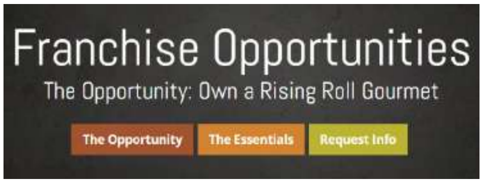
It seemed she had almost been waiting for me as when she began to describe how she wanted her menu displayed she knew exactly what she wanted. She also knew exactly how she wanted it to look. I had done a few menus in the past and it appeared that this would be a similar experience. That is, until I had given her a link to review what I had put together.

The minute detail she had me go through seemed to be beyond the usual menu display, but I figured that was her style.

Consequently, I eagerly followed her instructions. What we ended up with was quite a menu indeed. And even I was impressed with the final version.

Unfortunately, not long after we parted ways as she had sold her restaurant to a major franchising company complete with their own professional web site design staff. They were in position to take over the site and handle the marketing package for any additional franchisees.

It turns out, she was using the design of her menu to attract suitors to establish the franchise tag all along. And although I did not get paid any more than I did for the other menus in the past, somehow there was a sense of pride that my design work had done the trick for her. She was always a most gracious customer and although tedious, my visits with her were always a pleasure. Not to mention the occasional exceptional free lunch.



Franchise Opportunities

The Opportunity: Own a Rising Roll Gourmet

Image #7 The 'Franchise Opportunity' (Rising Roll Gourmet Café' web site) [10]

I must admit, after going to their new website to research this paper, it appears that the menus have lost something in the translation.

~E-Commerce Rule #7 – Always put your best foot forward online when looking to market your company. Suitors usually do not take a second look.

7. A vacation property manager that was renting from an inventory of over 40 properties got a Flash web site, property rotating image galleries, and videos.

At a local business networking event, I met the owner of a company that was renting property to vacationers in condos at the beach in Florida. We negotiated for a web site and I produced an exciting Flash site (2010) complete with music, property rotating image galleries and videos that replaced them as the videos became available.

The ordering was conducted through email and phone and things were going along fine. Then, a service combined a calendar and scheduling automated service that far outstripped my capabilities and we amicably parted ways.

Not long after that, I found out the Tenant associations in the condo buildings they rented out of changed their rules to restrict access for short term rental tenants. Their business dried up overnight.

~E-Commerce Rule #8 – The assumptions underlying your business operations can change with the wink of an eye. Stay aware about outside related influences.

8. A real estate group with three owner principals and multiple agents listed their properties online.

Through another friend I was referred to three women that had started a real estate company and had been burned by a web site developer. They were left with virtually nothing to show for a substantial investment they had made.

I went to work right away and with the help of a talented graphics artist family member of one of the three, and got the site running quickly. They had been left wounded by the previous web developer and did not have much left for my services, but my interest in quality was well respected, nonetheless.

The problem was that after they finally realized the problem they were in, got together with me and got me going, the real estate market of 2009 started to nosedive.

Image #8 Ended before it really began [11]

It was not long before the real estate group of three had disbanded with each person going their own separate way.

~E-Commerce rule # 9 – Make certain that you do not spend all your money in one place. Hold back a good percentage until you see actual working documents (with sources) that can be transferred to someone else if need be later. Remain cautious of web site prototypes.

Unfortunately, they also were victims of E-Commerce Rule #8.

9. Three different food caterers who listed their menus online with party and event platter images. 1st caterer used a block of images representing menu items.

2nd caterer web site image is below:

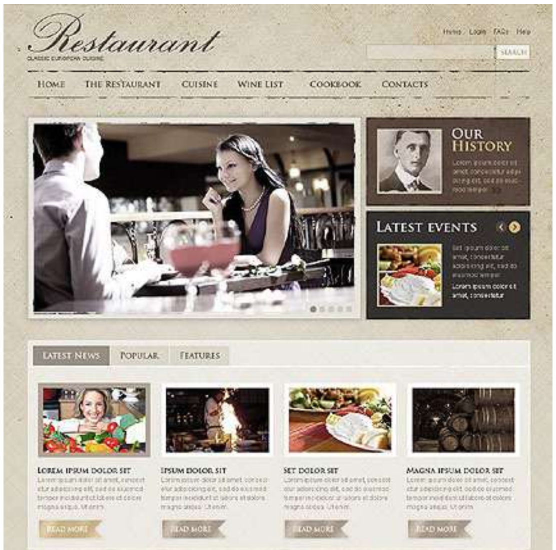

Image #9 Home Page Template [12]

All three companies were eager to display images of their most delectable offerings (1st and 3rd not shown). But what was missing was a customer reference tied to each one of those images. The first and third company had never thought to document those originally and the second one was too new in the business to have enough to be worthwhile.

In all cases, it was a challenge to convince them that images alone were not enough to attract new customers. The cost associated with setting up that capability was beyond their budget expectations.

~E-Commerce Rule #10 – Before beginning a web site, be certain to document images with customer reactions to your services. On the site, allow customers to post references with images and if possible, capture their reactions on video as part of your standard operating procedures at your events.

Today, of course, customer testimonials in the form of videos are catching on, but even in the past, the most effective images were those that were directly representing actual customer testimonials.

III. TEN E-COMMERCE RULES

#1. Try anything with a time sensitive test. Be willing to change course as needed and if it takes off, take immediate action.

#2. When the government makes a compliance decree, waste no time in responding no matter how cumbersome it appears to be. Try to use the opportunity to your advantage to accomplish something on the ‘nice to do’ list simultaneously.

#3. There is a time for everything and if the situation dictates a change, cut your losses, make the change and move on.

#4. Keep your technical support nearby. Even with today’s collaboration, it is best they be near you.

#5. Having a retail establishment in a large market to fuel online sales of additives, supplies and accessories does not necessarily translate well to a fully online entity somewhere else.

#6. Do not be limited by what your situation dictates. Expand by offering what is available per diem if possible and limit acquisition expenses.

#7. Always put your best foot forward online when looking to market your company. Suitors usually do not take a second look.

#8. The assumptions underlying your business operations can change with the wink of an eye. Stay aware about outside related influences.

# 9. Make certain that you do not spend all your money in one place. Hold back a good percentage until you see actual working documents (with sources) that can be transferred to someone else if need be later. Remain cautious of web site prototypes.

#10. Before beginning a web site, be certain to document images with customer reactions to your services. On the site, allow customers to post references with images and if possible, capture their reactions on video as part of your standard operating procedures at your events.

IV. CONCLUSION

I have close to twenty additional case studies and in the future, my plan is to expand this document to edit a small book of SMB E-Commerce web cases for use in the academic classroom environment.

***Abstract*—For decades, school attendance has an important role in determining student success and ensuring that students regularly come to classes. Traditionally, a sheet of paper and a pencil or pen is used to document school attendance at universities. In most cases, the professor would hand out a piece of paper to a student. This student would mark their presence on the paper sheet and pass it to the person sitting next to them. The piece of paper would then travel throughout the classroom until the final student received the paper. Finally, the piece of paper would be given back to the professor or the teacher's assistant, so they may take note of which student is present and which student is absent. In the age of the COVID-19 pandemic, this method of taking attendance poses a great risk to possible disease transmission. Everyone within the room would be touching the same piece of paper, and sometimes students may even share the same pen or pencil with their classmates. Everyone in the classroom, including the professor, would be at risk if one student were infected with the COVID-19 virus. This is attributed to the attendance method. This paper proposes a zero-effort, zero-interaction attendance method based on two aspects that are currently present in a typical classroom: access points and a student's Wi-Fi enabled devices (e.g., smartphones). Our research found this method to be a no-hassle attendance-taking method that pinpoints where a student is within the classroom, without the class suffering from any disruption in learning.**

***Index Terms*—access point, attendance system, RSSI, Wi-Fi, trilateration system, zero-effort, zero-interaction.**

I. Introduction

USER authentication is critical in confirming a user's identity and their presence [1]. This same idea is used in classroom attendance. Traditional methods of taking attendance can be inaccurate. Students can mark their absent classmates as present, so they do not miss out on points. Besides, if attendance is taken at the beginning of class, students could leave right after attendance is counted. Having the professor take time out of their lesson in order to search through the attendance or seating chart for each student takes away valuable lesson time from the professor and the students. The traditional pen-and-paper methods of attendance take effort and cost the professor and class time.

COVID-19 pandemic has also shown how obsolete the traditional methods of conducting attendance have become—traditional pen-and-paper methods of attendance risk the transmission of possible disease particles. The passing of paper and the possibility of sharing writing utensils make it challenging to keep others safe from the virus. As schools are preparing to conduct more in-person classes, there is a growing need for a safer and more hygienically friendly way of conducting attendance. This can be achieved utilizing technology (i.e., access points broadcast signals) already available in most modern classrooms and schools.

The proposed scheme aims to present a zero-effort and zero-interaction method of classroom attendance. The presented attendance system utilizes students' smartphones and access points located within the school. Most college students within the twenty-first-century own Wi-Fi enabled devices that connect to the outside world through the Internet. The principal benefit of broadcast signals that the Wi-Fi-enabled devices can receive and read them from different radio frequency technologies within range without being connected to the broadcaster. The broadcast signals are utilized to take a student's attendance and submit it to his/her professor with requiring zero-effort and zero-interaction to conduct attendance within the confines of a worldwide pandemic safely.

In the next section, existing research regarding attempts to modify school attendance systems is discussed technologically, followed by the proposed scheme's model and the experiments that have been conducted.

The research has been funded by:
(1) WiSys Spark Grant, Code WISYS-AAI7814, www.wisys.org/grants/spark.
(2) University of Wisconsin-Green Bay, College of Science, Engineering, and Technology.

II. Literary Review

Several methodologies and solutions have been proposed to mitigate the issue of classroom attendance and monitoring. Each methodology and solution are unique, solving the problems in their own unique way.

In 2019 Koppikar, et al., showcase their solution in their work titled, ”IoT Based Smart Attendance Monitoring System using RFID” [2]. The authors propose an RFID-based attendance monitoring system using student or employee-based identification cards. Students and faculty would need to register themselves into the RFID attendance monitoring program before attending their class. Registration would occur through a graphical user interface. On the day of class, the user would need to place their RFID tag near the RFID reader. The information is then sent to an Arduino module to process the information.

In 2020 Liu, et al., proposed using R-FCN technology and video surveillance to monitor student attendance in their work titled, ”Intelligent Counting System for Classroom Numbers Based on Video Surveillance” [3]. R-FCN is used in this scenario to detect targets within a given space. The work also features different formulas for calculating the position of a student. The layered feature maps ensure targets will not be lost within the system. This solution needs stable classroom lighting in order to remain effective.

Bai, et al., proposed in 2020 a facial recognition solution in their work titled ”Design of Attendance System Based on Face Recognition and Android Platform” [4]. This system requires the use of the Adaboost algorithm and includes the calculation of errors within the dataset. The system needs to detect a face, run it through the algorithms, and then use facial recognition algorithms to determine if the system detected the correct person. This would require users to have pictures taken of themselves while showing different facial expressions, and if the user wears glasses, they will need to have pictures taken with or without glasses.

In 2019 Zhi-heng and Yong-Zhen proposed using facial recognition technology with a camera placed within the classroom to monitor attendance, in their work ”Design and Implementation of Classroom Attendance System Based on Video Face Recognition” [5]. The video feed from the classroom camera is separated into still frames and relies on pictures with stable lighting and clear facial features in order to accurately verify the students. Like the previous work, this work also uses the Adaboost cascade classifier to detect the faces quickly. This proposal also discusses the advantages of using machine learning to train the software. However, as mentioned, this proposal relies heavily on clear lighting and positioning of the camera.

Chennattu, et al., in 2019, proposed a fingerprint identification system to monitor classroom attendance in their work titled, ”Portable Biometric Attendance” [6]. On the user's end, the system would use an LCD and button interface. The teacher and the students would need to scan their fingerprints, where the teacher would be required to authenticate first before the students. The teacher would terminate the attendance cycle by scanning their fingerprint again. The data is then sent to an AWS database. After the data is assorted into the correct tables, it is then shown to all students.

As of today, there are a numerous number of attendances extracting techniques. In 2019 a paper was published that was based on a frequency distribution algorithm with passive RFID tags to take attendance [7]. In 2020, another paper utilized beacon frames to prove the location of users [8]. In addition, a proposed system was published in 2020 that uses a single image to tack attendance [9].

In this section, numerous attendance extracting techniques have been discussed. The following section presents the proposed scheme from different aspects.

III. System Model

The proposed scheme aims to utilize the access points broadcast signals to pinpoint students' location by applying the trilateriation approach. If the smartphone is found to be within a certain distance and within the classroom confines, the student is confirmed to be attending the class. However, if the student's cellular device is not found or is not determined to be within the classroom's confines, the student is found not to be in attendance of the class. In the proposed scheme, students' devices measure the Received Signal Strength Indicator (RSSI) reading utilizing the broadcast signals, then transmit them to a centralized application. The centralized application then utilizes the collocated RSSI reading to determine a student's attendance status. A completed list of attendees vs. non-attendees will then be sent to the professor, requiring zero-interaction and zero-effort from neither students nor the professor.

There are benefits to this method compared to other proposed school attendance methods. Wi-Fi-enabled devices do not necessarily need to be connected to the school's access points in order to receive the broadcast signals. Also, the transmitted signals are limited to a physical area that limits students from spoofing their locations or impersonating other students, which means the student needs to be physically within the classroom to be counted as present.

A. Architecture

The proposed scheme architecture consists of:

1) Participating devices: Wi-Fi-enabled devices, such as a smartphone installed on it a relevant application.
2) Wireless access points are located within the school: Access points utilize to determine a student's position within the room by automatically scanning the student's environment and sending the measured RSSI readings off to the remote server.
3) A remote server collocates the RSSI reading received from a student's Wi-Fi-enabled device and determines which students are present and which students are absent.

4) An application located on the server which totals the calculations and sends the attendance list to the instructor.

The Proposed school attendance system is zero-effort and zero-interaction as the data collection and verification occurs without the users' involvement, whether the user is the professor conducting attendance or the student who is present in class.

B. Operation

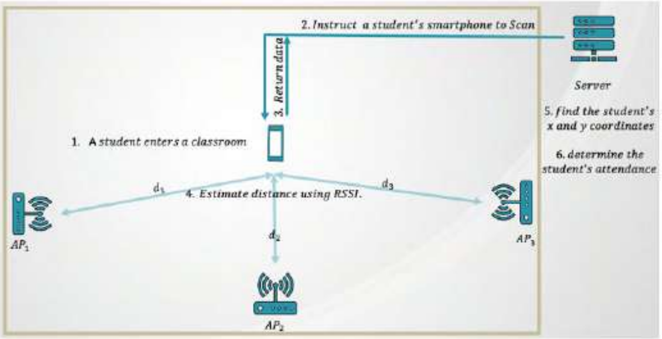
- Client-side interaction:
  The student will need to register their device prior to the beginning of the first day of class or the first day of implementation. Then, the student enters the classroom and finds a seat within the room. While this is occurring, the professor enters the classroom and begins to prepare for the lesson. As students begin to enter the classroom, their wireless devices are started to receive the broadcast signals that transmitted by schools' routers. As the class continues, the messages continue, sending the results back to the server. When a class is over, the attendance list is sent to the professor, that shows which students were present in comparison to the students who were absent.
- Server-side interaction:
  This section shows the authentication procedure between the student devices, the access points, and the server. The steps and an overview can be found in Figure 1
  1) A student enters a classroom.
  2) The server instructs the student's device to scan.
  3) The student's device sends the needed information (i.e., RSSI values) back to the server.
  4) The RSSI values will be used with equation (1) to calculate the distance from the student's device to the access points.

$$PL_{log} = PL_0 + 10\gamma \; log_{10} \frac{d}{d_0} \tag{1}$$

  where PL_{log} is the transmitted power minus the power which is received. PL_0 is the path loss in dB, γ is the path loss exponent, and d_0 is the reference distance (1m).
  5) The results from step 4 will be plugged in equation (2) to determine the student's position (i.e., the student's x and y coordinates).

$$\begin{aligned} (x - x_1)^2 + (y - y_1)^2 &= d_1^2 \\ (x - x_2)^2 + (y - y_2)^2 &= d_2^2 \\ (x - x_3)^2 + (y - y_3)^2 &= d_3^2 \end{aligned} \tag{2}$$

  6) The system uses the student's position to determine whether the student is present or absent. These results get sent to the instructor at the end of the lesson.



2. Instruct a student's smartphone to Scan
3. Return data
Server
5. find the student's x and y coordinates
6. determine the student's attendance
1. A student enters a classroom

IV. Experiment

This section describes the setup for our experiment and the multiple experiments which were conducted. A smart device was placed throughout the 18ft by 9ft room. The access points were placed in a triangular position within the room. The positions of the access points were measured for our experiment. The smart device was also located in specified, physically mapped locations, so we may scan the access points along with the corresponding RSSI values. Our data was then collected from the physically mapped access points and calculated for authenticity.

A. Location Accuracy

Three experiments were conducted to test the location accuracy of the devices using RSSI values. In each experiment, the access points scanned for the devices 30 times from 7 different points. These values were then calculated, giving us the first values, the maximum values, and the average values. Results are shown in Tables I, II, and III below.

TABLE I
Experiment One (First)

Actual points	*Calculated points*	*Difference*
(2 , 17)	(4.2 , 14.3)	1.1 m
(3 , 2)	(1.3 , 7.7)	1.8 m
(4.5 , 9)	(4.3 , 9.3)	0.1 m
(5 , 14)	(4.1 , 12.3)	0.6 m
(6 , 2)	(10.7 , -1)	1.7 m
(7 , 2)	(-0.1 , 7.4)	2.7 m
(8 , 17)	(6.4 , 9)	2.2 m

TABLE II
Experiment Two (Mix)

Actual points	*Calculated points*	*Difference*
(2 , 17)	(4.2 , 14.3)	1.1 m
(3 , 2)	(1.5 , 7.3)	1.7 m
(4.5 , 9)	(3.3 , 10)	0.5 m
(5 , 14)	(3.8 , 12.5)	0.6 m
(6 , 2)	(5.3 , 4)	0.6 m
(7 , 2)	(1.3 , 6.6)	2.3 m
(8 , 17)	(4.6 , 9.9)	2.1 m

TABLE III
EXPERIMENT THREE (AVERAGE)

Actual points	***Calculated points***	***Difference***
(2 , 17)	(5.2 , 15.4)	1.1 m
(3 , 2)	(1.4 , 7.5)	1.7 m
(4.5 , 9)	(3.9 , 9.9)	0.3 m
(5 , 14)	(4 , 12.6)	0.5 m
(6 , 2)	(7 , 2.4)	0.3 m
(7 , 2)	(3.2 , 4.5)	1.4 m
(8 , 17)	(10.5 , 15)	0.8m

B. Success Rate

In this experiment, the proposed scheme's success rate was assessed by applying every RSSI value to calculate the location of the device using equation (1) and equation (2). The results are showing in Table IV. The proposed attendance system provided a 95.24% success rate that was calculated using equation (3).

TABLE IV
SUCCESS RATE

	Actual	
N=210	***Positive***	***Negative***
True	TP = 108	FP = 4
False	FN = 6	TN = 92

$$\frac{True\ Positive + True\ Negative}{N, Total\ number\ of\ a\ dataset} \times 100 \tag{3}$$

V. CONCLUSION

As shown from the experiments, the proposed attendance system is an effective, zero-effort and zero-interaction method for conducting attendance in a post-pandemic society. From the results of our experiment, we believe our proposed attendance system is a sound method due to its success rate of 95.24%. The experiments were performed during different times of the day, and we believe this system will encourage instructors to take attendance in a safe and fool-proof way. In the age of the pandemic, implementing an effective and socially distant attendance method is integral for schools across the world.

***Abstract*— The purpose of this study is to identify how different government measures impacted the level of Covid-19 influence on countries of similar nature. Demographic, economic, health, and weather conditions were considered to identify countries that are inherently similar in nature. This grouping along with Covid-19 epidemiology data was used to cluster countries over a period of time after Covid-19 struck. We identified those countries which changed clusters over a time period and were influenced differently by the impact of Covid-19. We then looked at the government measures through the stringency index of containment measures and observed a relation in how different stringency measures impacted the countries differently even though they belonged to the same original group. We also observed that countries that eased restrictions quickly after containment measures had to go back to the earlier stringent measures. Gradual ease of containment measure was more efficient in tackling Covid-19. The inherent grouping of countries done in our study can be used in the future as well to deploy similar measures when faced with Covid-19 like pandemic situation. The strategies adopted on average by countries within each inherent cluster can become the base for handling Covid-19 or any such pandemic in the future. The significance of the work resides in the fact that the strategies would not be aligned to economic conditions of a nation (developed versus developing) or a single factor like healthcare facilities but based on a varied list of inherent factors using machine learning methods.**

Keywords — Covid-19, k-means, clustering, unsupervised learning, machine learning

I. Introduction

After Covid-19 struck the world in early December 2019 and until the World Health Organization (WHO) declared the novel coronavirus outbreak as a public health emergency of global concern on 30th January 2020 [1], none of the countries were prepared on how to deal with such an emergency. There were varying degrees of strategies and responses adopted by different countries with varying degrees of effectiveness [2], [3], [4]. Some countries went as far as complete lockdown [5], [14] and other countries went for herd immunity (Sweden [16], [17]). Some countries tried for herd immunity, but due to increased infection rates and the associated burden on the health infrastructure of the nations they had to change the strategy to lock down and restrictions (United Kingdom [5]). There is no clear solution that people know might work for any particular country at any stage of the pandemic impact.

The purpose of this study is to help the countries identify what strategies they can adopt at what stage of a pandemic and what might work best for that country based on their socio-economic and other relevant parameters. The premise is that what might work best for one country may not be ideal for other countries at any given stage of the pandemic. Covid-19 was one such pandemic which had a global impact where the majority of the countries were unprepared to handle such a crisis. This research using Machine Learning techniques on historical data of Covid-19 is an attempt to get meaningful suggestions for policy makers and governments to be better prepared for any such future risks based on the countries classification type at that point in time.

There are already some studies done using machine learning techniques to predict the Covid-19 cases and its impact. One such study tried to identify the covariates that are important to predict the total confirmed cases and whether there are clusters of countries possibly associated with these covariates [6]. Data considered for this study was the global Covid-19 data for 133 countries from the worldometer website [18]. Their study indicated 4 major clusters of countries that contributed towards the global number of confirmed cases. This study only considered the Covid-19 related data for the clustering purpose and doesn't consider what type of country it was before the pandemic struck. There is an opportunity here to analyze why two countries which might be similar by demographic, economic, health and weather parameters before the pandemic could end up in

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

different clusters when affected by the pandemic. The difference could be because of the response action of the government agencies, which is what we aim to analyse as part of this study.

Another study applied supervised machine learning (ML) approaches to identify the key factors affecting COVID-19 infected and death counts from a list of features including GDP, gender, ethnicity, health care, homeless, lockdown type, population density, airport activity, and age groups [5]. They concluded that population density, testing numbers and airport traffic emerge as the most discriminatory factors, followed by higher age groups (above 40 and specifically 60+). We wish to consider these factors as part of our analysis for clustering purposes.

Other studies on impact of weather [14], age [12], comorbidities [11], [12], vaccinations [13], economic and social factors [5] on the Covid-19 cases have also been carried out. The aim of those studies was to see to what extent each of the individual attributes are correlated to the Covid-19 cases. But to the best of our knowledge there is a lack of study that looks at demographic, economic, health and weather parameters holistically together with the infection rate to identify clusters of countries.

In this paper we tried unsupervised machine learning techniques like k-means clustering and agglomerative clustering to cluster a set of 142 countries. We took a 2-stage process where we first tried to identify which countries are similar in nature (fall into the same group) based on demographic, economic, health and weather conditions. This would give us an indication of the countries that are similarly placed with respect to the potential influence of pandemic on them. We then considered this information as a feature along with the global covid-19 data to see how the clustering of the countries within each original group changes over a period of time. This is a unique approach taken by the authors as the inherent nature of a country is considered as one of parameters in clustering along with Covid-19 data. Further based on the strategies adopted by different countries within the clusters we will aim to identify what strategy or combination of state policies might work best for the cluster to deal with Covid-19 impact. Our hypothesis is that most of the variation within the same inherent group could be explained by a difference in the government response and mitigation strategies adopted by various countries. This analysis can give rich insights on what response strategy is best for which inherent country group at any particular stage during the fight against pandemic like Covid-19.

II. Dataset and Methods

A. *Dataset used for the Analysis*

We wanted to process several open-access datasets to collect parameters like the weather of the nation, general health index of people, medical facilities, economic conditions, poverty levels, population density, demographic details etc. to create an integrated dataset of overall factors that might impact COVID cases in the countries. One of the repositories that compiles this information is [19] and available here: *https://github.com/GoogleCloudPlatform/covid-19-open-data*.

We have used the GoogleCloudPlatfrom Covid-19 open data from 1st January 2020 till 11th of December 2020 for the purpose of this study. The main data set is this repository is daily level time series data that comprises demographic, economic, epidemiology, geography, health, hospitalizations, government response and weather data. We considered the data at country level and identified data attributes under 3 categories:

1. Demographic, economic, health and weather data (pre-Covid data)
2. Covid-19 epidemiology data
3. Data related to government measures and responses

We have identified 142 countries for our analysis from the main data set. These countries have data captured for all the important attributes which are required for analysis.

B. *Methodology*

The data from the first category mentioned in the above section was used for clustering exercise to identify the inherent clusters that each of the 142 countries falls into. Since the data points considered in the first category don’t change by time series on a daily or monthly level, we have considered the data points for a date before the impact of pandemic. We selected a data view on the 15th of March 2020 for the filtered 142 countries to carry out the clustering exercise. The mentioned data set has so many dimensions and few are similar to each other. In order to improve efficiency in forming clusters, PCA is performed. principal components are extracted with a goal of at least 90% explained variance. K-means clustering (Fig. 1) and agglomerative clustering (Fig. 2) was done on the data set and we found 4 prominent clusters emerging out of the analysis.

We used the k-means clustering method with 4 clusters to identify the inherent groups of the 142 countries. Table 1 captures the grouping of the countries from this clustering exercise.

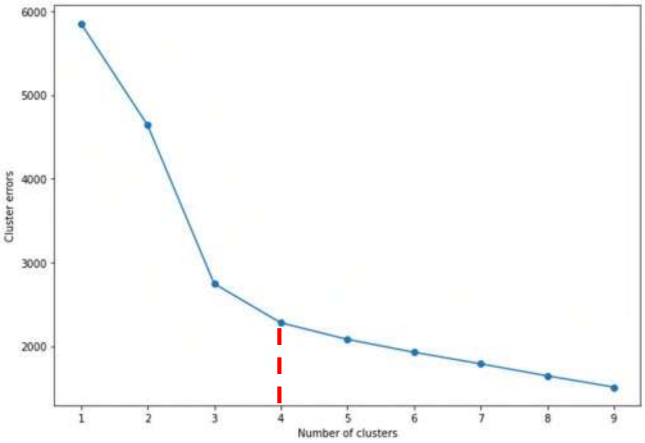

Fig. 1. Elbow plot of k-means clustering to identify inherent country clusters. There are 4 major clusters observed from the plot.

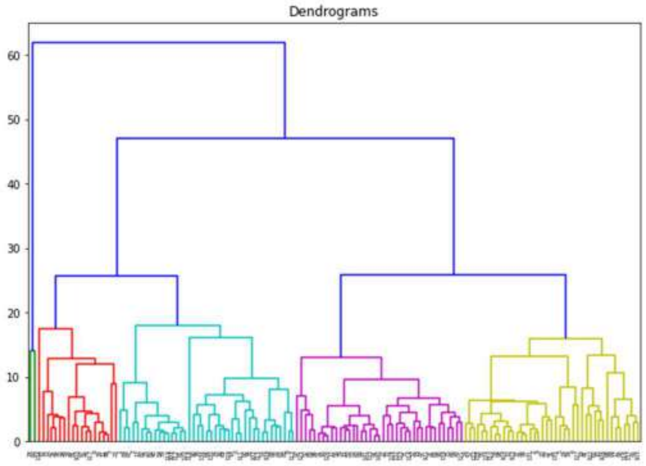

Fig. 2. Four major inherent country clusters observed from Dendrogram distances from agglomerative clustering exercise.

We then used the epidemiology data of Covid-19 to generate a Covid-19 indexed monthly time series data. The day when each of the country reaches 10 Covid-19 cases is indexed as the start of the 0th time period. We considered a moving time period of 30 days to get to the monthly indexed time series data. The epidemiology data was normalized by per million population or as a percentage of Covid-19 cases to get all countries' data to a comparable scale.

TABLE I. INHERENT CLUSTERS WITHOUT COVID-19 DATA

Group 0	Afghanistan, Angola, Bangladesh, Burkina Faso, Burundi, Benin, Bhutan, Botswana, Ethiopia, Fiji, Gabon, Ghana, Gambia, Guinea, Equatorial Guinea, Guinea-Bissau, Guyana, Haiti, Indonesia, Kenya, Comoros, Laos, Liberia, Mali, Myanmar, Malawi, Mozambique, Namibia, Niger, Nigeria, Nepal, Papua New Guinea, Philippines, Pakistan, Rwanda, Senegal, São Tomé and Príncipe, Chad, Togo, East Timor, Tanzania, Uganda, Vanuatu, South Africa, Zambia, Zimbabwe
Group 1	Armenia, Austria, Australia, Bosnia and Herzegovina, Belgium, Bulgaria, Belarus, Canada, Switzerland, Cyprus, Czech Republic, Germany, Denmark, Estonia, Spain, Finland, France, United Kingdom, Greece, Croatia, Hungary, Israel, Iceland, Japan, South Korea, Lithuania, Luxembourg, Latvia, Moldova, Mongolia, Malta, Netherlands, Norway, Poland, Portugal, Romania, Serbia, Sweden, Slovenia, Slovakia, United States of America
Group 2	China, India
Group 3	United Arab Emirates, Antigua and Barbuda, Argentina, Barbados, Bahrain, Brunei, Bolivia, Brazil, Bahamas, Belize, Chile, Colombia, Costa Rica, Cuba, Cape Verde, Dominican Republic, Algeria, Ecuador, Egypt, Grenada, Guatemala, Honduras, Iraq, Iran, Jamaica, Jordan, Kuwait, Lebanon, Saint Lucia, Sri Lanka, Morocco, Mauritius, Maldives, Mexico, Malaysia, Nicaragua, Oman, Panama, Peru, Paraguay, Qatar, Saudi Arabia, Solomon Islands, Singapore, Suriname, El Salvador, Thailand, Tunisia, Turkey, Trinidad and Tobago, Uruguay, Vietnam, Samoa

The inherent group number from the earlier mentioned clustering exercise is also considered as one of the attributes for identifying the cluster of the countries post Covid-19 impact. We then performed the k-means clustering to identify 7 clusters (Fig. 3) into which the countries can fall into as the impact of Covid-19 progressed over the indexed time period.

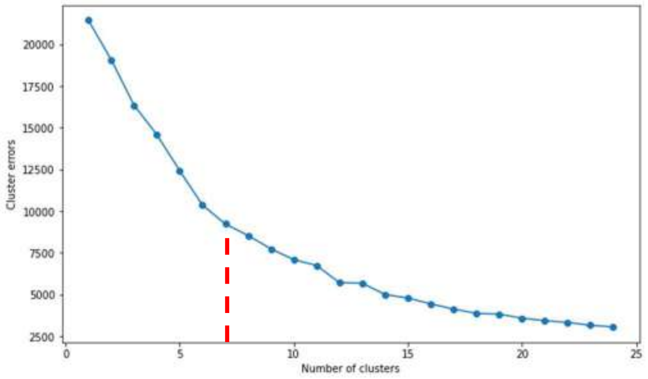

Fig. 3. Elbow plot of k-means clustering of post Covid-19 impact on countries shows 7 major clusters.

We then looked at each of the inherent groups individually to see how the countries which stacked up together in the same cluster pre-Covid moved into different clusters based on the extent of Covid-19 impact. The difference and movement of different countries into different clusters from the same inherent clusters can be attributable to the responses and measures taken by the local governments which we evaluated through the stringency index parameter provided by Oxford Covid-19 government response tracker [20]. The stringency index captures all the containment and closure policy indications along with the public information campaign indicator.

III. RESULTS AND OBSERVATIONS

A. *Results from Group Level Clusters*

When we observed the countries from Group 0 from Table 1, for the differences in impact of Covid-19 we didn't notice much difference. All those countries continued to fall in the same cluster post Covid-19 impact which also didn't change over a period of time. Same goes for the Group 2.

There were some differences noticed between a few countries from Group 1 as depicted in Fig. 4. The differences were pronounced after time period 6 and later. Till period 6 mostly all countries continued to fall under the same cluster barring a couple of exceptions. For the purpose of further analysis in this paper we are considering the time period 6 as a representative view of the differences between the countries. This also provides a good time period for evaluating the different measures adopted by various countries as the governments would have got enough time of 6 months to act upon the pandemic threat.

From Fig. 4 we could notice that while most countries had similar impact there were a few countries which ended up being different. Belgium, Denmark, France, Iceland, Israel, Malta and the United States are countries which fell into different clusters compared to the rest of the nations. Among them Belgium and France seem to have experienced unique scenarios because of Covid-19.

Similarly, for Group 3 there were a few countries which had different impact than the rest of the countries in the same group. Argentina and Brazil had similar experiences while Bahrain, Jordan, Kuwait, Maldives, Panama, Qatar and Trinidad and Tobago had different experiences in dealing with Covid-19 as shown in Fig. 5.

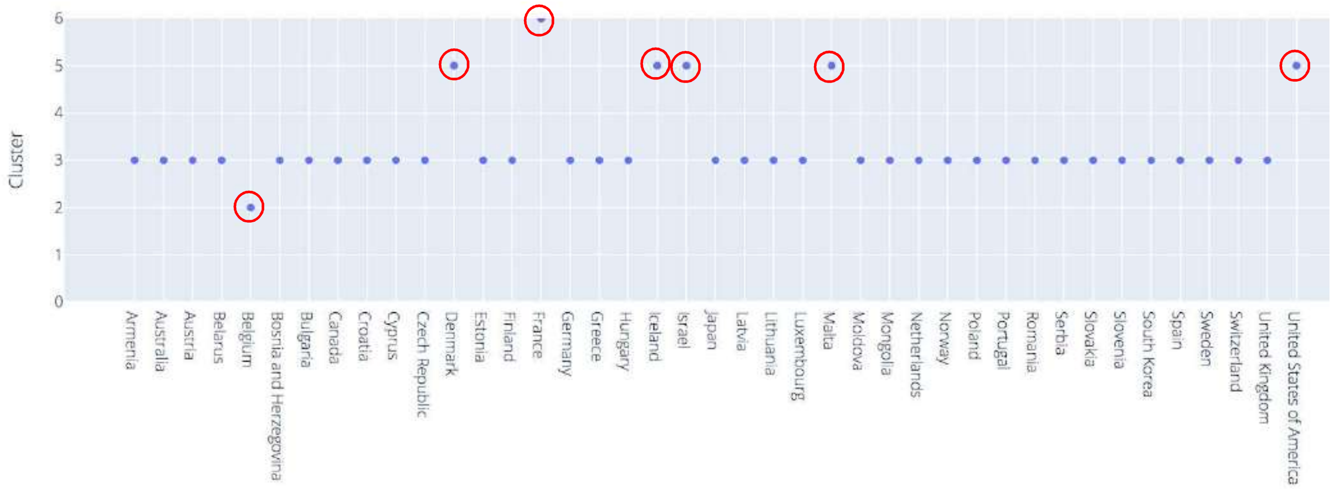

Fig. 4. Clustered view of countries in Group 1 at time period 6 (roughly 6 months) after the start of Covid-19 shows countries that show different behavior compared to others (Belgium, Denmark, France, Iceland, Israel, Malta and the USA).

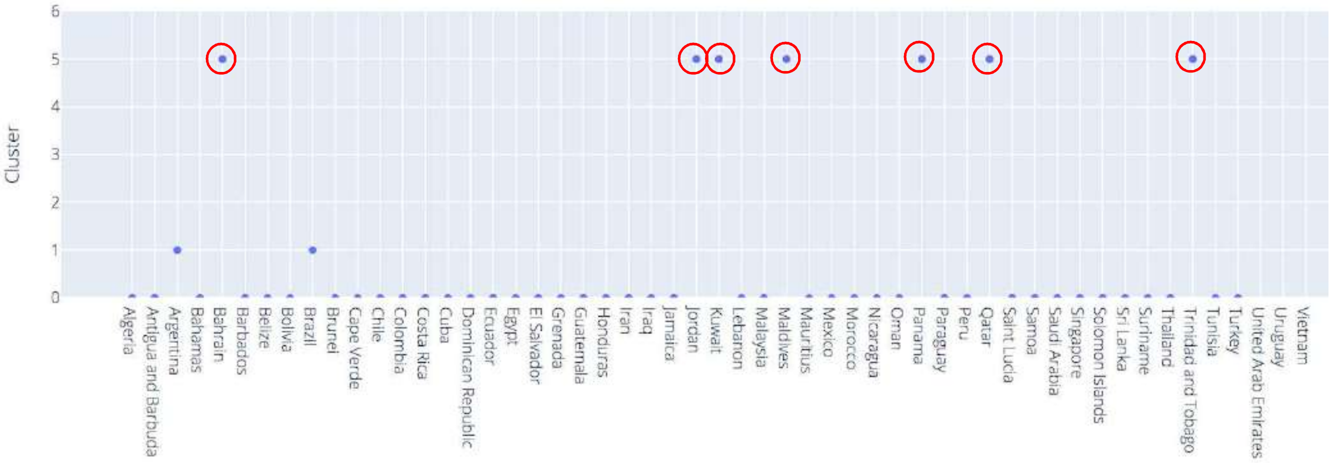

Fig. 5. Clustered view of countries in Group 3 at time period 7 (roughly 7 months) after the start of Covid-19 shows countries that exhibit different behavior than the others in the group (Bahrain, Jordan, Kuwait, Maldives, Panama, Qatar, Trinidad and Tobago)

B. Analysis of Government Measures

To analyze the government measures we looked at the stringency index of countries within each inherent group and the observations for Group 1 are captured in Fig. 6, Fig. 7 and Fig. 8. Note that as a representative of Group 1 we considered Germany as reference which happens to fall in the same cluster as the rest of the typical countries in Group 1.

Measures taken by the government generally played an important role to curb Covid. As mentioned earlier, countries from the group 1 like Belgium, Denmark, Malta, Israel, Iceland and France not only had a difference in Covid spread but also in the measures taken by the government in comparison to other countries. Countries like Denmark and Iceland Israel did not have a complete lockdown in the month of march to June unlike other countries which can clearly be observed in Fig. 7. Iceland never had a complete lockdown through 2020. Though these countries had restrictions in a limited scale, the lockdown and strict curfew were imposed widely later in Q3 2020.

Belgium had early government measures related to containment compared to other countries as observed from Fig. 6. This resulted in fewer cases in Belgium and because the government continued with the containment measures, it stayed comparatively different from the rest of the countries in the group.

On the other hand France imposed a lockdown in march and relaxed the lockdown at the end of April. Similarly Israel had varying government measures related to containment and lockdown. As France and Israel had a rise in cases, the countries went into lockdown again and had curfew during later parts of 2020.

It can be observed from Fig. 9 that both Argentina and Brazil had stricter government measures as compared to the average of the countries in the inherent Group 3. While no specific pattern could be observed for the other countries (Bahrain, Jordan, Kuwait, Maldives, Panama, Qatar and Trinidad and Tobago) that differed from average of Group 3, it can be observed from Fig. 10 that these countries tried to alter the containment policies a bit too quickly resulting in going back to the earlier stricter measures.

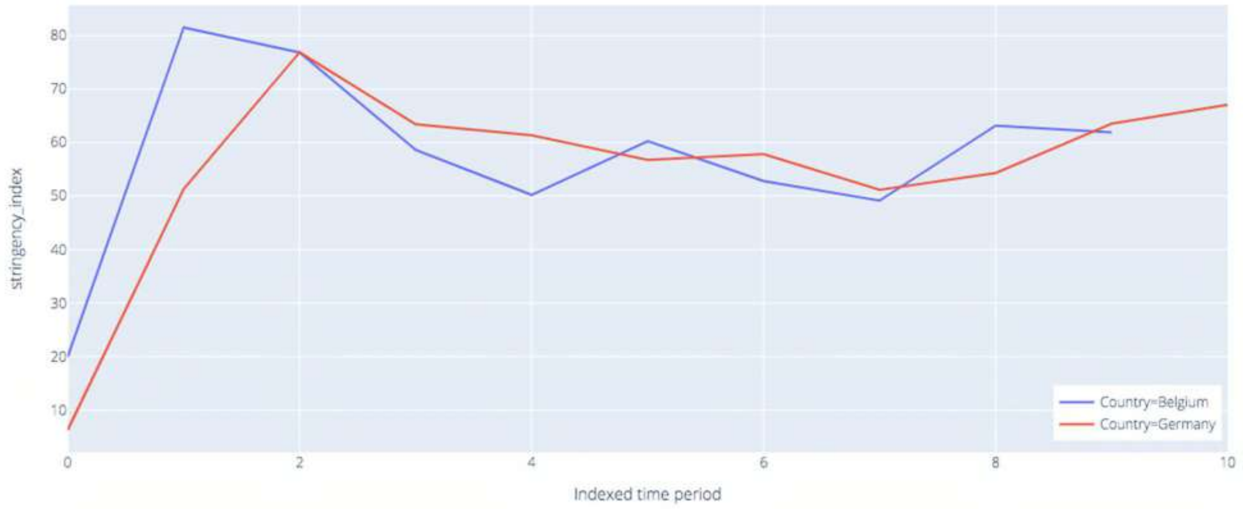

Fig. 6. Stringency index comparison between Germany & Belgium over a time period of 10 months from start of Covid-19. Notice the early government measures adopted by Belgium.

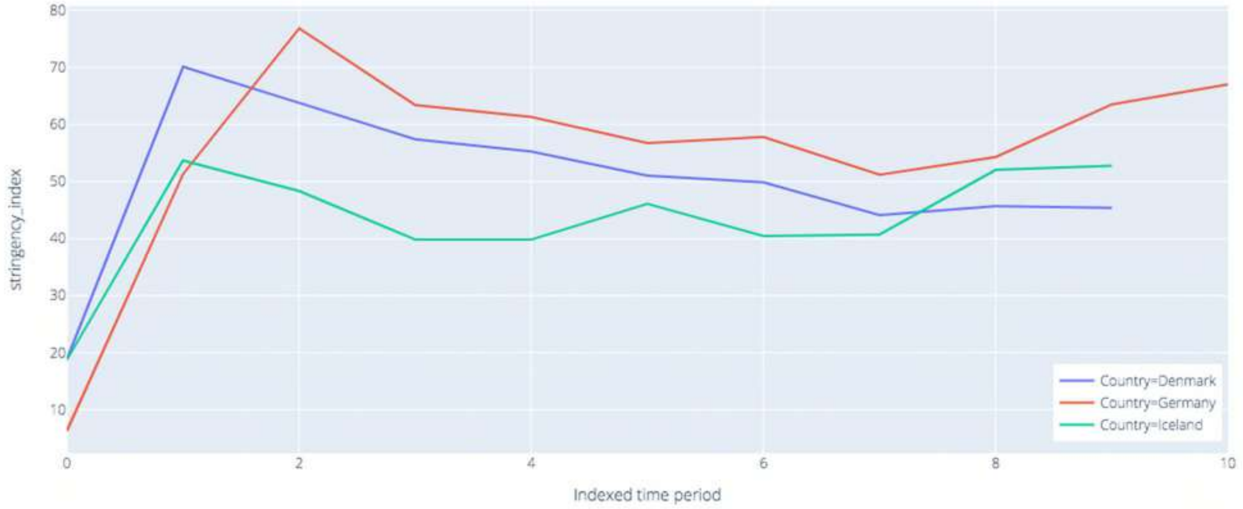

Fig. 7. Stringency index comparison between Germany, Denmark and Iceland. Notice Iceland had little government restrictions while Germany was more proactive to take appropriate containtment measures.

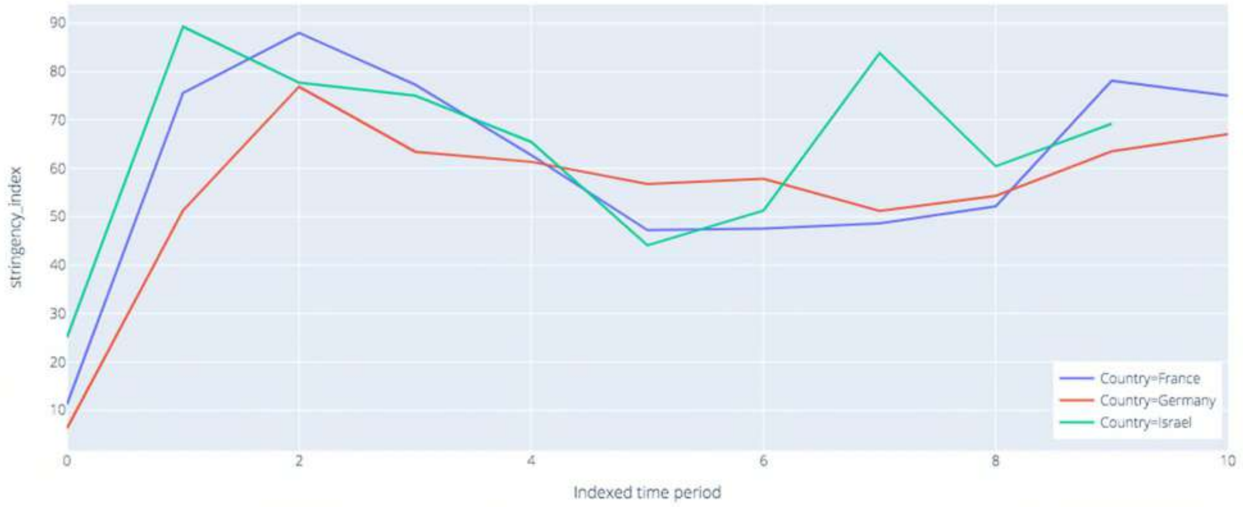

Fig. 8. Stringency index comparison between Germany, France and Israel. Notice how France and Israel had to go back to stricter restrictions because of faster easing of government measures.

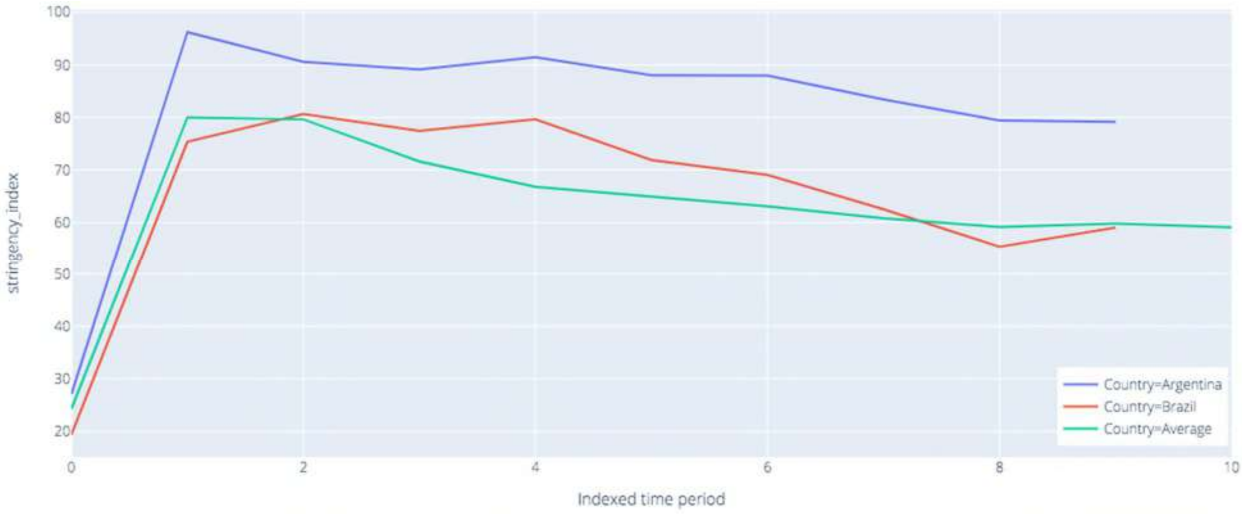

Fig. 9. Stringency index comparison between Average of Group 3 countries, Argentina and Brazil. Argentina had more stricter measures which were eased out in a very gradual manner which seemed to help fight Covid-19 effectively.

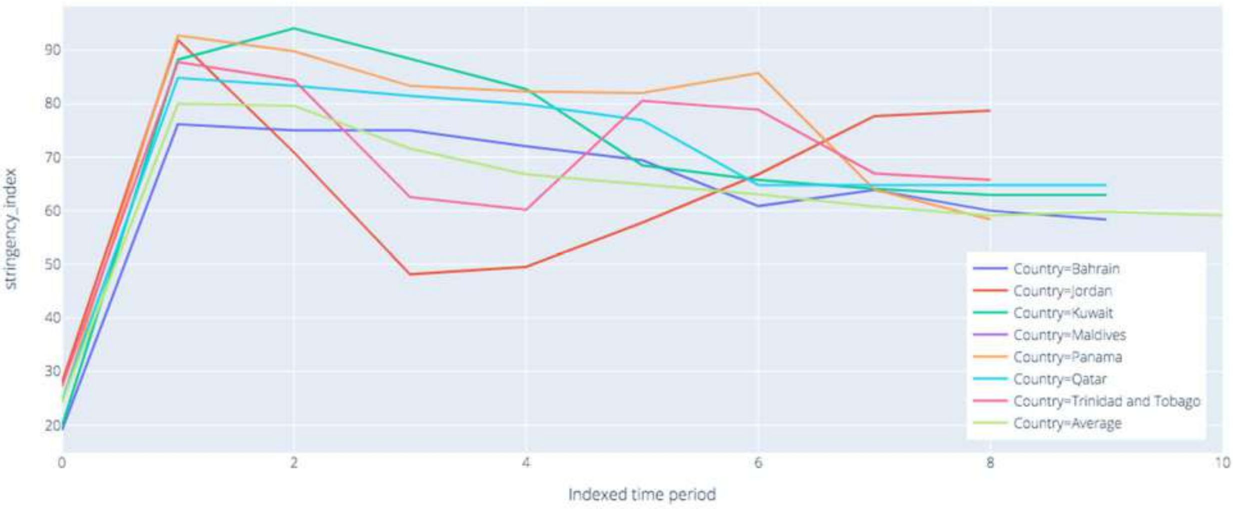

Fig. 10. Stringency index comparison between average of Group 3 countries and other deviating countries. Gradual easing of restrictions seem to be ideal.

IV. Discussions and conclusions

This study looked at identifying inherent groups of countries from a perspective of potential impact to pandemic like Covid-19. These countries within each group can continue to be looked at as a cluster for policy decisions making in future and potential impact from Covid-19 like scenario in future. The impact of Covid-19 on some of the countries within each inherent group was different most possibly due to the government containment measures and policies adopted locally. While it is obvious that countries which took a stringent containment policy stood out from the rest and also the other way around as well, one observation that came out from our study is that countries which eased out the restrictions within a month or two had to suffer adverse consequences and had to go back to the earlier restrictions. Examples being France, Israel (Fig. 8), Jordan and Trinidad and Tobago (Fig. 10). The observation infers the countries to start with stricter containment measures quickly and ease out restrictions slowly and gradually rather than sudden eases. Argentina (Fig. 9) is a good example of how the restrictions could be eased out in a controlled way, so the countries won't have to go back to stricter measures to avoid a spike in cases.

Oxford Covid-19 government response tracker [20] captures various containment, health system, economic policies taken by 180 countries. A combination of various parameters are used to calculate four major indices - overall government response index, containment and health index, stringency index and economic support index. This study only evaluated the effect of the stringency index (which majorly captures the containment and closure policies) on the differences of Covid-19 impact on similarly grouped countries. We didn't look at the combination of all the indices or permutations and combinations of the indices on what impact it would have on the way countries were impacted by Covid-19. That could be a good next step to this exercise to understand which indices could have a major impact on countries falling into different clusters and which indices might have a high correlation with the Covid-19 cases.

Further analysis could also be conducted at the individual indicators which contributed significantly towards the stringency index like closing public transport, restrictions on public gathering etc. This will help to understand what measures works better for a specific cluster.

***Abstract* -- With the increasing number of health issues reported due to obesity and overeating, people have become cautious about their diet intake to prevent themselves from the diseases such as hypertension, diabetes, and other heart related problem which are caused due to obesity. As per the data shared by WHO, at least 2.8 million people are dying each year because of being overweight or obese. The important part of any healthy diet plan is its calories intake. Hence, we propose a deep learning-based technique to calculate the calories of the food items present in the image captured by the user. We used a layer-based approach to predict calorie in the food item which include Image Acquisition, Food item classification, Surface area detection and calorie prediction.**

Keywords – Mask R-CNN, ROI (Region of Interest), IOU (Intersection Over Union), Resnet 50

I. INTRODUCTION

It is very important in today's time that people should be aware of what they are consuming and what will be its impact on the body. So, a system that can help individuals to maintain their calories intake is very important. Most of the world's population live in countries where overweight and obesity kills more people than any other health disease. The problem here is not about having enough food, it is about the people not knowing what is in their diet. If people could estimate their calorie intake during a day, they can easily decide on the number of calories they want to consume. However, managing calorie intake is a very cumbersome task which involves the people to manually keep a track of food item they have consumed throughout the day and they must determine the calories they have consumed. This process is not only manual but also inaccurate as the calorie estimation not only depends on what you are eating but also depends on how much are having.

With the advancement in the field of image processing techniques, the image recognition models are in demand. Researchers are aggressively deploying image recognition model for various uses such as self-driving cars, cancer detection, video frame analysis etc. Researchers have also shown keen interest in predicting the calories present in the food item with the help of the image. Researchers have used various machine learning and deep learning techniques to perform the task of calories estimation with the help of supplied images.

Manal Chokr and Shady Elbassuoni (2017) [8] proposed a solution in which they used the supervised learning technique to perform the single food classification and its calorie prediction. They used the model which takes an image of the food item as input and provides the calorie as output. They developed a Mathwork Image Process tool which was used to extract features from the image. Extracted features were then compressed and fed to a classifier and regressor to identify the food type and determine the size of the food item respectively. Finally, the output of both classifier and regressor is fed to another regressor which provides the calories as the output.

Parisa Pouladzadeh1, Abdulsalam Yassine1, Shervin Shirmohammadi (2015) [9] developed a deep learning-based model which takes a food image clicked from the mobile camera which is capable of estimating calorie for the mixed portion of the food item as well. The dataset used contained 3000 images clicked under different condition with different camera model and then the clicked image is given as input. They used color segmentation, k-mean clustering, and texture segmentation tools. They employed Cloud SVM and deep neural network to increase the performance of the image identification model. For calorie prediction they used the reference object approach wherein they mandated the presence of the thumb in the image so that their model can use the thumb present in the mage as reference for the size estimation of food item present in the image which helped in calorie estimation.

In earlier researches, the researchers have collected 101 different food images [10] such as Chicken Wings, Tacos,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

Bread pudding etc. The dataset has 101 food categories with 101000 images where most of the images contains mixed food items. They used 750 images for model training purpose and 250 images for testing purpose. They used model based on Random Forests to mine discriminative visual components and efficient classification of the images. However, they used the model for the image classification only

Nowadays, there are many android and web-applications available which allows users to track the food intake to help them manage their calorie. However, these applications rely on the users to manually select the food items they had and the size and dimension of the food items they ate to track record of the diet and to further estimated the calorie consumption. This process is not accurate as it is almost impossible for the user to input the accurate food size they ate.

Hence, we propose a solution to this problem. The proposed model can predict the calories user consumed with the help of the image of the food portion user had. The model basically makes use of layered approach wherein each layer performs different tasks. The first layer takes the image as the input from the user and prepares it to be fed to the second layer. The second layer employs the deep learning method known as Mask R-CNN which performs the food identification task along with the bounding box and mask generation. The third layer calculated the surface area covered by the food items which in turn is fed to the last layer. The fourth layer predicts the calories consumed by the user based on the surface area covered by the food item present in the supplied image.

The model provides satisfactory results in estimating the calories intake by the user with the help of image. This model uses the dataset which contains 638 images of food item which belongs to 6 different categories (Apple, Oranges, Omelet, Pizza toast, Banana and Idli). These images are collected from internet, hand-picked from the available dataset such as Food 101[4], UNIMIB2016[5] and UEC FOOD-100[6]. The images are preprocessed as per the model requirement and used to train our model.

In this paper, the model employs Mask R-CNN deep learning technique for the mask and bounding box determination for the image containing different food items which helps the model to identify the food item, estimate the surface area occupied by the food item and to determine the calorie associated with it with the help of defined mathematical formula. The model provides the satisfactory results in determining the calorie in the food portion present in the image.

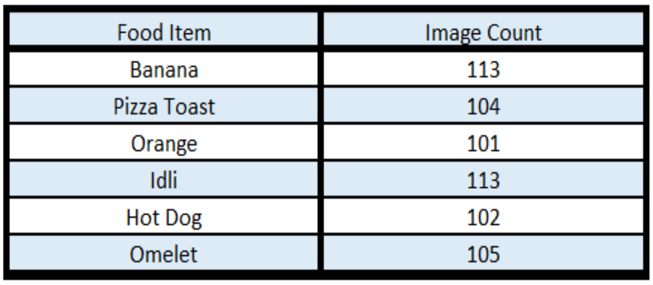
II. MATERIALS AND METHOS

A. Overview

Our model takes Image of the food items as input and give calories of the food item as output. In this there are number of middle process which are done to achieved to this. Firstly, food item whose calorie need to be predicted is identified in the captured image. After the food item identification its size and volume are determined and at last food calorie is estimated to 128*128 pixels before they are used in the model. Mask R-CNN Algorithm is used for image recognition and calorie prediction is done using approximate proportion approach format.

B. Dataset

Our dataset has six different food items. Dataset is custom generated by selecting food item image from internet and by selecting images from the existing dataset such as Food 101. Food Item are Banana, Pizza Toast, Orange, Idle, Hot Dog, Omelet.



Food Item	Image Count
Banana	113
Pizza Toast	104
Orange	101
Idli	113
Hot Dog	102
Omelet	105

Fig.1.: Dataset details

As images are gathered from different sources it is important to scale them, so they are scaled to 128*128 pixels before they are used in model Also images are manually annotated using Pixel Annotation tool and masks are created for model training purpose.

C. Food-Item Identification

We use instance segmentation to create a pixel wise mask of object in the image. This technique gives us more granular understanding of the food data in the image. Here we use Mask R-CNN for image segmentation which used ROI and IOU to generate bounding boxes, provide labels and mask.

As in figure 2. Bounding box is created across the identified food item and label omelet is assigned to the food item.

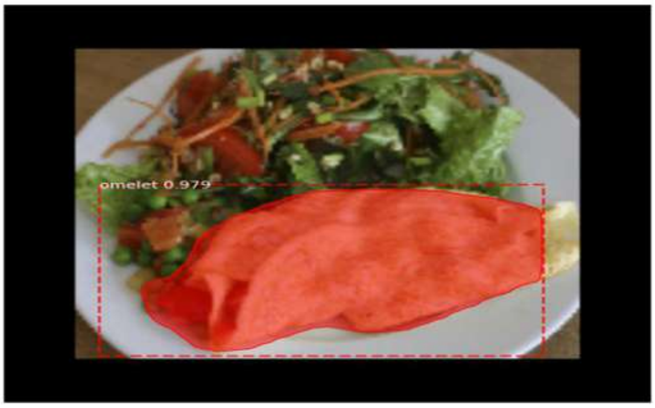


Fig.2: Mask output of omelet

Mask R-CNN is a deep neural network aimed to solve instance segmentation in machine learning. It separates different objects in an image or a video and gives out the objects bounding boxes, classes and masks. There are two stages in mask R-CNN first is to generate a proposal about the reason where there might be an object based on the input image second is to predict the class of the object, refines the boundary boxes and generate mask in pixel level. Both stages are connected to the backbone structure which helps in feature extraction. Here we are using Resnet 101 as backbone. Mask R-CNN Model is initialized with preloaded weights.

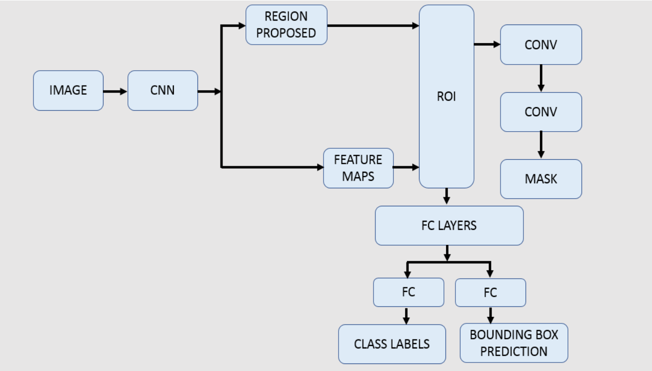

Fig.3: Mask R-CNN Model

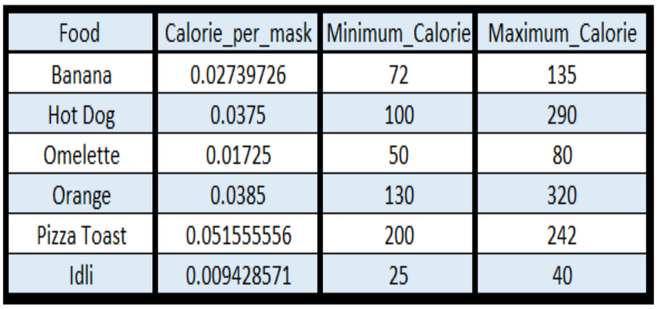
To train a Mask R-CNN based image recognition model, we need many images to train deep learning models. Since the dataset we collected is not large enough to train the model, we used transfer learning approach from matterport repository [7].

With the help of **transfer learning**, instead of training a model from scratch, we started with a weights file that is been trained on the COCO dataset. COCO dataset contains lot of images (~120K), so the trained model weights have already learned a lot of the features common in natural images, which really helps.

D. Food Calorie Prediction

As the same food can be taken at different depths to generate different picture sizes, we need a method to calculate calorie or estimate the size of the food in a real-world scenario. After we get the desired food items detected along with their masks, we need the real object sizes, which is not possible through a pin-hole camera image alone. So, we take a referencing approach that references the food-objects to the size of the pre-known object to extract the actual size of the food contained in that specific image.

For food calorie prediction, method used is approximation of proportions. In this approach calorie per mask of the food class is taken as reference for predicting calorie of the input image. A spread sheet has been prepared containing "Class", "Calorie Per Mask", "Minimum Calories", "Maximum calorie".



Food	Calorie_per_mask	Minimum_Calorie	Maximum_Calorie
Banana	0.02739726	72	135
Hot Dog	0.0375	100	290
Omelette	0.01725	50	80
Orange	0.0385	130	320
Pizza Toast	0.051555556	200	242
Idli	0.009428571	25	40

Fig.4: Calorie details used in predicting food calorie

In Proportion Approximation Approach each image has been scaled to the size of (128*128) and segmented area of the food class is calculated and further multiplied with "Calorie per Mask ".

III. EXPERIMENTAL RESULTS

In this section we present the experimental result of all the sections like Food identification which generate bounding boxes, provide labels and mask. Dataset is divided in train and test (Validate) set in the ration of 80:20.

A. Dataset Inspection

Our dataset has six food items named banana, Pizza Toast, omelet, orange and idle.

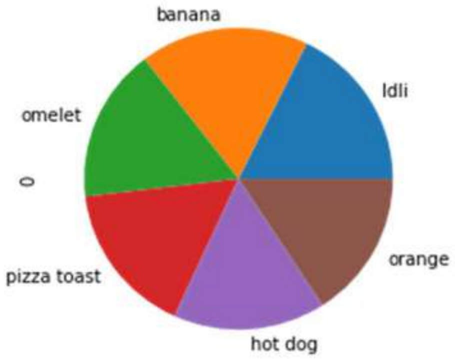


Fig.5: Food classes in dataset

Images are of different lengths, so we converted them to 128 * 128 and loaded them. Similarly, mask images had also converted them to 128 * 128. Initial dataset was class imbalanced, so we added more images and did data augmentation.

During Visual dataset inspection it was observed classes were initially imbalanced, which were balanced by adding new images. Also, Image size is changed to 128*128. Minimum class image is 101 and maximum class image is 113.

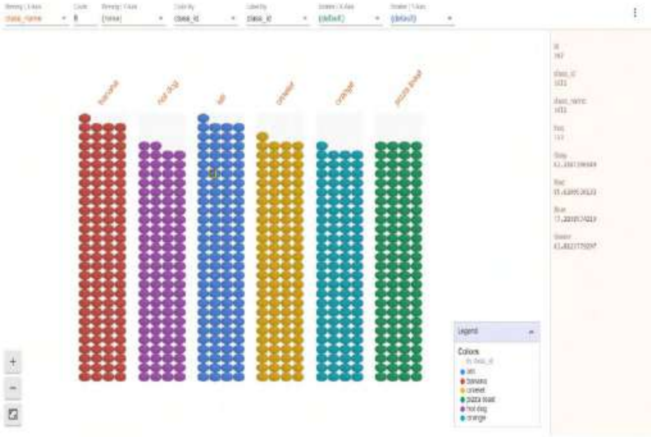

Fig.6: Initial Visual representation of dataset

B. Food Item Identification

Our goal is to identify the type of food item after extracting the features from the image. Here Mask R-CNN is used to generate bounding box, assign labels and mask to the image.

Analyzing images and mask after preprocessing, converting to 128 * 128 dimensions.

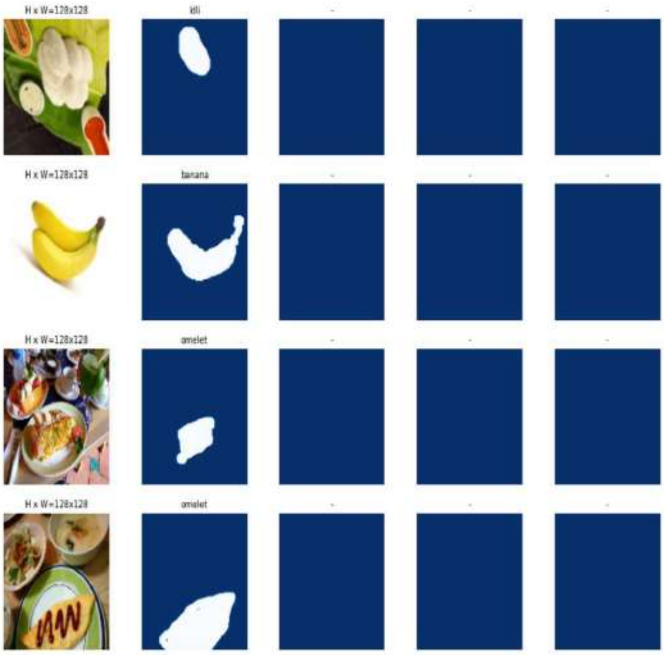

Fig.7: Analyzing images and mask after preprocessing

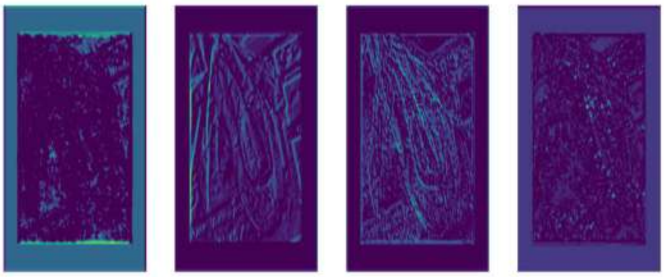

Fig.8: Analyzing activation of hidden layers

C. *Calorie Prediction*

A referencing approach that references the food-objects to the size of the pre-known object to extract the actual size of the food contained in that specific image. Refer figure 4

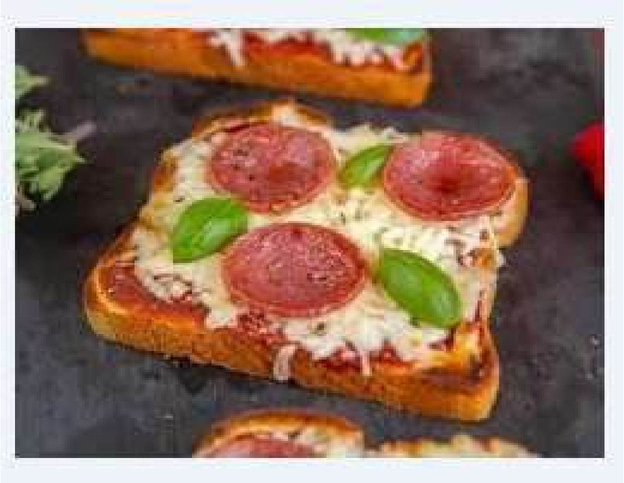

Fig.9: Actual Image- Image before Mask R-CNN and calorie prediction

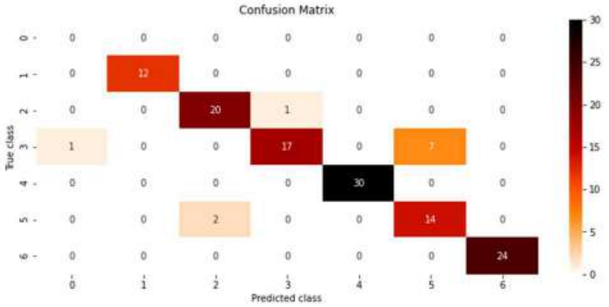

Fig.16: Confusion matrix while Validating/testing the Test data (0=Background ,1=Orange, 2=hot dog, 3= omelet ,4=banana, 5=pizza toast , 6=idli)

IV. CONCLUSION

In this paper, we have used the deep learning-based model to predict the total calories of the food item present in the image. To develop this solution, we used Mask R-CNN technique to create mask and bounding boxes. This in turn helped the model to calculate the surface area occupied by the different food items in the image which further facilitated the model with the ability to satisfactorily predict the calories associated with each food item. Calorie are estimated with the help of mathematical formulas which compares the proportion of the image occupied by each food items and determines the calories associated with it.

In future work, we plan to extend the scope of model by increasing the ability of the model to identify a greater number of food items instead of 6 food items, which we used in our current dataset. The dataset we used contain 638 images of food item with 6 different categories, which will be extended in our next model. Finally, we would like to calculate the calories of the food item based on their volume with the help of 3D images. As the technology is advancing, it would be interesting to work on the model development which can handle 3D image as input and predict the calories of the food item with better results.
