Abstract. *The article describes an improved implementation of the encryption scheme based on the automorphism group of Ree function field. Our proposal is to use the Ree function field automorphism group to encrypt the whole group with key bindings. We extended the logarithmic signature to the entire group and got changed the encryption algorithm to protect against a sequential key recovery attack.*

Keywords: *MST cryptosystem, logarithmic signature, random cover, automorphism group, Ree function field.*

I. Introduction

The advent of quantum computers capable of solving arbitrarily complex problems casts doubt on the existence of modern cryptography. Classical public key cryptographic protocols exploiting the idea of the complexity of solving the problem of factoring large numbers. This idea become insecure with implementation of quantum algorithms. The implementation of cryptosystems resistant to quantum cryptanalysis becomes relevant. The idea of constructing public-key cryptosystems on the basis of the intractable word problem was proposed in 90th. The basis is the use of permutation groups. One possible solution is to exploit the idea of Wagner and Magyarik, which proposed the concept of a cryptosystem based on the unsolvable problem of words in groups and semigroups [1]. Birget et al. [2] projected this idea into a public key cryptosystem with finite generated groups. The type of cryptosystems based on group factorization has developed rapidly [3-7].

In 1986, Magliveras [5] proposed a symmetric cryptosystem based on factorization in finite permutation groups called logarithmic signature (LS). In 2009, Lempken et al. [4] developed a new public key cryptographic system - MST3, based on random covers and Suzuki 2-group. In 2008 Magliveras et al. [8] presented a comprehensive analysis of the MST3 cryptosystem and stated that the transitive logarithmic signature is not suitable for the MST3 cryptosystem. In 2010, Svaba et al. [6] analyzed all published references to attacks on MST cryptography and built a more secure eMST3 cryptosystem by adding a secret homomorphic coverage. In 2018, T. van Trung [9] proposed a general method for constructing strong aperiodic logarithmic signatures for abelian p-groups and contributed to the practical application of MST cryptosystems. Since the 2000s, several dozen group cryptosystems schemes have been proposed. Further development of MST3 cryptosystems is proposed in [11–13].

In this paper the implementation on multiparameter groups are considered for the first time. The main idea lies in the plane of solving the problem of optimizing overhead costs by reducing the large size of keys and increasing the efficiency of the encryption (decryption) algorithm. It was shown that on groups of large order it is possible to construct cryptosystems with calculations of the LS outside the center of the group over finite fields of small dimension.

The implementation of an encryption algorithm with LSs based on the automorphism group of the Ree function field [13] allows increasing the size of the cipher text and reducing the requirements for the size of LS. At the same time, despite the very large order of the group, the secrecy of this implementation turned out to be unrelated to the order of the automorphism group of the Ree function field and is determined by the dimension of the finite representation field. This article discusses brute force attacks on key recovery for a cryptosystem with of the Ree group of automorphisms and presents a new encryption algorithm with associated keys.

II. Encryption secrecy based on the group of automorphisms of the Ree functional field

The concept of constructing the MST cryptosystem is based on application of non-commutative group algebra to cover the logarithmic signature. LS as a mapping is given by the following definition 14].

Definition 1 (cover (logarithmic signature) mappings). Let $\alpha = [A_1, \dots, A_s]$ be a cover (logarithmic signature) of type $(r_1, r_2, \dots, r_s)$ for G with $A_i = [a_{i,1}, a_{i,2}, \dots, a_{i,r_i}]$, where $m = \prod_{i=1}^{s} r_i$. Let $m_1 = 1$ and $m_i = \prod_{j=1}^{i-1} r_j$ for $i = 2, \dots, s$. Let τ denote the canonical bijection

$$\tau : \mathbb{Z}_{r_1} \times \mathbb{Z}_{r_2} \times \ldots \times \mathbb{Z}_{r_s} \rightarrow \mathbb{Z}_m ,$$

$$\tau(j_1, j_2, \dots, j_s) = \sum_{i=1}^{s} j_i \cdot m_i .$$

Then the surjective (bijection) mapping $\alpha' : \mathbb{Z}_m \rightarrow G$ induced by is

$$\alpha'(x) = a_{1j_1} \cdot a_{2j_2} \cdots a_{sj_s}$$

where $(j_1, j_2, ..., j_s) = \tau^{-1}(x)$.

More generally, if $\alpha = [A_1, ..., A_s]$ is a LS (cover) for, then each element $g \in G \in$ can be expressed uniquely (at least one way) as a product of the form

$$g = a_1 \cdot a_2 \cdots a_s,$$

for $a_i \in A_i$.

Let G is ultimate nonabelian group with nontrivial center $\mathbf{Z}$, such that G does not decompose over $\mathbf{Z}$. Suppose that $\mathbf{Z}$ is quite large, such that the search is over $\mathbf{Z}$ is computational impracticable.

The cryptographic hypothesis, which is the basis for the cryptosystem, is that if $\alpha = [\mathrm{A}_1, \mathrm{A}_2, ..., \mathrm{A}_s] := (a_{i,j})$ – accidental cover for a "large" matrices S at G, then search for the layout $g = a_{1j_1} a_{2j_2} \cdots a_{sj_s}$ for any element $g \in G$ relatively α is, in general, not a solvable problem.

One of the concepts of secrecy is based on use of aperiodic logarithmic signatures. Constructions of aperiodic logarithmic signatures are widely presented [9,16]. Research and estimates carried out in [9] are quite optimistic. There are also questions for MST cryptanalysis related to group algebra. We omit the subtle issues of basic attack analysis here, although the details are essential.

The MST implementation cryptosystem on the group of automorphisms of the Ree function field exploits the idea that good implementation and secrecy characteristics can be obtained on a large-order multivariable group.

The group of automorphisms of the Ree function field is defined over a finite field F_q, $q = 3^{2s+1}$, where $s \in N \setminus \{0\}$ and $q_0 = 3^s$ [10].

The Ree function field F over K is defined as $S = K(x, y, z)$ where

$$y^q - y = x^{q_0}(x^q - x),$$
$$z^q - z = x^{2q_0}(x^q - x).$$

It has $N = q^3 + 1$ rational places and genus $g = 3q_0(q-1)(q+q_0+1)/2$.

The automorphism group A of F is the Ree group $\mathrm{Ree}(q)$ and has order $|\mathrm{Ree}(q)| = q^3(q^3+1)(q-1)$.

Let P_∞ denote the unique pole x in F. Let

$$A(P_\infty) := \{\sigma \in A | \sigma(P_\infty) = P_\infty\} \subset A.$$

$A(P_\infty)$ consists of all automorphisms $\psi_{a,b,c,d}$ with $a, b, c, d \in K, a \neq 0$, which are defined as

$$\psi_{a,b,c,d} := \begin{cases} x \mapsto ax + b \\ y \mapsto a^{q_0+1} y + ab^{q_0} x + c \\ z \mapsto a^{2q_0+1} z - a^{q_0+1} b^{q_0} y + ab^{2q_0} x + d \end{cases}$$

We have $|A(P_\infty)| = q^3(q-1)$, and the subgroup $A(P_\infty)$ is a maximal subgroup of A.

The each element of $A(P_\infty)$ can be expressed uniquely

$$A(P_\infty) = \{S(a,b,c,d) | a \in F_q^* := F_q \setminus \{0\}, c, b, d \in F_q\},$$

where $S(a,b,c,d) = [a,b,c,d]$ and group operation is defined as

$$S(a_1, b_1, c_1, d_1) \cdot S(a_2, b_2, c_2, d_2) =$$
$$S(\ a_1 a_2, a_2 b_1 + b_2, a_2^{q_0+1} c_1 + a_2 b_1 b_2^{q_0} + c_2, a_2 b_1 b_2^{2q_0} - a_2^{q_0+1} b_2^{q_0} c_1$$
$$+ a_2^{2q_0+1} d_1 + d_2\ )$$

The identity is the 4-triple $[1,0,0,0]$ and the inverse of $S(a,b,c,d)$ is

$$S(a,b,c,d)^{-1} = S(\ a^{-1}, -a^{-1}b, (a^{-1}b)^{q_0+1} - a^{-(q_0+1)}c,$$
$$-(a^{-1}b)^{2q_0+1} - a^{-(2q_0+1)} b^{q_0} c - a^{-(2q_0+1)} d\ ).$$

The encryption scheme based on the automorphism group of the Ree function field was proposed in [13] The correctness of the proposed algorithm was also verified by practical assessment.

For the purposes of cryptoanalysis of encryption scheme let's consider key generation and encryption steps as follows.

Input: a large group on the field F_q, $q = 3q_0{}^2$, $q_0 = 3^s$

$$A(P_\infty) = \{S(a,b,c,d) | a \in F_q^* := F_q \setminus \{0\}, c, b, d \in F_q\}.$$

Choose a tame logarithmic signatures $\beta_{(k)} = [B_{1(k)}, ..., B_{s(k)}] = (b_{ij})_{(k)}$, $(b_{ij})_{(k)} \in A(P_\infty)$ of type $(r_{1(k)}, ..., r_{s(k)})$, $i = \overline{1, s(k)}$, $j = \overline{1, r_{i(k)}}$, $b_{ij(k)} \in F_q$, $k = \overline{1,3}$. Group element $(b_{ij})_{(k)}$ has a value in only one coordinates b, c or d, respectively.

Select a random covers $\alpha_{(k)} = [A_{1(k)}, ..., A_{s(k)}] = (a_{ij})_{(k)} = S(a_{ij(k)_1}, a_{ij(k)_2}, a_{ij(k)_3}, a_{ij(k)_4})$ of the same type as $\beta_{(k)}$, where $a_{ij} \in A(P_\infty)$, $a_{ij(k)_1}, a_{ij(k)_2}, a_{ij(k)_3}, a_{ij(k)_4} \in F_q \setminus \{0\}$, $k = \overline{1,3}$.

Choose $t_{0(k)}, t_{1(k)}, ..., t_{s(k)} \in A(P_\infty) \setminus Z$,

$t_{i(k)} = S(t_{i(k)_1}, t_{i(k)_2}, t_{i(k)_3}, t_{i(k)_4})$, $t_{i(\mathrm{k})_j} \in F^\times$, $i = \overline{0, s(\mathrm{k})}$, $j = \overline{1,4}$, $k = \overline{1,3}$. Let's $t_{\mathrm{s}(1)} = t_{0(2)}$, $t_{\mathrm{s}(2)} = t_{0(3)}$.

Construct a homomorphism f_k, $k = \overline{1,3}$ defined by

$$f_1(S(a_1, a_2, a_3, a_4)) = S(1, a_1, a_2, a_3),$$
$$f_2(S(a_1, a_2, a_3, a_4)) = S(1, 0, a_2, a_3),$$
$$f_3(S(a_1, a_2, a_3, a_4)) = S(1, 0, 0, a_3).$$

Let's do the following calculations

$$\gamma_{(k)} = [h_{1(k)}, ..., h_{s(k)}] = t_{(i-1)(k)}^{-1} f_k((a_{ij})_{(k)})(b_{ij})_{(k)} t_{i(k)},$$

where $k = \overline{1,3}$, $i = \overline{1, s(k)}$, $j = \overline{1, r_{i(k)}}$,

$$f_1((a_{ij})_{(1)})(b_{ij})_{(1)} =$$
$$S(1, a_{ij(1)_1} + b_{ij(1)}, a_{ij(1)_2} + a_{ij(1)_1} b_{ij(1)}^{q_0}, a_{ij(1)_1} b_{ij(1)}^{2q_0} + a_{ij(1)_3}),$$
$$f_2((a_{ij})_{(2)})(b_{ij})_{(2)} = S(1, 0, a_{ij(2)_2} + b_{ij(2)}, a_{ij(2)_3}),$$
$$f_3((a_{ij})_{(3)})(b_{ij})_{(3)} = S(1, 0, 0, a_{ij(3)_3} + b_{ij(3)}).$$

An output public key $[f_k,(\alpha_k,\gamma_k)]$, and a private key $\left[\beta_{(k)},\left(t_{0(k)},\dots,t_{s(k)}\right)\right]$, $k=\overline{1,3}$.

Encryption. Let's have message $m\in A\left(P_\infty\right)$, $m=S\left(m_1,m_2,m_3,m_4\right)$, $m_1\in F_q\setminus\{0\}$, $m_2,m_3,m_4\in F_q$, the public key $[f_k,(\alpha_k,\gamma_k)]$, $k=\overline{1,3}$, $R=R_1,R_2,R_3\in Z_{|F_q|}$

Compute

$$y_1=\alpha'(R)\cdot m=\alpha_1{}'(R_1)\cdot\alpha_2{}'(R_2)\cdot\alpha_3{}'(R_3)\cdot m,$$

$$y_2=\gamma'(R)=\gamma_1{}'(R_1)\cdot\gamma_2{}'(R_2)\cdot\gamma_3{}'(R_3)$$

$$=S(\ *,a_{(1)_1}(R_1)+\beta_{(1)}(R_1)+*,a_{(2)_2}(R_2)+\beta_{(2)}(R_2)+*,$$

$$a_{(3)_3}(R_3)+\beta_{(2)}(R_3)+*\ ).$$

Here, the $(*)$ components are determined by cross-calculations in the group operation of the product of $t_{0(k)},\dots,t_{s(k)}$ and the product of $a_{(k)_j}(R_k)+\beta_{(k)}(R_k)$.

Compute

$$y_3=f_1\left(\alpha_1{}'(R_1)\right)=S\left(1,a_{(1)_1}(R_1),*,*\right),$$

$$y_4=f_2\left(\alpha_2{}'(R_2)\right)=S\left(1,0,a_{(2)_2}(R_2),a_{(2)_3}(R_2)\right),$$

$$y_5=f_3\left(\alpha_3{}'(R_3)\right)=S\left(1,0,0,a_{(3)_3}(R_3)\right).$$

Output (y_1,y_2,y_3,y_4,y_5).

This encryption scheme has a serious flaw. In the proposed implementation of the algorithm, we have R_1 and R_2 as encryption keys. They are not bound and allow for a sequential key recovery attack. The keys can be restored on the basis of calculating the $\alpha_k{}'(R_k{}')$ for each $k=\overline{1,3}$ and comparing it with the y_3,y_4,y_5 according to the values of the corresponding coordinates.

$$y_3=f_1\left(\alpha_1{}'(R_1)\right)=S\left(1,a_{(1)_1}(R_1),*,*\right),$$

$$y_4=f_2\left(\alpha_2{}'(R_2)\right)=S\left(1,0,a_{(2)_2}(R_2),a_{(2)_3}(R_2)\right),$$

$$y_5=f_3\left(\alpha_3{}'(R_3)\right)=S\left(1,0,0,a_{(3)_3}(R_3)\right).$$

The complexity of key recovery attack of $R=(R_1,R_2,R_3)$ equals to $3q$.

III. Improved Encryption Based on the Automorphism Group of the Ree Function Field

In the new implementation of the cryptosystem, we changed the encryption algorithm in a way to bind the keys of the logarithmic signatures and protect against a sequential recovery attack. Our suggestion is to use the group of automorphisms of the Ree function field for the encryption on full group $A\left(P_\infty\right)=\{S(a,b,c,d)\}$ with the bound keys $R=(R_1,R_2,R_3)$. In such case, the brute force attack complexity with equal to q^3.

Description of the Scheme. Key Generation.

Input: a large group on the field F_q, $q=3q_0{}^2$, $q_0=3^s$

$$A\left(P_\infty\right)=\left\{S(a,b,c,d)\middle|a\in F_q^*:=F_q\setminus\{0\},c,b,d\in F_q\right\}.$$

Choose a tame logarithmic signatures $\beta_{(k)}=\left[B_{1(k)},\dots,B_{s(k)}\right]=\left(b_{ij}\right)_{(k)}$, $\left(b_{ij}\right)_{(k)}\in A\left(P_\infty\right)$ of type $\left(r_{1(k)},\dots,r_{s(k)}\right)$, $i=\overline{1,s(k)}$, $j=\overline{1,r_{i(k)}}$, $b_{ij(k)}\in F_q$, $k=\overline{1,3}$. Group element $\left(b_{ij}\right)_{(k)}$ has a value in only one coordinates b, c or d, respectively.

For example $\left(b_{ij}\right)_{(1)}=S\left(1,b_{ij(k)_a},0,0\right)$.

Select a random covers $\alpha_{(k)}=\left[A_{1(k)},\dots,A_{s(k)}\right]=\left(a_{ij}\right)_{(k)}=S\left(a_{ij(k)_a},a_{ij(k)_b},a_{ij(k)_c},a_{ij(k)_d}\right)$ of the same types as $\beta_{(k)}$, where $a_{ij}\in A\left(P_\infty\right)$, $a_{ij(k)}\in F_q\setminus\{0\}$, $i=\overline{0,s(\mathrm{k})}$, $j=\overline{1,r_{i(k)}}$, $k=\overline{1,3}$.

Choose $t_{i(k)}=S\left(t_{i(k)_a},t_{i(k)_b},t_{i(k)_c},t_{i(k)_d}\right)$ $t_{\mathrm{i}(k)}\in A(P_\infty)\setminus Z$, $t_{i(k)_a},t_{i(k)_b},t_{i(k)_c},t_{i(k)_d}\in F_q/\{0\}$, $i=\overline{0,s(\mathrm{k})}$, $k=\overline{1,3}$.

Let's $t_{\mathrm{s}(k-1)}=t_{0(k)}$, $k=\overline{1,3}$.

Construct a homomorphisms defined by

$$f_1\left(S(a,b,c,d)\right)=S(1,b,c,d),$$

$$f_2\left(S(a,b,c,d)\right)=S(1,0,c,d),$$

$$f_3\left(S(a,b,c,d)\right)=S(1,0,0,d).$$

Let's do the following calculations

$$\gamma_{(\mathrm{k})}=\left[h_{1(\mathrm{k})},\dots,h_{s(\mathrm{k})}\right]=t_{(i-1)(\mathrm{k})}^{-1}f_k\left(\left(a_{ij}\right)_{(\mathrm{k})}\right)\left(b_{ij}\right)_{(\mathrm{k})}t_{i(\mathrm{k})},$$

$i=\overline{1,s(\mathrm{k})}$, $j=\overline{1,r_{i(\mathrm{k})}}$, $k=\overline{1,3}$

and

$$f_1\left(\left(a_{ij}\right)_{(1)}\right)\left(b_{ij}\right)_{(1)}=$$

$$S\left(1,a_{ij(1)_b}+b_{ij(1)_b},a_{ij(1)_c}+a_{ij(1)_b}b_{ij(1)_b}^{q_0},a_{ij(1)_b}b_{ij(1)_b}^{2q_0}+a_{ij(1)_d}\right),$$

$$f_2\left(\left(a_{ij}\right)_{(2)}\right)\left(b_{ij}\right)_{(2)}=S\left(1,0,a_{ij(2)_c}+b_{ij(2)_c},a_{ij(2)_d}\right),$$

$$f_3\left(\left(a_{ij}\right)_{(3)}\right)\left(b_{ij}\right)_{(3)}=S\left(1,0,0,a_{ij(3)_d}+b_{ij(3)_d}\right).$$

An output public key $[f_k,(\alpha_k,\gamma_k)]$, and a private key $\left[\beta_{(k)},\left(t_{0(k)},\dots,t_{s(k)}\right)\right]$, $k=\overline{1,3}$.

Encryption

Input: a message $m\in A\left(P_\infty\right)$, $m=S\left(m_1,m_2,m_3,m_4\right)$, $m_1\in F_q\setminus\{0\}$, $m_2,m_3,m_4\in F_q$ and the public key $\left[f_k,\overset{\square}{f}_1,\overset{\square}{f}_2,(\alpha_k,\gamma_k)\right]$, $k=\overline{1,3}$.

Output: a ciphertext $\left(y_1,y_2,y_3\right)$ of the message m.

Choose a random $R=(R_1,R_2,R_3)$, $R_k\in Z_{|Z|}$, $k=\overline{1,3}$.

Let's set the encryption key through the mapping $R'=\pi(R_1,R_2,R_3)=(R_1{}',R_2{}',R_3{}')$.

Compute

$$y_1=\alpha'(R')\cdot m=\alpha_1{}'(R_1{}')\cdot\alpha_2{}'(R_2{}')\cdot\alpha_3{}'(R_3{}')\cdot m.$$

Compute component y_2.

$$\gamma(R)=\gamma_1'(R_1)\cdot\gamma_2'(R_2)\cdot\gamma_3'(R_3)=$$
$$S(\ 1,\sum_{i=1,j=R_{i(1)}}^{s(1)}\left(a_{ij(1)_b}+\beta_{ij(1)_b}\right)+*,\sum_{i=1,j=R_{i(2)}}^{s(2)}\left(a_{ij(2)_c}+\beta_{ij(2)_c}\right)+*,$$
$$\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_c}+\beta_{ij(3)_c}\right)+*\ ).$$

Here, the $(*)$ components are determined by cross-calculations in the group operation of the product of $t_{0(k)},\ldots,t_{s(k)}$ and the product of $a_{(k)}(R_k)+\beta_{(k)}(R_k)$.

$$y_2=\gamma(R)\cdot\overset{\square}{f}_2\left(\alpha_3'(R_3)\right)\cdot\overset{\square}{f}_1\left(\alpha_3'(R_3)\right)\cdot\overset{\square}{f}_1\left(\alpha_2'(R_2)\right),$$

where

$$\overset{\square}{f}_1\left(\alpha_k'(R_k)\right)=\prod_{i=1,j=R_{i(k)}}^{s(k)}S\left(1,a_{ij(k)_b},0,0\right),\ k=2,3$$

$$\overset{\square}{f}_2\left(\alpha_k'(R_k)\right)=\prod_{i=1,j=R_{i(k)}}^{s(k)}S\left(1,0,a_{ij(k)_c},0\right),\ k=3$$

and

$$y_2=S\left(1,\sum_{k=1}^{3}\sum_{i=1,j=R_{i(1)}}^{s(1)}a_{ij(k)_b}+\sum_{i=1,j=R_{i(1)}}^{s(1)}\beta_{ij(1)_b}+*,\right.$$
$$\sum_{i=1,j=R_{i(2)}}^{s(2)}\left(a_{ij(2)_c}+\beta_{ij(2)_c}\right)+\sum_{i=1,j=R_{i(3)}}^{s(3)}a_{ij(3)_c}+*,$$
$$\left.\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_d}+\beta_{ij(3)_d}\right)+*\right).$$

Compute component y_3.

$$\lambda(R)=f_1\left(\alpha_1'(R_1)\right)\cdot f_2\left(\alpha_2'(R_2)\right)\cdot f_2\left(\alpha_3'(R_3)\right),$$
$$y_3=\lambda(R)\overset{\square}{f}_1\left(\alpha_3'(R_3)\right)\cdot\overset{\square}{f}_1\left(\alpha_2'(R_2)\right),$$

where

$$f_1\left(\alpha_k'(R_k)\right)=\prod_{i=1,j=R_{i(k)}}^{s(k)}S\left(1,a_{ij(k)_b},a_{ij(k)_c},a_{ij(k)_d}\right),\ k=1$$

$$f_2\left(\alpha_k'(R_k)\right)=\prod_{i=1,j=R_{i(k)}}^{s(k)}S\left(1,0,a_{ij(k)_c},a_{ij(k)_d}\right),\ k=2,3$$

and

$$y_3=S\left(1,\sum_{k=1}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_b},\right.$$
$$\left.\sum_{k=2}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_c}+*,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_d}+*\right).$$

Output (y_1,y_2,y_3).

Decryption

Input: a ciphertext (y_1,y_2,y_3) and private key $\left[\beta_{(k)},\left(t_{0(k)},\ldots,t_{s(k)}\right)\right]$, $k=\overline{1,3}$.

To decrypt a message m, we need to restore random numbers $R=(R_1,R_2,R_3)$.

Compute

$$D(R_1,R_2,R_3)=t_{0(1)}y_2y_3^{-1}t_{s(3)}^{-1}=S\left(1,\sum_{i=1,j=R_{i(1)}}^{s(1)}\beta_{ij(1)_a},*,*\right).$$

Restore R_1 with $\beta_{(1)}(R_1)=\sum_{i=1,j=R_{i(1)}}^{s(1)}\beta_{ij(1)_b}$ using $\beta_{(1)}(R_1)^{-1}$, because β_1 is simple. For further calculation, it is necessary to remove the component $\gamma_1'(R_1)$ from y_2 and $\alpha_1'(R_1)$ from y_3.

Compute

$$y_2^{(1)}=\gamma_1'(R_1)^{-1}y_2=S\left(1,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(\mathrm{k})}}^{s(\mathrm{k})}a_{ij(k)_b}+*,\right.$$
$$\left.\sum_{i=1,j=R_{i(2)}}^{s(2)}\left(a_{ij(2)_c}+\beta_{ij(2)_c}\right)+*,\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_d}+\beta_{ij(3)_d}\right)+*\right)$$

and

$$y_3^{(1)}=f_1\left(\alpha_1'(R_1)\right)^{-1}y_3=S(1,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_a},$$
$$\left.\sum_{k=2}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_b}+*,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(k)}}^{s(k)}a_{ij(k)_c}+*\right).$$

Repeat the calculations for $D(R_2,R_3)$

$$D(R_2,R_3)=t_{0(2)}y_2^{(1)}\left(y_3^{(1)}\right)^{-1}t_{s(3)}^{-1}=$$
$$\left.S\left(1,0,\sum_{i=1,j=R_{i(2)}}^{s(2)}\beta_{ij(2)_c},\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_d}+\beta_{ij(3)_d}\right)+*\right)\right).$$

Restore R_2 with $\beta_{(2)}(R_2)=\sum_{i=1,j=R_{i(1)}}^{s(2)}\beta_{ij(1)_c}$ using $\beta_{(2)}(R_2)^{-1}$, because β_2 is simple. Remove the component $\gamma_2'(R_2)$ from $y_2^{(1)}$ and $f_1\left(\alpha_2'(R_2)\right)$ from $y_3^{(1)}$.

$$y_2^{(2)}=\gamma_2'(R_2)^{-1}y_2^{(1)}=S\left(1,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(\mathrm{k})}}^{s(\mathrm{k})}a_{ij(k)_b}+*,\right.$$
$$\left.\sum_{i=1,j=R_{i(3)}}^{s(3)}a_{ij(3)_c}+*,\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_d}+\beta_{ij(3)_d}\right)+*\right)$$

and

$$y_3^{(2)}=f_2\left(\alpha_2'(R_2)\right)^{-1}y_3^{(1)}=S\left(1,\sum_{k=2}^{3}\sum_{i=1,j=R_{i(\mathrm{k})}}^{s(\mathrm{k})}a_{ij(k)_b},\right.$$
$$\left.\sum_{i=1,j=R_{i(3)}}^{s(3)}a_{ij(3)_c}+*,\sum_{i=1,j=R_{i(3)}}^{s(3)}\left(a_{ij(3)_d}+\beta_{ij(3)_d}\right)+*\right).$$

Compute

$$D(R_3)=t_{0(3)}y_2^{(2)}\left(y_3^{(2)}\right)^{-1}t_{s(3)}^{-1},$$

$$D(R_3)=t_{0(3)}y_2^{(2)}\left(y_3^{(2)}\right)^{-1}t_{s(3)}^{-1}==S\left(1,0,0,\sum_{i=1,j=R_{i(3)}}^{s(3)}\beta_{ij(3)_d}\right).$$

Restore R_3 with $\beta_{(3)}(R_3)$ using $\beta_{(3)}(R_3)^{-1}$.

We obtain $R'=\pi(R_1,R_2,R_3)=(R_1',R_2',R_3')$ and recovery the message $m=\alpha'(R_1',R_2',R_3')^{-1}\cdot y_1$.

Example

We will show the correctness of the obtained expressions in the following simple example.

Fix the subgroup $A(P_\infty)=\{S(a,b,c,d)\}$ for the group of automorphisms of the Ree function field over F_q, $q=3^5$, $q_0=3^2$, $g(\mathrm{x})=x^5+2x+1$.

First stage is to generate a tame logarithmic signature with the dimension of corresponding selected type $(r_{1(k)},...,r_{s(k)})$ and finite field F_q. The construction of arrays of logarithmic signatures is presented in [15].

For our example, we use the construction of simple logarithmic signatures without analyzing the details of their secrecy. Let's $\beta_{(k)}$, $k=\overline{1,3}$ have the types of $(3^2,3^2,3)$, $(3,3^2,3^2)$, $(3^2,3,3^2)$. They are represented as a strings and elements of the group over the field F_q.

$\beta_k=\left[B_{1(k)},B_{2(k)},B_{3(k)}\right]=\left(b_{ij}\right)_{(k)}$, $\left(b_{ij}\right)_{(k)}\in U(q)$, $k=\overline{1,3}$

For example, let $R_1 = \left(R_{1(1)}, R_{2(1)}, R_{3(1)}\right) = (2,3,0) = 29$.

$\gamma_1(29) = h_{1(1)}(2)\, h_{2(1)}(3)\, h_{3(1)}(0) = S\left(\alpha^0, \alpha^{66}, \alpha^{62}, \alpha^{29}\right)$.

For $R_2 = \left(R_{1(2)}, R_{2(2)}, R_{3(2)}\right) = (1,1,1) = 31$. Compute γ_2

$\gamma_2(31) = h_{1(2)}(1)\, h_{2(2)}(1)\, h_{3(2)}(1) = S\left(\alpha^0, \alpha^{160}, \alpha^{112}, \alpha^{186}\right)$.

For $R_2 = \left(R_{1(2)}, R_{2(2)}, R_{3(2)}\right) = (3,1,1) = 39$. Compute γ_3

$\gamma_3(39) = h_{1(3)}(3)\, h_{2(3)}(1)\, h_{3(3)}(1) = S\left(\alpha^0, \alpha^{5}, \alpha^{72}, \alpha^{215}\right)$.

Encryption

Input: a message $m \in A(P_\infty)$, $m = S(m_1, m_2, m_3, m_4)$, $m_1 \in F_q \setminus \{0\}$, $m_2, m_3, m_4 \in F_q$ and the public key $[f_k, (\alpha_k, \gamma_k)]$, $k = \overline{1,3}$.

Let $m = \left(a^0, a^1, a^2, a^3\right) = S\left(a^0, a^1, a^2, a^3\right)$.

Choose a random $R = (R_1, R_2, R_3) = (29, 31, 39)$. Lets define a mapping for the encryption keys such as

$R' = \pi(R_1, R_2, R_3) = (R_3, R_2, R_1)$

Compute cipher text

$$y_1 = \alpha'(R)\cdot m = \alpha_1'(R_3)\cdot\alpha_2'(R_2)\cdot\alpha_3'(R_1)\cdot m =$$
$$S\left(\alpha^1, \alpha^{71}, \alpha^{159}, \alpha^{131}\right) S\left(a^0, a^1, a^2, a^3\right) = S\left(\alpha^1, \alpha^{11}, \alpha^{187}, \alpha^{216}\right)$$

Calculate

$$\gamma(R) = \gamma_1'(R_1)\cdot\gamma_2'(R_2)\cdot\gamma_3'(R_3) = S\left(\alpha^0, \alpha^{140}, \alpha^{184}, \alpha^{155}\right)$$

and second component of the cipher text

$$y_2 = \gamma(R)\cdot \square f_2\left(\alpha_3'(R_3)\right)\cdot \square f_1\left(\alpha_3'(R_3)\right)\cdot \square f_1\left(\alpha_2'(R_2)\right) =$$
$$S\left(\alpha^0, \alpha^{21}, \alpha^{191}, \alpha^{65}\right).$$

Compute component y_3.

$$\lambda(R) = \alpha_1'(R_1)\cdot f_1\left(\alpha_2'(R_2)\right)\cdot f_1\left(\alpha_3'(R_3)\right) =$$
$$S\left(\alpha^0, \alpha^{25}, \alpha^{142}, \alpha^{53}\right),$$

$$y_3 = \lambda(R)\square f_1\left(\alpha_3'(R_3)\right)\cdot \square f_1\left(\alpha_2'(R_2)\right) = S\left(\alpha^0, \alpha^{107}, \alpha^{60}, \alpha^2\right).$$

We obtained output $y_1 = \left(\alpha^1, \alpha^{11}, \alpha^{187}, \alpha^{216}\right)$, $y_2 = \left(\alpha^0, \alpha^{21}, \alpha^{191}, \alpha^{65}\right)$, $y_3 = \left(\alpha^0, \alpha^{107}, \alpha^{60}, \alpha^2\right)$.

Decryption

Input: a ciphertext (y_1, y_2, y_3) and private key $\left[\beta_k, \left(t_{0(k)}, \ldots, t_{s(k)}\right)\right]$, $k = \overline{1,3}$.

Output: the message $m \in A(P_\infty)$ corresponding to ciphertext (y_1, y_2, y_3).

To decrypt a message m, we need to restore random numbers $R = (R_1, R_2, R_3)$.

Compute

$$D(R_1, R_2, R_3) = t_{0(1)} y_2 y_3^{-1} t_{s(3)}^{-1} = S\left(\alpha^0, \alpha^2, \alpha^{148}, \alpha^{213}\right).$$

We get $\beta_1(R_1) = \alpha^2 = (00100)$.

Perform inverse calculations $\beta_3(R_3)^{-1}$.

<table>
<tr><td>00|10|<b>0</b></td><td>R_1=(*,*,0)</td></tr>
<tr><td>01|12|<b>0</b></td><td>row 0 from $B_{3(1)}$</td></tr>
<tr><td>00|10|<b>0</b>−01|12|<b>0</b>=02|<b>01</b>|0</td><td>R_1= (*,3,0)</td></tr>
<tr><td>12|<b>01</b>|0</td><td>row 3 from $B_{2(1)}$</td></tr>
<tr><td>02|<b>01</b>|0−12|<b>01</b>|0=<b>20</b>|00|0</td><td></td></tr>
</table>

We get $\beta_1(R_1)^{-1} = (2,3,0) = 29$

For further calculations, it is necessary to remove the components of the components $\alpha_1'(R_1)$ and $\gamma_1'(R_1)$ from ciphertext (y_2, y_3).

Compute

$$y_2^{(1)} = \gamma_1'(R_1)^{-1} y_2 = S\left(\alpha^0, \alpha^{37}, \alpha^{225}, \alpha^{62}\right)$$

and

$$y_3^{(1)} = \alpha_1'(R_1)^{-1} y_3 = S\left(\alpha^0, \alpha^{65}, \alpha^{129}, \alpha^{115}\right).$$

Compute

$$D(R_2, R_3) = t_{0(2)} y_2^{(1)} \left(y_3^{(1)}\right)^{-1} t_{s(3)}^{-1} = S\left(\alpha^0, 0, \alpha^{227}, \alpha^{175}\right).$$

We get $\beta_2(R_2) = \alpha^{227} = (10110)$. Restore R_2 with $\beta_2(R_2) = \alpha^{227} = (10110)$. We use the same calculations as in the example for $\beta_1(R_1)^{-1}$, and we get

<table>
<tr><td>1|01|<b>10</b></td><td>R_2=(*,*,1)</td></tr>
<tr><td>1|21|<b>10</b></td><td>row 1 from $B_{3(2)}$</td></tr>
<tr><td>1|01|<b>10</b>−1|21|<b>10</b>=0|10|00</td><td>R_2= (*,1,1)</td></tr>
<tr><td>2|<b>10</b>|00</td><td>row 1 from $B_{2(2)}$</td></tr>
<tr><td>0|<b>10</b>|00−2|<b>10</b>|00=1|00|00</td><td>R_2=(1,1,1)</td></tr>
</table>

$$\beta_2(R')^{-1} = 1|01|10 = \left(R_{1(2)}, R_{2(2)}, R_{3(2)}\right) = (1,1,1) = 31.$$

Perform inverse calculations $\beta_2(R_2)^{-1}$. Select bit groups in vector $\beta(R)$ according to type $\left(r_{1(2)}, \ldots, r_{s(2)}\right) = \left(3, 3^2, 3^2\right)$. We use the same calculations as in the example for $\beta_1(R_1)^{-1}$, and we get $\beta_2(R')^{-1} = (1,1,1) = 31$

Remove the component $\gamma_2'(R_2)$ from $y_2^{(1)}$ and $f_1\left(\alpha_2'(R_2)\right)$ from $y_3^{(1)}$

$$y_2^{(2)} = \gamma_2'(R_2)^{-1} y_2^{(1)} = S\left(\alpha^0, \alpha^{83}, \alpha^{211}, \alpha^{61}\right)$$

$$y_3^{(2)} = f_1\left(\alpha_2'(R_2)\right)^{-1} y_3^{(1)} = S\left(\alpha^0, \alpha^{65}, \alpha^{207}, \alpha^{160}\right).$$

Compute

$$D(R_3) = t_{0(3)} y_2^{(2)} \left(y_3^{(2)}\right)^{-1} t_{s(3)}^{-1} = S\left(\alpha^0, 0, 0, \alpha^{227}\right).$$

We get $\beta_3(R_3) = \alpha^{227} = (10110)$. Perform inverse calculations $\beta_3(R_3)^{-1}$. Select bit groups in vector $\beta(R)$ according to type $\left(r_{1(3)}, \ldots, r_{s(3)}\right) = \left(3^2, 3, 3^2\right)$. We get

<table>
<tr><td>10|1|<b>10</b></td><td>R_3=(*,*,1)</td></tr>
<tr><td>02|0|<b>10</b></td><td>row 1 from $B_{3(3)}$</td></tr>
<tr><td>10|1|<b>10</b>−02|0|<b>10</b>=11|1|00</td><td>R_3= (*,1,1)</td></tr>
<tr><td>10|<b>1</b>|00</td><td>row 1 from $B_{2(3)}$</td></tr>
<tr><td>11|<b>1</b>|00−10|<b>1</b>|00=01|0|00</td><td>R_3=(3,1,1)</td></tr>
</table>

$$\beta_3(R')^{-1} = 1|01|10 = \left(R_{1(3)}, R_{2(3)}, R_{3(3)}\right) = (3,1,1) = 39.$$

Receive a message $m = \alpha'(R)^{-1} y_1 = S\left(a^0, a^1, a^2, a^3\right)$.

Security Analysis

Consider a brute force attack of key recovery. There are three possible schemes for such an attack.

Brute force attack on cipher text. By selecting $R = (R_1, R_2, R_3)$ try to decipher the text $y_1' = \alpha'(R')\cdot m = \alpha_1'(R_1')\cdot\alpha_2'(R_2')\cdot\alpha_3'(R_3')\cdot m$. The covers $\alpha_{(k)} = \left(a_{ij}\right)_{(k)} = S\left(a_{ij(k)_a}, a_{ij(k)_b}, a_{ij(k)_c}, a_{ij(k)_d}\right)$ are selected randomly and the value is determined by multiplication in a group with no coordinate constraints. The resulting vector $\alpha'(R')$ depends on all components $\alpha_1'(R_1'), \alpha_2'(R_2'), \alpha_3'(R_3')$. Enumeration of key values $R = (R_1, R_2, R_3)$ has an estimation of complexity. For a practical attack, the message m is also unknown and has uncertainty to choose from q^3 . This makes a brute-force attack on a key infeasible. If we take an attack model with a known text, then the attack complexity still remains the same and equal to q^3 .

Brute force attack on the cyphertext y_2 . Select $R = (R_1, R_2, R_3)$ to match y_2 . The vector y_2 has a following definition over the components $\alpha_i'(R_i)$

$$y_2 = S\left(1, \sum_{k=1}^{3} \sum_{i=1, j=R_{i(1)}}^{s(1)} a_{ij(k)_b} + \sum_{i=1, j=R_{i(1)}}^{s(1)} \beta_{ij(1)_b} + *, \right.$$
$$\sum_{i=1, j=R_{i(2)}}^{s(2)} \left(a_{ij(2)_c} + \beta_{ij(2)_c}\right) + \sum_{i=1, j=R_{i(3)}}^{s(3)} a_{ij(3)_c} + *,$$
$$\left. \sum_{i=1, j=R_{i(3)}}^{s(3)} \left(a_{ij(3)_d} + \beta_{ij(3)_d}\right) + * \right)$$

The values of the coordinates y_2 are defined by calculations over the vectors $\alpha_1'(R_1), \alpha_2'(R_2), \alpha_3'(R_3)$. The keys R_1, R_2, R_3 are bound and changes in any of them leads to change y_2 . The brute force attack on key $R = (R_1, R_2, R_3)$ has a complexity equal to q^3 .

Brute force attack on the ciphertext y_3 . Select $R = (R_1, R_2, R_3)$ to match y_3 . The vector y_3 has a following definition over the components $\alpha_i'(R_i)$

$$y_3 = S\left(1, \sum_{k=1}^{3} \sum_{i=1, j=R_{i(k)}}^{s(k)} a_{ij(k)_b} , \right.$$
$$\left. \sum_{k=2}^{3} \sum_{i=1, j=R_{i(k)}}^{s(k)} a_{ij(k)_c} + *, \sum_{k=2}^{3} \sum_{i=1, j=R_{i(k)}}^{s(k)} a_{ij(k)_d} + * \right).$$

The values of the coordinates y_2 are defined by calculations over the vectors $\alpha_1'(R_1), \alpha_2'(R_2), \alpha_3'(R_3)$. The keys R_1, R_2, R_3 are bound and changes in any of them leads to change y_2 . The brute force attack on key $R = (R_1, R_2, R_3)$ has a complexity equal to q^3 .

Brute force attack on the $\left(t_{0(k)}, \ldots, t_{s(k)}\right)$. The brute force attack on $\left(t_{0(k)}, \ldots, t_{s(k)}\right)$ is a general for the MST cryptosystems and for the calculation in the field F_q over the group center $Z(G)$ has an optimistic complexity estimation equal to q . For the proposed algorithm all calculations are executed on whole group $|G| = q^3$ and is a such case the complexity of the brute force attack on $\left(t_{0(k)}, \ldots, t_{s(k)}\right)$ will be equal to q^3 .

Attack on the algorithm. The given estimation of such an attack will be valid for the MST cryptosystem implementation based on any non-commutative group and requires a separate analysis. This attack has many details that related to logarithmic signature vulnerabilities and possibly group operation.

IV. Conclusions

Our suggestion is to use the automorphism group of the Ree function field for full group $A(P_\infty)$ encryption with bound keys $R = (R_1, R_2, R_3)$ and brute force attack complexity q^3 . We have improved the encryption algorithm to bind logarithmic signature keys and protect against sequential recovery attacks.

A Systematic Literature Review on Malware Analysis

Fahad Mira
Fahad.Mira@beds.ac.uk

Department of Computer Science and Technology, University of Bedfordshire, Luton, UK

***Abstract*— Malware is a significant security danger on the Internet nowadays. Hostile to Virus organizations get a huge number of malwares tests each day. It is intended to harm PC frameworks without the information on the proprietor utilizing the framework and method headways are presenting enormous difficulties for scientists in both the scholarly world and the business. Malware tests are arranged and gathered for additional investigation. In this literature review, we did the manual research on the publications from the year 2014 to 2020. We selected about 27 articles out of 55 articles as primary studies and applied quality evaluation criteria and deducted research questions from them. The motivation behind this SLR is to inspect the accessible literary works on malware examination and to decide how exploration has developed and progressed regarding the amount, substance, and publication outlets. We also discussed the issues and challenges we are facing in malware analysis along with detection system requirements. Large numbers of the malicious programs are tremendous and confounded so it is difficult for researchers to fathom its subtleties. Scattering of malicious data beyond clients of the web and furthermore preparing them to effectively utilize against malicious items are critical to shielding clients from malicious attack. This review paper will give a comprehensive book index of techniques to help with battling malicious data.**

Keywords*— *Malware; Malware analytics; Malware code; Taxonomy; Signature-based; Anomaly-based; Malware system requirements.

I. Introduction

Malware is an overall term that incorporates infections, Trojans, Spywares, and other obtrusive code is far and wide today. Malware investigation is a multistep cycle giving knowledge into malware design and usefulness, encouraging the development of a cure.

The expression "malware" here is being utilized as the conventional name for the class of code that is pernicious, including infections, Trojans, worms, and spyware. Malware writers use generators, fuse libraries, and get code foremothers—there exists a hearty organization for trade, and some malware writers set aside an effort to peruse and comprehend earlier methodologies.

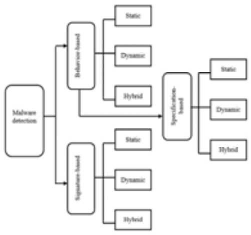
first-historically speaking PC infection (malware) Brain showed up in 1986 [1].

Malware is utilized to send spam messages, to perform web cheats, to take individual data like MasterCard data, and for some, other accursed assignments like Ransomware [2] and counterfeit antivirus programming [3].

Since 1988 [4, 5] the increment in the quantity of PC-based security penetrates affirms that noxious programming has arrived at practically unmanageable levels. Mulling over the degree of potential harm brought about by noxious programming, its discovery alone has caused huge issues for both the agents and the overall public. Recognition frameworks made by examiners are consistently put to broad use in identification works out. This paper is committed to investigating malignant programming location systems.

A. Malware analysis with respect to behaviour and signature-based:

Malware programming identification is divided into two parts: Signature-and Behavior-based advances and every innovation can be utilized with static, dynamic, or hybrid examination [5][16]. The specific technique for an oddity or mark put-together method is based on respect to how the innovation orders the data to distinguish noxious programming [6-9]. How noxious programming discovery is overseen is appeared in Fig. 1.



*F*ig.1 Flow-chart of malware detection

I. Behavior (Anomaly) based:

An anomaly-based put together discovery attracts with respect to its database to decide the presence of ordinary conduct to choose the firmness of malware in examination. Another type of inconsistency-based discovery is called specification-based recognition. This type of discovery examination occurs in 2 circumstances:

- In preparing and learning circumstance. While in the preparation circumstance, an indicator attempts to get familiar with a typical conduct. It is very conceivable that an indicator is learning the host's conduct or the PUI's or possibly the two joined. The principal advantage of anomaly-based identification is the capacity to identify ‘zero-day” interruptions.
- having location and observing circumstance

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

The 2 fundamental downsides of such system are:

- Immense bogus caution charges: It is apt of unreasonable bogus alert charges, which are characterized as 'typical' yields sorted as (bogus positive) and separated by the all-out figures of 'ordinary' conduct.
- Also getting trouble in guaranteeing what boundaries must realize in preparation circumstance.

II. Detection by signature-based

Signature based discovery uses technology-based character to observe malicious code and thus affirm a malignant idea of a program in examination. Putting aside, the signature-based discovery attempts by setting a criterion for utilizing a malicious code and accordingly uses it as the sort of perspective for distinguishing another noxious programming. In gathering every one of these models, the signature-based recognition creates an information base for itself. In an ideal framework, it is basic that the mark ought to perceive any program showing conduct fitting the mark's malignant data set. This data set contains all data required by the mark to recognize vindictive programming. This data set is counseled at whatever point here lies a possible issue with PUI.

The one of most fundamental issues of the signature-based recognition technique is the failure to perceive 'zero day' interruptions. A zero-day interruption means where there is none comparative mark lies in any information base to contrast and additionally, the accomplished individual is likely expected to plan a mark. Besides offering an approach to administrator mistakes it is a dreary cycle if the plan and establishment are not set up to work naturally. The way that certain malware can multiply the capacity to plan and introduce a more exact mark is amazingly basic. Engineers of such marks, which work on a programmed mode, could be found absent a lot of exertion, however altogether more energy should be placed into doing this. Be that as it may, all recognition systems could utilize one of three different philosophies.

TABLE 1 SUMMARY

Analysis tools	Purposes	Tools
Static	Use whatever number antivirus recognition motors as could reasonably be expected to help characterization.	“Virus Total” (2008)
	Search the body of the malware for strings.	‘Strings” (Microsoft, 2008)
Dynamic	Document respectability check to record gauge setup.	“Winalysis” (2008)
	Record observing. Discover which devices are opening, perusing and composing documents.	“Filemon” (2008)
	Vault observing. Screen vault exercises as they happen.	“Regmon” (Microsoft, 2008)
Hybrid	Dismantling, investigating	“IDA Pro” “OllyDbg” (Yuschuk, 2008)

B. Analysis Methodologies

The three principal malware investigation procedures are static, dynamic, and hybrid examination. Every examination strategy has its own favorable circumstances and weaknesses which have been talked about in this segment. Table 1 shows the outline of investigation devices.

1. Static Analysis

It is an examination of programming executed without truly performing a program [10]. Different procedures are carried out to play out this examination. While a few rely upon the characteristics of the twofold record, by removing “byte code courses” of action from a combined one, and isolating Op code progressions in the wake of destroying the twofold report, to eliminate the “control stream graphical figures” among the party record, and eliminating API calls, from the equal, and the like. Each addresses the rundown of capacities and anyone or many are utilized for malicious area.

2. Dynamic Analysis:

It is the analysis in which while executing the program, a programming is done [17]. An information segment can achieve by the one of the examinations that is API calls, structure calls, direction follows, dirty assessment, vault changes, memory makes, etc. A part of the malware acknowledgment procedure utilizing dynamic one that has been investigated formerly is according to the accompanying.

II. METHODOLOGY

In this section, we are going to apply the methodology for this systematic review that was proposed by ‘Kitchenham” [35]. This part presents the technique to achieve the objectives of literature review. The phases of our procedure include:

(1) Data planning
(2) Making of research questions
(3) Searching measures
(4) Addition and rejection measures

A. Data planning

In this phase, to achieve the goals of the current examination we recognized the important ways. In the given underlying process, it was guaranteed that the key and specialized plans were appropriately defined. This is guaranteed that different periods of the proposed philosophy were appropriately completed in a coordinated and standard way. This arranging stage shaped the reason for a fruitful usage of the proposed SLR strategy.

B. Forming research questions:

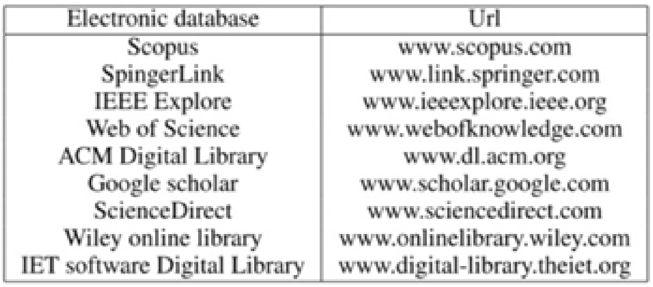
In the given section, we present the exploration addresses researched in the flow SLR study. The exploration addresses RQs examined in our investigation are:
RQ1. What number of yearly number of studies on malware examination have there been since 2010?
RQ2. What types of datasets are used?

RQ3. What is the size of datasets?
RQ4. What types of analysis methods are used in this research?
RQ5. Which are the requirements of malware programming detectors?
RQ6. What are the advantages and disadvantages of malware identification draws near?
RQ7. What are the issues and challenges faced in malware analysis?

C. Searching measures

In the following part, we illustrate the measures to distinguish the given articles for this examination. To remove pertinent SLR concentrates on malware investigation, various electronic information bases were thought of and gotten to. The rundown of information bases looked, and their comparing URL is introduced in Table 2.

TABLE 2 ELECTRONIC DATABASES



Electronic database	Url
Scopus	www.scopus.com
SpingerLink	www.link.springer.com
IEEE Explore	www.ieeexplore.ieee.org
Web of Science	www.webofknowledge.com
ACM Digital Library	www.dl.acm.org
Google scholar	www.scholar.google.com
ScienceDirect	www.sciencedirect.com
Wiley online library	www.onlinelibrary.wiley.com
IET software Digital Library	www.digital-library.theiet.org

We take out each article from the given electronic databases utilizing the customary searching measures from conferences and journals individually.

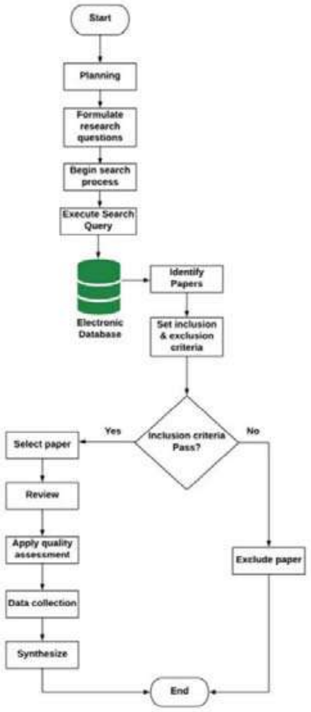


Fig.2. SLR process

The pursuit string was consequently adjusted to suit the necessities of every information base. We looked through every information base by titles, edited compositions, and catchphrases. The figure 2 depicts the rules of deliberate cycle.

D. Inclusion and rejection measures:

The investigations remembered for this SLR depended on specific measures that decided that if an examination matches the condition of inclusion, otherwise such an investigation will be precluded. Articles written in language other than English were excluded from the current examination on the grounds that such articles would be hard to peruse and comprehend.

	Table 5	**[Primary studies]**			
Ref. no.	**Author, year**	**Area of research**	**Institutions**	**Publications**	**Contributions**
[PS5]	B.Yu et al. 2018	A survey of malware behavior description and analysis	National university of defense technology	journal	This paper conducted a survey on malware behaviour description and analysis considering description, analysis and visualization methods.
[PS11]	Parmjit et al. 2014	Literature Analysis on Malware Detection	Chandigarh University	Journal	This paper gives the android architecture, various types of malware and literature analysis for security considerations in android smartphones.
[PS12	H.M Deylami et al. 2016	Taxonomy of malware detection techniques	Universiti Kebangsaan	Conference paper	This gives a comprehensive list of sources of strategies to help with battling malware.
[PS13]	Maigida et al. 2019	SLR and metadata analysis of ransomware attacks and detection mechanisms	Federal University of Technology	journal	This paper fills in as a benchmark for new analysts in proposing the ransomware discovery technique.
[PS14]	Ya Pan et al. 2020	An SLR of android malware detection using static analysis	Nanjing university	journal	A systematic literature review is performed to perform the clarification on Android malware detection by using malware detection method

III. Conclusion and Furture work

Malicious arracks lead to the typical danger for PC and correspondence frameworks to harm gadgets or take classified data. The reason for this SLR is to concoct a proficient procedure for malware location that consolidates the upsides of anomaly and signature based detection. This paper identified a definite order of malignant programming detection and evasion programs for specialists to 'nibble into'. Devoted significance was doled out to malignant programming necessities and acknowledgment given to the basics of malware recognition and avoidance strategies..

[1*]qasem.abualhaija@uop.edu.jo, [2] smadi@hu.edu.jo, [3] omabio@hu.edu.jo

Abstract*—Understanding the role of neurotransmitter dopamine in brain function under normal or pathological states is one of the most active areas of research in neurosciences. Failures in dopamine neurotransmission affects tremendous amount of brain abilities including movement, mental, and motivation and reward systems of the brain. Ability to measure phasic release of dopamine in specific locations of the brain will lead to a powerful tool for the neuroscientists, However, the tremendous amount of image-formed data as produced from different locations of the brain makes the manual analysis of these data cumbersome. Luckily, image processing techniques will help in solving these problems effortlessly to ease and speed the analysis for neuro-physicians. In this paper, we propose a deep-learning based identification scheme to identify the release case of phasic dopamine by examining the dopamine analysis (DA) imaging attributes using a convolutional neural network (CNN). More precisely, the proposed scheme exploits the transfer learning based DarkNet-19 network to train and identify the phasic dopamine release-2019 (PDR19) dataset into two-classes; namely, "release images, "or "non-release images" The experimental outcomes demonstrated the distinction of our identification scheme, recording an identification accuracy of 99.1% with a cross entropy loss of 0.022 attained after 25 epochs each with 100 iterations (i.e., 2500 iterations) for the 2-class classifier. Besides, our identification scheme was assessed using many other assessment factors, such as the identification precision percentage (IPP), the identification sensitivity percentage (ISnP), the identification specificity percentage (ISpP), and the identification weighted average percentage (F1P). Consequently, the performance of the proposed scheme surpassed several existing dopamine identification schemes.

***Keyword* — DarkNet-19, Phasic dopamine release, Identification, Convolutional Neural Network, Deep learning, Image Classification.**

I. Introduction

Dopamine is a neurotransmitter produced in both central and peripheral nervous systems. Its receptors are commonly uttered in the body and function in both systems. The dopaminergic system shows important roles in neuromodulation of motor control, incentive, reward, mental function, maternal, and reproductive behaviors [1]. As part of the reward system, the brain releases dopamine once doing things that humans or animals crave to it, contributing to feeling of pleasure and fulfillment. It creates reward seeking loops, lifts mood, and helps regulate movement, learning and emotional responses [1]. Opiates, on the other hand, affect the brain by increasing the amount of dopamine available to act on D2 receptors on the nucleus accumbens of the brain thus acutely stimulates the reward system. Long term addiction involves the development of tolerance, i.e., the need for increased amount of drug to produce a "high" phenomenon [2].

Abnormal conditions affect the dopaminergic systems and leads to pathologies in movement (Parkinson's disease), psychiatric (schizophrenia) and reward / motivation related disorders (drug addiction) [7]. As an example, defects in mesocortical, long dopamine system which projects from the midbrain tegmentam to limbic cortex, was responsible for the development of some of the symptoms of schizophrenia disorder and D4 receptors in the brain had been reported to be increased six-folds in this condition. Researchers also approved that there was a steady loss of dopamine receptors in the basal ganglia of the brain with age while the loss was greater in men than in women [2]

Understanding the role of neurotransmitter dopamine in brain function under normal or pathological states is one of the most active areas of research in neurosciences. Fast dopamine release, in less than a second period depending on crave stimuli, causes phasic release of dopamine which increases the activation of specific neurons to start a learned action. Failures in dopamine neurotransmission affects tremendous amount of brain abilities including movement, mental, and motivation and reward systems of the brain [3]. Ability to measure phasic release of dopamine in specific locations of the brain will lead to a powerful tool for the neuroscientists. However, the tremendous amount of image-formed data as produced from different locations of the brain makes the manual analysis of these data cumbersome. Luckily, image processing techniques will help in solving these problems effortlessly to ease and speed the analysis for neuro-physicians.

In this paper, we make use of DarkNet-19 Convolutional neural network (CNN) to identify the dopamine analysis imaging (DA) using Phasic Dopamine Release-2019 (PDR-19) dataset to assist at delivering an early identifying of the failures in dopamine neurotransmission. The PDR-19 dataset [10] comprises a set of 6030 images distributed into two main classes; namely, "release images, "or "Non- release images". Considering the obtained dataset, after applying a number of data wrangling operations, we employ the DarkNet-19 Convolutional neural network with customized input and output layers, frozen network parameters using transfer learning technique, and fine-configuration for the network hyper-parameters. We show the supremacy of our identification scheme scoring an outstanding classification

978-1-7281-9615-2/20/$31.00 ©2020 IEEE

accuracy. More specifically, the primary contributions of this work can be itemized as follows:

- We provide an accurate and precise identification model utilizing the powerful DarkNet-19 CNN with pre-learned trainable parameters (i.e., weights and biases) to train and validate the phasic dopamine release dataset (PDR2019) using our commodity machine equipped with NVIDIA Quadro GPU for enhanced computing.
- We provide an inclusive simulation results and investigation of our identification scheme to extend the comprehension of proposed methodology and experimental check. Besides, we benchmark our results with the recent related work to demonstrate the gain of the achieved performance trajectories.

The subsequent sections of this paper are arranged as follows: Section II investigate the dataset of phasic dopamine releases employed in this study. Section III describes and discusses the phasic dopamine identification system using DarkNet-19, experimental setup and configurations. Section IV provides details about the model evaluation, results and discussion. Finally, Section V concludes the paper.

II. Dataset of Phasic Dopamine Releases

In our research, we utilized the latest dataset introduced by Matsushita et al. [7]. This dataset is extremely comprehensive, and it is the only public dataset of fast-scan cyclic voltammetry (FSCV) images that we are aware of. The authors in [4] used FSCV data to create images depicting plots of 20-second-long experimental recordings. These recordings were made at the Federal University of Parana's (UFPR) Laboratory of Central Nervous System in Curitiba, Brazil, and D. Robinson's Laboratory at the University of North Carolina (UNC) in Chapel Hill, United States of America. The experiment was carried out by the two laboratories on different animals and FSCV configurations, resulting in slightly different plots. The experiment was carried out using a total number of 30 recordings. In the same experiment, the UFPR lab used 29 male Swiss mice while the UNC lab used six male Sprague Dawley rats. Moreover, and for legalization purposes, all experiments were carried out in conjunction with the National Institutes of Health's Guide for the Treatment and Use of Laboratory Animals, with procedures approved by the University of North Carolina's Institutional Animal Care and Use Committee and the Federal University of Parana's Institutional Ethics Committee for Animal Experimentation. For more information, a detailed description of the dataset is available in [10].

The basic idea of Matsushita et al. dataset configuration is that for each image, columns from the beginning, middle, and end were chosen, and the values of those columns were subtracted from the values of the other columns, yielding three distinct images distinguished by their backgrounds. There are a total of 1005 induced dopamine release images and 1005 images without dopamine release for each background. To better view the transformations, FSCV analysis software was used to apply a regular false color palette. Except for the UNC laboratory's experiment "RIX2," which includes all the mixed readings collected from the other experiments, each image is classified by its experiment.

Matsushita et al. dataset was extensively studied by Patarnello et al. [6]. The authors in [6] branched Matsushita et al. approaches into two groups: Global methods and Patch methods. The global methods include original photos as well as zoning variations. The first zoning method was applied on the y-axis of the image from pixel 320 to pixel 520, resulting image size of 875x200 pixels. It has been observed that the phasic Dopamine release episodes frequently established in this zone, hence it was named “common release region of the dopamine”. The second zoning method was applied on the first 90 pixels of the y-axis and the common dopamine release region, causing an 875x290 pixels image size. This region was called “concatenated zones” since some releases include visual data that can be used to abstract features. The global methods are graphically described in Fig. 1.

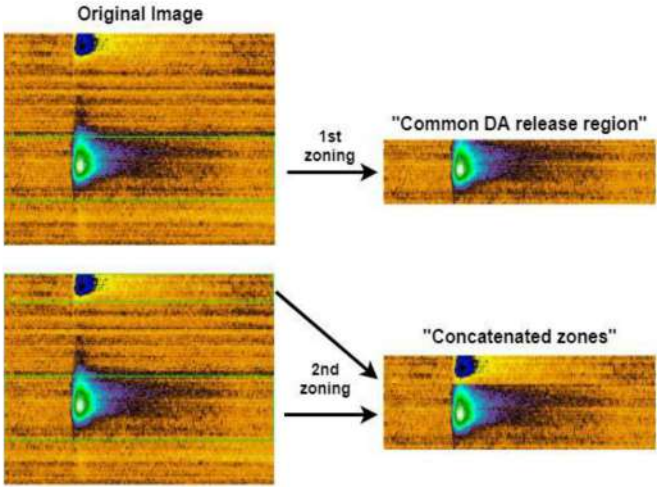

Fig. 1. Zoning variations and the original image [6].

Patch extraction methods, on the other hand, manually and automatically extract patches of size 200x200 from the common release area. The dataset includes a release peak position that used to remove manual patches, which is set as the image's core. Over the common release, a sliding window with a resolution of 200x200 pixels and a window slide of 135 pixels are used to extract automatic patches. The slide size is justified by the fact that it is a divider of the original image's width size; as a result, no pixels are left over, and six patches are removed per image. The authors in [6] recommended that size 290x290 patches be extracted from the concatenated zones in addition to the 200x200 patches. Although the method for applying manual patches hasn't changed, the fact that the image's width and height can easily be increased to 290 pixels, whereas the sliding process continues to use a 135-pixel slide. As a result, patches of size 200x290 are created by automated extraction, which are then padded to make them 290x290. Patches examples can be made clearer in Fig. 2.

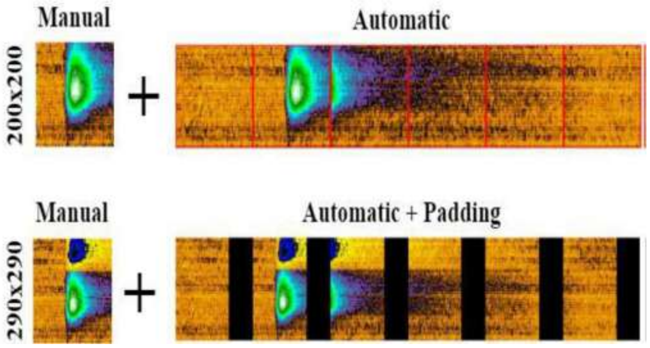

Fig. 2. Patches variations [6].

III. Identification Model Using DarkNet-19

To develop the proposed deep learning based identification system, we firstly collected the aforementioned recent dopamine analysis imaging introduced in 2019 [7]. Initially, the collected images were imported using Image-Data-Store component provided by the MATLAB's image processing objects. Thereafter, they undergone a set of preprocessing processes in order to be prepared for use by the deep learning model. Therefore, the preprocessing stage included (a) Image Resizing to unify the size of all images to $256 \times 256 \times 3$ all with JPG image extension, (b) Target Encoding to encode the two categories using binary as "0: release images" and "1: non-release images", (c) Shuffling operation to perform a stochastic re-distribution for images' dataset at every training epoch to ensure the unprejudiced distribution for the image categories, (d) Data Augmentation for dataset expansion using several image processing operations, as such, random image warping transformations, cropping transformations, color transformations, synthetic noise, synthetic blur and others [19], (e) Dataset Allocation to divide the dataset into training dataset and testing dataset using k-fold cross validation mechanism [20]. Afterward, the resulting preprocessed images can be fed to be trained and validated using the deep $DarkNet$ network, engaged in this research.

$DarkNet$ is a convolutional neural network, developed to enable the efficient training and validation of very deep neural network with more than 53+layers. Typically, $Darknet$ employs a number of global kernels and doubles the number of channels after every pooling layer [12]. The original version of $Darknet$ was written in C and CUDA, employing CPU and GPU computations, and its available as an open source framework [11]. $DarkNet$ is developed based on several preceding ideas such as $Network\ In\ Network$ [13], $Inception$ [14] and $Batch\ Normalization$ [15].

In this work, we have used the 19-convolutional layers' deep version of $DarkNet$, which is known as $DarkNet-19$. DarkNet-19 comprises exactly 19 convolutional layers and 5 max-pooling layers, involving only 3×3 and several 1×1 convolutional kernels to minimize the amount of trainable parameters [18]. We have employed the $DarkNet-19$ with the transfer learning techniques using a pretrained network that is trained on ImageNet dataset comprising a set of 1,000,000+ images [17], which provide the network with rich feature representations. While $DarkNet-19$ can be used to classify the images into 1000 classes, we have customized the output layer of $DarkNet-19$ to have two-classes to accommodate our identification outcomes. Also, since DarkNet-19 uses an input layer size of $256\ x\ 256$, we have resized all the images of the phasic dopamine releases dataset (PDR19) to be in $256\ x\ 256$ pixles to accommodate the input layer of the $DarkNet-19$. The simplified architecture of $Darknet-19$ neural network showing the main layers of the $DarkNet-19$ network is illustrated in Fig.3.

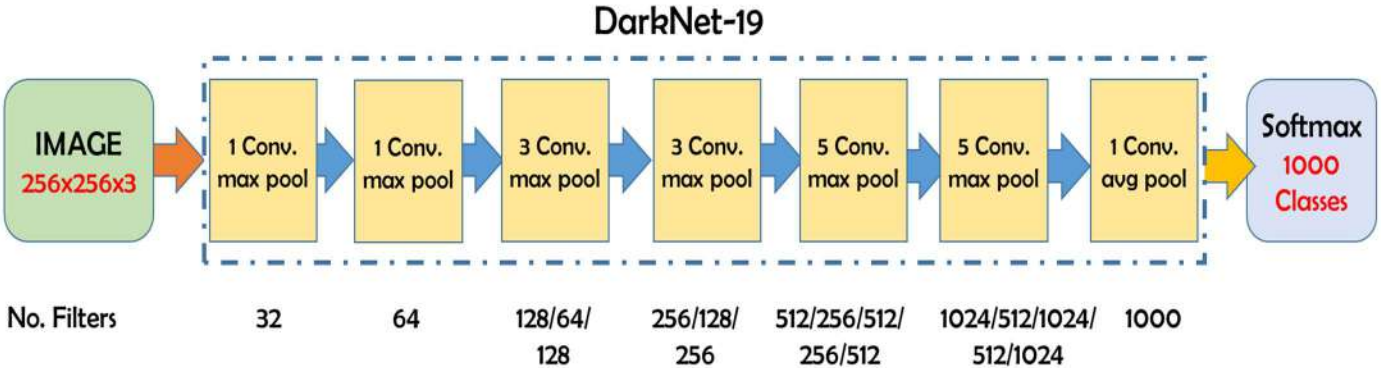

Fig. 3. Top-View Architecture of Darknet-19 neural network

Also, the prescribed identification scheme has been carried out using MATLAB computing system and its supplementary components including the image processing, the parallel computation and the deep learning toolboxes as well as the corresponding machine learning methods and approaches. Moreover, to train and test the performance of deep learning scheme, we have allocated 80% of the collected dopamine analysis imaging (i.e. PDR19) dataset for training process and 20% for the validation/testing process using random cross validation experiments. Besides, the rest of other system development are provided in Table 2, below.

TABLE. I. SUMMARY OF SYSTEM DEVELOPMENT CONFIGURATIONS

Development Items	**Description**
Training/Testing Model	Transfer Learning via DarkNet-19
Execution Environment	CPU + GPU/Auto
Input Image dimensions	256 x 256 x 3
Solver Approach	Stochastic Gradient Descent (SGD)
Loss Function Computation	Cross Entropy Loss Function
Binary-Classifier technique	Onevsall (one-vs-both classification)
Classification Learner	Linear learner algorithm
Validation Frequency	10-Fold Cross Validation
Max number of Epochs	25, with Shuffling at Every Epoch
No. of iterations per Epoch	100, accumulated 2500 iterations.
Mini Batch Size	32
Initial Learning Rate	0.01 with Momentum of 0.9
L2Regularization	0.0001

IV. EVALUATION AND DISCUSSION

A reliable auto-recognition deep-learning model to classify the weather condition images with high-level of classification accuracy, precision, and recall. To enhance the performance of feature extraction and learning, we have utilized the power of transfer learning technique with fine-tuning of the recognized deep ResNet-18 CNN pretrained on ImageNet dataset. The developed model uses the multi-class weather recognition dataset with 75% of the images used for training and 25% used for testing. Actually, the proposed work provides an inclusive framework model for multi-class image classification applications from input layer to the output layer. Finally, based on the comparison with other related research in the field, the obtained results outperform the results of existing automated classification models for weather conditions images.

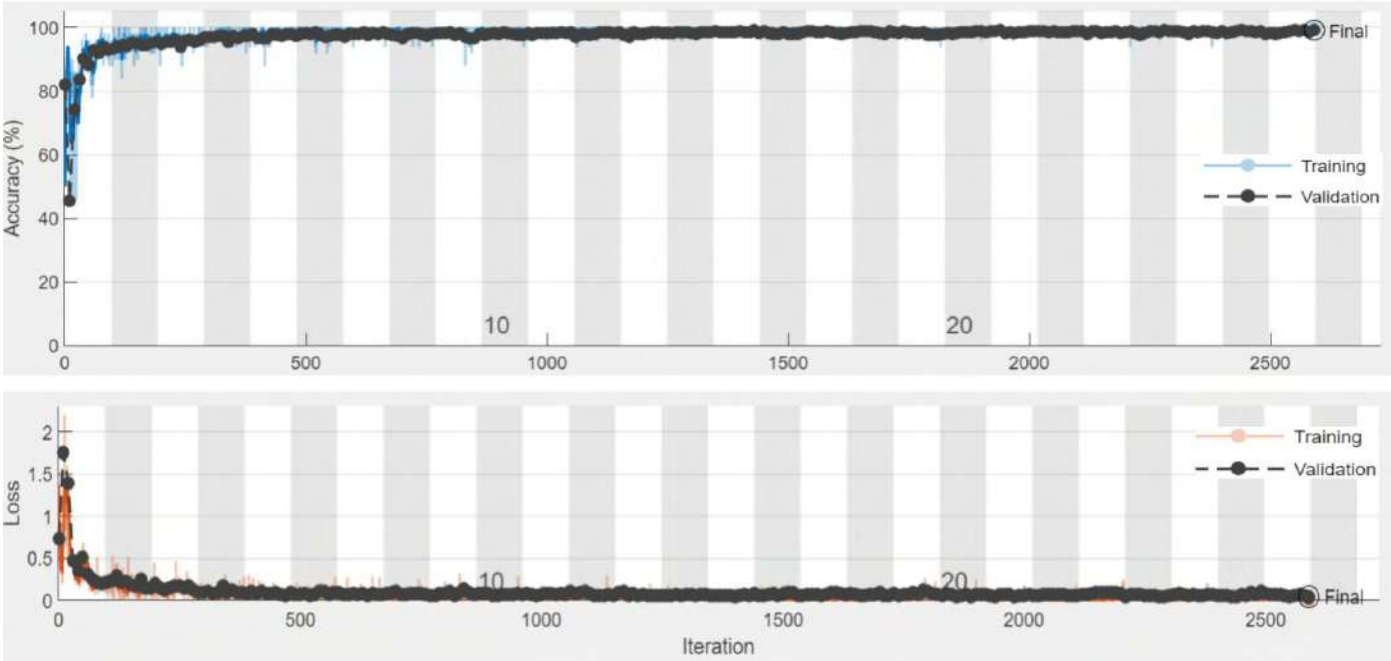

Fig. 4. Trajectories of {Identification Accuracy, Identification Loss} vs. Number of Epochs for training and testing datasets

The effectiveness of the PDR identification model can be measured using several performance assessment factors including the number of true positives samples (NTP), the number of true negatives samples (NTN), the number of false positives samples (NFP), the number of false negatives samples (NFN), the identification precision percentage (IPP), the identification sensitivity percentage (ISnP), the identification specificity percentage (ISpP), and the identification weighted average percentage (F1P). Hence, Table 1 shows summery of result obtained for the proposed PDR identification model.

TABLE II. SUMMARY OF EXPERIMENTAL RESULTS OBTAINED FOR THE AFORESAID EVALUATION METRICS

NTN	***NFP***	***NFN***	***NTP***	***IAC***	***IPP***	***ISnP***	***ISpP***	***F1P***	***IER***
605	6	5	590	99.10%	98.99%	99.16%	99.35%	99.08%	0.90%

Finally, to have additional perception into the benefits of our proposed solution, we have compared the performance measures of our identification system with the existing machine-learning-based dopamine release identification systems in terms of the identification accuracy factor. As a result, the benchmark evaluation revealed the preponderance of our proposed phasic dopamine release identification based DarkNet-19 model with greater identification accuracy using the PDR-19 dataset in comparison with other existing deep learning based models in the field by an improvement percentage (IM%) of ≈ (1.0% – 4.0%) and lower identification overhead.

TABLE III. COMPARISON WITH RELATED RESEARCH METHODS EMPLOYING SIMILAR DATA OF PHASIC DOPAMINE RELEASES.

Research Method		**Year**	**Classification Technique**	**Comments**	**Accuracy**
Russakovsky et. al.	[9]	2015	Inception v3 network + Roecker CNN	Hybrid, Complex design, Very high overhead	≈ 95.6%
Matsushita, et. al.	[7]	2019	Roecker CNN [5] + YOLOv3 Detectors	Hybrid, Larger dataset, with low harmonic mean	≈ 97.3%
L. Patarnello et. al.	[6]	2020	60-AlexNet CNN Networks + 3 YOLOv2 Detectors	Non-reasonable number of Combined CNNs, Complex design, Very high overhead	≈ 98.7 %
This Model		2021	DarkNet-19 Convolutional Neural Network	Employs Transfer learning from DarkNet-19, Low overhead	≈ 99.1 %

V. CONCLUSIONS

An automated intelligent identification model for dopamine analysis (DA) to classify the DA imaging for phasic dopamine releases has been developed and analyzed in this article. The model exploits of pretraind DrakNet-19 CNN with re-configuration of the simulation environment, the hyperparameters and the softmax layer (reduced to output 2-classes instead of 1000-classes). Also, the suggested model utilizes the images of dopamine analysis dataset, PDR2019, providing around 6,000 images, fairly balanced into two classes including “release images, “or “non-release images”. The images were distributed 80%: 20% for training and testing datasets respectively. Moreover, the identification model has been trained for 25 epochs each with 100 iterations scoring the best identification accuracy at 99.1% attained for the binary identification model. Furthermore, the identification model was validated through several other performance evaluation factors to achieve more perceptions of the model behavior identification precision percentage (IPP), the identification sensitivity percentage (ISnP), the identification specificity percentage (ISpP. In conclusion, the proposed identification model has beaten other available identification models for phasic dopamine releases in terms of identification accuracy and computation overhead.

***Abstract*—The use of drones for civilian purposes has recently grown. Drones are used for recreational, commercial, and governmental purposes. Today's drones can fly over a long range and many of them are equipped with cameras and a GPS chip to allow users to control them over a long range. This creates privacy and security concerns. For example, drones flying in restricted areas, or using the camera to spy on individuals and entities This paper addresses this issue and proposes a method to respond to violating drones by exploiting the lack of source authentication in GPS systems. In this paper, we propose a technique to ground and find the launch location of violating drones. This is done by invoking the rescue mode, then, employing Radio frequency software-defined radios to broadcast manipulated GPS signals following a novel algorithm that not only grounds violating drones but also find the drone's launch location, which is what unique about our approach. In this paper, we present the proposed method. Then, we perform both hardware tests and a simulation to demonstrate the proposed system's performance.**

***Index Terms*—drone, GPS, spoofing, bisection, algorithm**

I. Introduction

Recently there has been an increase in the use of drones by individuals. A drone is an aircraft without a human pilot on board but instead uses a ground-based controller. Drones are used by recreational flyers, enthusiasts, photographers, public safety, and governmental entities. The number of drones is on the increase from previous years. As of January 2021, there were 1,782,479 drones registered in the United States by the FAA. 71 percent of registrations were for recreational purposes. 27 percent of registrations were for commercial operation with 15 percent of those Americans having never flown a drone before [1]. The global drone market reached 22 billion dollars in 2020 with the majority of production being done in the United States and China[2]. Despite a large number of drones are airborne, privacy violations by drones are oftentimes overlooked. Modern-day drones are equipped with a camera and can fly incredibly far from where the user is piloting them. Drones can also legally fly above private property and photograph/record with little to no repercussions because they are treated as aircraft in the eyes of the law [3]. This can create what feels like an invasion of privacy for some who do not wish there to be a drone recording them or what is around them. On the other hand, drones create a security threat, as some drones can fly into restricted areas such as airports or sensitive facilities. An area where drones are not allowed to fly is known as " no drone zone". Despite the existence of some techniques that can ground violating drones, it is often difficult to catch the drone's pilot. Without any information on the pilot or where the drone came from, it allows for repeated offenses by individuals for violations.

Many of today's drones are equipped with a GPS chip. This allows the controller to track and manage drones over a long-range. GPS is the Global Positioning System, and is a global navigation satellite system that provides location, velocity, and time synchronization. It is used in products all across the world with the most common being cars. A utilization of GPS in drones is supporting the rescue mode or return to home functionalities. These functionalities enable the drone to return to the launch location if the video feed or the controller signal are lost. Despite, the functionalities enabled by GPS, GPS location can be exploited since there is no source authentication procedure in place to verify the source of GPS signals [4]. In other words, a GPS chip does not verify if the GPS signal came from a satellite or other malicious entities. GPS manipulation can be done by transmitting spoofed GPS signals using a radio frequency software-defined radio (RF-SDR). In this paper, we propose a method to ground violating GPS-enabled civilian drones in rescue mode and find the launch location of a violating drone. This is done by utilizing an RF-SDR to transmit manipulated GPS signals and using our algorithm to use the drone's response to the transmitted signals to find the launch location of the drone.

II. Background

Many modern-day solutions for dealing with such a problem would be physically taking the drone down using force, but there could be legal retaliation from the drones' pilot [5]. There is no one "correct" approach to solving the problem of eliminating a drone since there can be multiple solutions. One solution is to transmit jamming signals [6][7]. However, drones are equipped with rescue mode which enables the drone to return to the launch location making this only a short-term solution. Moreover, there have been techniques to detect jamming attacks on drones [8][9]. Other solution

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

includes sending a spoofed signal that overcomes the original controller signal [10]. However, such attacks can be overcome by utilizing cryptography to source authenticate the controller [11].Another method used exploits the optical sensors that are built into some types of drones. The reasoning for attacking the optical sensors was to make it appear that the drone was drifting and needed to remain steady using its built-in functions. Through projecting images onto the ground level, the drone cannot differentiate between what the actual surfaces are versus what is being generated [12]. This has more noticeable constraints in order to work as intended that have been noted by the creators of this study. The first is that the ground can be changed enough that the projected image seems natural to the drone, which heavily limits where this method would work. The next piece of information that must be known is how the drone will respond to the image, or more specifically the algorithm used. While information can be inferred about how the drone will avoid a potential crash, actions such as turns, accelerating, and magnitude changes can not be as easily predicted.

Other research work proposes targeting the network security of Wi-Fi-enabled drones [13][14]. These systems aim to break into the Wi-Fi system to hack into the drone and possibly control it. In fact, even extremely secure networking such as WPA2 can be broken through a third-party source by forcing a key reinstallation [15]. However, Wi-Fi attacks take a long time and might not be practical in case of a security violation. Other research works proposed spoofing GPS locations to take over unmanned aircraft vehicles (drones) and control their movements [16][17][18]. The spoofed GPS signals are used as an attack to confuse the original receiver and lock them out of locating the true coordinates While this is an efficient method to use, it has some drawbacks that are apparent with it. The first is that this gives no information about where the drone originated from, or who would have launched it. It is useful for the current time but still allows for more potential situations that would be similar in the future from the same location and launcher. As seen from the related work, none of the approaches attempt to determine the launch location of the drone, which is what unique about this work. The next section demonstrates the proposed method.

III. Method

In this section, we discuss the method used by the proposed system. In order to be able to determine where the launch occurred, the current location is used to evoke the rescue mode in the drone or GPS rescue mode in the case of a GPS-enabled drone. GPS-enabled rescue mode is intended to bring the drone autonomously in case of an emergency such as loss of video or radio link [19]. Therefore, rescue mode can be invoked by transmitting jamming signals on the frequency of the radio link or the video link. After the rescue mode is in action, the drone is going to return to the launch location at a constant speed and with bearing as shown in equation (1):

$$\theta = atan\frac{sin\Delta\lambda.cos\phi_2}{cos\phi_1.sin\phi_2 - sin\phi_1 cos\phi_2.cos\Delta\lambda} \tag{1}$$

Where $\Delta\lambda$ is the difference in longitude between the current drone's coordinates and the launch coordinates. ϕ_1 is the latitude of the current drone's coordinates. ϕ_2 is the latitude of the current drone's coordinates.

Consequently, the $x-$component and the $y-$component of the drone's speed is going to be:

$$\begin{aligned} x_{speed} &= A.cos\theta \\ y_{speed} &= A.sin\theta \end{aligned} \tag{2}$$

Where A is the constant speed the drone travels in when rescue mode is in action.

For equation (1), the current coordinates of the drone are known or can be obtained. The goal here is to find the coordinates of the launch location. In the proposed method, iterative launch coordinates longitude and latitude guesses are used to find the value of these coordinates. These values cause the $x-$component and the $y-$component in equation (2) to go to zero. In other words, the coordinate values that lead to that are the drone's launch coordinates. This is because in rescue mode the drone is going to stop moving once it arrives at launch coordinates. In the proposed method, the coordinates guesses are broadcasted by using a manipulated GPS signal through an RF-SDR. This is possible because unlike smartphones [20] a drone's GPS chip does not verify the authenticity of GPS signals it receives. Once the Drone receives the manipulated GPS signals, it recalculates its current GPS location and adjusts the travel bearing accordingly as in equation (2). This change in the bearing is going to be observed and is used to calculate the next guess. This process continues until the $x-$component and the $y-$component of the drone speed become zero. Once the components are discovered that means so are the launch coordinates.

It is important to minimize the number of coordinates guesses in the algorithm to decrease the time required for the proposed system to retrieve the drone's launch location. Therefore, an efficient root-finding method is required. In this paper, the bisection method is employed. The bisection method is a root-finding method that repeatedly bisects the interval defined by these values and then selecting the sub-interval in which the function changes sign, and therefore must contain a root. [21]. In the proposed method, the bisection method is applied to find the root of both equations in (2). The interval is determined by defining the maximum range from which the drone is launched from. Usually, civilian drones have a limited range measured in miles. This is because the distance the drone controller's signal can travel is limited as the radio signals attenuate with distance. These limits are going to be the initial interval for the bisection method. Then the interval is updated based on how the drone changes the travel bearing once it receives the manipulated GPS signal. A step by step explanation of the proposed is as follows:

1) The rescue mode is invoked by transmitting jamming signals either on the drone's controller frequency or the video feed frequency.

2) Once rescue mode is in action, the drone is going to return to its launch location, using a constant speed A and bearing θ as shown in (1).
3) The maximum longitude and latitude and the minimum Longitude and latitude for the launch location are determined based on the current location and the maximum drone's range.
4) The bisection algorithm starts with the interval [Minimum longitude, Maximum longitude] for the $x-$component of the speed and the interval [Minimum latitude, Maximum latitude] for the $y-$component of the speed. It is known that there is a root for equations in (2) in these intervals.
5) Manipulated GPS signals are transmitted according to the bisection algorithm according to the intervals above for first coordinates guess.
6) Once the drone receives the manipulated signals, it recalculates its current GPS location. This changes current longitude and current latitude. Consequently, a new θ is calculated as in equation (1) impacting the $x-$component and the $y-$component of speed in (2).
7) Based on the change of the values of the $x-$component and the $y-$component of speed (whether they increase or decrease). The bisection interval is adjusted. Then, new coordinates guess is transmitted.
8) Bisection intervals are adjusted according to the changes in the $x-$component and the $y-$component of speed. Based on the new interval, the bisection algorithm generates new guesses. This process continues until the $x-$component and the $y-$ are zero or very close to 0. The coordinates guess that leads to zeroing the $x-$component and the $y-$component of speed are the drone's launch coordinates.

As seen from the steps above, several guesses can lead to finding the drone's launch coordinates. Moreover, the correct guess causes the drone to land. As at this point the drone is deceived that it is at the launch location. The next section shows the experiments conducted to inspect the proposed method's performance.

IV. Experiments and Results

In this section, we present the experiments that were performed to analyze the proposed method's performance. Then, the experiment's results are analyzed and discussed. In this paper, we performed two experiments. The first, experiment inspects hardware performance for the RF-SDR that transmits manipulated GPS performance and for a drone's chipset. The second is a simulation to measure the proposed system's performance in determining a drone's launch coordinates.

A. Hardware Performance

The purpose of this experiment is to show a proof of concept on how manipulated GPS signals can lead the drone to update its rescue mode travel bearings. In this experiment, The RF-SDR used is the HackRF[22]. This RF-SDR was used to transmit manipulated GPS signals[23]. An Arduino chipset with a GPS-chip was used for the drone. Arduino GPS drone firmware was installed[24] on the Arduino Chipset. Arduino data was then logged into an SD. The logged data shows the Arduino calculating a cheated GPS location and adjusting bearing as shown in the method. This experiment was performed on the drone's chipset only (not a full drone). Moreover, the hack RF antenna and the chipset were in close proximity to allow transmitting the manipulated GPS signals at low power to avoid impacting the surroundings.

B. Algorithm Performance

The purpose of this experiment is to simulate the performance of the proposed method to find a drone's launch coordinates. The drone movement in rescue mode is simulated by writing a python function that takes transmitted manipulated GPS signal as an input and returns the bearing of the travel. Then, a second function was written that simulates the proposed method. First, it determines the bisection interval, for simulation purposes, the maximum range of the drone was considered 1 mile. Accordingly, the maximum and minimum longitude was determined using Haversine formula[25]. In the second function, the bisection algorithm calculates what GPS coordinates to be broadcast by the RF-SDR. Consequently, the transmitted coordinates are plugged into the drone rescue mode python function which returns the updated bearing. Then, the $x-$component and the $y-$component of the speed are calculated, and based on these changes the next bisection interval is calculated and transmitted. This algorithm iterates until the difference between the guessed launch coordinates and the actual launch coordinates is less than an error of 1 percent. Since the bisection method is a root finding algorithm, the run-time for the implemented function is $O(log_2 N)$, where N is the range of the drone. Fig. 1 shows how the algorithm closes into the launch coordinates as it iterates. Fig. 2. shows how the $x-$component and the $y-$component go to zero as the algorithm iterates. As can be seen from Fig. 1, the algorithm closes in the launch location as it iterates. In other words, it calculates the possible launch location in every iteration, with the accuracy of the calculation increasing as it iterates. This is important as it can allow law enforcement to provide a faster response to violators. As can be seen in Fig. 2, in the simulation, it took seven guesses to get the $x-$component and the $y-$component of the speed close to zero. An error of 1 percent was tolerated to a decrease in the number of iteration. The proposed algorithm still finds the launch coordinates in high accuracy even with this error included, as it gets the launch area determined within inches. Moreover, it is possible to get higher accuracy with more iterations but it would come at the cost of using more time which may not always be needed.

V. Conclusion

The drone market is expanding exponentially each year with more civilians purchasing drones. With the lack of regulations that monitor malicious drone-flyers behavior, privacy and security concerns are raised. Such violations can be in the form

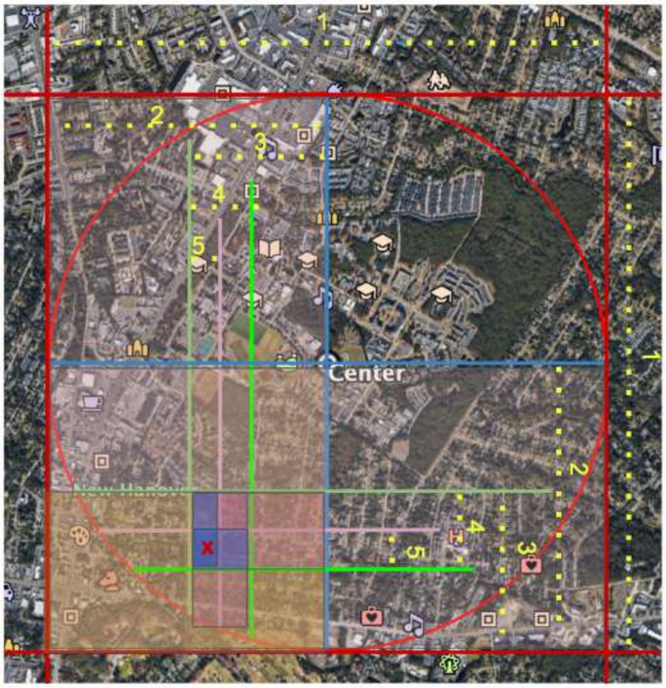

Fig. 1. Closing into the launch location as the algorithm iterates

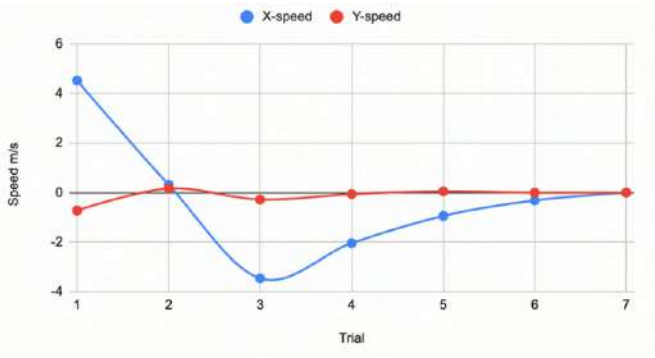

Fig. 2. The $x-$component and the $y-$component of the drone's speed going to 0 as the bisection algorithm iterates

of flying into restricted areas or violating people's privacy. This paper addresses this issue by proposing a scheme to counter violating drones. The proposed approach exploits the lack of source authentication in GPS systems and utilizes RF-SDR to transmit manipulated GPS signals according to the proposed algorithm to ground drones in rescue mode. Moreover, the proposed algorithm finds the drone's launch location, which is what is unique about our approach. In this paper, we explained the proposed algorithm's operation step-by-step, then ran hardware and simulation tests to validate the proposed system's performance. Future work will include working to minimize the number of guesses by the algorithm. Moreover, it will include testing the proposed method on flying drones by utilizing RF-SDR and directional antennas.

***Abstract*—The security of web-applications has become increasingly important in recent years as their popularity has grown exponentially. More and more web-based enterprise applications deal with sensitive personal and private information, which, if compromised, can not only lead to system downtime, but can also cause mean millions of dollars in damages to the organization. It is critical to protect web-applications from the constant onslaught of hacker attacks. Remote Code Execution (RCE) attacks are one of the most prominent security threats for software systems, especially Java-based systems. In the current study, we have studied the security update reports for RCE vulnerabilities published by two Java-based projects: Apache Tomcat and Android. We analyzed and categorized the code-fixes (i.e., patches/updates) that were applied to mitigate/fix fifty-one (51) RCE vulnerabilities in the two above-mentioned Java projects. Our analysis showed that a significant majority of the RCE vulnerabilities found in Java projects can be mitigated with just five (5) types/categories of code-fixes. Overall, our goal was to study RCE vulnerabilities in an effort to provide programmers with a handy list of code-fixes, thus making it easier for them to effectively mitigate known RCE vulnerabilities in their own Java-based applications.**

Keywords—software security, software engineering, vulnerabilities, remote code execution, open source software

I. Introduction

Software security bugs, also known as vulnerabilities, continue to be an important and potentially the most expensive issue affecting all aspects of our cyber society. There has been significant research effort toward preventing vulnerabilities from occurring in the first place, as well as toward automatically discovering vulnerabilities, but so far these results remain fairly limited [15, 16].

Remote Code Execution (RCE) has been recognized as one of the most harmful threats for web applications [1]. Although RCE is a special kind of cross-site scripting attack, RCE attacks have some variants including requiring state consideration of both server and client, both string and non-string manipulation of client inputs, and involving multiple requests to more than one server-side scripts [1]. Static analysis tools can be potentially used for detecting vulnerabilities [17, 18, 19]. Static code analysis tools locate vulnerabilities within source code using data flow analysis or taint analysis techniques [20]. As RCE attacks mostly depend on path conditions and involve both string and non-string operations, most static analysis tools fail to detect RCE attacks as they follow context free grammar and model only string operations [21, 22]. As a result, the false positive rates are high in those tools. On the other hand, the existing literatures do not focus on how RCE vulnerabilities have been resolved in real world applications so that developers can have a handy list of techniques to mitigate those problems.

In this paper, we focus on identifying the various ways developers (i.e., programmers) mitigate/fix RCE vulnerabilities that are reported in Java-based software systems (fixing a reported or known security vulnerability is more commonly referred to as security update or patch and is generally done by changing/adding/deleting lines of code).

In a sense, the primary objective of this study is to identify the most common types of code changes (i.e., updates/patches) that are applied by programmers when RCE vulnerabilities are reported in their software. To meet our objective, we reviewed different systems that publish security update reports and determine if there are any similarities in the RCE vulnerabilities and the updates that were implemented to fix them. In our research, we reviewed security updates reports for Apache Tomcat and Android. The major contributions of our work have been stated below:

1. The study is conducted on two major Java-based systems: Apache Tomcat and Android. The study has identified the most frequently used mitigation techniques for fixing RCE vulnerabilities that can be exemplary for Java based software developers.
2. We anticipate the findings in this study may be of assistance to the developers in avoiding frequent programming mistakes that can lead to RCE attacks.
3. The common security updates discussed in this paper will help the developers to mitigate (or fix) RCE issues and thus reduce the likelihood of RCE attacks in the future.

In Section II, we discuss some related works to our study. Section III describes our research methodology. Section IV focuses on data analysis and results. In Section V, we discuss the limitations of our work. Section VI provides a brief discussion on the implications of our findings and finally Section VII concludes the paper with some future plan.

II. Related Work

In this section, we highlight some existing works that focused on remote code execution (RCE) vulnerability analysis and detection.

Remote Code Execution is considered as a special kind of Cross Site Scripting (XSS) attacks [1]. Like XSS and SQL injection attacks, RCE occurs when invalid client-side inputs

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

are undesirably converted to scripts and executed [1]. Although researchers have already put significant efforts on identifying and mitigating XSS and SQL injections vulnerabilities [2-7], RCE vulnerability got very little attention due to its unique characteristics [1]. Zheng et al. [1] proposed a path and context sensitive inter procedural static analysis to detect RCE vulnerabilities in PHP scripts. They devised a novel algorithm featuring both string and non-string behavior of a program and successfully could detect RCE vulnerabilities in PHP scripts with less false positive rates [1]. In another study [8], the authors assessed the multi-variant code execution technique to prevent the execution of malicious code. The idea of multi-variant code execution is detecting any malicious attempt during run-time. While running two or more slightly different variants of the same program in lockstep on a multiprocessor, the variants are monitored and any divergence from the regular behavior raises an alarm indicating the possible anomaly. The trade-off between security and performance is the major limitation of this approach [8]. Hannes et al. [9] studied expert opinions on how three variable (i) non-executable memory, (ii) access and (iii) exploits for High or Medium vulnerabilities as defined by the Common Vulnerability Scoring System contribute to the successful remote code execution attacks. Both access and the severity of the exploited vulnerability were perceived as important by the experts; non-executable memory was not seen as relevant to RCE according to the study [9]. In [10], the authors presented a case study on RCE vulnerability and analyzed different types of RCE and their impact on applications. Another paper [13] proposed a new mechanism for trusted code remote execution. The method creates a trusted platform integrating the identity authentication, platform authentication and behavior authentication based on trusted computing technology, remote attestation and trusted behavior for remote code execution [13]. There are some other research studies on remote code execution which focused on remote code execution vulnerabilities in specific domains or platforms [11, 12, 14].

Overall, there is a shortage of research on modeling of discovered security vulnerabilities to capture how and why an implementation fails to achieve the desired level of security. This paper analyzes some real vulnerable code and their fixes so that programmers can be aware of those frequently happened programming mistakes and are aware of their possible mitigation techniques.

More specifically, we focused on Java-based applications and identified common code changes/fixes that are used to mitigate RCE vulnerabilities (which has not been investigated in earlier research). Most of the previous studies either devised techniques to prevent RCE or detect RCE during runtime. Those studies lack in highlighting some common programming practices that are used by developers to fix RCE vulnerabilities. In our study, we present RCE updates/fixes so that developers can be guided during the maintenance phase and can ensure future software releases are secure.

III. Methodology

This section describes the Research Questions (RQs) and the data collection process for this study.

A. Research Questions

The following research questions were formulated to guide the data collection for this study:

RQ1: Do software systems suffer from Remote Code Execution (RCE) vulnerabilities more frequently when compared to the other types of security vulnerabilities?

RQ2: What types of patches (i.e., code-fixes) are usually added to mitigate the known RCE vulnerabilities in Java-based software systems?

B. Data Collection

The following paragraphs describe the data that we collected to answer the two research questions (RQs).

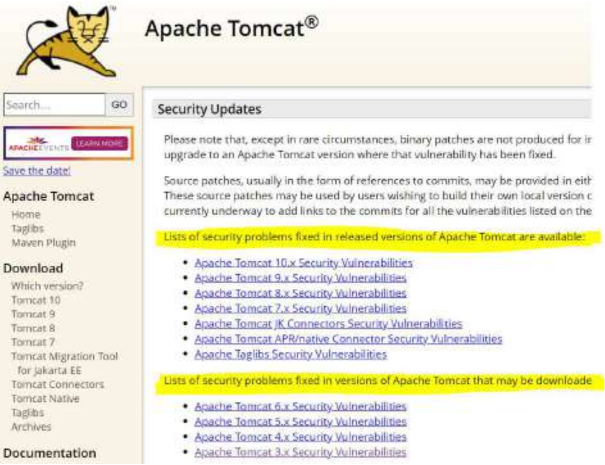
To answer *RQ1*, we collected the vulnerability-counts for the last 5 years (2015 to 2019) for the most common types of vulnerabilities (RCE, Denial of Service, Overflow, XSS, SQL injection) reported to a vulnerability datasource called CVE Details (https://www.cvedetails.com/).

With respect to *RQ2*, we focused specifically on collecting information about Remote Code Execution (RCE) vulnerabilities reported in Java-based software projects. Furthermore, we wanted to collect information about *how programmers fix the RCE vulnerabilities* reported in their Java-based software systems. Many open-source software projects publish *security update reports* on their project websites (for example, the security reports for Apache Tomcat are publicly available and can be found here: http://tomcat.apache.org/security.html).

We identified two such open-source Java-based software projects: ***Apache Tomcat*** (mentioned above) and ***Android*** (https://source.android.com/security/bulletin). An overview of the steps taken to collect the code-fixes (i.e., patched) applied to fix RCE vulnerabilities reported in each of the two systems is provided below:

1) Apache Tomcat Data Collection

To gather the data from Tomcat, we first went to the Tomcat's Security Reports page: http://tomcat.apache.org/security.html. This page displays a list of the known security vulnerabilities for each version of Tomcat as illustrated in Fig. 1. Tomcat Release 3.x was selected and all the Remote Code Execution (RCE) updates within this release were identified and reviewed. This was the most time and effort intensive step of our data collection process. Please note that our goal was to collect information regarding what kind of updates (i.e., patches or code-fixes) are applied by the programmers to known RCE vulnerabilities.



Security Updates

Please note that, except in rare circumstances, binary patches are not produced for ir upgrade to an Apache Tomcat version where that vulnerability has been fixed.

Source patches, usually in the form of references to commits, may be provided in eitl These source patches may be used by users wishing to build their own local version c currently underway to add links to the commits for all the vulnerabilities listed on the

Lists of security problems fixed in released versions of Apache Tomcat are available:

- Apache Tomcat 10.x Security Vulnerabilities
- Apache Tomcat 9.x Security Vulnerabilities
- Apache Tomcat 8.x Security Vulnerabilities
- Apache Tomcat 7.x Security Vulnerabilities
- Apache Tomcat JK Connectors Security Vulnerabilities
- Apache Tomcat APR/native Connector Security Vulnerabilities
- Apache Taglibs Security Vulnerabilities

Lists of security problems fixed in versions of Apache Tomcat that may be downloade

- Apache Tomcat 6.x Security Vulnerabilities
- Apache Tomcat 5.x Security Vulnerabilities
- Apache Tomcat 4.x Security Vulnerabilities
- Apache Tomcat 3.x Security Vulnerabilities

Author: markt

Date: Wed Sep 27 20:27:55 2017 UTC (20 months, 2 weeks ago)

Changed paths: 4

Log Message:

```
Add some additional checks required on Windows to keep all the checks in one place and to avoid exceptions later in the processing.
Includes utility class to determine if platform is Windows and performance test case for alternative implementations.

Includes updates after kkolinko review
- Correct comment
- Use correct regular expression match that makes regular expressions as even more optimal
- Improve (roughly x2) performance of invalid filename check
This is the fix for CVE-2017-12617
```

Fig.2. Tomcat: Security Update Details for a Sample RCE Vulnerability found in Tomcat

Therefore, for each RCE update found during our search, the revision number was selected as presented in the information page for that particular revision. Fig. 2 contains the information page for Revision 1809921. As can be seen in Fig. 2, each revision page contains a "path changed" link which in turn contains the line(s) of code that were added and/or removed to fix/mitigate the reported RCE vulnerability.

Table I presents a sample set of RCE vulnerabilities in Apache Tomcat that were identified and investigated during this study.

TABLE I. TOMCAT: SAMPLE SET OF RCE VULNERABILITY PATCHES/UPDATES THAT WERE FOUND AND STUDIED

Common Vulnerabilities and Exposures No. (CVE No.)	Affected Versions	Fixed version
2013-4444	7	7.0.39
2016-8735	7, 8, 9	9.0.0.M12
2017-12615	7	7.0.80
2017-12617	7, 8, 9	9.0.0.M15
2019-0232	7, 8, 9	9.0.17

2) Android Data Collection

Similar to Tomcat, for Android we reviewed the Security Bulletins page of the Android website (https://source.android.com/security/bulletin). From here we selected a year and month from the dropdown on the left side of the webpage as shown in Fig. 3. Next, we searched for RCE updates (see Fig. 4) and clicked on the selected reference number which brought up the information page for that specific update. The information page for a sample RCE update is shown in Fig. 5. By selecting the "diff" link (highlighted in yellow in Fig. 5), a page containing the code that was added and/or changed to fix/mitigate the reported RCE vulnerability was displayed.

Following the data collection process described above, we collected a total of fifty-one (51) RCE updates/patches (including both the systems, Tomcat and Android). We analyzed these patches to understand if there are certain frequently used patterns in these RCE updates/patches. The data analysis conducted using the above-mentioned 51 RCE updates/patches is presented in Section IV. B.

IV. DATA ANALYSIS AND RESULTS

This section presents the results and findings obtained from analyzing the data collected during this study. This section is organized around the two research questions (RQs) that were described in Section III.A.

Fig.5. Android: Security Update Details for a Sample RCE Vulnerability found in Android

A. *RQ1: Do software systems suffer from Remote Code Execution (RCE) vulnerabilities more frequently when compared to the other types of security vulnerabilities?*

As mentioned before, we hypothesized that RCE vulnerabilities are the most frequently found vulnerabilities in software systems. In order to evaluate our hypothesis, we collected the vulnerability-count data from the "CVEDetails.com" datasource. This datasource receives its vulnerability data through National Vulnerability Database (NVD) xml feeds provided by NIST (National Institute of Standards and Technology). We collected the vulnerability-count data for the top-5 vulnerability types for the recent five (5) years, i.e., from the year 2015 to 2019 (please note that currently the CVEDetails datasource has vulnerability-count data till the year 2019).

Fig. 6 provides an overview of the data analyzed for RQ1. As can be seen in Fig. 6, RCE vulnerabilities were reported more frequently than other types of vulnerabilities during the years 2015, 2018, and 2019. Even during the other years (2016 and 2017), RCE vulnerabilities remained in the top-2 most reported vulnerabilities.

Furthermore, in the year 2019, the count of reported RCE vulnerabilities (2277) was significantly higher than the count of next most reported vulnerability (1593 Cross-Site Scripting

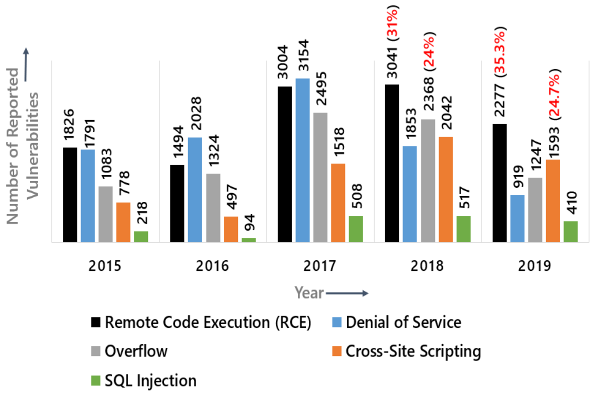

Fig. 6. Vulnerability-count by Type (for five recent years)

vulnerabilities were reported). Therefore, 35.3% of all the vulnerabilities reported during the year 2019 were of the type RCE (as can be seen in Fig. 6).

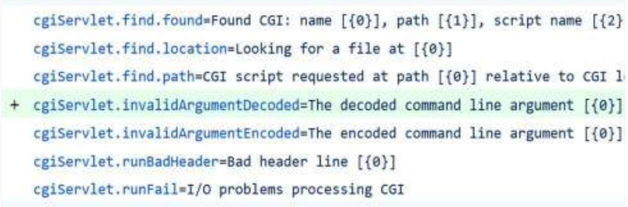
The data analysis described above and displayed in Fig. 6 clearly shows that software systems often suffer from RCE vulnerabilities more frequently than the other types of vulnerabilities. This in turn leads to a frequent need for programmers to fix RCE vulnerabilities through adding/editing lines of code in their software systems (i.e., adding updates/patches to mitigate the reported RCE vulnerabilities). This motivated us to identify some common patterns that are used by programmers when they are trying to fix the RCE vulnerabilities (with a focus on RCE vulnerabilities in Java-based software systems). The next section describes some of the patterns that we identified during this study.

B. *RQ2: What types of patches (i.e., code-fixes) are usually added to mitigate the known RCE vulnerabilities in Java-based software systems?*

As described in Section III.B (Data Collection), we identified a total of fifty-one (51) patches/updates that were made to fix RCE vulnerabilities in two Java-based software projects (Tomcat and Android). These patches are essentially changes/edits that made to lines of code to mitigate or fix a reported security vulnerability. Our primary goal with RQ2 was to identify and list some code-fix patterns that were used frequently to mitigate reported RCE vulnerabilities.

For a study such as ours, projects such as Tomcat and Android are a great resource as they highlight exactly what code changes/edits were made in order to fix a vulnerability. As an example, in Fig. 7, in order to fix the vulnerability titled CVE-2019-0232, the following variable was added: cgiServlet.invalidArgumentDecoded.

Similar to the process described above, we analyzed the updates/patches (i.e., code changes) that were applied to all fifty-one (51) RCE vulnerabilities that were part of this study.



```
  cgiServlet.find.found=Found CGI: name [{0}], path [{1}], script name [{2}
  cgiServlet.find.location=Looking for a file at [{0}]
  cgiServlet.find.path=CGI script requested at path [{0}] relative to CGI l
+ cgiServlet.invalidArgumentDecoded=The decoded command line argument [{0}]
  cgiServlet.invalidArgumentEncoded=The encoded command line argument [{0}]
  cgiServlet.runBadHeader=Bad header line [{0}]
  cgiServlet.runFail=I/O problems processing CGI
```

Fig. 7. Code Change (or Patch) Applied to Fix/Mitigate an RCE Vulnerability (CVE-2019-0232) in Apache Tomcat

Next, in order to find if there were similarities (i.e., patterns) between the coding changes that were made by the programmers in order to fix the RCE vulnerabilities, we converted the code-changes (patches/updates) into pseudocode. After converting the code-changes into pseudocode, we found that the code-changes (patches) could be classified into five (5) categories or patterns.

The five types of code-changes or updates (identified as a result of our analysis of 51 RCE vulnerabilities) that can be used to fix or mitigate a majority of RCE vulnerabilities are described as follows:

RCE Update Type 1 *– Check if the Packet Size is a Positive Integer*: For this update the programmer added an If Statement to check that the packet size was a positive integer (i.e., not negative or zero). That is, check if the source buffer contained enough bytes to copy the packet and check that the packet size does not exceed the destination buffer. The pseudocode for this type of update is shown in Table II.

TABLE II. RCE UPDATE TYPE 1

Pseudocode for RCE Update Type 1

```
if ((size <= 0) || ((read - sizeof(var1) - sizeof(var2)) < size) || (sizeof(msg)
< size)) {
        return -1;
}
```

RCE Update Type 2 *– Checking for the Proper Variable Size*: Another common update made by the programmers was that they checked for the proper size. In this If statement, they check if the variable is greater than the max size. And if the variable is greater than the max size, then set the variable to the max size. The pseudocode for this type of update is shown in Table III.

TABLE III. RCE UPDATE TYPE 2

Pseudocode for RCE Update Type 2

```
if (result->num_val > MAX_ATTR_SIZE) {
   errorWriteLog;
   result->num_val = MAX_ATTR_SIZE;
}
```

RCE Update Type 3 *– Applying an Offset*: In many reported RCE vulnerabilities, it was found that the buffer is not properly calculated causing a memory overflow. To fix this, they adjusted the calculation by dividing the offset. The pseudocode for this type of update is shown in Table IV.

TABLE IV. RCE UPDATE TYPE 3

Pseudocode for RCE Update Type 3

```
display->buffer = buffer + (offset / FACTOR);
```

RCE Update Type 4 – In another commonly used patch/update for RCE vulnerabilities, the programmer moved the If Statement to the top. The intention is to run the fail-check before creating a new class and assigning the size. The pseudocode for this type of update is shown in Table V.

RCE Update Type 5 *– If statement to prevent out of bounds in the function*: In another common patch/update, the programmer added an If statement to check validity of pSettings->noOfPatches to prevent out of bounds in the function, which can also cause the memory size to be negative.

The pseudocode for this type of update (i.e., Update Type 5) is shown in Table VI.

TABLE V. RCE UPDATE TYPE 4

Pseudocode for RCE Update Type 4

```
status = function();

    if (status != SUCCESS) {
      variable1 = NULL;
      return ERROR;
    }
variable1 = new class;
variable1->size = sizeof(object);
```

TABLE VI. RCE UPDATE TYPE 5

Pseudocode for RCE Update Type 5

```
if (noOfPatches > 0) {
  int target = array[x].targetStartBand + array[x].numBandsInPatch;

  int size = (64 - target) * sizeof(FIXP_DBL);
  if (!useLP) {
    for (i = startSample; i < stopSampleClear; i++) {
      function1(&array2[i][target], size);
      function1(&array3[i][target], size);
    }
  } else
    for (i = startSample; i < stopSampleClear; i++) {
      function1(&array2[i][target], size);
    }
}
```

As is evident from the above-mentioned five commonly used updates/patches, most of the code updates was to account for changes in size of boundaries and buffers. When the size was not properly accounted for, it caused errors in the application which in turn leads to a potential for bad actors to perpetrate a Remote Code Execution (RCE) attack.

Overall, we believe that the five update types that we have identified can provide a good starting point for programmers when they are trying to fix/mitigate reported RCE vulnerabilities in their Java-based software systems. We anticipate that a list of commonly used updates/patches (such as the one presented in this study) can improve the efficiency of programmers when they are trying to determine the best way to fix vulnerable code in their software system.

V. THREATS TO VALIDITY

In this section, we describe the major threats to the validity of the results found in this study.

One major validity threat is to the generalizability of our results. This is because we have studied RCE vulnerabilities and their respective updates/patches in a limited number of systems (two systems, Tomcat and Android). Owing to this, even though we have been able to locate some viable fixes (i.e., updates/patches) for RCE, they may not resolve each and every RCE vulnerability. Through our study we saw that many instances of RCE vulnerabilities can be mitigated by fixing buffering and boundary issues. At this time, our research is limited to Tomcat and Android, and thus there are likely other instances of RCE vulnerabilities and their respective updates/patches that we have not come across in our research.

Another limitation arises from the unavailability of public vulnerability datasets for software projects. Most software projects do not make their vulnerabilities and related fixes public (with a few exceptions such as Android and Tomcat). The scarcity of vulnerable dataset makes any vulnerability related research challenging.

The authors also note that our findings do not guarantee prevention against an RCE attack from a malicious actor (i.e., attacker). Our goal is simply to provide a readily usable list of updates/patches that can be potentially employed for fixing RCE vulnerabilities. The final decision about using the most appropriate update/patch has to be made by the programmer by conducting a thorough evaluation of the vulnerability they are trying to fix.

VI. DISCUSSION ON IMPLICATION OF RESULTS

In this section we provide a brief discussion about the implications of our findings on programming practices that lead to injection of RCE vulnerabilities. Although, our main goal in this study was to identify what kind of code-changes (i.e., updates/patches) are commonly used to fix RCE vulnerabilities, our data analysis also highlighted some weaknesses or issues in coding practices (when the software systems are being developed). The paragraphs below provide a discussion related to such bad coding/programming practices that lead to injection of RCE vulnerabilities when the software is being developed.

Overall, we found that the vulnerability landscape for remote code execution (RCE) needs to be approached with a persistent and analytical approach. We must not only rely on advisories but also correlate the weakness types and attack vectors that are associated with each vulnerability type. Having such insight is meaningful in making informed decisions as well as prioritize each vulnerability based on their risk factor. Although not every RCE instance will have the same weakness type, we learned that some weakness types still correlate with the root causes that were found for the associated vulnerability. Our research was able to successfully identify a root cause (size of boundaries and buffers) that frequently leads to injection of RCE vulnerabilities.

Our research has shown that the opportunity for RCE vulnerabilities can be reduced by simply ensuring that buffers and boundaries are developed with proper sizing. With this is mind, developers can develop more efficient code and avoid at least some of the on-going RCE attacks being deployed by hackers worldwide. This research has also highlighted that some cognitive issues such as carelessness or inattention when coding can lead to vulnerability injection. We intend to integrate existing research [23, 24, 25, 26] on human cognition and human error in our future research on vulnerability prevention and vulnerability mitigation. Section VII further highlights our future research directions.

VII. CONCLUSION AND FUTURE WORK

We have conducted a detailed analysis of the updates/patches (i.e., code-changes) that were applied by programmers to mitigate/fix fifty-one (51) RCE vulnerabilities reported in two Java-based software projects: Apache Tomcat and Android.

Based on our analysis, we proposed a list of five common updates/patches (see Table II through Table VI) that can be used to mitigate or fix a significant majority of RCE vulnerabilities in Java-based systems. We believe that our findings about these common RCE updates/patches can be handy and readily-usable when programmers are trying to determine ways or means to fix RCE vulnerabilities in their own system. Therefore, we anticipate that our list of common RCE updates (shown in Tables II to VI) will help in reducing the time that is required by programmers to fix RCE vulnerabilities that have been reported in their system. To our knowledge, this is the first study of its kind that has focused on analyzing RCE vulnerabilities and their relevant updates/patches.

The results from this initial investigation are anticipated to be beneficial in reducing RCE attacks and hence the results motivate further research in the area. We plan to extend our research to other programming languages and systems to determine if such update (i.e., code-fix) patterns exist in systems coded in languages such as Python, PHP, C#, etc. Once this research is extended to other languages and systems, the natural evolution of this research is to study more vulnerabilities such as Elevation of Privilege, Information Disclosure, and SQL Injection in the future. In closing, our intent is to continue to learn about the nature of vulnerabilities and how to mitigate/fix them so that we may enhance our research to help prevent future exploits or attacks.

***Abstract*—Very few models have been proposed for estimating the energy consumption of mobile robots based on fuzzy controller methods. In comparison to the classical controllers, using this approach offers many advantages. In this paper, a complete energy model has been developed in the Simulink tool to illustrate that. The estimated energy consumption is compared with the typical controllers. This comparison shows that energy losses in based-fuzzy Differential Wheeled Mobile Robot are 2.51 % per actuator less than the others. This model is more accurate and helps to optimize the consumption of power in mobile robots.**

***Index Terms*—Energy model, Fuzzy Controllers, Simulation, Differential Wheeled Mobile Robot.**

I. Introduction

Nowadays, mobile robots are commonly used in education, military, space, medicine, rescuing, agriculture, mining, entertainment, and many more. In these fields, mobile robots are expected to have good energy autonomy in order to perform long-range, long-term, and complex missions. These missions require a good energy model to predict the energy consumption of the robot with acceptable accuracy.

The Energy Consumption (EC) studies on mechatronic systems, especially mobile robots, are categorized into two aspects: hardware and software. Studies at the hardware level consider the EC characteristics of single-board microcontroller, sensor, DC motor drivers, communication system, and actuators to evaluate consumed energy or to design more energy-saving hardware components [1]. On the other hand, there are many studies in EC estimation and optimization of software for computer systems [2]–[4]. In this context, fuzzy set theory is a mathematical method that allows designers to achieve a lot of advances. For instance, the fuzzy logic-based model for Li-ion battery, considering state of charge and temperature effect on parameters is common-used for its simplicity and suitability for control and energy estimation [5]. The solutions are mature with years of development. Combining those strategies with the optimization of the mobile robot movements lead to design systems globally efficient.

Many researchers have been focused on designing models that can reduce energy consumption of mobile robots. Most of these works are based on the optimization of robot movement. Carabin et al [6], presented a survey of existing techniques based on Richiedei et al [7] classification. A. Stefek et al [8], firstly concluded, after reviewing many pieces of research, that these studies refer only to continuous or smooth curves, where the energy consumption of the robot is not mentioned. Secondly, it is difficult for the robot to track the given path smoothly in an uncertain or harsh environment. But,recent works [9], show that there is a great scope in applying newly developed algorithms such as Shuffled frog leaping algorithm, Cuckoo search algorithm, Invasive Weed Optimization, Bat Algorithm, Harmony Search Algorithm, Differential Evolution Algorithm, Bacterial foraging optimization Algorithm , Artificial bee colony Algorithm and Firefly Algorithm for navigation in an unknown complex environment in the presence of maximum uncertainty and these can be used to develop new kinds of hybrid approaches.

In this paper, we adopted a comparison approach to investigate the energy consumption for different controllers in a mobile robot. In this case, the losses contributions of DC motors, and motion strategies are taken into account to perform an accurate model.

II. Methodology

The original aim of our work is to identify the relationship between the control method adopted for the mobile robot and energy-efficiency improvement opportunities.

To illustrate this approach, firstly a total energy consumption model is adopted in the section II.A. Secondly, we based the controllers design, simulation, and comparison for tow driving Direct Current (DC) motor actuators of the mobile robot, on a study conducted by Shamshiri et al in [10]. In this study three control methods were used for the robot motion: (i) a common PID controller, (ii) a lead-lag compensator filter, (iii) a fuzzy logic controller. The control objective was the angular rate of the rotation shaft by varying the applied input voltage. More information about the control criteria can be found in the work cited above. However, we reported in section IV some results that helped us to design the controllers.

A. Total Energy Model

The total energy consumption of the mobile robot is divided into four parts and represented by equation:

$$E_{Tot} = E_{DC} + E_G + E_K + E_f \tag{1}$$

978-1-6654-4067-7/21/$31.00 © 2021 IEEE

Where E_{DC} term symbolize the Energy losses in DC Motors, E_G the energy losses in gearhead, E_K the kinetic losses, and E_f the energy losses due to friction.

B. Mobile robot kinematic Energy

To develop an energy model, a kinematic model of the robot is needed. A Wheeled Differential Drive Mobile Robot $(WDDMR)$ is used in this work. It has two driven wheels that are attached to DC motors and a rear castor which is added for balancing. The rotation of the wheels produces linear and angular motions of the robot. The kinematic model is given in Fig 1. Where r is drive wheel radius, b symbolize the axle length, x and y denote the position of the center of axle, ϕ is the angle between the robot axle and X- axis, $\dot{\theta}_L$ and $\dot{\theta}_R$ are the angular velocities of the wheels, which are related to the linear v and angular ω velocities of the robot by the following equations:

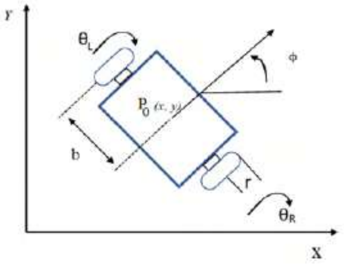

Fig. 1. Schematic diagram of the mobile robot.

$$v = \frac{r\left(\dot{\theta}_R+\dot{\theta}_L\right)}{2} \tag{2}$$

$$\omega = \frac{r\left(\dot{\theta}_R-\dot{\theta}_L\right)}{2b} \tag{3}$$

So the kinetic energy loss equation, can be expressed as same as in [11]:

$$E_k = \frac{1}{2}\left(mv\left(t\right)^2 + I\omega\left(t\right)^2\right) \tag{4}$$

Where m is the mass, and I is the moment of inertia of the robot.

In this study, we only focus on the kinetic energy losses of the robot.We have already studied the other energy losses in a previous work [12].

C. Modeling Energy DC motor

The DC motor behavior is characterized using an equivalent circuit model. Fig. 2 shows the DC motor circuit with torque and rotor angle consideration. The differential equations that describe the dynamic model are:

$$\begin{cases} L\frac{di}{dt} + Ri + K_\omega\dot{\theta} = V \\ I_s\ddot{\theta} + K_t i + f\dot{\theta} + \tau = 0 \end{cases} \tag{5}$$

Where:
V and i are the armature voltage and current.
R and L are the armature resistance and inductance.
f is the viscous friction coefficient.
τ is the dynamic load applied to the motor.
K_t is the motor torque constant.
K_ω is the voltage constant.
I_s is the motor shaft inertia.
$\theta = [\theta_R\theta_L]$ are the angular positions of the wheels.

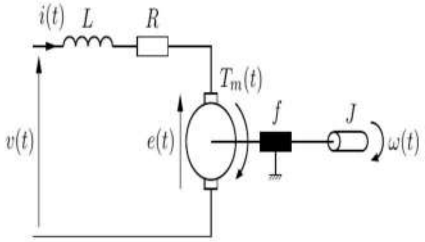

Fig. 2. Schematic diagram of the DC motor.

Using equation (5) we can describe the behavior of the motor speed for given voltage by the open-loop transfer function (6) in laplace domain with voltage $V(s)$ as input and shaft speed $\dot{\theta}\,(s)$ as output [13]:

$$\frac{\dot{\theta}\,(s)}{V\,(s)} = \frac{\frac{K_t}{I_sL}}{s^2 + \frac{(I_sR + fL)\,s}{I_sL} + \frac{fR + K_eK_t}{I_sL}} \tag{6}$$

We can deduce the relationship between the reference speed $\dot{\theta}_{ref}$ and the output speed $\dot{\theta}_{out}$ with a constant gain of K as:

$$\frac{\dot{\theta}_{out}\,(s)}{\dot{\theta}_{ref}\,(s)} = \frac{\frac{KK_t}{I_sL}}{s^2 + \frac{(I_sR + fL)\,s}{I_sL} + \frac{KK_t + fR + K_eK_t}{I_sL}} \tag{7}$$

III. Model Implementation

In order to estimate the energy for the mobile robot, a simulation was performed with SIMULINK. The result is displayed in Fig. 3. The structure of the model is:

- the upper branch shows DC Motor with Fuzzy Controller.
- In the middle we have DC Motor with Lead-lag Compensator filter.
- the lower branch shows DC Motor with PID Controller.

IV. Model Results

A. Energy model results

To set up the energy model that is represented in Fig. 3, the mobile and motor parameters of the mobile robot present in [10], [14] were used. These parameters are shown in the tables (table I, II and III). A typical structure of a fuzzy logic controller is shown in Fig. 3,Fig. 4 and Fig. 5. The final transfer function of the complete lead-lag compensator filter is:

$$G_{lead-lag}\,(s) = \frac{1.233s^2 + 25.88s + 98.6}{s^2 + 64.55s + 3.64} \tag{8}$$

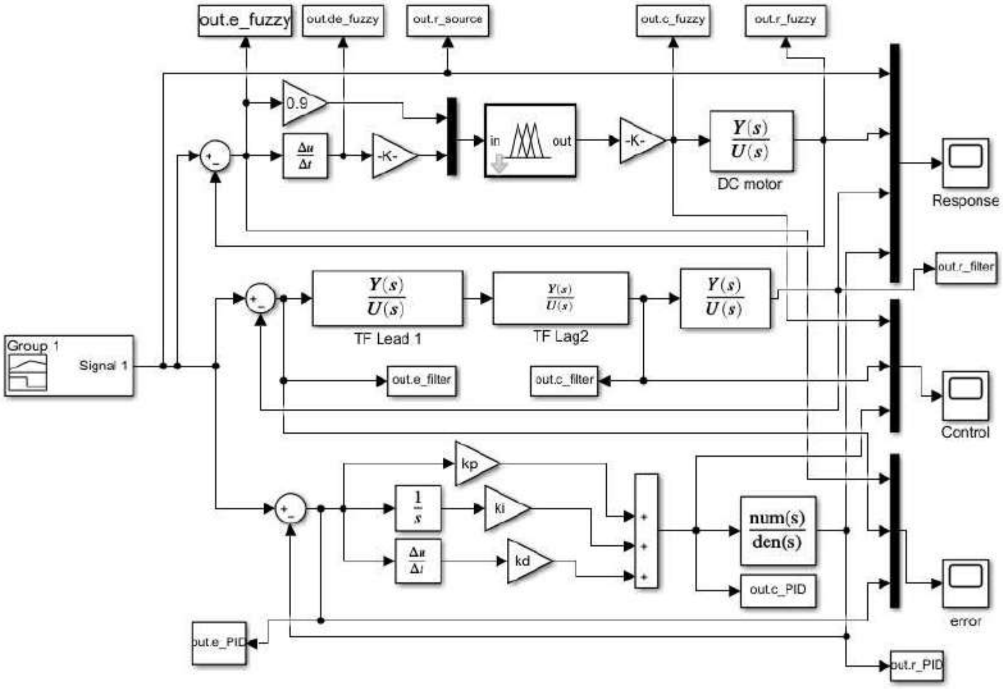

Fig. 3. Blocks diagram of controllers for DC motor speed

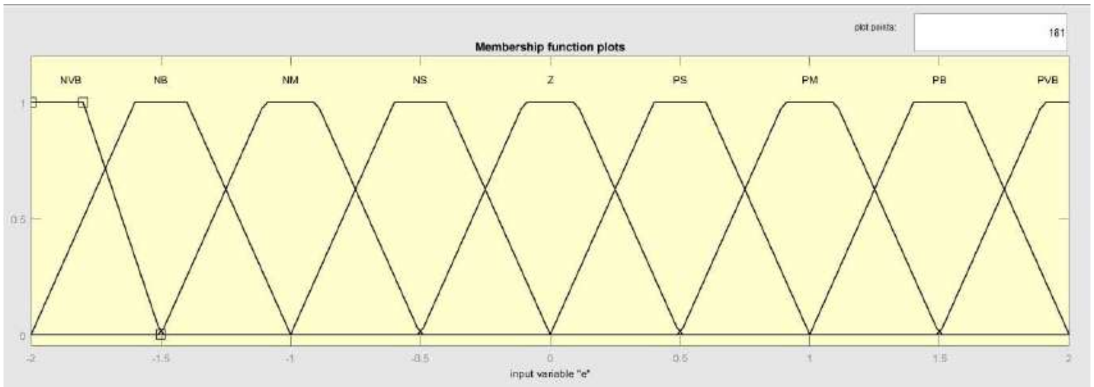

Fig. 4. Fuzzy logic first input variable, error

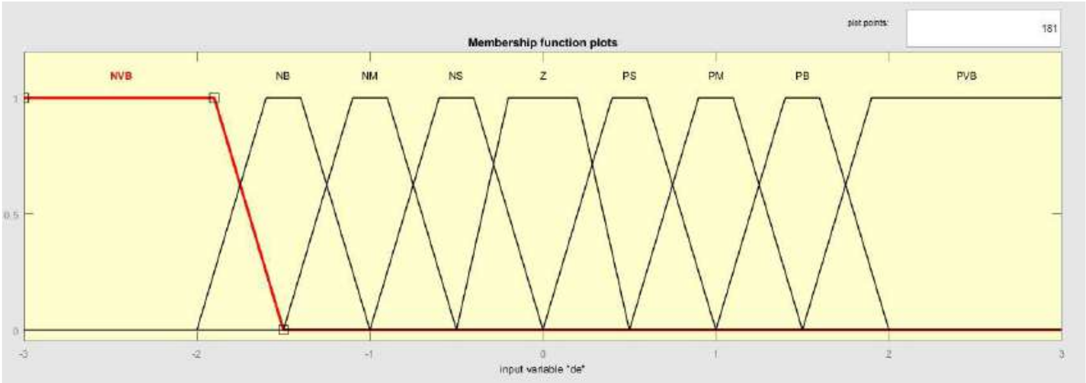

Fig. 5. Fuzzy logic second input variable, change of error

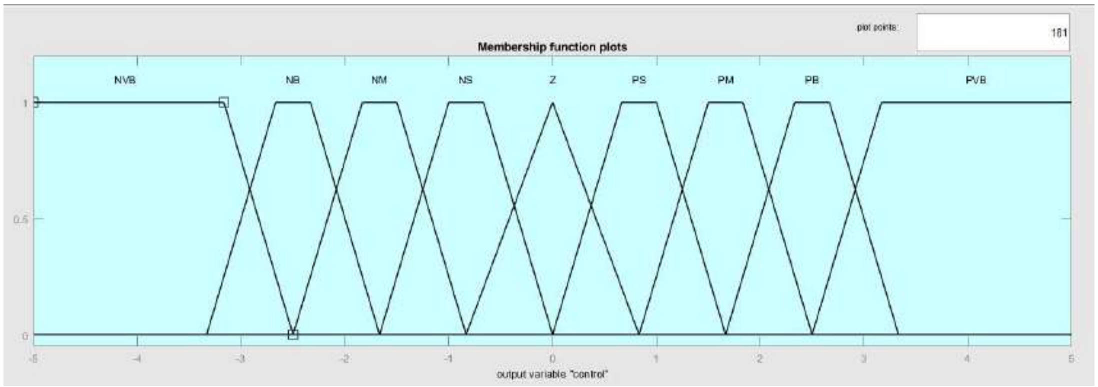

Fig. 6. Fuzzy logic output variable, control

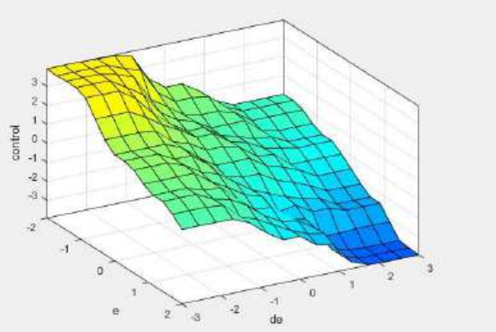

Fig. 7. Fuzzy logic rule surface

TABLE I
MOTOR PARAMETER OF THE WDDMR

Parameters	Values	Parameters	Values
R	0.7 Ω	K$_t$	0.88 Nm/A
f	0.035 Nm/(rad/s)	K$_\omega$	0.88(rad/s)/V
I$_s$	$0.0713 Kgm^2$	K	0.01

In this section, we present simulation to estimate the total energy consumption using as input a step velocity profile. The simulation tests were performed by driving the robot in a straight line on a flat surface. The robot accelerated from 0 to the desired velocity $(1m/s)$. It maintained this velocity for 1s and 10s respectively. As output, we have the angular velocity of the wheels. Fig. 8 shows the velocity obtained by the model, that were put in equation (4) to calculate total kinetic energy loss as shown in Fig.9 , Fig. 10 and Fig. 11. From the result shown in figure 8, we can affirm that the PID controller provides the smallest energy loss during the beginning of the movement, and this is due to the smallest overshot time. However, if the motion takes more than 10 seconds as in Fig. 9 and Fig. 11, the output trajectory provided by the fuzzy logic controller converges to steady-state faster with smaller tracking errors leading to energy saving up to 2.5% per motor.

V. Conclusion

A comparison of PID,Fuzzy controller and Lead-lag compensator filter for a differential wheeled drive robot mobile was performed using SIMULINK. An energy model is presented based on the dynamic motor and mobile robot parameters. Our model shows that we can achieve up to 2.51% per motor when the fuzzy controller is used. In this work, we have studied the control motion algorithm influence on energy consumption, we conclude that by implementing the fuzz controller in WDDMR we can improve the saving energy with more efficiency. In our future work, we plan to incorporate new kinds of hybrid approaches for controller algorithms into the model to provide a better energy consumption estimation.

***Abstract*—Multihoming technology is widely used to contribute reliability and performance improvement in network mobility by providing multiple connections to mobile routers. The mobile router may have to choose a suitable connection among available connections for the mobile node. In this paper, we propose a handover method for network mobility that utilizes the multihoming feature of a mobile router in SDN–based network mobility (SDN–MNEMO). We newly introduce an access router (AR) selection method to select the optimal AR for seamless handover in multihoming network mobility. The optimal AR is selected considering throughput of the backhaul links and downlink bit rate information of the available ARs in the mobility network. Using an experimental testbed, we present a thorough handover performance evaluation of our proposed scheme, and compare it with a conventional SDN–NEMO scheme. The results show that the proposed scheme outperforms the conventional scheme while achieving seamless handover. The handover delay in the conventional scheme is 7.15s compared to 72ms in the proposed scheme. Also, average throughput for the mobile node reached up to 950Kbps and it remained constant during the handover for the proposed scheme.**

***Index Terms*—Software–defined networking (SDN), multihoming, seamless handover, network mobility**

I. Introduction

Recently there has been a massive growth in size of mobile networks and number of mobile devices. In addition to increase in mobile applications, mobile consumers have been increasing every year [1]. Due to geographic location mobility, mobile devices may lose connectivity by changing their association to another access point. Researchers have proposed several hosts and network–based systems for mobility management. Internet engineering task force (IETF) has worked on mobile IPv6 (MIPv6) [2] for handling mobility in networks. In their proposal, a host–based system supports mobility of mobile devices. To improve management of mobility function in a network, proxy mobile IPv6 (PMIPv6) and MIPv6 were introduced.

Since the handover is done between mobile device and mobile access gateway (MAG), mobile devices must support features required for handling mobility. In PMIPv6, tunnelling has been used to transmit network traffic between the local mobility anchor (LMA) and an MAG [3]. Tunneling has been used to encapsulate and de–capsulate packets of network traffic at each endpoint of the tunnel. However, tunneling requires higher bandwidth and can cause performance degradation, such as longer delays. To overcome these issues, researchers have worked on group mobility scenarios. In order to provide group IP mobility management to users, IETF has worked to standardize a mobile network mobility protocol referred to as network mobility (NEMO) [4]. NEMO supports features for mobility of an entire network via mobile router (MR).

Multihoming is a method of connecting a host or network to more than one network. It has been used to increase stability of a network and improve network performance [5]. In an existing studies using multihoming, the authors performed handover by comparing the layer 2 signal strength after each care–of–address (CoA) was assigned to two interfaces [6]. Multihoming was required to make multiple connections that enables effective control to connects to multiple networks. Multihoming has been supported by using software defined networks (SDN). SDN provides easier management of an efficient and adaptable network architecture built supported by open source API Open–Flow. Open–Flow has been introduced as a standard communication interface defined between control and forwarding layer. Open–Flow has been developed to suit the high bandwidth and dynamic characteristics demands of current applications. It separates control and forwarding functions of the network to enable direct programming of network control and abstracts the underlying infrastructure for application and network services.

In conventional multihoming NEMO, two WiFi interfaces were considered at the MR to connect to multiple ARs for seamless handover. In general, the ARs for the handover are selected by the MR considering the received–signal–strength information (RSSI) of the available ARs. However, since the RSSI–based selection method only considers signal strength, it is difficult to provide a network environment suitable for a service because the network state of the corresponding AR is not considered. The corresponding AR may be overloaded and the mobile nodes (MNs) connected to it may receive degraded service after handover. To overcome this problem, we propose a new AR selection method.

In this paper, we propose a SDN–based network mobility architecture, SDN–MNEMO. Our proposed scheme provides seamless handover of MR by selecting the optimal AR considering the downlink bit rate information and throughput of the backhaul links of the available ARs in the mobility network. Rest of the paper is organized as follows. In Section 2 we briefly describe network mobility basic support protocol (NEMO–BSP) and SDN–NEMO. In Section 3, we explain our proposed scheme. In Section 4, we describe performance evaluation and in Section 5 we conclude the paper.

II. Background

A. NEMO–BSP

To support group mobility, MIPv6 was extended to NEMO–BSP [4]. In this scheme, a mobile router (MR) was installed in public or private transport vehicles. MR connects to an access router (AR) of a network domain in order to support seamless internet connectivity for MNs. MR works as an intermediary between the AR and active MNs of AR's network. MR provides continuous monitoring of attachment and de–attachment of MNs that connect and disconnect from the network. Multiple MNs can connect to a MR and a MR can connect to different ARs simultaneously to support network group mobility.

In a mobility scenario, users travelling in a vehicle and receiving service, connect to the internet via a MR installed in the vehicle. Consequently, in the case of a handover, only the MR performs binding update instead of all these users travelling in that group. This reduces the amount of communications between the MNs and the network. In such a case, MNs are not involved to supporting mobility which reduce processing at these devices. In addition to this, group mobility for the MNs reduced the complexity of network providers to implement the network. However, all network traffic was transmitted using tunneling between home agent (HA) and MNs. Therefore, network may experience congestion at the HA. This may degrade the network performance due to single point of ingress/egress for the network domain.

B. SDN–NEMO

SDN–based solution was introduced to support distributed mobility management (DMM) for NEMO [7]. Several advantages such as global network view, centralized network control, flexible routing methods, dynamic data plane configuration and management, of SDN were leveraged to support DMM. SDN–based network mobility architecture overcame several existing problems such as traffic transmisison without tunneling and centralized mobility management. Also, the mobility management features were no longer required at the AR.

In SDN–NEMO, the control plane is decoupled from the data plane. It provides centralized network control similar to efficient PMIPv6–based distributed network mobility management (EPD–NEMO). The data plane was constructed in a distributed architecture. The main communicaton protocol used between the control and data plane was the south–bound API such as Open–Flow. The data plane consists of software switches such as OpenVswitch (OVS) installed on the ARs that can be dynamically configured by the SDN controller at the control plane. Furthermore, network mobility status of MNs and MRs is tracked based on DMM. The solution provides seamless IP connectivity for MNs connected to the network. The mobility management features have been implemented at the application plane. The applications on the application were controlled by the SDN controller.

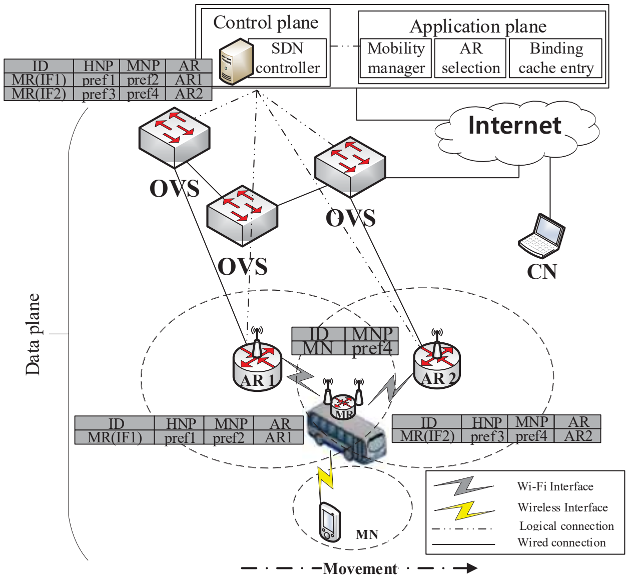

Fig. 1. An example of SDN–MNEMO

III. Proposed scheme

In this section, we describe the proposed system architecture, the attachment procedure of MR and MN, handover procedure of MR, and handover procedure of MN.

A. System architecture

An example architecture of SDN–MNEMO is shown in Fig. 1. The architecture consists of the control plane, the data plane and the application plane. The control plane consists of the controller. The data plane consists of the OpenVSwitch (OvS), access router (AR), mobile router (MR), mobile node (MN) and corresponding node (CN). The application plane consists of the mobility manager module, the AR selection module, and the binding cache entry. The mobility manager is responsible for providing mobility support for the MNs and MR. The AR selection module selects the optimal AR from available ARs in the mobility network. The binding cache entry is a database that stores the IP address of ARs, MR, and MN. The SDN controller allocates IP to MR and MN, and stores and manages mobility session information and location of MN and the gateway. Here, the gateway is referred to as the MR.

AR acts as an Open–Flow support switch that exchanges and manages Open–Flow messages with the controller. MR is used to transmit all traffic from MNs to/from the network.

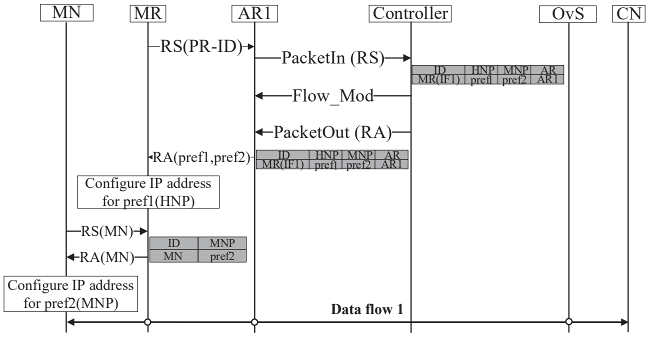

Fig. 2. Attachment procedure of MR and MN

Also, MR provides internet service to the MNs connected to it that is communicating within its coverage area. It also handles all signalling data and procedures for all MNs connected to it. MR can be connected to AR1 and AR2 through two WiFi interfaces. MN has a wireless interface to connect with the MR. It can use WiFi communication link to communicate with a CN. When the mobile vehicle moves from coverage region of an AR, i.e., AR1 to the coverage region of another AR, i.e., AR2, as indicated in the Fig. 1, handover is required for communication link of the MN.

In the proposed architecture, we newly introduce an access router (AR) selection method to select the optimal AR for seamless handover in multihoming NEMO. The optimal AR is selected considering the downlink bit rate information and throughput of the backhaul links of the available ARs. We refer to the available ARs as those in the coverage region of the MR. The information of the selected AR is sent to the MR via the AR. To handle the seamless handover for the MN, we consider two WiFi interfaces at the MR such as IF1 and IF2. When IP address allocation request is received at the controller from MR via AR, the controller allocates two IP addresses: one to the MR and other to the MN. The controller transmits Open–Flow "PacketOut" message containing the RA message to the AR. The RA message contains the IP addresses of the MR and MN. AR receives this "PacketOut" message and extracts the RA message and it then transmits RA message to the MR.

B. Attachment procedure of MR and MN

The attachement procedure of MR and MN is presented in Fig. 2. When a MR (IF1) connects to AR1 for the first time, it transmits a router solicitation (RS) to AR1 [8]. This RS message contains its own MR–ID value and a flag 'N'. This flag 'N' is sent to request a subnet prefix for the MN. On receiving this message, AR1 transmits 'PacketIn' message including RS message to the controller. The controller that received the 'PacketIn' message allocates HNP (Home Network Prefix) and MNP (Mobile Network Prefix), which is the subnet prefix of MR (IF1). It then transmits 'Packetout' message including router advertisement (RA) message to AR1. At the same time, the controller updates the flow table by sending the 'Flow_Mod' message to AR1. AR1 receives this 'PacketOut' message and transmits the RA message to the MR.

Fig. 3. Handover procedure of MR

The MR that receives the RA message configures its own IP using HNP (pref1). When the MN accesses the MR, the pre-allocated IP address from the controller, i.e., MNP (pref2), is notified to the MN via a RA message. Consequently, MN can communicate with a CN by transmitting data from AR1 via MR.

C. Handover procedure of MR

A handover is required when the mobile vehicle moves away from AR1 and is in the coverage area of AR2. The handover procedure of MR to a new AR is presented in Fig. 3. During mobility, the MR approaches the area that overlaps AR1 and AR2. The AR selection module receives the network status information, such as bit rate for downlink and throughput of backhaul link of available ARs via controller. It then processes the received information to select the optimal AR with the highest bit rate and throughput values.

Once the AR is selected, the information of the selected AR, i.e., AR–ID, is transmitted in a AR Selection Response message to the MR. The MR then transmits an RS message containing MR–ID to the AR2. AR2 transmits a Open–Flow "PacketIn" message to the controller containing the RS message. This information is transmitted to the mobility manager. The mobility manager extracts the binding cache entry information of MR and MN from the binding cache entry module.

The mobility manager compares current network status, i.e., prefix information of MR and MN. If there is some change in the network status, the mobility manager transmits this information to the controller. The controller receives this information and transmits the RA message to the MR through AR2 using Open–Flow "PacketOut" message. When the MR receives the RA message, the prefix in AR1 is set to depre-

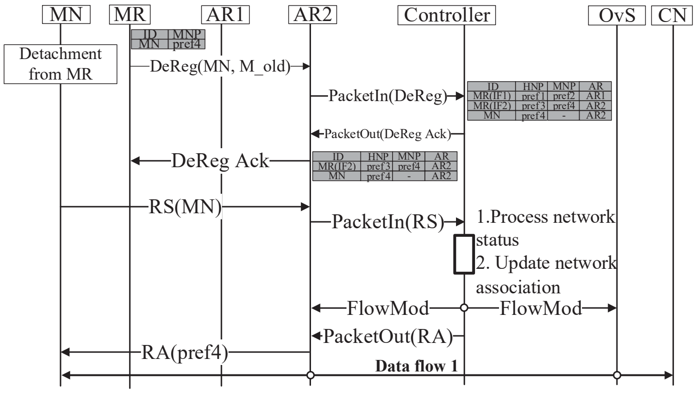

Fig. 4. Handover procedure of MN

cated, and the new prefix for use in AR2 is provided within the RA message. Consequently, the new prefix, i.e., pref4, used for AR2 enables session continuity, i.e., the MN doesnot experience session break for the existing communication. This enables route optimization and seamless connectivity for the communications for of MNs and MR during handover.

D. Handover procedure of MN

When the MN accessing the MR in a mobile vehicle leaves, it needs handover to a new AR of the same network provider. The procedure when the MN leaves the MR and hands over to the new AR is shown in Fig. 4. Since the MN is travelling in a group mobility scenario and MN is connected to the MR, we assume when the MR handovers to AR2, MN handovers along with. For mobility management, when the MN leaves the MR area, the MR sends a 'DeRegister message' to AR2 of the disconnected MN's ID and previous IP address. Upon receiving this, AR2 sends a 'PacketIn message' to the controller. Controller registers MN's information in binding caching entry. Following this, when MN is connected to AR2, it transmits an RS message which contains its ID and previous address. Upon receiving this, AR2 transmits the RS message to the controller through the 'PacketIn message'. Controller compares MN's prefix with existing prefix information, if it is the same prefix as AR2's MNP. In addition, the controller provides the optimal path by updating the flow table of AR2 and OVS through the 'Flow_Mod messages'.

IV. Performance evaluation

Performance of the proposed scheme has been evaluated using an experimental testbed. Wireshark packet analyzer version 2.6.10 and iPerf version 2.0.5 tools have been used to obtain the results. The experiment was repeated 30 times.

A. Testbed environment

To evaluate the performance of SDN–MNEMO, we build an experimental test bed with the ONOS controller and java–based application layer modules, i.e., AR selection module, mobility manager module, and the binding cache entry module. We configure desktop computer having Ubuntu operating system version 18.04 LTS 64 bits, as an SDN controller by installing ONOS Drake version 1.3.0 [9] on it. Also, the application layer modules are implemented on the desktop computer.For the data plane three OVS, two ARs with WLAN APs[1], and MR as shown in Fig. 5. OF–SW refers to an OVS switch and OF–AR refers to an AR. OF–SW and OF–AR enable the functions of the Open–Flow protocol by installing the OVS inside the WLAN AP. It is noted that the ONOS controller has a fixed global IP address, so OVS can connect with it via internet.

Ubuntu mate 18.04 version is installed on the open source Raspberry pi 3 which serves as an AR [10]. The AR has a OVS and WLAN AP installed on it . Open–Flow protocol version 1.3 is used as the communication protocol in the test bed [11]. We use Wireless8265 Intel dual chipset to create wireless interfaces at the MR. We use iptime N600UA WLAN USB adapters to create two WiFi interfaces at MR and AR. Raspberry pi is used to create OF–ARs by installing hostapd package in them [12]. We use laptops with Ubuntu 18.0.4 OS to work as MN and CN.

B. Experimental results

CN operates as the server and MN as the client. An UDP session is established between the client and the server. UDP transmission speed between MN and CN is set as 1MBps, and traffic is generated using the iPerf application. CN receives data traffic from the MN. In this paper, throughput is defined as number of successful bytes received at the client per unit time and is given as:

$$T_h = \frac{B_{t_{n+\Delta}} - B_{t_n}}{t_{n+\Delta} - t_n}, \tag{1}$$

where $B_{t_{n+\Delta}}$ and B_{t_n} are the bytes received at time $t_{n+\Delta}$ and bytes received at t_n. The throughput of CN for SDM–MNEMO for a sample pass during handover between AR1 and AR2 is shown in Fig. 6. In the conventional scheme, it is observed during handover that in the interval [25s,32s] of experiment time, throughput goes to 0. The throughput for the proposed seamless handover strategy reduces but does not drop the connection.

Fig. 7 shows the delay experienced by a MN during handover from AR1 to AR2 for a sample pass. Handover delay H_d is measured using:

$$H_d = P_{AR2_f} - P_{AR1_l}, \tag{2}$$

where P_{AR2_f} and P_{AR1_l} are the first packet received at AR2 after handover and last packet received from AR1 when the handover started. MN connects with CN using a TCP connection at transmission rate of 1MBps using the iPerf application. Data captured form CN using wireshark packet analyzer is analyzed to measure the handover delay. It is noted that the delay experienced by the MN from time 10s to 25s is nearly similar. It is because the test environment is identical for the proposed and conventional scheme and there is no interference

[1] Wireless APs operate on 802.11n

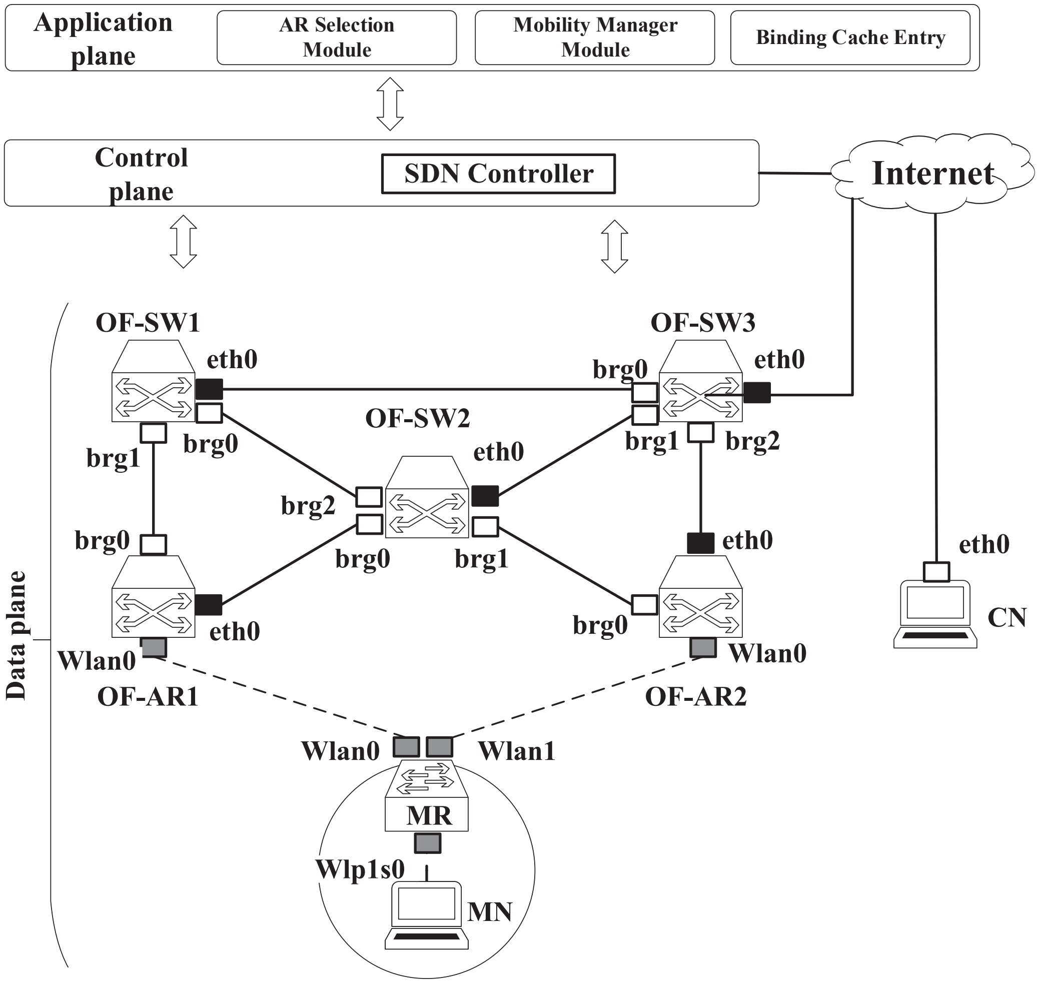

Fig. 5. Test bed architecture.

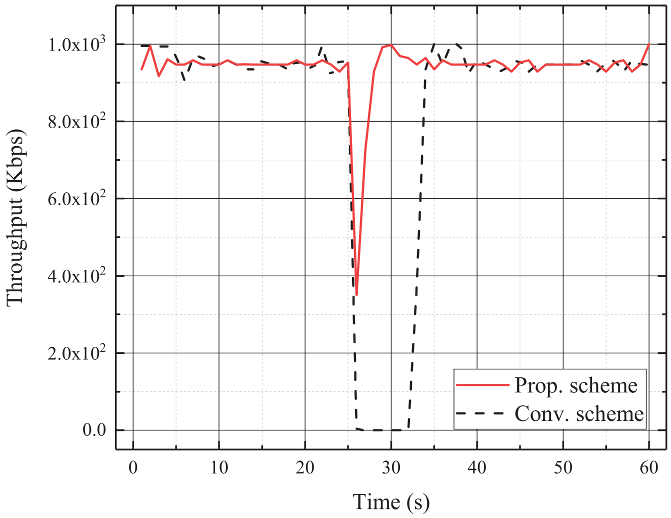

Fig. 6. Throughput of MN during handover

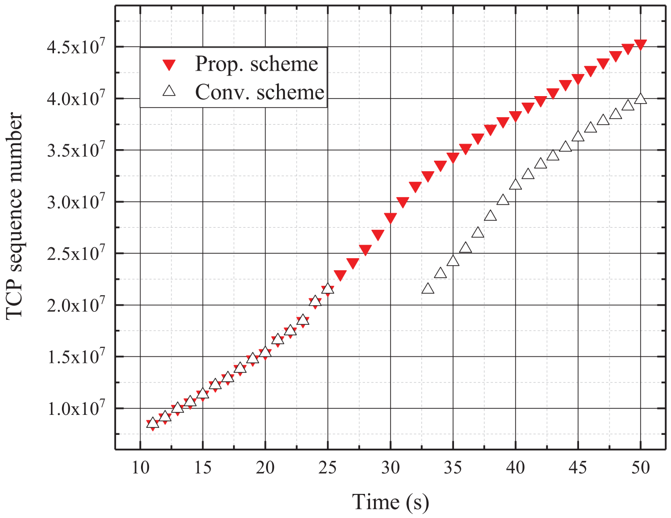

Fig. 7. Delay experienced by MN during handover

from any other access point/router. Consequently, there is insignificant difference in delay values from time 10s to 25s. The handover occurs at time t=25s approximately. At time t = 25.0125s, the CN receives the last packet with sequence number 21472393 via AR1, and at t = 25.0845s the first packet of sequence number 21473841 arrives at the CN via AR2. Therefore, the handover delay for the proposed scheme is 72msec. In comparison, the conventional scheme experiences handover delay of 7.15s. Also, the proposed scheme provides seamless handover, whereas in case of conventional scheme, the MN loses connectivity during the handover.

V. Conclusion

In this paper, we proposed a SDN–based MR multihoming scheme for seamless handover of MR and AR in a mobility scenario. We introduced an AR selection module at the control plane that selects an AR from available ARs for handover considering the downlink bit rate information and throughput of the backhaul links of the available ARs in the mobility network. An experimental testbed was implemented to measure the performance of the proposed scheme in terms of the handover throughput and delay. The proposed scheme outperformed the conventional scheme and the results showed that the handover delays for conventional scheme and proposed scheme were 7.15s and 72ms, respectively. For the conventional scheme, the connection was dropped and throughput went to zero during the handover. However, in the proposed scheme, average throughput for the mobile node reached up to 950Kbps and it remained constant during the handover. In case of mobility, the new prefix information of access router is transmitted to the mobile router, whereas the old prefix information is set to be deprecated. This enables session continuity and the throughput is maintained during handover.

***Abstract*—Student attendance tracking is a vital process in education. This process can be tiring and time-consuming. We believe it is possible to automate it using technologies available in the educational infrastructure and user smartphones. Today smartphones can sense several types of signals over the air using radio frequency technologies (e.g., Wi-Fi, Bluetooth, cellular signals, etc.). Furthermore, smartphones receive broadcast messages from transmitting entities and can measure the received signal strength. We believe that these signals can be utilized in the context of classroom attendance tracking, primarily because they can indicate the location of a user's device. The proposed system aims to have student smartphones in the classroom generate "location proofs" based on the radio frequency fingerprints scanned by their devices, which are later used to verify their locations. In this paper, we propose the utilization of Wi-Fi access points in buildings on school campuses in conjunction with the instructor and student smartphones to build a zero-effort and privacy-preserving attendance tracking system. Our system is unique as it does not require any effort from users in the system. Moreover, it is privacy-preserving, as the App server has no information about user identities nor class locations.**

***Index Terms*—Class attendance, tracking, Wi-Fi, Privacy, zero-effort**

I. Introduction

Attendance tracking is necessary for both students and instructors. If students miss lessons they lose out on information essential to their learning that may be the basis for future classes. On the other hand, instructors also suffer. It is difficult for instructors to determine whether the course material is being taught adequately without student feedback. Studies indicate a strong positive correlation between attendance and grades, with mandatory attendance policies having an additional positive effect [1]. One randomized experiment conducted in a class of 114 students yielded an improvement of 9.4 to 18.0 percent on exams, depending on the frequency of attendance [2]. This observation makes streamlining attendance tracking and incentivization paramount in enhancing students' overall academic performance. Traditional attendance tracking methods often exhaust a substantial portion of class time, preventing instructors from maximizing instruction time. Additionally, conventional strategies are particularly susceptible to dishonesty from students regarding truthfulness about attendance. The drawbacks of traditional methodology call for a more modern and foolproof approach towards the matter, especially with the technology available today in the educational infrastructure (e.g., wireless networks) and user devices (e.g., laptops, tablets, and smartphones).

Today, there has been increasing utilization of smartphones. According to Pew research center [3], 81 percent of Americans own smartphones. Smartphones can sense several types of signals over the air using divergent radio frequency technologies (e.g., Wi-Fi, Bluetooth, cellular signals, etc.). Furthermore, smartphones receive broadcast messages from transmitting nodes (e.g., network access points, cellular phone towers, etc.), in which it receives connectivity information about the transmitting nodes. Also, smartphones can measure the received signal strength of the broadcast messages transmitted b these entities. With the availability of these technologies in the classroom, we believe it is plausible to exploit them for class attendance. In this paper, we explore the feasibility of using existing technology in educational infrastructure to build an automated, zero-effort, and privacy-preserving class attendance system. The proposed system utilizes the Received Signal Strength Indicators (RSSI) measured in dbm that instructor and student smartphones collect from nearby network access points to determine room-level proximity between the student devices and the instructor device. Then, this room-level proximity determination is used to track student attendance.

II. Background

This section surveys previous attempts at utilizing technology to automate attendance tracking in educational settings. Hoo and Ibrahim [4] discussed using biometric recognition systems such as the iris, voice, fingerprint, and face to validate user information through systems that do not suffer from the same drawbacks as other techniques. However, their system requires integrating potentially expensive and complex hardware into an educational environment. Moreover, there are also significant security and privacy concerns associated with collecting biometric data from users. Another project proposes using location and voiceprint [5]. However, their system requires users to speak to verify their identity, which might cause distractions in the classroom. Other systems propose using QR codes [6], RFID [7], [8], and a secret code [9]. However, these systems need extensive interaction from students. Another technique utilizes an android application in which the user stores the GPS location and radius of a room [10]. Once the users enter the room they are clocked in and clocked out when they leave using GPS on their android devices. However, GPS suffers from performance limitation indoors and it would be challenging to use GPS-based systems in educational buildings as many of these buildings are multi-story.

Other research projects propose using Bluetooth and Wi-Fi. These technologies are a popular method for indoor localization. There are many research projects that produce indoor location for Wi-Fi using Wi-Fi fingerprint [11], [12], Bluetooth fingerprint [13], Wi-Fi beacons [14], [15], [16], and Bluetooth beacon [17]. Some of these systems were used in the context of attendance tracking using Wi-Fi [18] and Bluetooth [19]. However, these systems did not take any actions to ensure user privacy. Moreover, using Bluetooth beacons requires additional hardware that may not be available in the infrastructure. The related work demonstrates the difficulty of balancing user privacy and retaining the ability to verify the authenticity of attendance data without requiring extra effort from participants. Our approach utilizes previously integrated technology, does not send to the server any information that could lead to the session location, and perform attendance tracking without any effort from students nor instructors (we call it a zero-effort system).

III. Method

In this section, we discuss the system design and operations. As shown in Fig. 1., The proposed system consists of user devices and the application server. Then, we have the Wi-Fi access points in the infrastructure. The user devices scan Wi-Fi access points in the area. Then, the MAC addresses of the Wi-Fi access points are hashed and then uploaded along with the measurements to the application server. The application server compares the measurements and decides whether student devices are within room level proximity to the instructor device. Based on that, the attendance decisions are made and sent to the instructor device. Each element of the system is discussed in detail in the following subsections:

A. User device

In the proposed system, user devices are the student and the instructor smartphones with the mobile application installed. The mobile application has two types of users: the students and the instructor. Each student user has a unique userID, generated by hashing the student name with the course number used as a salt. During the class, the mobile application performs a Wi-Fi scan which returns the MAC addresses of nearby access points and their measured RSSIs. The devices then send the location proof to the application server along with the userID of the student. Location proof is shown in (1):

$$||_{i=0}^{n} Hash(MAC_{Api}).RSSI_{Api} \quad (1)$$

Where $||$ denotes concatenation. MAC_{Api} is the MAC address of access point i. $RSSI_{Api}$ is the RSSI measured for access point (dbm)i.

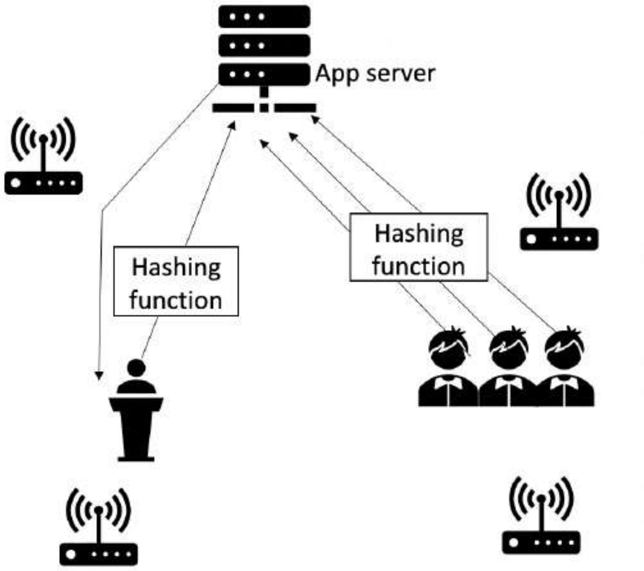

Fig. 1. System architecture

After the application server receives the data an attendance decision is made. The application server sends the decision to the instructor device where the userID is matched with the student name.

B. App server

As discussed in the previous section, the location proof is sent to the application server. The application server calculates the Euclidian distance [20] between every student datum and the instructor data as shown in (2):

$$D = \sum_{i=0}^{n} (InstructorRSSI_{Api} - StudentRSSI_{Api})^2 (2)$$

Where D is the Euclidian distance. If D is below a certain defined threshold, the attendance decision is present. If D is above this threshold, the attendance decision is absent. Finally, the application server relays userIDs and attendance decisions to the instructor device where userIDs are matched with student names.

The proposed system is zero-effort because no extra effort is required from the student to record attendance. All that it requires is the mobile app running in the background. Moreover, the proposed system is privacy-preserving as not the student names nor the MAC addresses of the access points are known by the application server. Thus, the server has no information about the identity of the students nor where the class is taking place.

IV. Experiment and Results

To test the proposed system, an experiment was conducted. The experiment took place inside a classroom in a campus building. We collected data from a total of 15 different locations in the building. Nine from inside the classroom and six from other locations in the building as shown in Fig. 2. Data collection was conducted using an android device with an application that scans for Wi-Fi access points and uploads the result to a server. A data point was collected every minute for one hour to provide sufficient data to analyze. To determine whether the student device is in the attendance range, the instructor device was set as a reference point. In the experiment, the instructor podium was used to collect the instructor data. The collected data was parsed in Python using the Pandas library DataFrame class. RSSI values for each access point MAC address were sorted for each data set. The top ten MAC addresses by RSSI were taken from the reference set. These MAC addresses were found in the other data sets along with their top ten RSSI values.

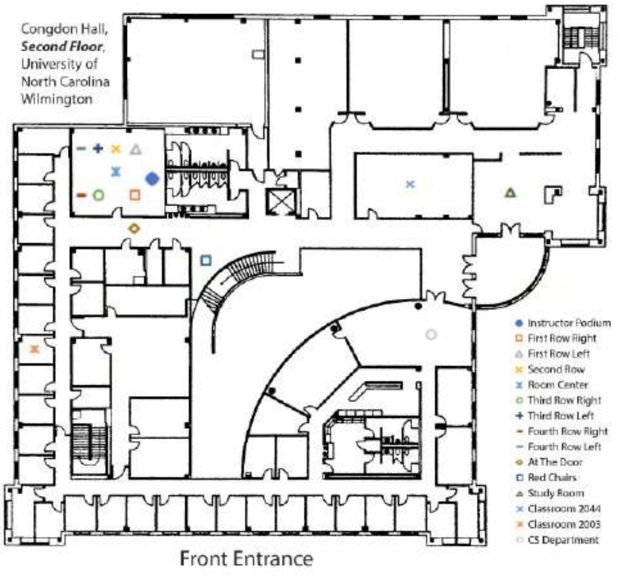

Fig. 2. Collected test points locations

After data collection, the ten access points with the highest average RSSIs were selected from the instructor podium as the reference set. Corresponding averages for the access points from the other datasets were aggregated into a single table to train the classifier. Visualization of the recorded data is shown in Fig. 3. Then, the Euclidean distance was calculated for each data set and reference point as in (2). The Euclidian distance between each test location and the reference set was calculated. An RSSI threshold value of 56.5 was found to provide the most accurate results. This threshold represents the maximum Euclidean distance value a data set can return to be classified as ”inside” the room. If a value over 56.5 is returned, the data is classified as ”outside” of the room.

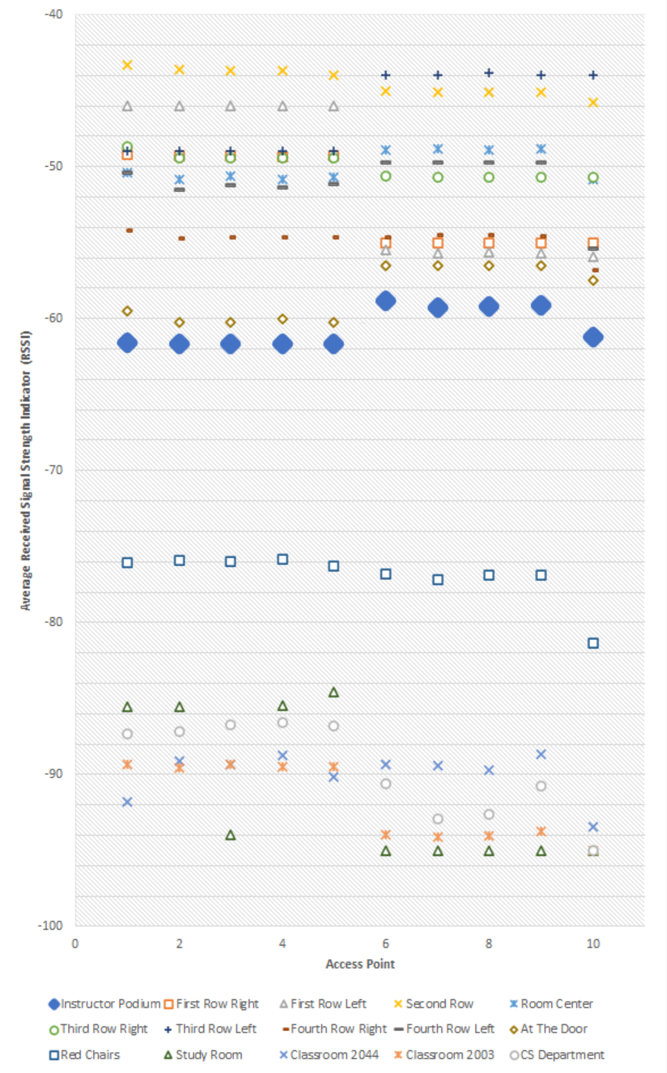

Fig. 3. Average RSSI for datapoints collected at different locations

To test our classifier, 198 test data points were collected. The Euclidean distance was calculated between each of the data points and the reference set. A threshold of 56.5 is considered to classify if the data point is inside or outside the classroom. The test results are shown in Fig. 4. Error reporting on the classification demonstrates that predictions for locations truly inside of the classroom were correct 100 percent of the time, while predictions for locations truly outside of the classroom were correct 98.75 percent of the time. The accounted for error is a result of the measurements recorded from the location at the door, which triggered a false positive in the classification due to its proximity to the classroom itself and the instructor podium.

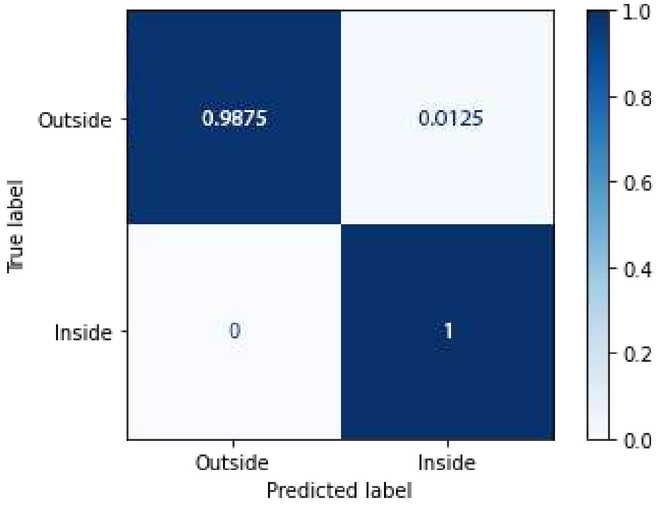

Fig. 4. Test results

V. Conclusion

Student attendance tracking is important in delivering quality education. To optimize the use of the class time we propose a system to automate class attendance tracking utilizing technologies available in the educational infrastructure and user smartphones. In the proposed system, student smartphones in the classroom generate “location proofs” based on the Wi-Fi RSSI fingerprints scanned by the user devices. The proofs are later used to verify user locations. Verification is completed by comparing the data from student devices with the data measured by the instructor device. Our system is unique as it does not require any effort from participating users, as scan and upload of data can happen in the background without any user involvement. Moreover, it is privacy-preserving, as the App server has no information about user identities nor class locations. Privacy is maintained by hashing the student names and access point MAC addresses and salting the student names before sending data to the App server.

***Abstract*—A novel radiation-hardened 4-transistor (4T) complementary metal-oxide-semiconductor (CMOS) image sensor pixel is proposed, employing a through-silicon-via (TSV) based metal-semiconductor-metal (MSM) photodetector as the photosensitive element. The presented pixel structure is designed and simulated in 0.18 μm CMOS technology. It is shown that deploying the TSV-based MSM photodetector decreases the pixel sensitive area to 3 μm^2 compared to conventional planar MSM ones, and enhances both the lower and higher wavelengths of the spectral response characteristic of the pixel as well. The designed pixel has a 2.75 μm radius circular structure, the dark current of 77 fA at 1 V reverse bias (at room temperature), a conversion gain of 116 μV.e^{-1}, a dynamic range of 58.62 dB, and an approximately linear spectral response in the range of 300 to 800 nm wavelengths of the incident light spectrum. The proposed pixel structure, enabled with a p+ guard ring, also demonstrates insignificant dark current degradation under gamma ray radiation of up to 1 Mrad.**

I. Introduction

A wide spectral response in parallel with high quantum efficiency (QE) performance is one of the key specifications of CMOS image sensor pixels required by a variety of applications such as astronomical, medical, as well as scientific imaging [1]–[3]. Due to the long absorption depth of light in silicon, which is near 10 μm for 800 nm wavelength of incident light [4], conventional pn-junction and planar metal-semiconductor-metal (MSM) silicon-based photodetectors (PDs) have the limitation to achieve a high spectral response at the whole visible spectrum simultaneously [5], [6]. In order to obtain a wide spectral response with high QE pixel, several attempts with different corresponding pixel structures have been made [7]–[11]. Since concurrently achieving both latter objectives in silicon-based PDs needs a relatively deep sensitive area, in [10] a lateral p-i-n photodiode was proposed deploying trenches to build a deep space-charge-region in the substrate depth, which could demonstrate an extended depletion region far below the photodetector's surface. On the other side, there are various individual attempts to enhance the spectral response of MSM photodetector implemented on silicon substrate [5], [6], [11]–[13]; however, these designs suffer from incompatibility with standard CMOS technology. In [14], a different type of MSM photodetector was proposed using modern TSV technology. This metal-trench-semiconductor photodetector (MTS-PD) creates a deep space-charge-region, where a high QE in UV to NIR range can be attained. It is noteworthy that this trench-like structure has been used in many applications such as metal-oxide-semiconductor capacitor [15].

Application of electronic devices under radiation environments could lead to displacement damage (DD) and total ionizing dose (TID) effects. These effect may potentially degrade electronic devices' performance [16]. The superiority of MSM photodetectors compared to pn-junction based ones has been demonstrated in terms of higher tolerance to TID effect under radiation environments [17], [18]. Deploying proper radiation-hardening design such as guard ring structures would help minimizing TID effect [19], although a combination of an MSM-based PD with the latter techniques could boost the performance of the radiation-hardened design.

In this paper, a 4-transistor (4T) CMOS image sensor pixel enabled by the MTS-PD as the sensitive area is proposed to reach a wider spectral response. Employing metallic-filled TSV-based PD to create a deep Schottky junction inside the silicon substrate enlarges the space-charge-region, and affords the absorption of low energy (i.e. high wavelength) photons as well.Furthermore, a simple p+ guard ring which surrounds the whole pixel design, along with the MTS-PD structure,

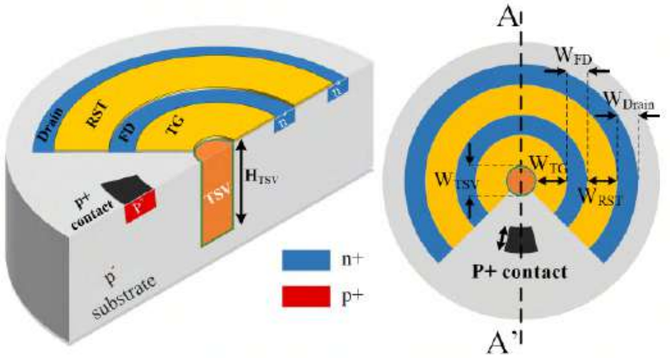

Fig. 1: Illustration of the proposed pixel structure. Top view (right), and perspective cross-sectional schematic view (left) along the AA' cutline of the proposed pixel structure.

demonstrates a radiation tolerance of up to 1 Mrad of gamma ray radiation.

II. Pixel Structure

Fig 1 illustrates the top and perspective schematic view of the proposed pixel including the photosensitive element - which is the TSV-based Schottky junction, floating diffusion (FD), transfer gate (TG), and the reset transistor (RST). The pixel is designed based on 0.18 μm standard CMOS process technology parameters, and simulations are performed using SILVACO TCAD simulator [20]. In order to make a Schottky junction inside the p-type silicon substrate according to the standard CMOS technology, Copper (Cu) can be used as a conductive metal to fill the TSV. The trench can be made, employing reactive ion etching (RIE) process, inside the substrate to etch the silicon for 10 μm in depth and 0.5 μm in diameter [21]. Creating deeper trenches are also possible using deep-RIE (Bosch DRIE process). Prior to filling the trench with Cu, the interior part of the trench wall should be covered with 50 nm of Titanium Nitride as a diffusive barrier to prevent Cu diffusion into the silicon, through a chemical vapor deposition (CVD) process [21]. For deeper trenches, this step can be done through an atomic layer deposition (ALD) process to ensure a complete step coverage of the trench interior parts. Following the MTS-PD design [14], the pixel structure is designed and simulated based on a cylindrical geometry which reduces the edge electric field distortion, and consequently produces a radial electric field around the Schottky contact (a radial deep space-charge-region). TG and RST are created using poly-silicon as a transparent metallic contact both with 1 μm width and a 270 degrees of a circle sector shape. The FD and the drain of the reset transistor (Drain) are defined sequentially with 10^{+19} atoms.cm^{-3} of n^{+} doping and metal contact. The p-type silicon substrate contact placement is designed through a 30 degrees sector shape, as illustrated in Fig 1 and is named p^{+} contact. The main geometrical dimensions of the proposed pixel are as W_{TSV}=0.5 μm, H_{TSV}=10 μm, W_{TG}=W_{RST}=1 μm, and W_{FD}=W_{Drain}=0.25 μm.

(b)

Fig. 2: (a) Circuit schematic of the proposed pixel; the dashed-line area which consists of sensitive area (MTS-PD), TG, FD, and RST is the circuit diagram of proposed structure. (b) Readout timing diagram illustration for one full cycle of pixel operation, including reset, illumination, and readout. The voltage of drain (V_{Drain}), the RST gate (V_{RST}), the transfer gate (V_{TG}), and the potential of MTS-PD (ψ_{MTS-PD}) and FG (ψ_{FD}) are illustrated in the timing diagram. The device has been illuminated between t_3 and t_7.

III. Results and discussion

A. Readout Timing Diagram

Fig 2(a) illustrates the circuit schematic and Fig 2(b) is a representation of the readout timing diagram in a full cycle of the pixel operation. During the reset cycle between t_1 and t_4, the RST and TG are both set to the high digital voltage level of 3.3 V, so that the MTS-PD potential well could be discharged from any charges stored during previous phases. Then, as the pixel is illuminated, the photo-generated carriers collection is triggered as soon as the TG sets to the low digital voltage level – from t_3 to t_7. During the illumination process and before it ends, a reset cycle will be conducted again — between t_5 and t_6 — in order to make the FD empty

(b)

(c)

Fig. 3: (a) Illustration of a complete cycle of one pixel operation in six steps including: (1) a prepared pixel after a reset cycle, (2) illumination and photo-generated charges storage, (3) transformation of charges to FD-node, (4) reading the FD-node, and (5, 6) a reset cycle; (b) Electron Quasi Fermi level when TG is off and pixel is ready to collect photo-generated charges; (c) Electron Quasi Fermi level when TG is on and photo-generated charges are being transferred to FD

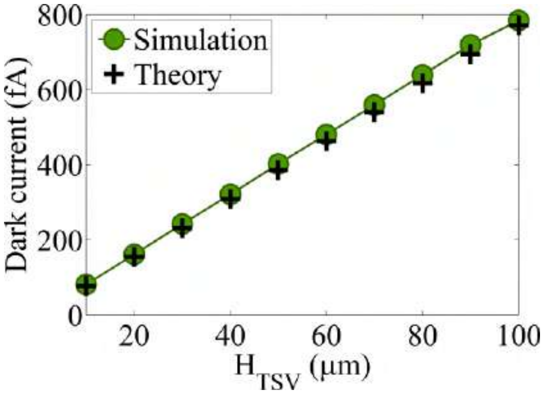

Fig. 4: Dark current evolution for different TSV depths. A linear increment of dark current versus the TSV depth is observed.

of any charges and to prepare this node for the next part of the readout cycle. Following this step, between t_7 and t_8, the stored photo-generated charges in the MTS-PD potential well will be transferred to the FD by lowering the TG potential barrier by setting the TG to a high-level value of V_{TG}, equal to 1.3 V. Albeit the high-level of TG is chosen to decrease the TG potential barrier but not to affect the potential level of the MTS-PD well, an approximately 0.15 V reduction in the MTS-PD potential level occurs due to the TG electric field effect. Simulation results of Fig 2 is based on 0.01 W-cm^{-2} of incident light power during 100 μsec illumination – between t_3 and t_7 [22]. The electrical potential drop in the MTS-PD under this incident light power is around 0.25 V, which is in correspondence with 0.76 V of electrical potential drop in the FD after transferring the stored photo-generated charges to the FD node. Fig 3(a) is an illustration of different steps during one full cycle of pixel operation including reset, illumination, and the FD-readout based on the readout timing diagram in Fig 2. Fig 3(b) and (c) show the 3D simulation results of the Electron Quasi Fermi level at two different scenarios, when TG is off (b) and on (c). The 3D simulation results demonstrate how lowering TG could facilitate the photo-generated charges transfer into the FD node through surface areas.

B. *Dark Current*

Simulation and verification of dark current for the designed MTS-PD has been previously investigated in [14]. Fig 4 illustrates the simulation and theoretical results of dark current evolution for different TSV depths. By the increase of the TSV depth from 10 μm to 100 μm, the dark current rises from 77 fA to 780 fA at 1 V reverse bias and 300 K temperature.

C. *Capacitance of MTS-PD and Floating Diffusion*

The dynamic range and the conversion gain calculation requires the exact capacitance value of MTS-PD and FD-node. Simulation results, showing the capacitance of the MTS-PD and FD-node, are illustrated in Fig 5. A 10 μm deep TSV shows a capacitance of 6.77 fF at 1 V reverse bias; the FD-node demonstrates a capacitance of 1.31 fF at 3.3 V reverse bias with 1 μm width and 270 degrees of a circle sector shape.

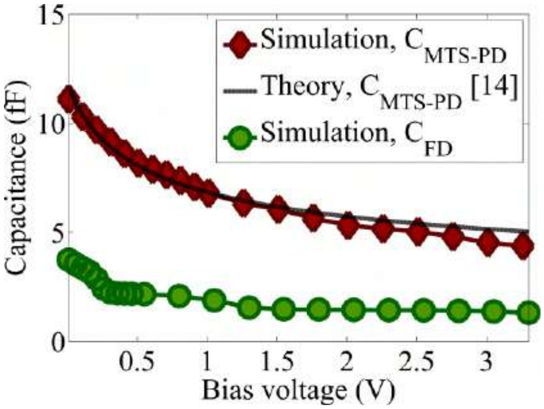

Fig. 5: The MTS-PD capacitance value attained by both simulation and theoretical analysis [14] as well as the simulation result of FD capacitance node under different bias voltage conditions.

Theoretical derivations to verify the MTS-PD capacitance are stated in (1) and (2):

$$C_{MTS-PD} = \frac{2\pi\varepsilon_{Si}L}{Ln\left(\frac{W+R_M}{R_M}\right)} \qquad (F) \tag{1}$$

$$W = \sqrt{\frac{2\varepsilon_{Si}\left(V_{bi} - V_a - {KT}/{q}\right)}{qN_A}} \qquad (m) \tag{2}$$

where C$_{MTS-PD}$ is MTS-PD capacitance; ϵ_{Si} is the silicon permittivity (due to standard CMOS usage); W is the depletion width around the TSV; V_{bi} is the built-in potential; V_a is the applied reverse bias; K is Boltzmann's constant; T is the temperature in Kelvin; q is the electron charge, N_A is the semiconductor acceptor concentration density; and L and R_M are the depth and radius of the TSV [4].

Enlarging the TSV depth increases its capacitance value and provides a greater charge storage well, which consequently leads to an enhancement in the spectral response at higher wavelengths. On the other hand, larger FD-node capacitance would result in a lower conversion gain value. Accordingly, from the design perspective, the FD-node capacitance value is determined based on the MTS-PD capacitance (small enough, 1.31 fF at 3.3V reverse bias, to obtain a considerable conversion gain, 116 μV-e$^-$); since higher conversion gain is advantageous toward minimizing the signal to noise ratio [23].

D. Conversion Gain

Conversion gain which presents the image sensor sensitivity is defined as the output generated signal voltage per photogenerated charge, and can be formulated as (3):

$$CG = \frac{q}{C_{FD}} \qquad (\mu V/e^-) \tag{3}$$

where C$_{FD}$ is the FD capacitance and q is the electron charge [24]. Since the C$_{FD}$ as shown in Fig 5, at 3.3 V reverse bias is calculated as 1.31 fF, the conversion gain will be 116 μV/e$^-$.

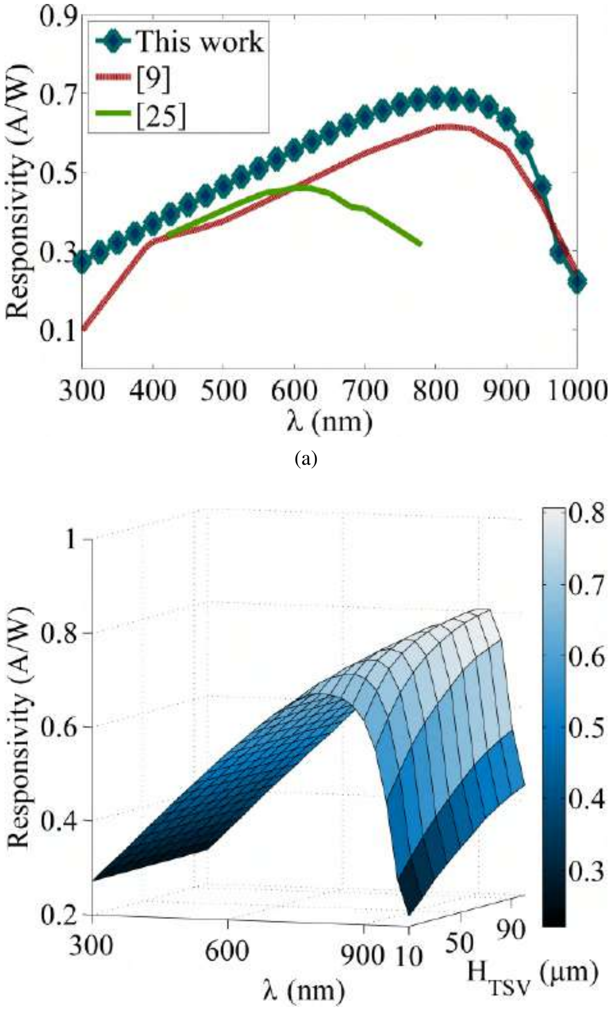

Fig. 6: (a) Spectral response derivation of the proposed pixel with 10 μm height of the TSV in comparison to [9] and [25]. (b) Simulation result of spectral response for different TSV depths (H$_{TSV}$) over different wavelengths of incident light (λ); as the TSV depth increases, the spectral response of higher wavelengths would be enhanced.

E. Spectral Response

Spectral response, or responsivity, of the proposed pixel–which is the ratio of photo-generated current to incident light power [4]–is compared with [9] and [25], two of the high spectral response image sensors implemented in CMOS standard technology. The result of this comparison is illustrated in Fig 6(a). The proposed pixel with a 10 μm deep TSV shows higher spectral response over the whole visible wavelengths; furthermore, TSV deepening causes an enhancement at higher wavelengths of spectral response because of the uniform depletion region extension within the silicon depth. Simulation result of the spectral response for different TSV depths (H$_{TSV}$) is also illustrated in Fig 6(b). In order to obtain such a result, several simulations with different depths of the

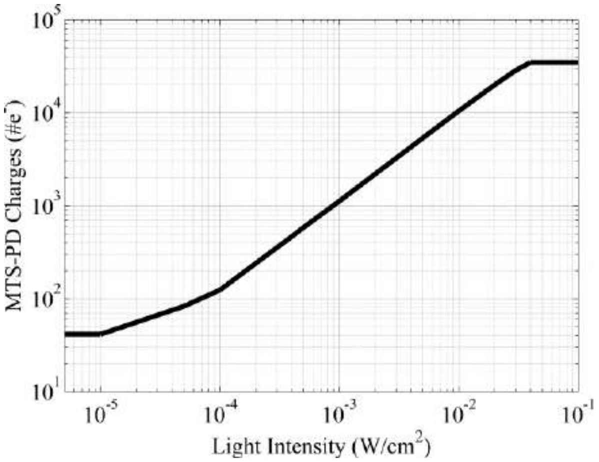

Fig. 7: Illustration of the photo-generated charges as a function of light intensity. The difference between minimum, dark current, and maximum, saturated-well of photodetector, is defined as the dynamic range.

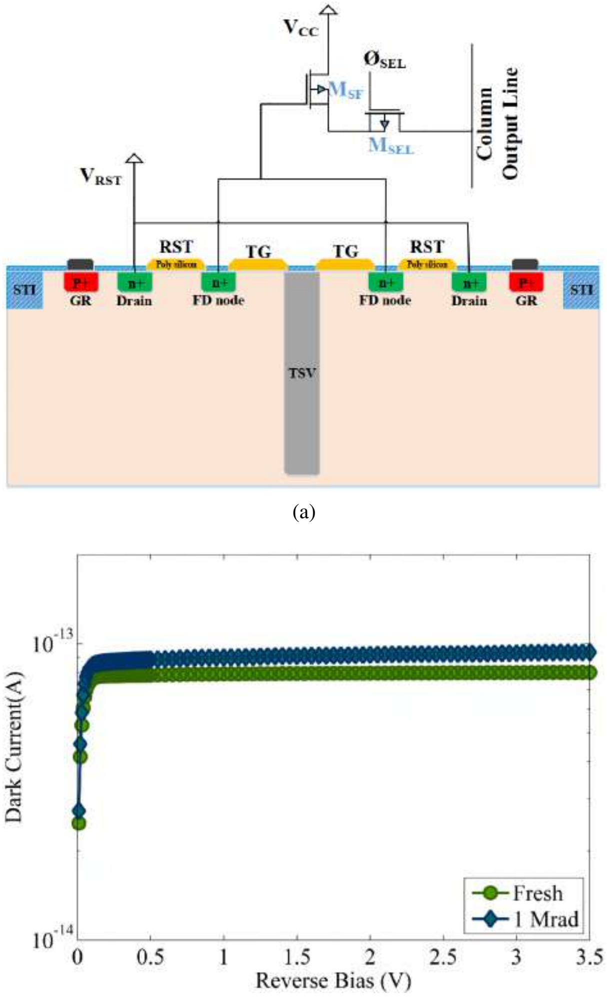

(a)

(b)

Fig. 8: (a) Illustration of p+ guard ring (GR) around the pixel, (b) simulation results of radiation effect on the dark current of a pixel before (fresh) and after exposure of 1 Mrad gamma ray radiation.

TSV are performed while the photo-generated current is swept for each simulation over a range of incident light wavelengths between 300 to 1000 nm. The linearity behavior of the spectral response over the range of 300 to 800 nm wavelength is due to the radial deep space-charge-region, created by the MTS-PD and extended from the surface to the H_{TSV}; hence any photo-generated charges inside the space-charge-region can be collected by the engineered Schottky contact (MTS-PD). The proposed design demonstrates a responsivity of 0.27 $A.W^{-1}$ at 300 nm wavelength which increases linearly to 0.68 $A.W^{-1}$ at 800 nm wavelength for a 10 μm deep TSV. Making the TSV deeper to 100 μm inside the substrate enhances the spectral response of higher wavelengths, where the linearity behavior extends to 900 nm wavelength – the spectral response at this wavelength reaches 0.8 $A.W^{-1}$.

F. Dynamic Range

Dynamic range in image sensors is defined as the ratio of the maximum photo-generated current to the non-illuminated current (i.e. dark current) [26]. Fig 7 shows the number of photo-generated charges versus light intensity. From the simulation perspective, dynamic range is attained by changing light intensity from the dark to the state as which the MTS-PD well is saturated with photo-generated charges. Eventually, the difference between the minimum stored charge in the MTS-PD—related to the dark current—and saturated-well charges is translated as light intensity and a 58.62 dB dynamic range is derived for the proposed pixel through the simulation.

G. Radiation-Hardening

According to [17], [18], an MSM-based design on its own demonstrates radiation tolerance to a reasonable extent. However, in order to isolate a pixel from its neighboring pixels and to minimize the TID effect, a p+ guard ring is considered in our design. This p+ guard ring design has been previously investigated in details in [19]. This p+ guard ring not only acts as the substrate contact, but also protects the pixel from any leakage current presents outside of the pixel–originating mainly from oxide defects and shallow-trench isolation (STI) defects due to the TID effect. Fig 8(a) illustrates the p+ guard ring (GR) around the pixel design in a cross-sectional view of one pixel. Simulation results in SILVACO demonstrates a radiation tolerance with insignificant dark current increase under gamma ray radiation of up to 1 Mrad (Fig 8(b)).

IV. Conclusion

A new type of 4T CMOS image sensor employing a TSV based MSM photodetector as the photosensitive element is designed and simulated in this work. To the best of the authors' knowledge, this is the first time a TSV-based photodetector is used to realize a complete pixel structure. Table I represents the comparison of the proposed pixel simulation results with two other structures. The dark current of the proposed pixel

TABLE I: COMPARISON OF THE SPECIFICATION AND PERFORMANCE OF THE PROPOSED PIXEL

Specification	**Ref [27]**	**Ref [11]**	**This Work**
Technology	0.18 μm CMOS	na	0.18 μm CMOS
Pixel Size (μm^2)	41	na	28
Active Area (μm^2)	na	143000	3
Responsivity (A/W)	na	0.24 @ 300 nm 0.66 @ 800 nm	0.27 @ 300 nm 0.68 @ 800 nm
Conversion Gain (dB)	na	na	58.62
Full Well Capacity (e^-)	40000	na	35000
Dark Current	50 e^-	In the range of nano-ampere	77 fA @ 1 V (41 e^-)

(77 fA) is slightly higher than state-of-the-art designs, which is because of using an MSM-junction based photodetector rather than a pn-junction based one. A semi-linear behavior spectral response of more than 0.27 $A.W^{-1}$ at the wavelength spectrum from 300 to 800 nm is achieved within 3 μm^2 active area using the TSV based photodetector. The proposed pixel shows a conversion gain and dynamic range of 116 $\mu V/e^{-1}$ and 58.62 dB, respectively. Furthermore, deploying a p+ guard ring design, along with the metallic-filled TSV based photodetector, demonstrates negligible dark current increase under simulated gamma ray radiation of up to 1 Mrad. More importantly, this pixel architecture is compatible with standard CMOS technology. The output of this work could be a preliminary result toward realization and fabrication of a 4T CMOS image sensor pixel using TSV based MSM photodetectors for various applications, such as astronomical or medical, where the image sensor is supposed to work under radiation.

***Abstract*— In the decommissioning of the Fukushima Daiichi Nuclear Power Plant (FDNPP), the Japanese government has drawn mid- and long-term roadmap towards 1F decommissioning. However, the decommissioning work of the three reactors has faced difficulties due to the lack of realistic information about the damaged cores such as distribution of fuel debris. Since the radiation levels inside the reactor buildings have been too high for human access, remote detection, which combines robot and measurement technique, is required. In this study, we proposed a remote controlling method. The experiment has been conducted remotely controlling the ultrasonic measurement. Finally, the experiment data and results are successfully obtained through remote control.**

Keywords—decommissioning of Fukushima Daiichi nuclear power plant, remote control, UVP method,

I. Introduction

A severe accident at TEPCO's Fukushima Dai-ichi Nuclear Power Plant (FDNPP) occurred due to a strong earthquake and massive tsunami that struck the eastern region of Japan on 11 March 2011. During this accident, the reactor core of Units 1, 2, and 3 of the 1F melted, and fuel debris formed in the reactor pressure vessel (RPV) and primary containment vessel (PCV). The Japanese government has drawn mid- and long-term roadmap towards 1F decommissioning [1]. In order to accelerate the decommissioning of 1F, information on fuel debris and contaminated water leakage becomes critical. Because the radioactivity inside the reactor is too high for human access, the detection and the location of fuel debris cannot be done by human beings. For this reason, researchers have proposed various methods and approaches to survey the interior of the reactor and to improve the understanding of the reactor conditions, such as accident sequence analysis [2], [3], detection of fuel debris [4] [5], internal inspection with mobile robots [6]. Meanwhile, ultrasound technique was applied to detect of fuel debris information and contaminated water leakage point [7] [8]. Ultrasound has advantages that other technologies cannot match in highly radioactive, turbid, and low luminosity environments. Among the ultrasound techniques, ultrasound velocity profiler (UVP) is noted for its ability to measure the velocity distribution of fluids in real-time. Thus, remotely control the UVP measurement in the reactor is a promising method of detecting the leakage point in the RPV and PCV.

The UVP method has already been combined with PIV [9]. In this study, the UVP experiment to detect the flow velocity near the leakage point and thus to get information about the leakage point was conducted, and PIV measurement was conducted to compare with UVP . Then, the UVP sensors were attached to the robot. The UVP measurement was conducted remotely by controlling the robot. The results demonstrate that remote control is possible for UVP flow velocity measurement experiments and a concept that combines experiment with remote control.

II. Experiment Method

A. Ultrasonic Velocity Profiler

The UVP method is based on pulsed ultrasound echography. Ultrasound pulse beam is emitted in-line by the element of the transducer and will be reflected from the surface of tracer particles. The reflected pulse is called echo signal, and it is Doppler-shifted because of the velocity of the tracer particles. Using the Doppler-shift frequency's method, the velocity of the tracer particle can be obtained through analyzing sequence of tracer particles' reflection. During the measurement, ultrasonic pulses are emitted at intervals, and each pulse is emitted multiple times to achieve the Doppler-shift frequency. This is called pulse repetition frequency. Generally, the number of pulses at an interval is 128. Y. Takeda [10] had explained the one-dimensional principle of UVP in his previous work. In this paper, it was expanded to the 2D environment. But the principle is same with the one-dimensional case.

In two-dimensional velocity profile, it required at least two measure lines interact and two velocity along the measure line can be synthesized into a velocity vector [11]. For instance, as shown in Fig. 1, the velocity components u₁ and u₂ are intersected at an intersection point, they are measured along the measure lines emitted by sectorial array transducers. In each measurement line, the calculation is based on the principle of one-dimensional UVP measurement method. Then, based on the incident angle of each transducer, the velocity components are synthesized into the velocity vector u of the intersection point. The velocity along the axis is expressed by (1) and (2):

$$u_1 = V_x \sin\alpha + V_y \cos\alpha \quad (1)$$

$$u_2 = -V_x \sin\alpha + V_y \cos\alpha \quad (2)$$

Then, the velocity along the axis can be expressed as:

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

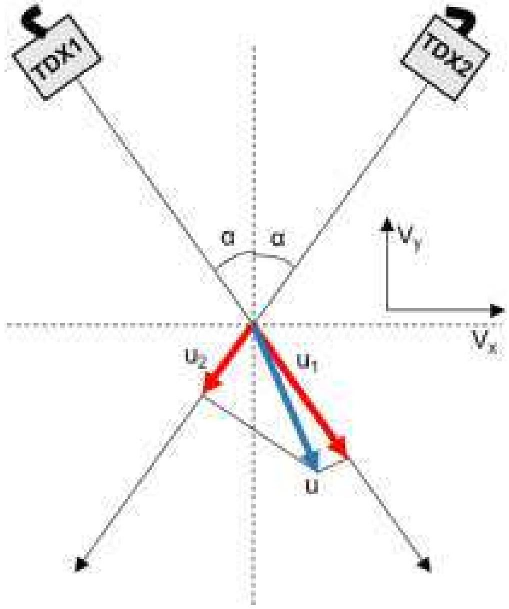

Fig. 1. Basic principle of vector reconstruction using two transducers.

$$\boldsymbol{u} = \begin{pmatrix} V_x \\ V_y \end{pmatrix} = \begin{pmatrix} \dfrac{u_1 - u_2}{2\sin\alpha} \\ \dfrac{u_1 + u_2}{2\cos\alpha} \end{pmatrix} \quad (3)$$

B. Robot System

The robot is utilized in carrying UVP sensors and controlling the position of it. In this case, a four-wheel and 3 degrees of freedom wheel-arm robot was applied. The applied robot is shown in Fig. 2. The robot arm tip can be operated from -180° to 180° around the vertical axis. The sensor unit is mounted via a horizontal compensation mechanism at the end of the hand. The ultrasonic sensor position was controlled by a motor driver (EPOS2 24/5, Maxon) using a DC motor (RE25 ϕ25 24V 20W, Maxon). The position of the sensor is calculated from the rotary encoder attached to the DC motor. The wheel body robot has EC motor (EC 25 φ 60 24 V 100 W, Maxon) mounted on each wheel, and independent control is possible by using each motor controller (EPOS2 24/5, Maxon). Using the robot can achieve high mobility and remote controllable of the UVP measurement.

C. Remote Control Method

The internet of thing (IoT) is a system that connects devices, mechanical machines and digital devices with unique identifiers (UIDs) [12] It can transfer data without any interaction from human-human or human-computer. Based on this technology, the remote control system can be built in any place [13] [14]. In this experiment, devices were controlled by the controller on the PC or cell phone through the set Wi-Fi signal with the internet services provider (ISP). The structure is shown in Fig. 4. ISP provides internet services that connect data sent through router devices (e.g. Dial, DSL, and wireless modems). The wireless modems was chosen in this study. Computers, tablets, and smartphones are responsible for remote control of the internet via 3G/4G or routers that communicate with the ISP.

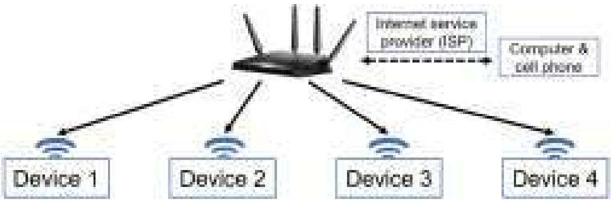

Fig. 3. Schematic diagram of communication between devices, Wi-Fi, and users.

III. Experimental Setup

A. UVP and PIV Experiment Setup

A simultaneous measurement was conducted by UVP and PIV. PIV measurement is aiming to compare with and validate the UVP data. UVP-DUO monitor with a multiplexer (from Met-Flow SA, Switzerland) were used in the UVP experiment. The Fluid container is a rectangular acrylic box with a size of 1200 mm×450 mm×450 mm. it has good transparency for the PIV measurement. Tap water was the measured fluid in this experiment, and the height of it is 290 mm from the bottom. Two sectorial array transducers from Japan Probe (shown in Fig. 4) were placed into the water and with a height of 140 mm, the distance between two transducers are 90 mm, and they are placed above the leakage point of the fluid container. The PIV experiment setup consists of a High-Speed Camera (HSC, FastCam mini AX50 type, 170K-M-8GB, Photron) and laser sheet (Raypower 450, Dantec), the laser sheet was placed above two sectorial transducers and in the middle of it, high speed camera was placed perpendicular to the fluid container to record the image sequence of the fluid. The experiment setup is shown in Fig. 5. The flow was controlled by the control value and the flow rate is displayed by the flowmeter, the flow rate was controlled in the 10L/min and the accuracy of it is ±5%, flow condition is shown in Table I.

The main parameters of UVP measurement are shown in Table II. the HSC camera provids a resolution of 896×512 pixels 250 fps and 12000 frames. The PIV result was performed in MATLAB to calculate the average velocity vectors from all sequences. The parameters of PIV measurement are shown in Table III.

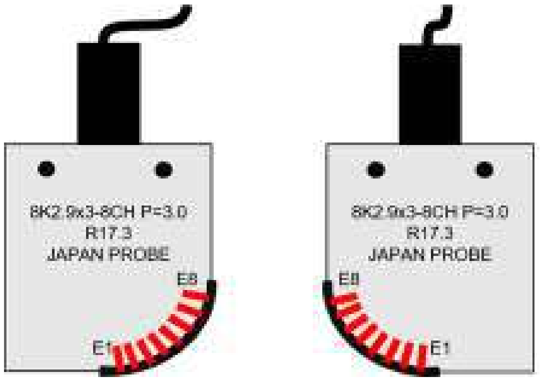

Fig. 4. Schematic diagram of the ultrasonic sectorial sensor

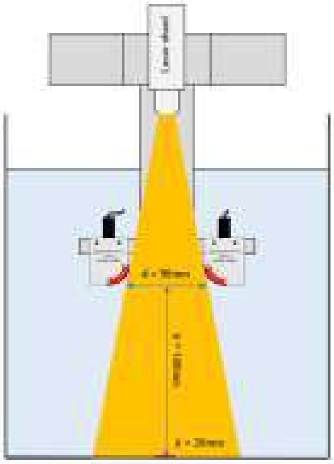

Fig. 5. Schematic diagram of experimental conditions.

TABLE I. EXPERIMENT CONDITION

Experiment conditions	Value
System pressure	Atmospheric
Water temperature (℃)	29±1
Flow rate [L/min]	10±1
Nylon particle size [μm]	80
Distance between transducers [mm]	90
Distance from the bottom wall to transducer surface [mm]	140

TABLE II. PARAMETERS OF UVP MEASUREMENT

Parameters	value
Number of channels	178
Number of profiles	12000
Maximum depth [mm]	129.96
Channel width [mm]	0.72
Channel distance [mm]	0.72
Repetitions	96
Cycles number	8
Time of capture one sample [ms]	32

TABLE III. PARAMETERS OF PIV MEASUREMENT

Parameters	value
Frame per second (fps)	250
Shooting Duration [s]	49.892
Number of frames	12000
Shutter speed	1/2000
Spatial resolution [pixels]	896×512

B. *Remote Control Measurement Setup*

Fig. 6 illustrates the schematic diagram of the remote control experiment (the X, Y, and Z axis are shown in Fig. 6, Y-axis is perpendicular to the direction of the paper surface). The system contains three parts: UVP measurement part, robot part and remote controlling part. To keep the result's consistency and to compare it, the UVP setup is kept same with first experiment. The remote control part is divided into two parts. Firstly, we set a computer in the room where is far away from the experiment site, we call this computer as operating computer. Secondly, another computer which we called experimental computer is placed in the experiment site, it is used to connect all the experimental equipment, receive commands from the operating computer, and will communicate the commands to each experimental device. The ISP between operating computer and experimental computer is the key point of this experiment. In this case, we use a commercial software Team viewer to build up the bridge between two computers. In order to remotely control the robot and UVP measurement. a Wi-Fi router is placed in the experiment site, experimental computer, UVP-DUO multiplexer and robot are connected by accessing the Wi-Fi. In this case, a control panel that integrate the UVP-DUO switch and robot switch had been designed and used to control the switch of the UVP-DUO multiplexer and robot remotely. Fig. 7 illustrates the control panel on the experimental computer. On the other hand, UVP-DUO and robot connected with experimental computer through USB, the operating software for both are integrated into the experimental computer to simultaneously control both UVP measurement and robot movement. The operating program of the robot is shown in Fig. 8. In addition to the experimental robot and UVP measurement apparatus, there are two USB cameras have been prepared in the experimental site, two cameras are directly connected to the experimental computer through USB, the experimental computer has already installed the software can simultaneously view the two cameras real-time shooting and video recording.

IV. Result and Discussion

A. UVP and PIV Measurement results

Unlike the one-dimensional velocity profile of UVP, the two-dimensional velocity profile measurement is based on the intersection point generated by two interacting ultrasonic pulses. Based on the calculation of the coordinates, a grid map of the UVP 2D velocity profile was drawn, and the generated intersection point locations are shown in Fig. 9. Flow maps measured by UVP and PIV were generated using TECPLOT software. The PIV images were preprocessed by PIVlab [15] in MATLAB. UVP results and PIV results were generated and compared, respectively. To calibrate the magnitude of the measurements, a calibrated PIV image was used to combine the UVP measurement locations with the PIV measurement locations, as shown in Fig. 10.

At the same time, because the sectorial array transducers have 16 measurement lines in total at this experiment (shown in Fig. 9), the upper part of the measurement line didn't show the enough information of the velocity profile. The reason is that those lines are too far away from the leakage point, (seeing the line emitted by E7, E8 and E15, E16 in Fig. 9). After comparing the profile between E1 to element E8, the result of E2, E3, E4 and E5 was decided to represent two-dimensional velocity profile (also symmetrically, E10, E11, E12, E13 was chosen) . Thus, the result from element 2 to element 5 of each side are selected as a UVP measurement result. Meanwhile, because of the flow rate is 10L/min, the PIV result is also obvious only in the region where near the leakage point. Seeing that, the region near the leakage point had been chosen as the overlapped UVP and PIV profile.

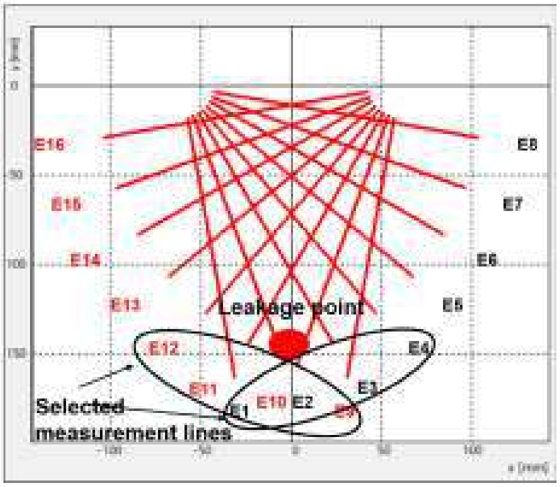

Fig. 9. Measurement grid map of sectorial array transducer.

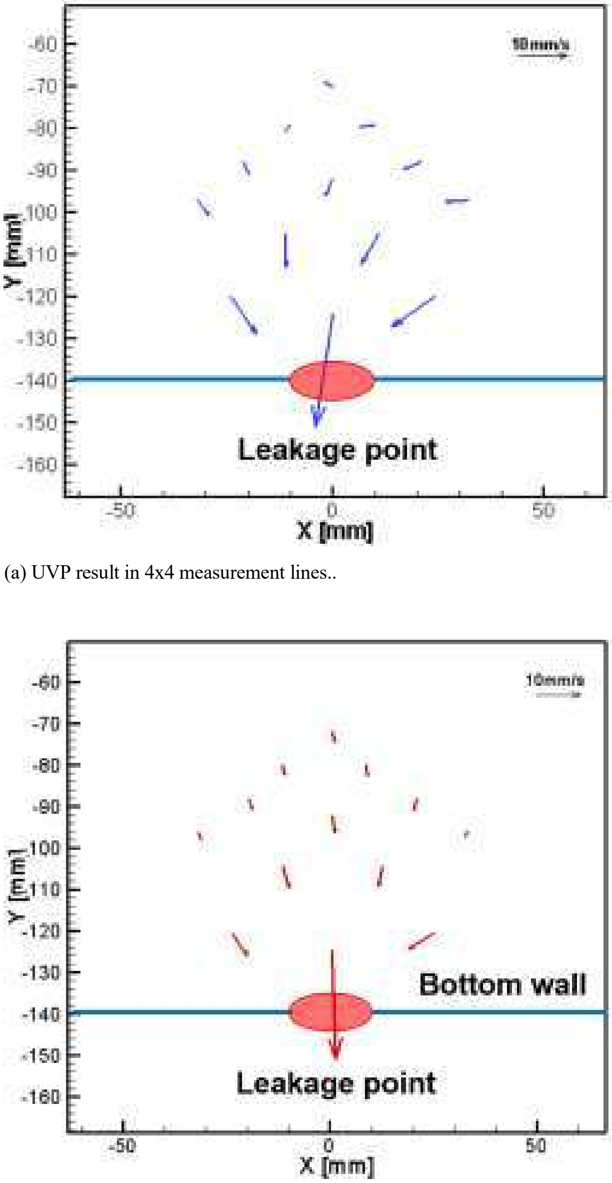

(a) UVP result in 4x4 measurement lines..

(b) PIV result in 4x4 measurement lines.

Fig. 10. Result of UVP and PIV measurement without remote control.

By comparing (a) and (b) in Fig. 10, we can observe that the result of UVP and PIV are overlapped well when closing to the leakage point. But when in the region where is further from the leakage point, the data between PIV and UVP start to generate the difference. The reason for this phenomenon is that the number of measurement repetitions required for the high accuracy of UVP measurements is sacrificed in the experiment to maintain the consistency of PIV and UVP results. It lead to a certain amount of errors in the UVP data. However, the high degree of agreement between the two results at locations close to the leakage point illustrates the usability of UVP measurements in this environment. Also, provides a direction for future enhancement of UVP measurement.

B. Remote Control UVP Measurement Results

Fig. 11 shows a screenshot of the remote controlling process using Team Viewer. In this experiment, most of the parameters of UVP measurement were kept same with first experiment, only depth of UVP sectorial sensors changed from 140 mm from the bottom wall to 120 mm from the bottom wall. The Wi-Fi control panel is remotely switched on in the operating computer through Team Viewer to power on the robot and UVP.

During the experiment, two cameras were set in different positions to observe different parameters in the experiment. Camera one was set behind the experiment site to capture the motion of the robot arm, and camera two was set at the front of the wheeled robot to capture the position of the simulated leak point in relation to the UVP sectorial transducer. On the other hand, the control panel of the robot and the software of UVP are integrated into one screen in order to achieve the simultaneous real-time remote control. The UVP sectorial transducers are attached on the tip of the robot arm and be carried to the 120 mm from the bottom wall. Then, multiple UVP measurements were performed at different (X, Y) values (move 50 mm on Y-axis) while keeping the Z-axis values constant to verify the validity of the remote UVP measurements and to observe the flow velocity distribution at different locations above the simulated leakage point (shown in Fig. 12). The result is shown in Fig. 13.

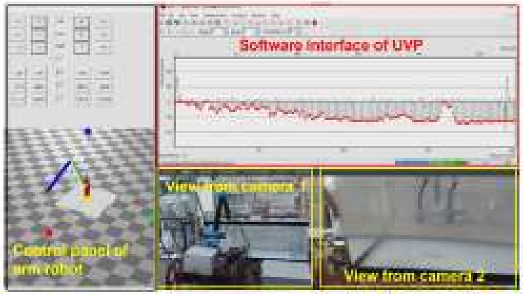

Fig. 11. Screenshot of remote controlling system.

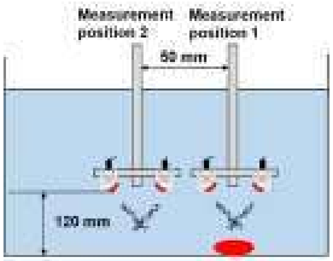

Fig. 12. Schematic diagram of UVP measurement in different position.

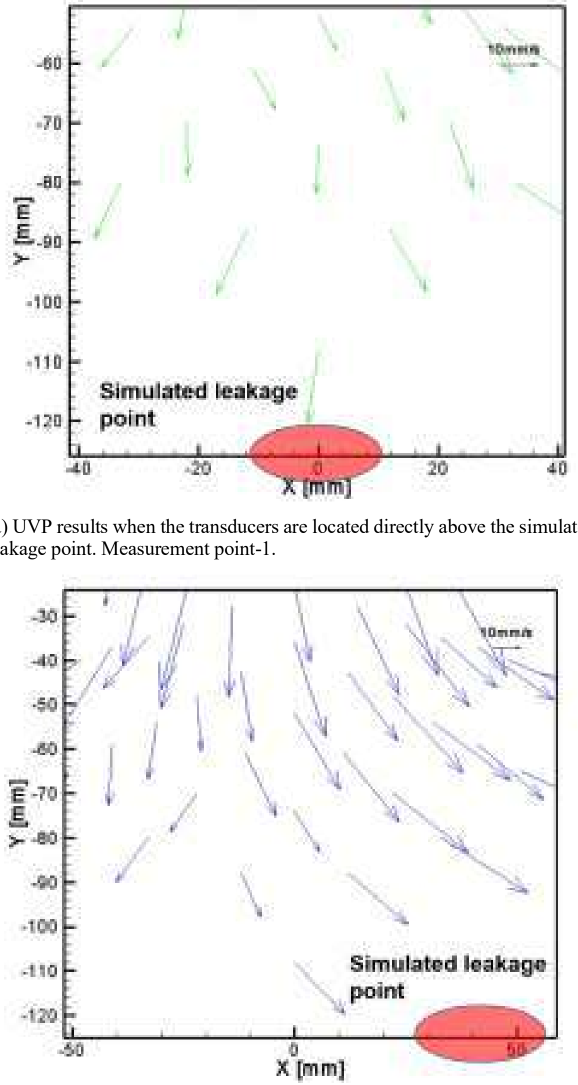

(a) UVP results when the transducers are located directly above the simulated leakage point. Measurement point-1.

(b) UVP result when the transducers are located upper left (50 mm from the leakage point) of the simulated leakage point. Measurement point-2.

Figure 13. Results of remote UVP measurement in different position.

From the results, we can find that when UVP sectorial transducers are located at different positions above the simulated leak, the results are completely different. When transducers are located directly above the simulated leakage point, the velocity profile in the measurement results points to the leak directly below; When transducers are located at the top left of the simulated leakage point, the velocity profile points to the simulated leak at the bottom right, The results demonstrate that remote control can be successfully applied to the UVP measurement.

However, as shown in the figure, there is still some errors that exist in the measurement results, which is related to two points: One is because the UVP measurement experiment was conducted in order to obtain the results quickly, the number of repetitions in the selection of measurement parameters sacrificed, thus reducing the accuracy of the data, and the second is because the UVP sectorial transducer connected with UVP-DUO through UVP transducer cable when the experiment was conducted. Compared with the vertical downward gravity of the transducers, the drag force from the gravity of the cable is relatively large, resulting the position of the transducer changed from perpendicular to the water surface to a certain angle with the water surface. These two problems also provide the direction for future improvement.

V. CONCLUSION

In this work, a telemetry system has been proposed to detect leakage point. A mock-up experiment was conducted in a laboratory scale tank. The experiment of UVP combined with PIV was first conducted and validated the UVP result. Then, the remote UVP measurement was conducted at a total telemetry environment. The results of the UVP flow map were obtained successfully through the remote control. At the same time, the experimental results showed some errors, which either occurred due to insufficient experimental conditions or improperly set experimental parameters, and in general, this provides a direction for future research.

***Abstract*—This paper examines how features affect student persistence or dropout at South African higher education institutions, based on three previous studies. In the previous studies, high school grades were used as a valid predictor of student success. The quality of a high school's learning environment has an effect on almost every aspect of higher education success. Students who are better prepared coming out of high school are ideally suited to do well in higher education institutions, who they are, how much money they have, and where they go don't matter. This review aims to identify effective features that warrant student success from high school grades and choice of academic courses during registration in higher education. The following questions are used to guide this review: How can we define student success? Which features should we focus on? Which models work? Based on data mining techniques such as machine learning models that the previous studies have used to predict student success, it has been revealed that the most important features that influence student success in a Computer Science programme are Prior Computer experience, Mathematics, English from High school and the choice of a course.**

***Index Terms*—Student success, Prediction, Higher Education, Machine Learning**

I. Introduction

Student success is significant in South African higher education because it is commonly used as a metric for the institution's performance. At-risk students would have a much greater chance of thriving if they are detected early and preventative measures are taken. High school grades have long been a strong predictor of student success in postsecondary institutions [10]. Students who complete four years of mathematics, science, and English in high school have an 87 percent chance of graduating from college, compared to a 62 percent chance for those who do not complete the coursework [1], [14]. Machine learning algorithms have been widely used for prediction in recent years.

Admission to science programmes in South African universities, requires that students perform well in both pure mathematics and English as confirmed by [12], [15]. However, studies that applied machine learning techniques show that pure mathematics and English cannot be the only predictors of student success in higher educational institutions [11]. The effective and efficient application of machine learning techniques entail many decisions, ranging from how to define student success, through which student features to focus on, up to which machine learning method is more appropriate to the given problem.

II. How can we define success?

The authors in each paper have outlined what drives student success, in simple words, they have defined what student success is. [6] defined student success as dependent on biographical and enrolment observations as features that ensures efficient student performance at a South African higher educational institution. This study argues that there exists characteristics, attributes, and features in a student profile that can accurately predict the student's performance from the first year of registration until qualifying, providing a contribution that suggests a support and supplementary mechanism to the current university Admission Point Score (APS) system, which has evidently been struggling, generating between 25.7% and 32.2% minimum time (3-year) graduates in South Africa for the academic years 2000 to 2017 [6].

[9] believes that student enrolment and biographical data are rich sources of information that can help universities and staff solve a number of problems, such as identifying at-risk students, restricting student intake, and changing course content to understand and assist disadvantaged students.

[11] predicted student success for first year computer science students based on three features and believes that prior computer experience is required for students to perform well in a computer science course.

III. Which Features Should we focus on?

The authors considered different features and looked closely at the extent to which these features impact student success.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

[11] considered two groups when investigating the effect that prior computer experience had on the final first year computer science results. Students in group 1 had no prior computer experience. Students in group 2 had prior computer experience. The paper further outlined all three features that were looked at when predicting success for first year computer science students. The features include: Final grade 12 results such as Pure Mathematics as a predictor (this is a known predictor of performance for computer science as confirmed by [15]), Past computer experience as a predictor and Language performance as a predictor. The features are shown in TABLE 1.

On the other hand, paper [9] considered school quintile, high school grades, Naional Banchmark Test scores as well as the major a student chose when registering at university as predictors when predicting the Success of First Year University Students. From the results it was concluded that a student's undergraduate major, school quintile, Life Sciences and Mathematics marks in matric have a significant effect on their chance of completing their studies. The features of this paper are outlined in Fig. 1.

Some features used by [6] are the same as the ones used by [9]. But some are different. TABLE I listed all the features that [6] used to predict student performance at each year of study until qualifying, for students at a South African higher education institution. Fig. 2 represents features used throughout in [6].

TABLE I: A table presenting the various features used for prediction of student success in [11].

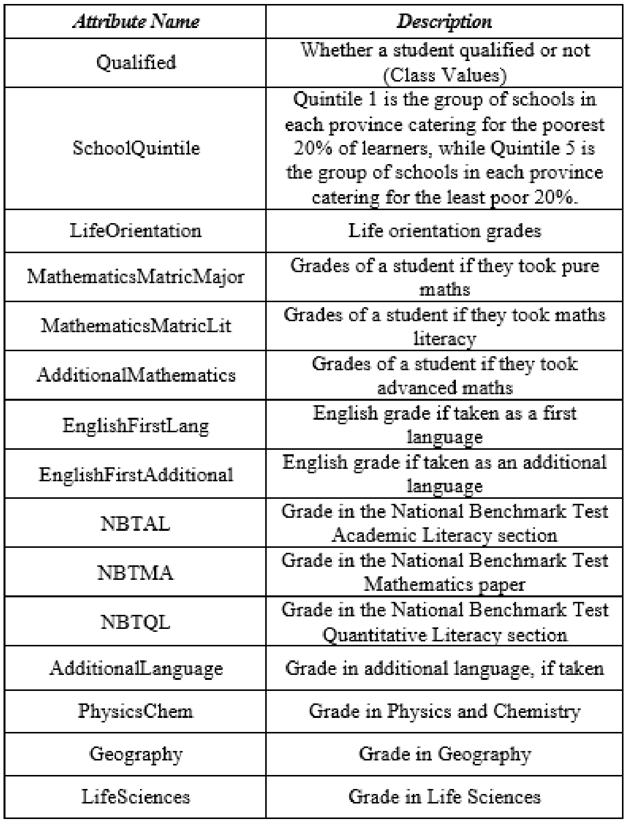
Features
Mathematics as a predictor
Past computer experience as a predictor
Language performance as a predictor

IV. Which Models work?

To achieve their objectives and answer research problem statement and questions that are set out for their papers to answer, the authors considered different models that are suitable and best possible approaches for their given problems.

[11] used four models. Linear regression was used to predict the true results of students, the outcome produced from the model is a real number. The classification models such as Logistic regression, Naive Bayes and Decision tree were used to predict a student's results as either a PASS or FAIL. The four models are used to identify which features are important in higher educational institution success to first year computer science students.

The three classification models performed very well in group 2 as they resulted in highest accuracy than in group 1. Although the classification models performed better in group 2, the difference in accuracies between group 1 and group 2 was not much when using the logistic regression model and Naive Bayes model. The differences for these two models between group 1 and group 2 are 2.65 and 0.37 percents respectively. The difference in accuracies when using the decision tree classifier model was greater between the two groups as compared to using the logistic regression model and Naive Bayes model. The difference was 8.51 percent when using the gini index and 13.2 percent when using entropy in decision tree model.



Attribute Name	*Description*
Qualified	Whether a student qualified or not (Class Values)
SchoolQuintile	Quintile 1 is the group of schools in each province catering for the poorest 20% of learners, while Quintile 5 is the group of schools in each province catering for the least poor 20%.
LifeOrientation	Life orientation grades
MathematicsMatricMajor	Grades of a student if they took pure maths
MathematicsMatricLit	Grades of a student if they took maths literacy
AdditionalMathematics	Grades of a student if they took advanced maths
EnglishFirstLang	English grade if taken as a first language
EnglishFirstAdditional	English grade if taken as an additional language
NBTAL	Grade in the National Benchmark Test Academic Literacy section
NBTMA	Grade in the National Benchmark Test Mathematics paper
NBTQL	Grade in the National Benchmark Test Quantitative Literacy section
AdditionalLanguage	Grade in additional language, if taken
PhysicsChem	Grade in Physics and Chemistry
Geography	Grade in Geography
LifeSciences	Grade in Life Sciences

Fig. 1: A figure presenting the various features used for prediction in [9].

Results from the hypothesis test and confidence interval test showed that the students in group 2 outperformed the students in group 1. Based on these results, it is worth considering past computer experience as an additional criterion to studying computer science. However, we should not ignore students without prior computer experience considering the fact that the accuracies produced from both group 1 and group 2 differed by a small percentage when using both the logistic regression model (difference of 2.65 percent) and Naive Bayes model (difference of 0.37 percent).

On the other hand, through six machine learning models like Random Forest, Logistic Model Trees (LMT), Decision Trees (J48), Sequential Minimal Optimization (SMO), Multinomial Logistic Regression and Naive Bayes, the authors predicted students' first, second, and final year outcomes based on synthetic dataset. In the 1st, 2nd and final years of student enrollment, all of these models performed outstandingly in predicting student success, however, amongst these models, Random Forests performed better with accuracy of 94.40%,

Fig. 2: A figure presenting the various features used for classification in [6]. The table sorts the features according to whether they were used for the prediction of the students' 1st Year Outcome, 2nd Year Outcome, or Final Year Outcome.

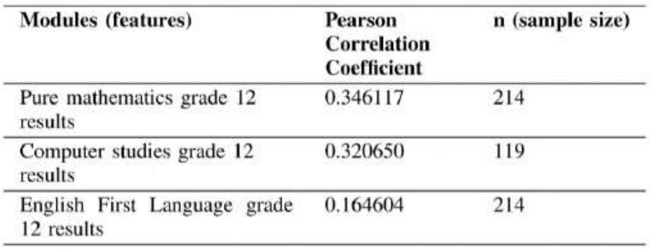
93.70% and 95.45% respectively [6].

Another study aimed at investigating which features of a student best predict whether they will graduate so as to identify vulnerable students and offer them crucial assistance applied six machine models such as Bootstrap Aggregating (Bagging), Bayesian Network, Logistic Regression, Multilayer Perceptron (MLP), K-Nearest Neighbours (KNN) and Random Forests. Bagging was found to be the most effective model for these features, correctly classifying 75.97% of the data. Random Forests followed closely, correctly classifying 75.57%, while KNN came in last with 64.83% [9].

These models are briefly described below.

- Bayesian Network - A probabilistic graphical model that represents a set of variables and their conditional dependencies via a directed acyclic graph (DAG).
- Logistic Regression - used to model the probability of a certain class or event existing such as pass/fail, win/lose.
- Multilayer Perceptron (MLP) - is a class of feedforward artificial neural network. The Perceptron consists of an input layer and an output layer which are fully connected.
- K-Nearest Neighbours (KNN) - K-Nearest Neighbour is a non-parametric classification algorithm. This algorithm works by finding the distances between a new data point and all the labelled datasets in the data, it reads through the whole dataset to find out the k nearest neighbours closest to the new data point, then the votes for the most frequent label in classification will be the class for the new data point [8].
- Bootstrap Aggregating (Bagging) – a machine learning ensemble meta-algorithm designed to improve the stability and accuracy of machine learning algorithms used in statistical classification and regression. It also reduces variance and helps to avoid overfitting.
- Random Forests - Random forest algorithm is a supervised classification model. This model creates the forest with number of trees [3]. Random forest classifier works well with missing values. It does not overfit the model when there are more trees in the forest.
- Naïve Bayes (NB) - has been widely used in text classification. Given a set of labelled data, NB often uses a parameter learning method called Frequency Estimate (FE), which estimates word probabilities by computing appropriate frequencies from data [13].
- Linear Regression - models a relation between a dependent variable and one or more independent variable.

Random Forest followed by Logistic model trees, Multinomial Logistic Regression, Sequential Minimal Optimization and Decesion tree are suitable and best possible approaches for predicting student success.



Modules (features)	Pearson Correlation Coefficient	n (sample size)
Pure mathematics grade 12 results	0.346117	214
Computer studies grade 12 results	0.320650	119
English First Language grade 12 results	0.164604	214

Fig. 3: This figure shows the result of the linear regression from [11].

TABLE II summarises and compares the accuracies of each model that the authors obtained when conducting their studies.

V. Discussion

All of these indicators of student success have been studied in the literature to varying degrees, and there is widespread consensus on their significance. How each model performed for any given feature indicates whether the feature is very important in influencing student success. While other studies have concentrated on Mathematics and English as the best predictors of student success in a Computer Science program, the findings in [11] indicate that previous computer experience is also important for student success in higher educational institutions.

On the other hand, [9] demonstrate that school quintile, NBT grades, a course or major a student registered for, life sciences and mathematics from high school matters. [6] has as well focused on high school and intra-university grades and individual attributes such as home language, home province, age, etc.

In other studies, a handful of additional elements of student success have emerged, representing new dimensions, and

TABLE II: The accuracy of each model.

Models	Paper1 [11]		Paper2 [6]			Paper3 [9]
	Group 1	Group 2	Year1	Year2	Year3	After
Logistic Regression	59.85%	62.5%	-	-	-	75.48%
Decision Tree	60.24%	79.10%	-	-	-	-
Naive Bayes	60.95%	61.32%	83.95%	83.40%	84.40%	-
Decision Tree (J48)	-	-	87.55%	86.20%	91.45%	-
Random Forest	-	-	94.40%	93.70%	95.45%	75.57%
Sequential Minimal Optimization (SMO)	-	-	87.25%	84.5%	89.20%	-
Multinomial Logistic Regression	-	-	87.80%	86.20%	90.70%	-
Logistic Model Trees (LMT)	-	-	91.90%	91.75%	93.15%	-
Bayesian Network	-	-	-	-	-	74.12%
Multilayer Perceptron (MLP)	-	-	-	-	-	75.09%
K-Nearest Neighbours (KNN)	-	-	-	-	-	64.83%
Bootstrap Aggregating (Bagging)	-	-	-	-	-	75.97%

variations on common indicators. Examples of such indicators are theoretical perspectives (such as Sociological Perspectives, Organizational Perspectives, Psychological Perspectives, Cultural Perspectives and Economic Perspectives). The indicators also includes student background characteristics, precollege experiences, and enrolment patterns. Student engagement such as Student behaviors, activities, and experiences in post secondary education [5].

The importance of student engagement can be divided into two categories. The first is the amount of time and effort students put into their studies and other educational pursuits. ”A person’s level of commitment to the learning process has a huge effect on learning.” [2]. The second category of student engagement is how the school allocates resources and organizes the curriculum, other learning opportunities, and support services to enable students to participate in behaviors that contribute to positive interactions and results such as persistence, satisfaction, learning, and graduation [4]. As [7] concluded, individual effort and participation in academic, interpersonal, and extracurricular offerings on a campus decide the effect of higher eductaional institution.

VI. Conclusion

From this review, it’s concluded that there are more influential features on student success other than high school grades and choice of course during registration. Everyone that tries to predict student success has to closely at various features that might just make a very huge difference in ensuring that the results are correct and efficient to make decisions. The best prediction models should be considered when predicting student success. Different students perform differently based on different features, that is why it is very vital that various features be considered when predicting student success.

***Abstract*—Agricultural environment monitoring has become a crucial field of control and protection providing a real-time system with the physical world. This paper is proposed the design and implementation of a wireless agricultural monitoring system platform based on the Mesh Wi-Fi Networking with low-cost and resource-limited hardware-ESP8266 Platform. The system includes a root, 3 stations-repeaters, and 6 nodes, each node has three sensors to measure parameters: soil moisture and soil temperature, the environmental temperature and environmental humidity of the farm, and light intensity. The collected data are transmitted from the nodes to the root and updated on the cloud database and displayed on the dashboard. The website based on the MEAN stack will be built for the owners to track real-time information and save historical data.**

I. Introduction

The Internet of Things (IoT) is one of the dynamic trends in the technology world, besides Artificial Intelligence (AI). IoT is becoming an explosion in the modern world and being a backbone for future technologies. Ericsson predicts the number of IoT devices reach 18 billion by 2022 [1]. Wireless Sensor Networks (WSNs) are key components of the Internet of Things (IoT). It is a network of small and inexpensive sensor nodes, that monitor and communicates with each other through radio signals, a controller, and a communication system. The integration of WSNs with IoT has huge potential applications, from smart homes to smart cities, remote healthcare, energy and water control, precision agriculture... [2], [3].

Precision Agriculture (PA) is a new method of farming by combining technology with traditional farming practices [4], [5], [6], [7] to achieve the maximum profitability of farm.

So we propose a greenhouse with an IoT system that can help farmers or growers monitor with required parameters of their farm with the primary objective of this project is to integrate and develop new applications so as to advance precision agriculture.

This paper is organized as Section 2 describes the Materials and Methodologies, Section 3 illustrates the Results with the implementation, and Section 4 includes a Conclusion.

II. Materials and methods

Figure.1 shows the system architecture organization. There are three main elements: (1) sensor nodes that measure the environmental information; (2) root-gateway, and (3) the server, which receives, stores, and displays the data.

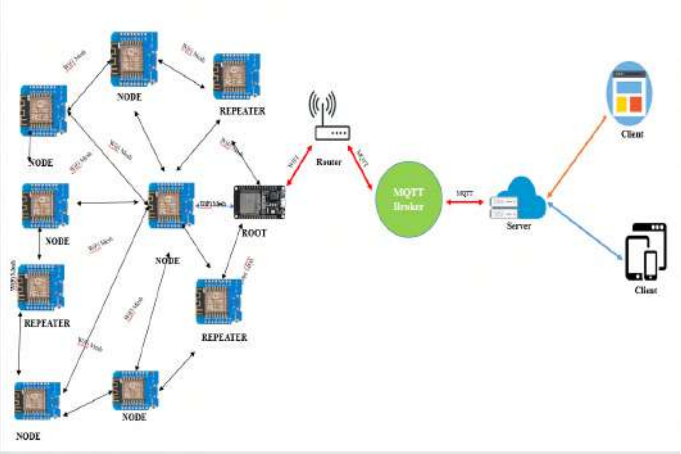

Fig. 1. System Architecture Overview

A. System Hardware

The following points describe the hardware used to implement the system.

1) Sensor Nodes:

- Soil Moisture Sensor: SHT-30 (manufactured by Sensirion) sensor has been chosen for moisture and temperature of the soil. It is encapsulated in a sintered metal mesh encasing so as to protect electronics when the sensor is submersible in the water in a short time-below 1 hour. The SHT30 sensor has an excellent ±2 percentage relative humidity and ±0.5°C accuracy for most uses. This sensor has an Inter-Integrated Circuit or I2C interface protocol and the 1-meter long cable [8].

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

- Temperature and Air Humidity Sensor: The DHT22 is a low-cost temperature and humidity sensor with a single wire digital interface. So, it interfaces with the microcontroller using I/O pins. The sensor is calibrated and does not require extra components so it can easily get right to measuring relative humidity and temperature. This sensor has ±2 percentage relative humidity (max ±5 percentage RH) and ±0.5°C in temperature accuracy [9].

- Light Intensity Sensor: The BH1750 FVI Ambient Light sensor is produced by Rohm Semiconductor, supports 16 bits unsigned integer output over I2C bus interface, includes a highly sensitive photodiode, a low noise amplifier, and the output data is directly a digital signal and no need to calculate complicatedly. The unit of output data is Lux (Lx). When objects which are lighted in homogeneous get the 1 Lx luminous flux in one square meter, their light intensity is 1 Lx [10]. Sometimes to take good advantage of the illuminant, a reflector is added to the illuminant. So that there will be a more luminous flux in some directions and it can increase the illumination of the target surface [11]. It is possible to detect a wide range and high resolution from 1 to 65535 Lux. If an error occurs, the negative value will be got.

- Processor and wireless communication module: The Wemos D1 Mini ESP8266-12 board has been chosen in this project for sensor node hardware because it is programmed in a well-known environment (PlatformIO [12] IDE and Arduino framework), which is used by a wide community of developers that freely share libraries and resources for programming. The WeMos D1 mini is a mini Wi-Fi integrated board, supports IEEE 802.11n2009 or 802.11n standard and works as a 2.4 GHz ISM band. It is based on the ESP8266EX microcontroller. Besides the Wi-Fi functionalities, ESP8266EX also integrates an enhanced version of Tensilica's L106 Diamond series 32-bit processor and on-chip SRAM. The chip runs at 80MHz and reaches a maximum clock speed of 160 MHz. It can be interfaced with external sensors and other devices through the GPIOs.

  The D1 Mini has 4MB Flash memory, a PCB antenna. It uses external SPI flash to store user programs and supports up to 16 MB memory capacity theoretically [13], small dimensions, and 11 digital IO pins, support many communication protocols like I2C protocol (Inter-Integrate Circuit), UART protocol (Universal Asynchronous Transmitter Receiver), ADC, and quite many peripherals [14]. The board has a typical current consumption of about 56 mA when receiving and 170 mA when transmitting data. The module also is used in connectivity applications, data collection, and control via Wi-Fi protocol [15].

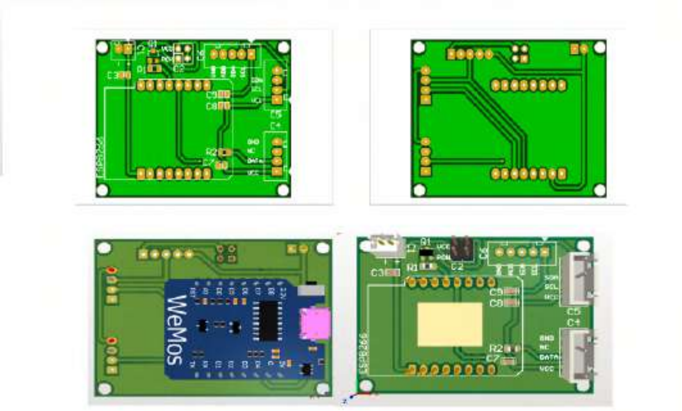

Fig. 2. PCB Connection Layout and 3D View

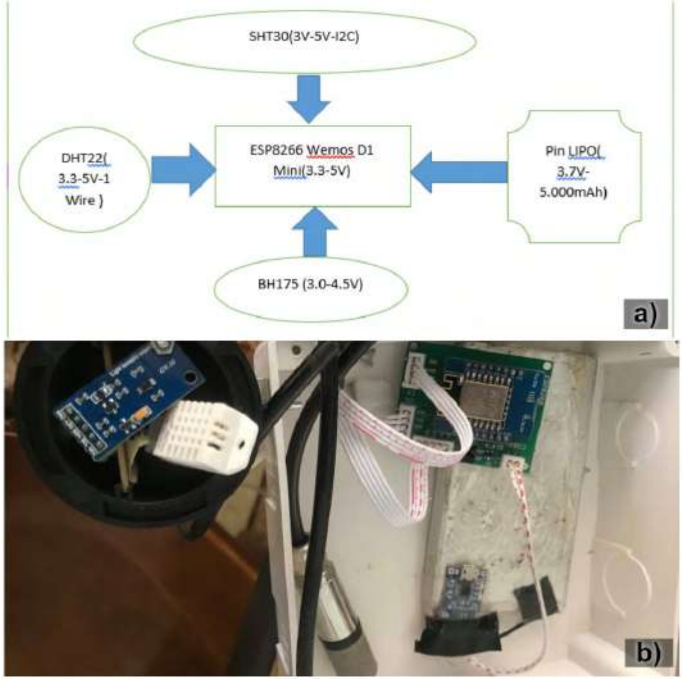

Fig. 3. a)High level block diagram of Sensor Node. b) Sensor Node

2) Gateway: In this system, we use ESP32-WROOM-32 development kit as a root node or gateway. It collects multi-sensor data simultaneously from sensor nodes then transmits it to the cloud in JavaScript Object Notation-JSON format. The ESP32-WROOM-32 is advertised as a low-cost, low-power System on Chip architecture with integrated CPU(s), RAM, Wi-Fi, and Bluetooth 4.2 capabilities on a single chip [16]. At the core, there is a dual-core Tensilica Xtensa LX6 microprocessor that runs up to 240MHz, 4MB of flash, and a PCB antenna.

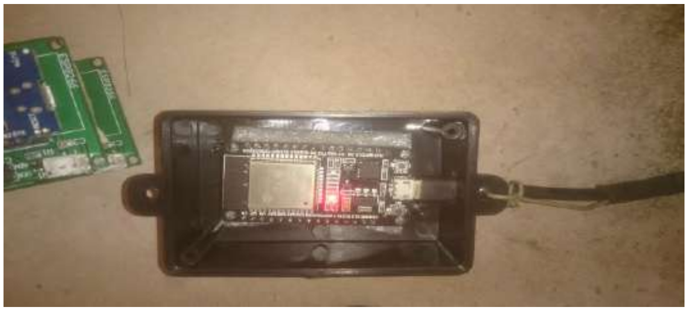

Fig. 4. Gateway

3) The Server: In the server section, there are two main elements: Message Queuing Telemetry Transport Protocol-MQTT protocol and MEAN Stack.

*MQTT Protocol: is a machine to machine or “Internet of Things” connectivity protocol on top of TCP/IP meaning it supports the event-driven exchange of messages through wireless networks. It allows extremely lightweight publish/subscribe messaging transport. MQTT protocol has clients-broker architecture and is used for the data transfer between the electronic system and the cloud. MQTT protocol has better performance than HTTP in IoT applications [17].

*Web developers have been used the LAMP open-source tool stack [18] (consisting of Linux Operating System, the Apache Web Server, MySQL as a database, and PHP as the scripting language). However, new applications faster and continually roll out enhancements and still ensuring that the application is highly available and can be scaled appropriately when needed by using the MEAN service Stack or just MEAN. MEAN stands for MongoDB, ExpressJS, AngularJS, and Node.JS [19].

MEAN also provide both client and server-side for interactive web applications. All four tools of MEAN are heavily based on JavaScript language. So each component in the MEAN full stack speaks the language of JavaScript Object Notation (JSON).

- Node.js: Node.js or just Node is an open-source, Javascript runtime environment built around Google’s V8 JavaScript engine and implemented in C++. Node provides a high-performance, asynchronous event-based server [20]. It uses an event-driven, non-blocking I/O model which makes it lightweight, efficient, and excellent for data-intensive real-time applications that run across shared devices [21]. Node.js is the most crucial tool of the MEAN stack.
- Express.js: is the framework built on the underlying capability of Node.js. It provides a web application server framework. This framework also provides a wrapper around a lower-level Node interface: giving the Web developers, a convenient means to handle routing, URL, and HTTP operations (such as GET and POST). Express.js module facilitates a simplified as well as a lean solution than implementing directly Node.
- MongoDB: MongoDB is an open-source, crossplatform database that is written in C++. It stores data in the keyvalue pair, using binary data type like JavaScript Object Notation (JSON), MongoDB provides persistence for application data and is designed with both scalability and developer agility in mind. And it bridges the gap between keyvalue stores, which are fast and scalable, and relational databases, which have rich functionality. Instead of storing data in rows and columns as one would with a relational database, so being a document-oriented NoSQL Database [22].
- Angular.js or Angular is a front-end web app framework, maintained by Google. The framework runs JavaScript code in the user’s browser and provide provides a client-side framework for MVC (Model-View-Controller) [23]. This allows the application User Interface to be dynamic.

B. System Software

1) Sensor Nodes: The sensor node is programmed in C++ language through PlatformIO IDE [12] and Arduino framework. After the node is powered up, the serial UART module starts, The if condition is used, if the node is a defined node, all sensors are initialized, and then will read physical data from the environment. If not, the node will move to the next task-Mesh Network initialization. It means that, in Mesh Wi-Fi Network, both sensor nodes and repeaters can piggyback the data of others. The sensing period is equal to 5 minutes.

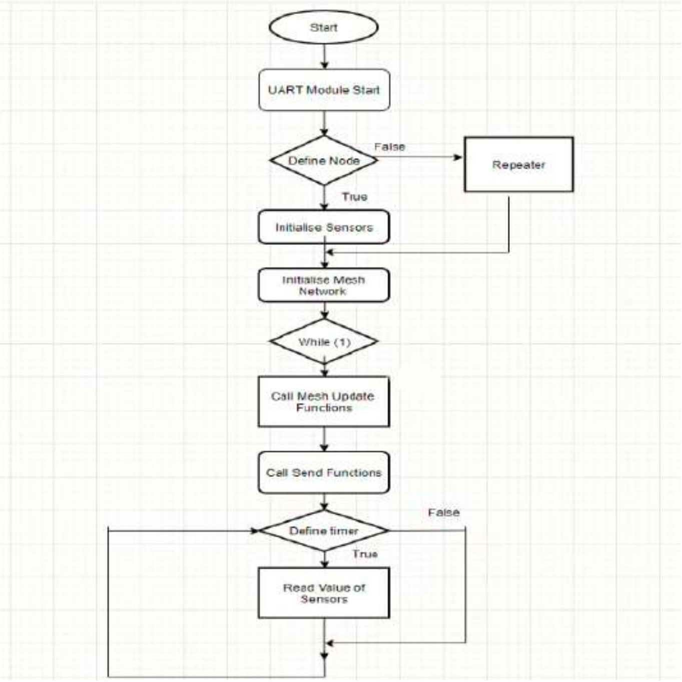

Fig. 5. Software Flow Diagram of Sensor Node and Repeater

2) The Gateway: The selected hardware to operate as a gateway has been the ESP32-WROOM-32 module, and its mission is to bridge between the sensor nodes and the server application. The ESP32-WROOM-32 module gateway is programmed in C++ language through PlatformIO IDE and Arduino framework. We set up the gateway into Access Point (AP) so as to the sensor nodes and repeaters can connect via the Mesh Wi-Fi network. The gateway connects to the cloud via an Internet connection, supplied by Tp-link M7350 4g LTE Mobile WiFi Wireless Router/Hotspot [24].

The hub initiates its Mesh Wi-Fi interface, after powering up, and seeks for available nodes at 2.4GHz, the radio frequency spectrum toed. When the setup is completed, the gateway requests commands through the TCP socket stored in the server. On the contrary, if the node is available, it will read and store the sensor's information coming from the other nodes through Mesh Wi-Fi. Afterward, the gateway will send an answer to the node with user-defined information related to the sensors and will send the information of nodes to the server through the MQTT protocol. Finally, it will update the server and database with the data of nodes.

Fig. 6. Software Flow Diagram of Gateway

3) The server: In this project, the server is implemented in a Virtual private server (VPS) with a MEAN service stack application, which has three layers: an MQTT Broker, the Web Page, and the NoSQL database.

Because we use Mosquitto MQTT Broker [25], "Mosquitto" is an MQTT Broker developed by Eclipse Organization, so the VPS must be installed in Mosquitto MQTT Broker library. The other library, as well as the frameworks, have to be installed: mongoose, Socket.IO [26], Express.js, and MongoDB. The installing process can be conducted via Plugin Remote-SSH, which can search in Microsoft Visual Studio. After done debugging and organizing, all of the coding files and library is upload to the BKhost hosting service. The Bkhost is a VPS hosting seller, our VPS Hosting address is http://103.130.212.132:8000/

The web page (Application) can be divided into a Front-end and Back-end. Angular.js with Bootstrap packet [27] provides for the client-side framework. The server-side or back-end side is used to query databases for information and processing any logic that a web application requires. Node.js is a server-side scripting language that is used to interact with the database as well as allows a server to a high number of connections while handling multiple requests.

III. Results and Discussion

The sensor nodes have been tested inside the Vietnamese German University campus - an ideal greenhouse, with three floors, covered by the metallic structure as well as concrete walls, which have over 5000-meter square surface. In our ideal greenhouse, the study is not much affected by natural reasons like wind, dust, rain. The nodes are installed at a height of 100 cm above the ground while the height of repeaters is 150cm. The gateway is put on the first floor. The distance between the sensor nodes and the other nodes or repeaters is 15m. And the distance between the gateway and nearest node (light of sight) is 100m.

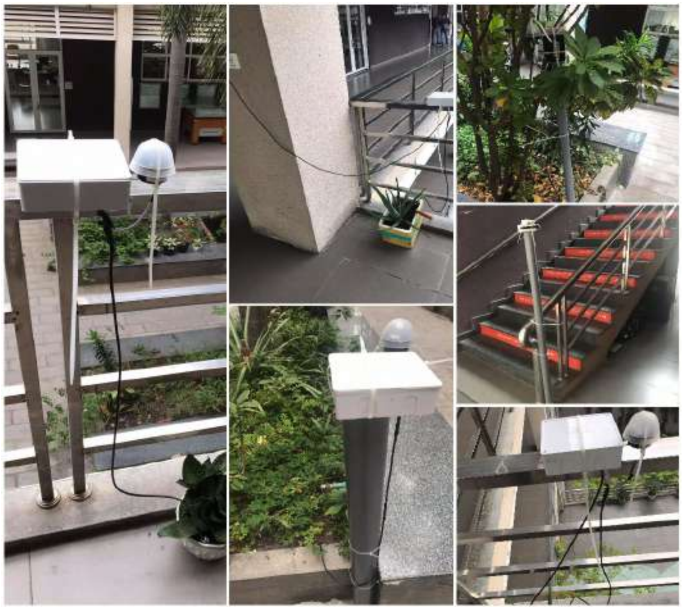

Fig. 7. Sensor Nodes and Repeaters Installation inside Vietnamese German University Campus

The results of the implementation of our system are shown:

1) Mesh Wi-Fi Network: The Fig.8. shows the Network topology of the system.

2) Power Consumption: This section demonstrates some data about battery tests. In this calculation, we performed the current measurement through the sensor node. We also calculated the total current consumption of the sensor node and found out how long the battery could last. The gateway is not included in this test because It is powered by the

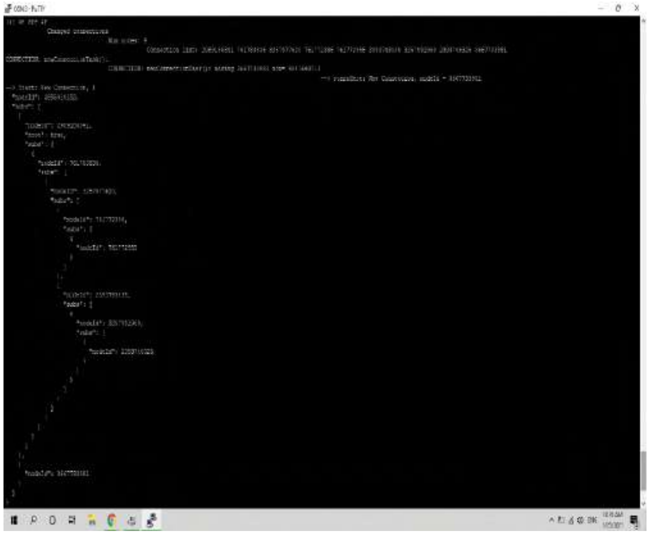

Fig. 8. The Topology of Mesh Network

wall outlet. The sensing device is powered by a small 3.7V Lithium Polymer (LiPo) battery, at a full charge voltage is 4.2V. The average power of node, measured, is 281mW (It is up to the distance of nodes). In our test, the line of sight distance of the two nodes is 15m, the current consumption is 74mA. Even when a node is not transmitting data, it has current consumption is about 70 mA [28] just because the Wi-Fi mode is always on so as to maintain the Mesh network. It also means that the current consumption of repeater is 70mA. However, it is negligible because according to [15] the current consumption of ESP8266 WEMOS D1 is 170mA in data transmission mode.

The battery life is calculated by the equation. It is very harmful to use an exhausted battery. In the battery, we attached a TP4056-Micro USB 5V 1A Lithium Battery Charger with Protection to protect it. The ideal time of the battery is calculated by 5000mAh/74mA = 67hours. However, in real testing, the time just lasts over 55 hours or within 2,5 days.

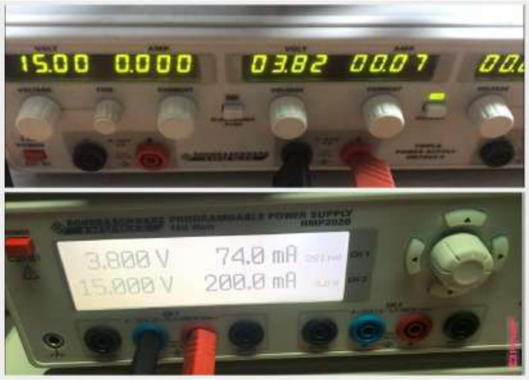

Fig. 9. Power Consumption of a Node

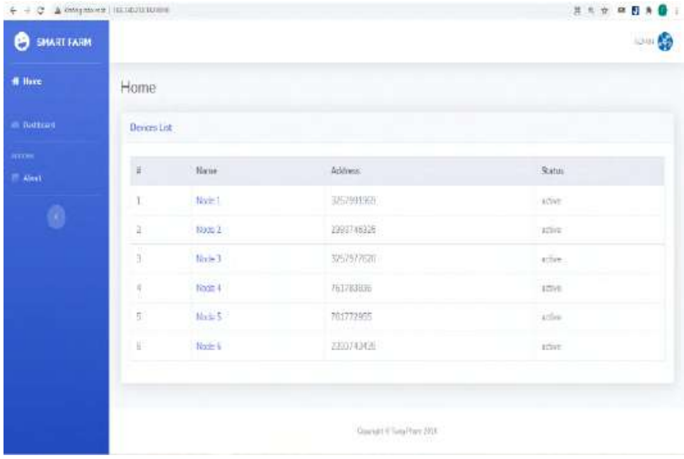
3) Functionality: The app's main screen is the map as shown in Fig.10. The monitoring platform server is available at the following URL: http://103.130.212.132:8000/. The main screen is the entry page the user sees when accessing the website. In there, there is a device list of nodes, node addresses, and the status activity as shown in Fig.10.



Home

IV. Conclusions

In this paper, a cost-effective and highly reliable system with high communication speed is implemented by using a mesh Wi-Fi wireless sensor network. Wi-Fi Mesh Network and the MEAN stack web development framework play a significant role in the monitoring system.

This work opens up new doors for future studies as well as developed new tasks for the foreseeable future. The first main goal of the system is to deploy in a near scenario of an agriculture application. Next, the necessary tasks will be carried in the near future, referred to as short-term (ST) like Powering system, Irrigation system whereas long-term (LT) tasks like Security and Privacy, Edge Analytic should be researched more to enhance the productivity of the field.

Abstract*- *There are many prostheses focused on people with an amputation below the elbow. There is also limited information for its development and construction, many studies provide information that helps the researcher, but these are scattered, each one proposing different characteristics and solutions. Based on this, the objective is to provide the researcher with a structured matrix that integrates different studies related to hand prosthesis, this will allow him to evaluate alternatives where he will be able to choose, analyze the study or characteristics that better contribute to his research topic. As methods, it used specialized search engines that helped to structure the matrix. Currently there is little information on prostheses based on encephalographic signals, so it was also incorporated into the matrix, likewise in the proposals it considers from 2 to 15 DoF (degrees of freedom), actuators used, and the classification of prostheses that are active, passive, electric, myoelectric and hybrid. In conclusion, the article will provide information to people who want to create a superficial extension below the elbow and make use of the control of electromyographic signals that are extracted from muscle contractions.

Keywords: Electromyography - Encephalography – Upper-Limb - Prosthesis - Degrees of freedom

I. Introduction

Currently, the development and creation of prostheses for people with upper-limb amputations are progressive because they are required for the advantages they can provide to the patient. But, although it knows that some prostheses are developed with a direct approach to the clinical problem and others created from the patient's specifications, then the problem arises to know if the artificial extension acquired meets the requirements that the patient wishes to obtain.

A very particular problem that affected people present are the injuries produced below the elbow, it is estimated that worldwide there are at least 10 million amputees, of which 30% (3 million) are amputations of the arm and hand, of which 2.4 million are people living in developing countries. [1] Given the problem, hand prostheses should be analyzed with respective importance since a well-developed prosthesis substantially improves the affected person's quality of life. On the other hand, it can see already models of feedback prosthesis as the myoelectric prosthesis (Otto Bock) and the most marketed which is the bionic prosthesis I-Limby. Each one is specifically differentiated by its characteristics, but despite the advances that hand prostheses show day by day, there are still limited functions that do not achieve the real performance of the hand in its totality. Any study can be achieved if it has a good base of relevant data. In general, most of the studies, literature reviews of hand prosthesis propose individual solutions considering separate characteristics of which it could be observed that independently each one contains very important information and these organized together can contribute a lot for the development of a hand prosthesis.

3D printing was seen as a new trend due to its low cost. This is the case of Ruiz et al.[2] who created a 3D prototype using electromyography, focused on the field of rehabilitation and with greater accessibility, Piazza et al. [3] showed the possibility of realizing prosthetic systems from a hybrid and electrical solution, using inputs from a shoulder harness to control 19 degrees of freedom (19 DoF), creating the SoftHand Pro-H, On the other hand, Castillo et al. [4] designed and fabricated a hand prosthesis with anthropometric and anthropomorphic characteristics extracted from radiographs, and Cognolato et al [5] created an efficient myoelectric control system based on the Myo bracelet and used a gesture classifier to control it.

Finally, there is already a prosthesis focused on upper-limb amputees who work in offices and want to resume work at the computer can do so thanks to this design where Lopez et al. [6] proposed a 3D prosthesis controlled by EMG signals, which facilitates the use of keyboards for development. Likewise, if it analyzes and evaluates the characteristics, it will provide complete information for people who want to develop a hand prosthesis. Therefore, this research aims to provide a structured

978-1-6654-4067-7 / 21 / $ 31.00 © 2021 IEEE

matrix with information from different studies that contain relevant data and provide true data. For the development of the matrix, it considered studies that were carried out in a certain period and with this, it has current information, it details the control inputs used in each study, the degrees of freedom they develop, the type of loss of the affected people, type of prosthesis, the actuators they used and finally the state of development in which it is.

II. Data Collection Methodology

The search was carried out in the specialized search engines "Google Schola", "IEEE Explore", "PubMed" and "ERIC" also open access articles from journals such as "Science", "Redalyc" as well as collaboration and dissemination platforms such as "ResearchGate", "Elsevier" and "Dialnet" were examined. The publication period of the selected articles spans from December 2016 to May 2020. Since the review aims to analyze publications that consider the design of upper-limb prostheses, either the control system or the physical implementation, the search terms used were: "prosthetic hand", "design" and "DoF" (degrees of free). A total of 83 articles were collected, 28 in Spanish and 55 in English. The result of the reading, analysis, interpretation, and integration of the information from each source is shown in the text presented here.

III. Publications Review

The reviewed publications of the last 5 years on upper-limb prostheses are shown in Table 1 in detail, considering the most important aspects of the publication.

E.: Not specified

A. Control inputs

It is possible to use different signals as device control inputs, depending on the type of control strategy to be used.

In Table II. Among the most used signals are electromyography (EMG) signals with a 47.6% share. These signals are used for the control of upper-limb prostheses. It is called (EMG) because the signals are captured from muscle contractions. The graph also shows that 13.4% of the EMG signals are complemented by inertial sensors (IMU). For example, commercial devices such as the Myo armband bracelets use sensors on their control card that read EMG and inertial signals (IMU). These devices have been used for the control of prostheses in various investigations. 84] On the other hand, other prostheses use other types of sensors complementary to EMG, such as those that measure force, EIT, pulse, EMG-EEG, EMG-pressure, EMG-gestures occupying 1.2% and those of light, force-position with 2.4%, but to date, they register an infrequent use and finally there are unspecified control inputs with 20.7%.

TABLE II. DISTRIBUTION PER CONTROL INPUT

Control input types	Quantity	
	Frequency of use	Percentage %
EMG	39	47.6%
Not specified	17	20.7%
EMG - IMU	11	13.4%
EEG	3	3.7%
Force – Position	2	2.4%
Light	2	2.4%
EMG–Force-Position	1	1.2%
EMG-Gestures	1	1.2%
EMG-Force	1	1.2%
EMG-Pressure	1	1.2%
EMG-EEG	1	1.2%
Pulse	1	1.2%
Force	1	1.2%
EIT	1	1.2%

B. Degrees of freedom (DOF)

According to the model proposed by Quiang Zhan [85] the human hand has 21 degrees of freedom [DoF]. The index, middle, ring, and little finger consist of 3 phalanges and 4 DoF, the thumb of 2 phalanges and 51 DoF, and the wrist of 3 DoF. See Fig1.

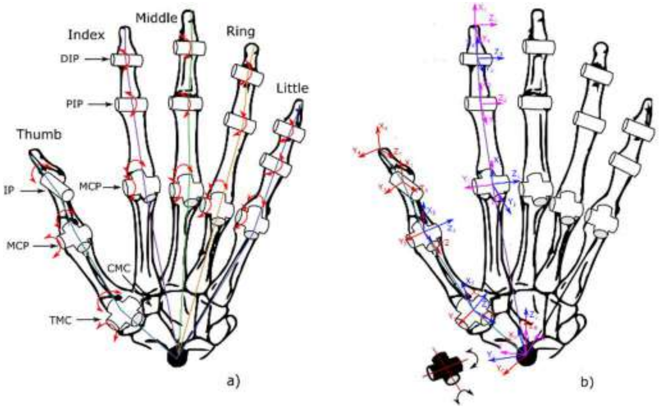

Fig. 1. Qiang Zhan 21 DoF model of the human hand. a) structural model and b) kinematic model Source: Zhan Q, Zhang C, and Xu Q. Measurement and Description of Human Hand Movement [2017].

It is considered ideal that a hand prosthesis manages to represent the total DoF that make up the hand and wrist, but generally, among the prototypes and designs proposed by various authors referenced in the research, they are mainly focused on representing between 2 to 15 DoF of the hand to perform the opening and closing movements of the fingers, among other movements. Likewise, the degrees of freedom of the wrist given to the prosthesis is necessary; most of the proposed prototypes consider between 1 to 2 DoF of the wrist. In the market, there are more advanced prostheses whose mechanism deploys the 3 DoF of the wrist, giving greater versatility of the prosthesis to perform more precise tasks, but they have a less accessible cost.

C. *Loss type*

There are different types of upper-limb prostheses in the biomedical market for users with congenital malformations or who have suffered a loss of the entire limb or specific segments.

In Table III. In the studies reviewed in this research, it was found that most researchers developed their prosthesis proposals oriented at 47.6% for users with trans-radial amputation (ATR) and 24.4% for users with amputation with wrist disarticulation (ADM). It was also found for users with other types of loss such as ADH (amputation with shoulder disarticulation) and ATH (transhumeral) with the participation of 6.1% as well as only ATR and ATMC (transmetacarpal) with 2.4%. Prostheses adaptable to their condition were also developed, but in smaller numbers, such as APM, ATC, DPM, ADH-ATH, ATR-DC, ATC-ATR-ATH, and 1.2%, and finally, there is a percentage of unspecified type of loss with 9.8%.

TABLE III. DISTRIBUTION BY LOSS TYPE

Loss Type	Quantity	
	Frequency	Percentage %
ATR	39	47.6%
ADM	20	24.4%
Not specified	8	9.8%
ADM-ATR	5	6.1%
ATMC	2	2.4%
ATH	2	2.4%
APM	1	1.2%
ATC	1	1.2%
DPM	1	1.2%
ADH-ATH	1	1.2%
ATR-DC	1	1.2%
ATC-ATR-ATH	1	1.2%

D. *Movement type*

From a physiological point of view, the hand represents the upper-limb's effector that forms its logistic support and enables it to adopt the most appropriate position for a specific action. [86] It should be noted that the hand is a complex limb; therefore, it is essential that the design of a prosthesis takes into consideration the movements and articular functions of the limb. According to the articular physiology of the wrist, Fig. 2 a) shows the terminology of the movements that the joint executes; similarly, Fig. 2 b) shows the terminology of the movements of the hand and fingers.

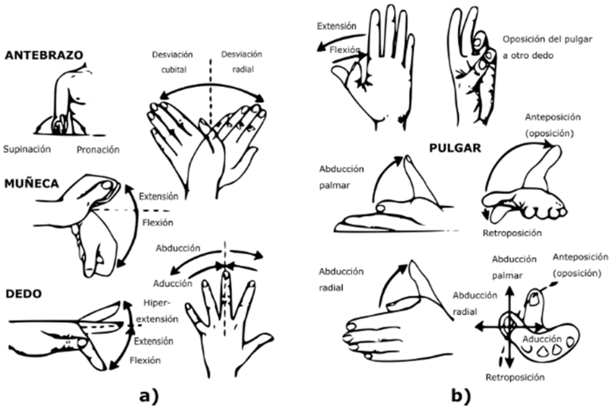

Fig. 2. a) Terminology of wrist and finger movements, b) Terminology of hand and finger movements. Sources: "The Hand: Examination and Diagnosis"(p. 11) by American Society for Surgery of the Hand.

Concerning the articles reviewed in this research in the last 5 years, the researchers considered some of the hand's movements and versatility in the development of the design and construction of the upper-limb prosthesis proposals. Table IV shows the most performed movements and functions that were granted to the prostheses.

TABLE IV. MOST PERFORMED MOVEMENTS AND FUNCTIONS

Upper-limb segment	Movement type
Hand	Opening and closing Clamp Hook grip Cylindrical grip Thumb abduction and adduction
Wrist	Pronation Supination Ulnar deviation Radial deviation Flexion Extension

In the upper-limb prostheses proposed in the research, the researchers represented up to 2DoF of the 3DoF that make up the wrist joint. This shows a limitation in their proposals. Among the most represented movements in the design and construction of the prostheses were the pronation-supination and flexion-extension movements.

E. *Prosthesis type*

In this area, 7 types of prostheses were found: myoelectric, mechanical, active, hybrid, electric, passive, and virtual.

Table V. Myoelectric prostheses with a percentage of 62.2% are the most applied since they currently have aesthetics, strength, and speed of grip, for myoelectric control, is based on the muscles' electrical signals (EMG). [87] The mechanical prostheses with a percentage of 7.3%, unlike the myoelectric ones, do not use any type of sensor for their activation. The control applied is using movements of the elbow, shoulders, or chest.

The active prostheses have a percentage of 7.3%, this type of prosthesis is defined because they have movement, unlike the passive prostheses with a 2.4% that do not generate any kind of movement its application is aesthetic and hide the injury that has in the upper-limbs, also shown with 15.9% to hybrid prostheses this type of prosthesis is practically the combination of myoelectric and mechanical prosthesis making it more versatile. [88]

Finally, it is observed that the types of electrical and virtual prosthesis occupying 3.7% and 1.2% values are minimal because its application, unlike myoelectric, hybrid, and mechanical prostheses, does not have the requirements to replace the operation of a human upper-limb.

TABLE V. DISTRIBUTION BY TYPE OF PROSTHESIS

Prosthesis Type	**Quantity**	
	Frecuencia	**Percentage %**
Myoelectrical	51	62.2%
Hybrid	13	15.9%
Mechanical	16	7.3%
Active	8	7.3%
Electrical	4	3.7%
Passive	2	2.4%
Virtual	1	1.2%

F. *Actuators*

In this area, a review of the types of actuators used for the development of prostheses, which are important to be able to mimic the movements of each joint that make up a human arm, 5 types of actuators were identified: linear actuator (ML), motors (DC), servomotor (S), micromotor (MC), micro servo (MS) and the conjugation of the DC-S motor.

In Table VI. The servomotors have a percentage of 32.9% and are the most used because of the ease of controlling these actuators since they have delimited rotations and are designed to move several degrees and remain stable in that position. DC motors have a percentage of 17.1%; these actuators have magnets inside generating a magnetic field to be powered by electricity-generating rotary movements. It is also observed that linear actuators have a percentage of 7.3%, placing them as the third most used actuator for the development of these robotic devices, the most relevant characteristic of these actuators is the movement in a straight line. Finally, the MS, DC-S actuators are found with 3.7%, which are not so widely used for the development of these robotic devices. And among others that could not be specified in the studies.

TABLE VI. DISTRIBUTION BY ACTUATOR TYPE

Prosthesis Type	**Quantity**	
	Frequency	**Percentage %**
S	27	31.7%
Not specified	26	32.9%
DC	14	17.1%
ML	6	7.3%
MC	3	3.7%
MS	3	3.7%
DC-S	3	3.7%

G. *Prosthesis development status*

In this area, a review of the status of prostheses such as prototype, design, study, simulation, comparison, and commercial prostheses was carried out.

Table VII. It shows the more significant number of studies that are reached with prototyping obtaining a percentage of 60.2% and 14.5% of the research remains in studies contributing new methods of prosthesis development. The 9.6% of the research has a validation of the functioning of its prototypes, and they are exposed in the market for its commercialization. It was also found research that reached to make the design of its prototypes with 9.6% of the total of the reviewed research. Furthermore, it found research that made comparisons of new control methods occupying 2.4% and simulations with 3.6% contributing to improving future research related to the creation of these robotic devices.

TABLE VII. PROPORTION BY STAGE OF DEVELOPMENT

Types of Advance	**Quantity**	
	Frequency	**Percentage %**
Prototype	50	60.2%
Studies	12	14.5%
Commercial Prosthesis	8	9.6%
Design	8	9.6%
Simulation	3	3.6%
Comparison	2	2.4%

IV. Conclusion

Since the number of users requesting the use of an upper-limb prosthesis due to traumatic amputation or malformation has been increasing in the last 5 years, numerous research groups have made proposals for upper-limb prostheses usually controlled with myoelectric signals and position signals from inertial sensors (IMU), with remarkable results. Similarly, proposals have developed from 2 to 15 DoF for finger movement in addition to wrist movement, but are still in the development stage.

The proposals are oriented to users with an amputation below the elbow since their control is based on acquiring muscle signals from the forearm. It should be noted that with these devices the user will be able to perform multiple grips, perhaps not all the movements made by the hand, but the necessary ones. The article reviewed various investigations regarding designs and prototypes of upper-limb prostheses, several aspects need to be improved such as the cost of development, ergonomics to achieve better adaptability with the upper-limb in question.

A lot of research has been done on material types. However, most of the devices did not focus on a special material that will have contact with the patient's residual limb as this is important in order not to generate injuries when using these robotic devices. There is still room for improvement and further development of more prostheses that come closer to the actual functioning of a human upper-limb.

***Abstract*— Studies on the development of lower-limb exoskeletons began in the 1960s. However, these robotic devices' technological progress has been plodding, despite being studied for a long time. Therefore, the purpose of this article is to document a systematic review of the trends in the application of components that are part of the development of exoskeletons applied to the rehabilitation of lower-limbs. The objective is to provide the researcher with a structured matrix that integrates these components related to lower-limb exoskeletons development. As methods, it used different databases and specialized search engines that helped collect research from 2016 to 2020. The process of filtering and selecting the reviewed research was carried out, leaving 90 selected. Finally, it is concluded that there is still room for improvement and continue development of lower-limb exoskeletons that contribute to the rehabilitation process and are closer to the human lower-limb's real functioning.**

***Keywords*— exoskeleton, lower-limbs, rehabilitation, TRL**

I. INTRODUCTION

Robotics is in development and growth; in recent years robotic structures such as exoskeletons are being created and manufactured to contribute and help human limbs in different tasks. Exoskeletons are mechanical structures attached to the human limbs to amplify or increase the user's strength. The main applications are in industries, military technology, and medicine. The exoskeleton can be applied to perform rehabilitation therapies for the upper and lower-limbs due to some type of disease or accident that produces a temporary loss of muscle activity [1].

The history of the development of exoskeletons began in the 60s with the name of Man Amplifier created by Neil Mizen; in 1965 the Hardiman Suit project led by General Electric in the United States was carried out; this Motorized exoskeleton was used to manipulate materials [2]. In 1980 Jeffrey Moore stated that the exoskeleton can help increase human performance for military purposes [3].

The lower-limb exoskeletons began to develop in the 1960s; the reasons for their development were muscle weakness. This robotic mechanism helped patients with spinal cord injury to regain their gait. Rehabilitation technologies for people with locomotion disabilities have been developed over the years in several institutions and universities around the world. Nowadays, there are different robotic devices that provide autonomy to people with walking difficulties, among which is the exoskeleton for lower-limbs.

People with some type of disability face common problems that are reflected in the deterioration of their quality of life, since in most cases they must depend economically and socially on someone for their integration into society. According to the World report on disability, in the year 2019, it is estimated that more than one billion people live with some type of disability, or about 15% of the world's population.

The main reasons for the disabilities can be divided into two groups: muscular diseases and diseases that affect the nervous system; in both cases, a treatment that favors the recovery of the affected parts must be chosen. It is crucial to perform rehabilitation therapy when you suffer from a temporary loss of the upper and lower-limbs. Research trends show that failure to perform good rehabilitation therapy results in the ultimate loss of limbs. Based on the literature, exoskeletons are being developed primarily for military, industrial, and medical purposes.

This article's objective is to systematically review the development and creation trends of lower-limb exoskeletons applied for rehabilitation where analysis of the characteristics that compose them such as type of loss, supported movements, degrees of freedom, material, actuators, and developmental stage of the exoskeleton. Finally, conclusions will be made based on recent trends shown by exoskeletons.

II. METHODOLOGY

For the development of this research, a search query was made in the database of "Scopus", "IEEE Explore", "Springer link", "PubMed", "Google Scholar", also access articles from journals such as "Redalyc", "Science" as well as collaboration and dissemination platforms such as "ResearchGate" and "Dialnet". Keywords were used such as an exoskeleton, lower-limbs, and control. Eight hundred eighty results were obtained and publications on lower-limb exoskeleton, movement

978-1-6654-4067-7 / 21 / $ 31.00 © 2021 IEEE

control, dynamic and kinematic analysis were excluded. This process resulted in an average of 90 publications that covered from 2016 to 2020.

III. REVIEW OF PUBLICATIONS

To simplify and structure the information. The lower-limb exoskeletons were classified according to the sensors implemented, degrees of freedom (DoF), type of loss of the lower-limbs, supported limbs of the exoskeleton, material used for manufacturing, actuators, and state of development of the exoskeleton [prototype or study].

The review describes the different designs of the mechanical and control parts of the lower-limb exoskeletons. Also, interface connection components connect the actuators with the human body.

Note: Abbreviation: AC: Strokes, H: Hypertrophy, PMI: Loss of lower-limb movement, P: Paraplegia, LME: Spinal cord injury, E: Sclerosis, DM: Muscle deficiency, AP: Leg amputation, CR: hip and knee, CT: Hip and ankle, RT: Knee and ankle, CRT: Hip, knee and ankle, R: Knee, C: Hip, T: Ankle, AL: Linear actuator, APP: Stepper Actuator, AN: Pneumatic Actuator, S: Servomotor, SH: Hydraulic Servo, AH: Hydraulic Actuator, AE: Elastic Actuator, TRL 1: Basic Research, TRL 2: Technology Formulation, TRL 3: Applied research, TRL 4: Small-scale development, TRL 5: Real-scale development, TRL 6: Valid system in simulated environment, TRL 7: Real-environment validated system, N.E.: Unspecified

A. *Type of loss*

Several types of loss were found in this group: loss of lower-limbs (PMI), muscular deficiency (DM), paraplegia (P), hypotrophy (H), cerebrovascular accidents (AC). Table II describes the characteristics of the types of losses mentioned.

TABLE II. TYPES OF LOSSES

DM (Muscle Deficiency)	Loss of strength in the muscles
P (Paraplegia)	Paraplegia reacts to the loss of control of the trunk and generates a paralysis of the muscles generating difficulty in mobilizing and walking [94].
H (Hypotrophy)	It is the decrease in muscle mass and this implies the loss of strength, generating the inability to stand.
AC (Cerebrovascular accident)	It is a neurological pathology more common in adults that generates severe disabilities such as muscle weakness, loss of volumetric movements, and causes difficulty in wandering [95].

It is crucial to consider the type of loss that the patient suffered and to be able to develop an appropriate exoskeleton to achieve rehabilitation since by not doing a good rehabilitation session it is very likely that the patient will lose the total mobility of their lower-limbs. As can be seen in Table III, most of the studies were focused on PMI with 78.9% [27,28,72], followed by AC with 7.8% [1,5,14] and the rest below 5%.

TABLE III. PERCENTAGE OF STUDIES IN FACIÓN TO THE TYPE OF LOSS

Muscle Deficiency	Amount	
	Frequency	Percentage
PMI	71	78,90%
AC	7	7,80%
Q	4	4,40%
H	2	2,20%
DM	2	2,20%
AP	1	1,10%
LME	1	1,10%

Note: AC: Strokes, H: Hypertrophy, PMI: Loss of lower-limb movement, P: Paraplegia, LME: Spinal cord injury, DM: Muscle deficiency, AP: Leg amputation

B. *Supported movements*

In this area, a review is carried out on the parts where rehabilitation is applied through the lower-limbs' exoskeletons. The lower-limbs count various movements are shown in Fig. 1; according to the reviewed research, applications were identified in the hip (C), ankle (T), knee-ankle (RT), hip-knee (CR), hip-knee-ankle (CRT), and knee-ankle (RT). In Table IV the application that stands out the most in the studies are the movements in CRT with 62.2% [33,37,45]. This reflects that the prototypes focus on performing a complete rehabilitation applying to the hip, knee, and ankle, which are the components of a human lower-limb. Furthermore, 23.3% focused on developing prototypes of movements in RC [54,83], and a percentage of 7.8% indicates that exoskeletons are applied to rehabilitate RT.

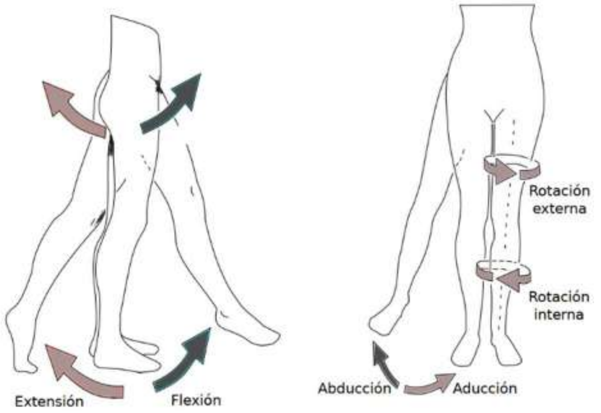

Fig. 1 Flexion / Extension, Abduction / Adduction and Internal / External Rotation movements. Source: K. L. Moore, A. F. Dalley, and A. M. Agur, Clinically Oriented Anatomy, Spain: Lippincott Williams & Wilkins, [2010]

The rest of the applications do not exceed 2.3% in Table IV, it is also observed that the most important supported movement is the knee since the mobility of the lower-limbs depends on that part of the body.

TABLE IV. PERCENTAGES OF STUDIES BASED ON SUPPORTED MOVEMENTS

Supported movements	Amount	
	Frequency	Percentage
CRT	56	62,20%
CR	21	23,30%
RT	9	10,00%
C	2	2,20%
T	2	2,20%

Note: CR: hip and knee, CT: Hip and ankle, RT: Knee and ankle, CRT: Hip, knee and ankle, R: Knee, C: Hip, T: Ankle

C. *Degrees of Freedom (DoF)*

In this area, a review is carried out on the degrees of freedom that exoskeleton prototypes have. The lower-limbs have a total of 8 DoF at the hip has 3 DoF as shown in Fig. 2, at the knee 2 DoF, and ankle 3 DoF as visualized in fig. 3 for each leg. It is considered ideal that a lower-limb exoskeleton has the total DoF that the lower-limbs makeup, Table V shows that the highest number of exoskeletons with a percentage of 38.2% have 6 DoF according to the reviewed research, with a percentage of 21.3% have 4 DOF followed by 13.5% with 2 DoF. The exoskeletons that have 3 DoF, according to the research reviewed with a percentage of 11.2%, are devices applied to a lower-limb. The image also shows exoskeletons with 1 DoF with a percentage of 6.7%; according to the research reviewed, these robotic devices consist of rehabilitating only a part of the lower-limb, be it ankle, knee, or hips. You can also find research on exoskeletons with 14 DoF occupying a 3.4% percentage, closer to the DoF that human limbs count.

Finally, with a percentage of 1.1%, investigations with 7 and 8 DoF were found according to the review carried out.

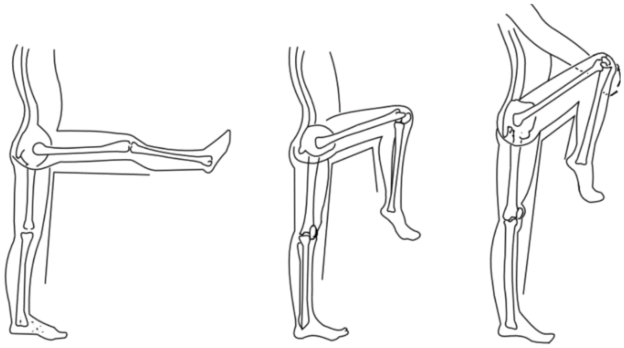

Fig. 2 Hip flexion increases by relaxing the hamstring muscles by flexing the knee. Passively the bending is greater. Source: R.C. Miralles Marrero, Clinical biomechanics of the locomotive system, Spain: MASSON, [2000]

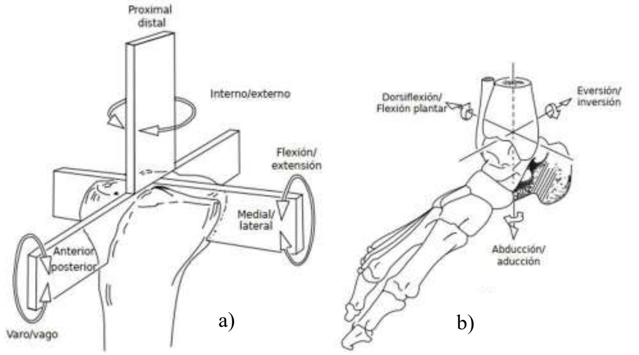

Fig. 3 (a) Representation and nomenclature of the six degrees of freedom of movement of the knee: anterior and posterior translation, medial/side translation and proximal/distal translation, flexion-extension rotation, internal-external rotation and b) Representation and nomenclature of the six degrees of knee freedom of movement: anterior and posterior translation, medial/side translation and proximal/distal translation, bend-extension rotation, internal-external rotation of varo-valgo. TABLE V. PERCENTAGE OF DOF OF LOWER-LIMB EXOSKELETONS

Degrees of freedom	Amount	
	Frequency	Percentage
1	6	6,70%
2	12	13,50%
3	10	11,20%
4	19	21,30%
6	34	38,20%
7	1	1,10%
8	1	1,10%
12	1	1,10%
14	3	3,40%
N.E.	2	2,20%

D. *Type of material*

In this area, a review is made of the type of material they tend to use to develop the exoskeleton. Table VI shows the various materials that are used for the construction of these robotic devices. 48.9% of the researches reviewed uses aluminum material, taking advantage of the properties it offers, unlike other materials, aluminum has a specific weight of one-third of the weight of the metal, and aluminum has a layer that protects it from rust; that is why most of the researches reviewed use aluminum for the creation of their prototypes [4]. As can be seen in the image for the development of the mechanical structures of exoskeletons, they combine other materials with PLA and aluminum with a percentage of 4.4%, aluminum, and steel with a percentage of 3.3%, carbon fiber and aluminum with a percentage of 2.2%, polypropylene, and aluminum with a percentage of 1.1%, steel and nylon with a percentage of 1.1% according to the research reviewed providing more versatility to your prototypes. The figure also shows the use of PLA in a percentage of 2.2%, it is a rarely used material, because the exoskeleton structure usually supports loads greater than what the PLA material can support, the use of steel is in the percentage 2.2% because this material is very heavy compared to aluminum and this generates muscle fatigue in patients when they undergo their rehabilitation treatment. Finally, materials such as MDF and nylon are rarely used for the development of exoskeletons due to their mechanical composition that does not provide the necessary support to support loads such as the weight of the patient.

TABLE VI. PERCENTAGE OF THE TYPE OF MATERIAL USED FOR THE DEVELOPMENT OF THE EXOSKELETAL STRUCTURE OF THE REVISED RESEARCH

Material	Amount	
	Frequency	Percentage
Aluminum	44	48,90%
PLA-Aluminium	4	4,40%
Aluminium-Steel	3	3,30%
PLA	2	2,20%
Steel	2	2,20%
Carbon-Aluminium Fiber	2	2,20%
MDF	1	1,10%
Nylon	1	1,10%
Polypropylene-Aluminum	1	1,10%
Carbon Fiber	1	1,10%
Steel-Nylon	1	1,10%
N.E.	28	31,10%

E. *Actuators*

The investigations developed solutions to imitating the movements with various actuators that do not affect the joints with sudden movements. Within these actuators, it was possible to identify linear actuators (AL), step by step (APP), hydraulic (AH), servomotors (S), and hydraulic servomotors (SH). In Table 7 it can be observed that the linear actuator stands out with a percentage of 54.4%, these actuators provide a greater force to perform the movements [30-32]. It is also possible to highlight the servomotors by restricting movements to delimited positions as the programming indicates and the patient requires [22, 25, 34]. In Table VII the stepper actuators are also shown with a percentage of 5.6%. And finally, the other actuators that do not exceed 2.2% are not as widely used for the development of these robotic devices.

TABLE VII. PERCENTAGES OF STUDIES BASED ON THE ACTUATOR EMPLOYED

Actuator	Amount	
	Frequency	Percentage
AL	49	54,40%
S	12	13,30%
APP	5	5,60%
SH	2	2,20%
OH	2	2,20%
AE	1	1,10%
AH-S-AL	1	1,10%
AH-AL-AN	1	1,10%
AL-SH	1	1,10%
AN	1	1,10%
N.E.	15	16,70%

Note: AL: Linear actuator, APP: Stepper actuator, AN: Pneumatic actuator, S: Servomotor, SH: Hydraulic servo, AH: Hydraulic actuator, AE: Elastic actuator.

F. State of exoskeleton development

Each investigation managed to determine different objectives to collaborate in developing an exoskeleton for the different types of rehabilitation reaching different states such as functional, prototypes, designs, and studies. Table VIII shows that the most significant number of studies managed to reach a prototyping state, managing to implement programming, mathematical analysis, and mechanical design in exoskeletons, which included 62.2% [34-60]. On the other hand, there were also investigations in charge of the analysis of the exoskeletons for the improvement of the functioning, being 24.4% [63, 66, 68] and with a percentage of 8.9% according to the reviewed investigations, the development of the exoskeletons remained in design by opening the possibility for other researchers to improve and prototype these proposed designs.

TABLE VIII. PERCENTAGES OF STUDIES BASED ON THE ACTUATOR EMPLOYED

State of development	Amount	
	Frequency	Percentage
Prototype	56	62,20%
Studies	22	24,40%
Design	8	8,90%
Functional	4	4,40%

IV. CONCLUSION

With population growth and a shortage of specialists, many researchers have come up with robotic devices to help with the rehabilitation process. The article reviewed various investigations regarding designs and prototypes of exoskeletons for lower-limbs applied to rehabilitation; several aspects must be improved, such as the cost of development, the ergonomics of the exoskeletal structure that is very important to consider so as not to generate injuries to the patients from prolonged use of these devices. There is still room to improve and continue developing more lower-limb exoskeletons that contribute to the rehabilitation process and are closer to the real function of a human lower-limb. These robotic devices are forecast to get closer and closer to ideal performance in the future. It is hoped that this review will help future projects and research to select the appropriate components for the development of new prototypes.

***Abstract*-- The objective of this work is to understand COVID-19 spread and lethality across the world along with the factors affecting them. For this, we first studied the impact of COVID-19 spread across the world and then did a time series analysis to figure out the trend in cases and deaths across the world using FBPROPHET and ARIMA algorithms. We used the publicly available data until 21 January 2021(365 days) for building this model. The second part of this work involves predicting the case fatality rate through country specific indicators such as Socio-Economic, Health, Diet and Weather. To assess these factors, we would use Statistical Analysis and Feature Selection techniques to eliminate insignificant features and provide the most significant features that the healthcare professionals may focus on. In wake of delay in the advent of vaccines and eventual roll-out, this study aims to provide a tool that will assist the already overloaded healthcare system with its recommendations.**

Keywords -- COVID-19; Global; Pandemic; Time Series; Forecast; FBProphet; ARIMA; CFR.

I. INTRODUCTION

The year 2020 is riddled with a global pandemic named Covid-19 which has impacted every living form on this planet. Novel Coronavirus is part of the SARS family which was first identified in December 2019 in Wuhan city in the Hubei Province in China. This disease caused respiratory tract infection and, in some cases, also resulted in severe pneumonia. The disease is found to be extremely contagious by means of droplets and fomites resulting in worldwide pandemic. [1] WHO has announced it as a pandemic on March 11, 2020. [2] Since then this pandemic is spreading exponentially worldwide. As on Dec 06th 2020, current active cases are 6.6million, and 1.5million deaths are reported around the world. One of the most important ways to measure the burden of COVID-19 is mortality. [3] In the current outbreak of novel COVID-19, machine learning techniques have played a vital role in finding the patterns among various countries and thus helping epidemiologists and scientists alike in their research to overcome the disease.

The forecasting of the spread of the pandemic helps to inform governments and healthcare professionals what to expect and which measures to impose, and secondly, to motivate the wider public to adhere to the measures that were imposed to decelerate the spreading lest a regrettable scenario will unfold [4]. Case Fatality Rate is a metric to evaluate the mortality associated with a disease, which can be defined as the portion of confirmed cases leading to fatality. In the modified formula by WHO, the number of closed cases is replaced by number of deaths and number of recovered cases.

$$CFR\,(\%) = (No.of\ deaths/\ No.of\ closed\ cases) * 100. \qquad (1)$$

Current data indicate that, worldwide, case fatality rate (CFR, the ratio between number of deaths and number of confirmed cases) might be around 4%. However, at the country level, CFR ranges from 0 to more than 20%. There are many possible reasons for such a variation. With this study we attempt to model the spread of the pandemic[22] and help recommend the governments and health departments on the management and availability of health infrastructure for their subjects. In absence and or delay of the vaccine this effort will help contain the disease by means of providing targeted healthcare based on

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

individual's needs, mitigate the risks and substantiate the efforts to manage the health infrastructure.

II. LITERATURE REVIEW

Forecasting can predict the cases/deaths through the patterns associated with the time series data, this prediction provides a good understanding of the Spread of virus. This was studied using Prophet and Seasonal Auto-Regressive Integrated Moving Average (SARIMA) model forecasting model. [5] These models were able to generate forecast for confirmed cases for Canada, France, India, South Korea and UK. Even though Prophet being the procedure that is widely used for forecasting time series problems. It was not able to address the complex and varying patterns in COVID-19 Time series data, a SARIMA forecasting model is used which generates more accurate forecasts. These predictions will act as early warnings for government policy makers and help health care authorities effectively allocate resources. [5]

To take necessary actions, areas that are likely to be vulnerable should be known. Forecasting can identify the zones which have potential risk and is demonstrated in COVID-19 risk assessment in Counties of the USA [6]. Mann-Kendall and Sen's slope estimator trend analysis and homogeneity analysis (Pettitt's test) classified counties into 0-5 ranks, with 5 being 'very risky'.A Random Forest classifier was trained to classify the counties into risk zones. Socio-Economic status, household composition & disability, housing type & transportation, epidemiological factors and healthcare system factors of the counties were used for building the model and validated using Receiver Operating Characteristic (ROC)-Area Under the ROC Curve. The model achieved 90% accuracy (AUC = 0.90) during the training phase and 84% accuracy (AUC = 0.84) during the testing phase. This resulted to a Map of the USA with colors denoting the risk associated, thus enabling the officials to focus on region and factors which had led to high risk using the feature importance of the RF classifier.[6]

Forecasting[21] associated with case fatality and mortality rate can provide us valuable insights on not only with the spread of the pandemic but also handling the exposed population effectively. Forecasting deaths for different countries can capture the variable rates of fatality. To understand the irregularities pertaining to Case Fatalities for various countries, a research was conducted on Socio-Economic Factors and Health Indicators for a country's impact on the fatalities [7]. The authors have analyzed 16 potential factors which included GDP, Population, GNI, along with Health Indicators like Current Health Expenditure (CHE), Hospital beds per 10000 population, median age. Countries with at least 50 confirmed cases were selected for study at the time of research (14/03/2020). Pearson Correlation Coefficient was calculated for all factors in which 7 were observed to have very little impact on CFR. The Linear regression model built on the other 9 factors using the Ordinary Least Squares method, could capture 30.6% variability in CFR (Adjusted R-Square), GDP per capita, and the number of confirmed cases had the most impact. The best result was obtained by using the forward feature selection technique. Since only 47 countries had 50+ cases the data was insufficient, which had been the major challenge. [7]

Another interesting indicator that proved to have a significant effect on CFR was the Diet. The association between the global mortality rate of COVID-19 cases across different countries and dietary intake of different food groups was studied using an ecological study design [11]. The mortality rate is expressed in terms of CFR (Case-fatality rate). A total of ten food groups have been considered across 144 countries, data for which have been from Food and Agriculture Organization of the United Nations. The food intakes data was expressed in terms of kilocalories per person per day. The mathematical model is built using Bayesian regression model using Random-walk Metropolis-Hastings sampling. Results derived from the mathematical model's reports that COVID-19 case fatality rates were associated with food intake. The study suggests that nutritional factors available at country level could have a role in the mortality of COVID 19 pandemic.[11]

III. MATERIALS AND METHODS

The study is divided into 2 major steps, firstly understanding the spread and impact of this pandemic and then evaluating various factors such as the socio-economic features in the lethality of this global spread.

A. *Predicting the global cases trend(time series)*

Time Series is a series of observations taken at specified (mostly equal) time intervals. Analysis of time series helps us to predict future trends based on previously recorded values. In the Time series, we have only 2 variables, time & the variable we want to forecast, in this scenario the number of cases and number of deaths. To see how Covid-19 has impacted our world we first need to collect the past worldwide data through open-source channels such as the dataset made available by John Hopkins University. The dataset is updated on a daily basis web scraped from reliable worldwide web sources, for this research we are using the dataset until yesterday (21Jan2021). We have created 2 data frames based on countries and dates (for cases as well as deaths). We have bucketed all the cases into labels of different ranges and plot it for the entire world (As shown in below picture). Each color represents the impact of Covid-19 on each country based on cases reported.

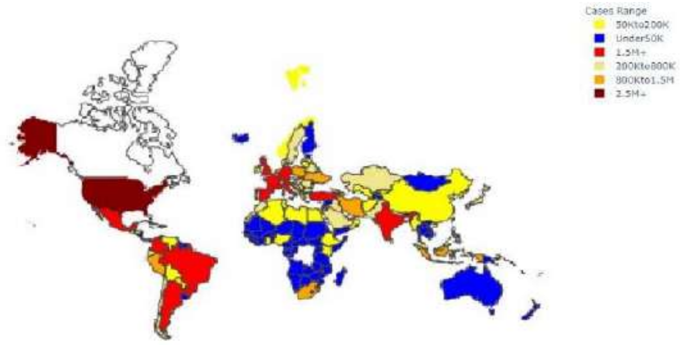

Fig 1. The map interprets the number of confirmed cases in each country (As per legend).

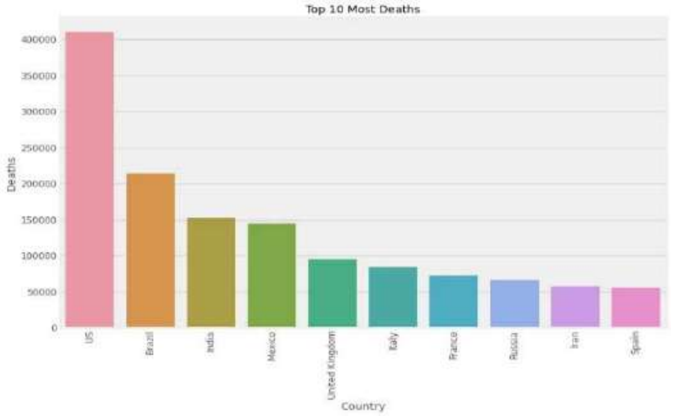

Fig 2. Histogram representation of top 10 countries based on deaths reported due to COVID_19.

For time series forecasting we have primarily used one of the 2 most popular algorithms.

1. Algorithm1- FBPROPHET:

FB Prophet is an open-source algorithm developed by Facebook for forecasting time series data based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality, plus holiday effects. It works best with time series that have strong seasonal effects and several seasons of historical data. Prophet is robust to missing data and shifts in the trend, and typically handles outliers well. Just as any time series model we first validate our data with respect to the rolling mean.

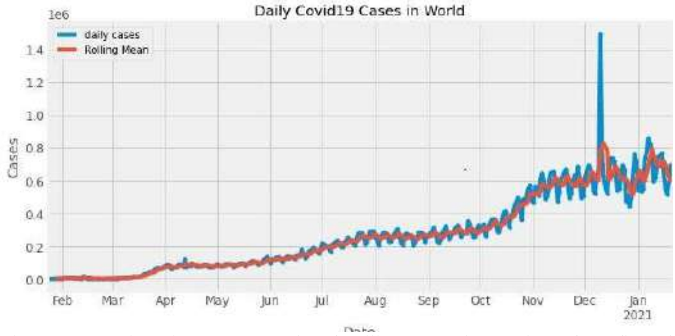

Fig 3. Comparison between actual and rolling mean in number of confirmed cases globally on daily basis.

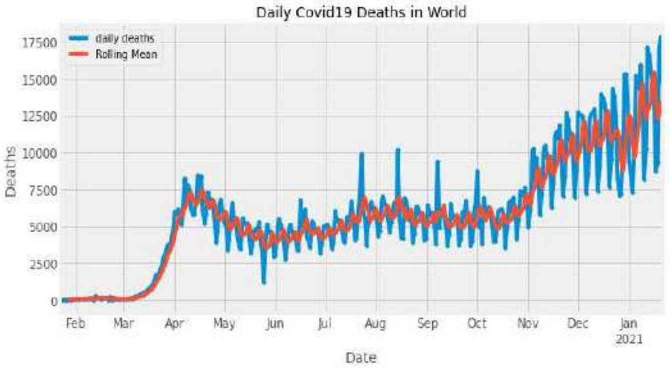

Fig 4. Comparison between actual and rolling mean in number of deaths due to covid-19 globally.

Before we look at the rolling mean one observation can be made with above graph on cases that during late December 2020 there was a sharp spike in cases observed mostly likely due to Christmas and US elections that saw mass gatherings leading to a surge in cases.

The rolling mean comparison is with the actual data that we train our model with and the moving average of that data (both confirmed cases and deaths), based on above graphs we can conclude that the rolling mean is neither overfitting nor deviating too much hence giving us the option for doing time series analysis.

2. Algorithm2 -: ARIMA:

After getting our predictions in one method we are following another algorithm named Auto Regressive Integrated Moving Average (ARIMA). ARIMA is a combination of 2 models AR (Auto Regressive) & MA (Moving Average). It has 3 hyperparameters – p (auto regressive lags), d (order of differentiation) and q (moving avg.) which respectively comes from the AR, I & MA components. The AR part is correlation between previous & current time periods. To smooth out the noise, the Moving Average part is used. The I part binds together the AR & MA parts. For the last model, ARIMA (1,1,1), a model with one AR term and one MA term is being applied to the variable

$$Z_t = X_t - X_{t-1} \qquad (2)$$

A first difference might be used to account for a linear trend in the data. The classical approach for fitting an ARIMA model is to follow the Box-Jenkins Methodology. Below is the summary of the ARIMA model developed for our modelling.

ARIMA basically involves 3 steps:

1. Model Identification: Use plots and summary statistics to identify trends, seasonality, and autoregression elements to get an idea of the amount of differencing and the size of the lag that will be required.

2. Parameter Estimation: Use a fitting procedure to find the coefficients of the regression model.

3. Model Checking: Use plots and statistical tests of the residual errors to determine the amount and type of temporal structure not captured by the model.

The process is repeated until either a desirable level of fit is achieved on the in-sample or out-of-sample observations (e.g., training or test datasets). The best fit is achieved using the lowest AIC value with respect to the best combination of p,d,q values.

To cross validate our predictions we will first split the data midway and then try to plot the predictions for the number of cases as well as deaths to see the accuracy we can achieve. Below mentioned graphs show the predicted value in red compared to the actual values in blue, showing us that our accuracy is pretty good in terms of predictions. We have split our daily data midway until June 2020.

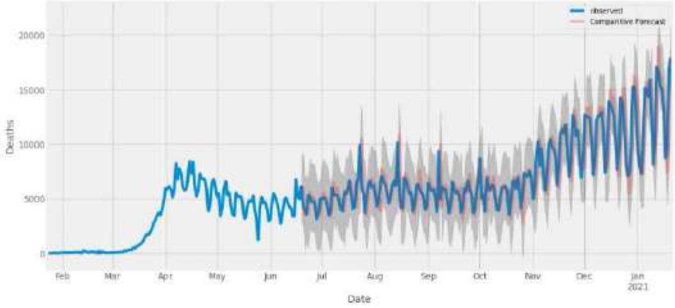

Fig 5. Cross validation between the actual data and predicted data in terms of deaths split midway over time.

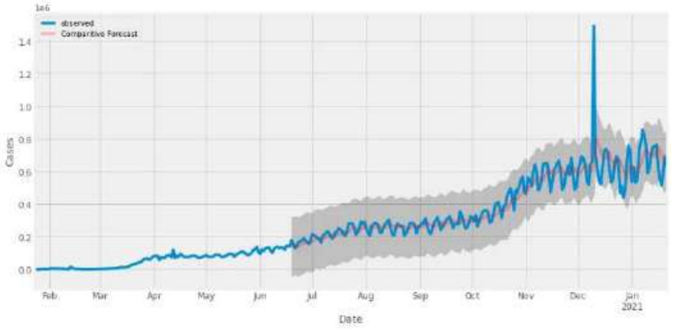

Fig 6. Cross validation between the actual data and predicted data in terms of cases split midway over time

B. *Analysis of factors impacting CFR*

The John Hopkins coronavirus dataset has been used to get the attributes ‘confirmed cases’, ‘recovered cases’ and ‘deaths’ until 15th Jan 2020 for every country. ‘WHO’ has recommended to calculate the CFR as ratio of deaths to sum of deaths and recovered cases, as active cases will not cause any bias in the study. Upon exploration of data, it has been observed that not all countries have followed the same standard to classify a case as recovered. For instance, in Belgium when the patient after treatment havingthe slightest of symptoms like headache were still considered as an active case. Therefore, having very low recovered cases leading to high CFRs. Hence the CFR for this study was calculated by ratio of deaths to sum of deaths and confirmed cases.

GDP, Population, Life Expectancy, GNI per capita, GDP per capita and Human capital Index (HCI) formed the socio-economic factors taken from the World Bank website. Current Health Expenditure (CHE) per capita, CHE as % of GDP, Hospital beds and number of doctors were extracted from WHO (World Health Organization). After the preprocessing and dropping countries with null values, the count came down to 136. Null values were not imputed as it will add a bias to the data.

As seen in research conducted previously in the Literature Review, CFR is treated as a regression problem. The model is expected to capture the maximum variability of the CFR for countries and in the process analyze the features which are able to explain this variability. R square is used as the metric to validate the model. Each attribute’s correlation with the CFR is studied as the univariate analysis. Feature Importance was evaluated with Recursive Feature Extraction (RFE) and Forward & Backward Feature Selection methods. Linear Regression and Random Forest regressor were built on the most important features.

In the next approach, the CFR was bucketed into two classes 0 and 1, where ‘0’ class indicates CFR less than 0.02 that is 2% of the confirmed cases lead to mortality. This approach gives the model to study the CFR by not precisely predicting the CFR. The aim is to study the features and not the precise prediction of CFR. Feature importance was evaluated the same way as the Regression, Logistic Regression and Random Forest Classifier were built to classify and CFR classes.

IV. Results

The FBProphet algorithms give us an estimated prediction in terms of both cases as well as deaths on a day-to-day basis that only suggest that the number of cases as well as deaths will rise going ahead with time.

However, the weekly trend shows a sharp drop during the weekends suggesting that increased number of gatherings and decreased number of testing during the weekends that lead to more cases being reported during weekdays.

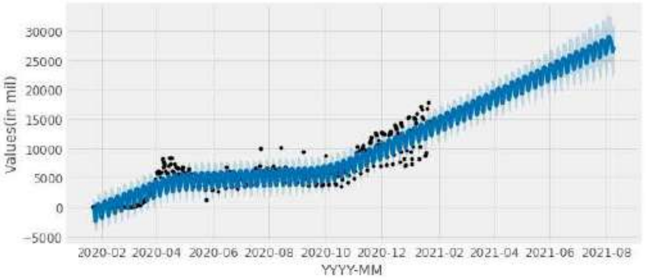

Fig 7. Getting the predictions of deaths (in thousands) for next 200 days (with black spots being the available data that was trained into model)

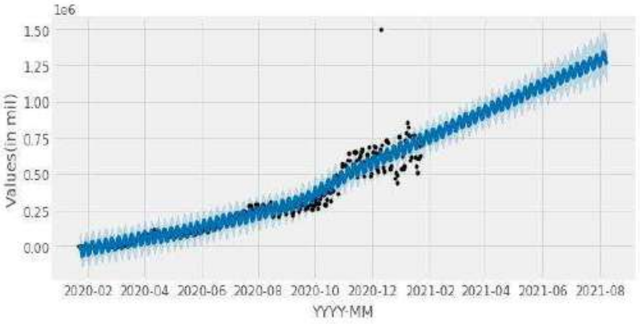

Fig 8. Getting the predictions of cases (in million) for next 200 days (with black spots being the available data that was trained into model)

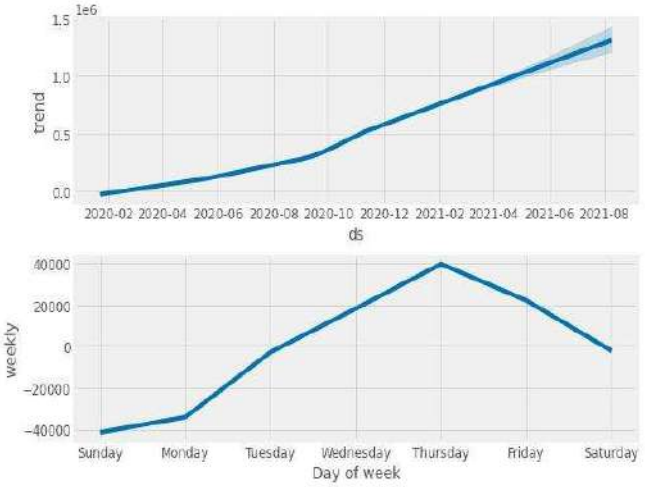

Fig 9. The monthly and weekly predictions of confirmed cases.

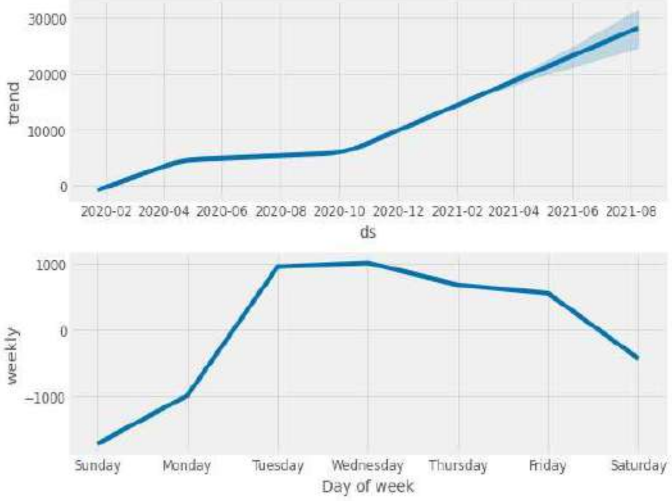

Fig 10. The monthly and weekly prediction of deaths globally.

In the case of ARIMA we can infer that even though the total number of cases in the next 200 days would increase but the number of deaths will probably see a gradual decrease mostly attributed to herd immunity

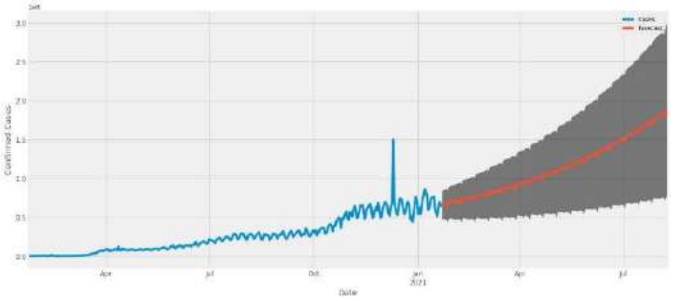

Fig 11. ARIMA prediction of total confirmed cases globally for next 200 days (Shown in red).

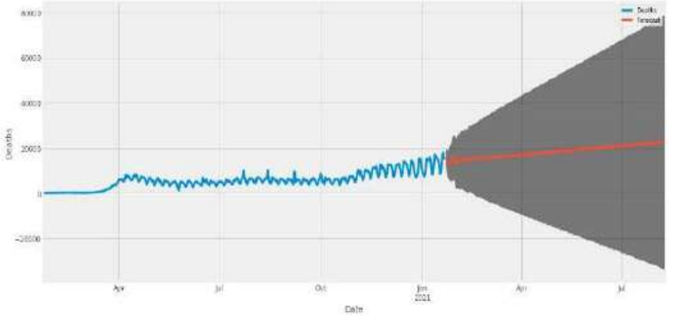

Fig 12. ARIMA prediction of total deaths globally for next 200 days (Shown in red).

The topmost impacting factors and their correlation to CFR can be seen in the below table

TABLE 1: TOP FEATURES HAVING GOOD CORRELATION WITH CFR

Attributes	Correlation	Sign
Stimulants	0.205982	-
Urban Population	0.200971	+
Miscellaneous	0.179596	-
Cereals - Excluding Beer	0.177802	+
Total Population	0.151331	+
Hospital Beds	0.146754	-
GNI/CAPITA	0.146533	-
Starchy Roots	0.140317	-
Fruits - Excluding Wine	0.116855	-
Spices	0.116002	-
HCI	0.114813	-
GDP	0.113702	+
Fish, Seafood	0.113460	-
CHE/CAPITA	0.111517	-
Milk - Excluding Butter	0.110685	-
Doctors	0.109849	-

The '+' correlation of CHE with confirmed, recovered and deaths shows that the countries with higher medical expenditure have covered more tests thus, the higher numbers. The countries with higher urban population reemphasize the above fact.

The regression analysis was conducted along with sequential feature selection with backward and forward selection. The

Linear Regression model has yielded a 0.277 R2 score which indicates the variability of the data around its mean. Random Forest Regressor was able to achieve -0.8489 R2. The table 1 and 2 represents the attributes and their influence on the Target which is the CFR. Of which It is observed that Doctors, HCI, Life Expectancy, CHE/GDP, CHE/CAPITA, Alcoholic Beverages are significant factors.

TABLE 2: FEATURES SELECTED BY BACKWARD SELECTION FOR LINEAR REGRESSION MODEL AND THEIR RESPECTIVE COEFFICIENTS.

Attributes	Coefficients	Sign
Cereals - Excluding Beer	0.012295	+
Animal Products	0.010490	+
HCI	0.008315	-
Obesity	0.008146	+
Life Expectancy	0.005329	+
DOCTORS	0.004749	-
Vegetable Oils	0.003736	+
CHE/GDP	0.003354	+
Alcoholic Beverages	0.002875	+
URBAN Population	0.002606	+

TABLE 3: FEATURES SELECTED BY BACKWARD SELECTION FOR RANDOM FOREST REGRESSOR AND THEIR FEATURE IMPORTANCE.

Attributes	Feature Importance
DOCTORS	0.140603
Spices	0.135485
Alcoholic Beverages	0.134923
CHE/GDP	0.100956
Milk - Excluding Butter	0.087006
CHE/CAPITA	0.079828
Vegetable Oils	0.078902
GNI/CAPITA	0.059623
Undernourished	0.057868
Vegetal Products	0.052789
Sugar Crops	0.040464
Animal Products	0.031553

Doctors, HCI CHE/GDP, CHE/CAPITA have Inverse effect on CFR, which implies higher values of these factors results in lower CFR and vice-versa. Life Expectancy and Alcoholic Beverages have a direct effect on CFR. The early trends of COVID19 outbreak in Italy, established that the aged population was worst affected when it comes to the infection/mortality.

To Understand the Data more and to identify underlying patterns, the classification analysis was conducted and the data was grouped by CFR <0.02.

TABLE 4: FEATURES SELECTED BY BACKWARD SELECTION FOR LOGISTIC REGRESSION AND THEIR COEFFICIENTS.

Attributes	Coefficients	Sign
DOCTORS	0.968987	-
CHE/CAPITA	0.687164	-
Starchy Roots	0.681179	-
CHE/GDP	0.552446	+
Miscellaneous	0.492156	-
Hospital Beds	0.393863	-
Meat	0.301703	+

Spices	0.174774	-
Undernourished	0.080433	-
GDP	0.055724	+
Animal Products	0.003265	-

The features that were selected for regression models along with hospital beds had significant effect on the classification of CFR classes. Logistic Regression was able to classify countries into low and high CFR classes with Cross validate mean accuracy of 65% and variance of 0.7%. Whereas the Random Forest Classifier had mean accuracy of 58% and variance of 3.5%.

TABLE 5: FEATURES SELECTED BY BACKWARD SELECTION FOR RANDOM FOREST CLASSIFIER AND THEIR FEATURE IMPORTANCE.

V. DISCUSSION AND CONCLUSION

Almost a year ago, not everyone in this world was aware of the severity related to Novel Coronavirus, which has now transpired into a global pandemic and the world is still trying solutions to deal with it. This study certainly hopes to help and clarify the impact of this pandemic. There were questions related to data that has been recorded as the data only reflects based on the number of tests carried out by respective governments. This issue of low number of tests being carried out can be attributed to the lack of medical professionals and infrastructure in some countries, while other countries intentionally carried out low miscellaneous political reasons. This does to an extent hinder research in drawing out a clear picture in dealing with such pandemic.

Our research involves validating the data available to perform modelling and predictions, we have done Exploratory Data Analysis (EDA) to make sure that there are no null/NAN values in the data used, also ensuring that such values are treated appropriately(imputation), The various data types of available columns have been changed accordingly so that the predictive modelling is done without any bias or misappropriation.

With both the algorithms one thing that can certainly be predicted that there will be a gradual increase in the total number of cases globally even though the number of deaths won’t see a huge spike. During the regression and classification study, it was found that there are common diet and socio-economic features that affect CFR. Countries that are predicted to have higher CFR could contain the increasing mortality by investing in healthcare infrastructure. The use of certain ingredients in the diet such as spices can contribute to reducing mortality. The diet factors can explain the low CFR for India and countries that use such ingredients in their cuisines. The timing of this study has not taken the exception of Covid-19 vaccine now available from 5 vaccine makers and vaccination drives set to begin across 150 countries, we can expect to see a sharp drop in the number of cases and deaths reported given the effectiveness of the vaccine. However, there are various mutations of this virus that have developed into regional strands showing divergent characteristics moving ahead, we have to wait and see how mankind would learn and respond to the pandemic that has already affected lives in a big way.

***Abstract*—With the development of artificial intelligence and driverless technology, the steer-by-wire system has become the mainstream direction of future development. Its structure is simple, lightweight, and real-time optimized steering gear ratio according to road conditions, steering road feel, and improved vehicle handling stability and active safety. Therefore, the research on the wire-controlled steering control system has great practical value. It is applied to platforms such as electric vehicles and intelligent networked vehicles to realize unmanned driving and optimize intelligent transportation, which has good application prospects. Based on the analysis of the structure of each component of the steer-by-wire system, this paper established the dynamic models of the steering execution part, the rack and pinion part and the steering wheel part, and completed the simulation model of each part and the three closed-loop control of the motor through Simulink. This paper, finally built a Carsim/Simulink co-simulation platform, integrated the motor control strategy into the vehicle model in Carsim, and verified the following characteristics and fast response characteristics of the steer-by-wire model.**

Keywords—Control, Steer-by-wire, Three closed loop, Carsim, Simulink

I. Introduction

Realizing the real-time control of the steer-by-wire system is crucial to the development and popularization of intelligent vehicles in the future. For this purpose, many scholars have conducted a lot of research on the control methods and strategies of the steer-by-wire system.

Zhao, Huiyong et al. proposed an energy-saving strategy for SBW vehicle steering motors by analyzing the relationship between steering wheel angle and road curvature, and proved the feasibility and effectiveness of the energy-saving strategy through closed-loop simulation[1]; Dankert, Jens etc. through an overview of the system prototype, focusing on the technical and electrical settings, the main hardware and software components, including a brief introduction to the safety concept[2]; Lee, Jaepoong and others have developed a haptic control of the steer-by-wire system. After experimental verification, the haptic controller proposed successfully tracks the steering feedback torque of the steer-by-wire system[3]; Scicluna, Kris et al. proposed a sensorless position control of a permanent magnet synchronous motor on the steering wheel side of a steer-by-wire system of an automobile, and tested the performance of the sensorless drive under forward and reverse load torque conditions[4]; Wang, Zezheng proposed a compound control scheme including proportional integral derivative controller and fuzzy logic system, and proved the rationality and superiority of the method through numerical simulation and hardware-in-the-loop experiment [5]; Scicluna, Kris et al. proposed a sensorless current control for the permanent magnet synchronous motor on the hand wheel side of the “steering-by-wire” system in automobiles, and compared the performance of vehicles with traditional steering devices through experiments[6]; Hua, Min et al. proposed the dual-motor synchronous control using differential negative feedback method for the non-synchronization of the double-steering actuator motor to reduce the adverse effects of the "servo fight" non-synchronization problem. The simulation results and hardware-in-the-loop experiments proved that the proposed

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

control strategy was effective and feasible[7]; Luo, Yutao and others proposed an adaptive neural network sliding mode control method that considers system disturbances. Research showed that RBFSMC has better robustness and stability than SMC[8]; Wu, Xiaodong and others designed the variable steering ratio of the steer-by-wire system. Experimental results showed that the system can not only improve the steering agility at low speeds and the steering stability at high speeds, but also reduce driving workload under critical driving conditions[9]; Ye, Mao et al. proposed a new type of robust adaptive overall terminal sliding mode control strategy based on extreme learning machine, and proved the excellent control performance of the proposed control through simulation [10]; Ma, Bingxin et al. proposed an event-triggered adaptive sliding mode control method for SBW systems, and the effectiveness of the method was demonstrated through numerical simulation and experimental results[11]; Huang, Chao et al. proposed a fault-tolerant model predictive control with fault compensation for an SBW system with actuator failure based on an incremental operator. The simulation results showed that the proposed fault-tolerant control strategy can cope with various types of actuator failures[12]; Zou, Songchun et al. proposed a dual-motor steer-by-wire system to improve the fault tolerance and reliability of the system, and verified the effectiveness of the control strategy proposed in this paper through simulation and experimental results[13]; Huang, Chao et al. proposed a fault-tolerant control method for actuators based on fault detection and isolation based on model predictive control. Simulation and experimental results showed that compared with traditional model predictive controllers, this method has no fault detection and isolation. It can achieve better steering performance and stabilize the entire SBW system in the event of actuator failure[14]; Deng, Bin et al. proposed a recursive sliding mode structure, which can effectively reduce shake without reducing the control accuracy, and experimentally proved the fast convergence speed and smaller shake of the proposed controller[15]; Jin, Zhilin and others proposed the multi-gain ratio of the steer-by-wire system, and studied the anti-rollover control strategy of the vehicle with the steer-by-wire system. The experimental results showed that the proposed anti-rollover strategy can effectively prevent the vehicle from tripping. A rollover occurred both in the case of a rollover without tripping, and the intervention of the driver's steering intention is reduced[16]; Zhang, Jie et al. proposed a robust adaptive sliding mode controller to improve the maneuverability and lateral stability of steer-by-wire vehicles. The results of hardware-in-the-loop simulations prove the proposed control excellent stability control performance of the system under different steering maneuvers[17]; Yu, Shu-You et al. proposed a tube model predictive control scheme for a four-wheel steer-by-wire vehicles. The scheme adopts an event trigger strategy to prevent potential adversary attacks and ensure information security[18].

The control of the steer-by-wire system based on the permanent magnet synchronous motor adopts the closed-loop control technology of position loop, speed loop, current loop and SVPWM. In order to study the steering control strategy of the SBW system, it is necessary to establish SBW vehicle dynamics based on Matlab/Simulink Models, including steering execution model, rack and pinion model, and steering wheel model. The SBW system is a complex mechanical structure. It is difficult to establish an accurate mathematical model. This paper made some necessary simplifications and assumptions when establishing the SBW system dynamics model, and adopted a reduced-order modeling method to establish the SBW system module and the front wheel steering module, and finally combined the vehicle model in the Carsim software to form the SBW vehicle dynamics simulation platform, and verified the accuracy of the co-simulation model established based on the Carsim-Simulink software. In order to verify the SBW vehicle simulation model and the traditional vehicle model with the same vehicle parameters in the Carsim software, chose the double line change test conditions for simulation. The process is shown as Figure 1.

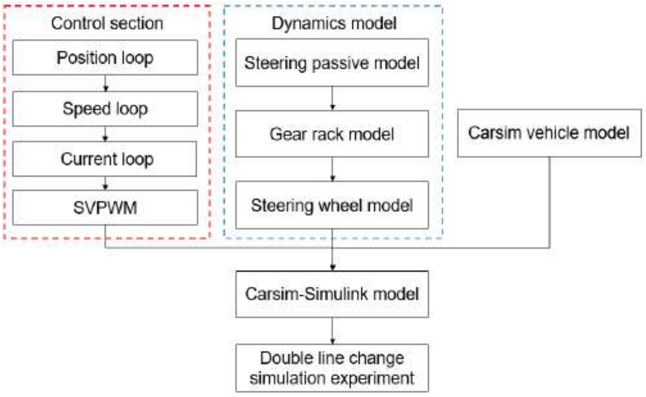

Figure 1 The process of steer-by-wire system

II. Models And Data

A. Dynamic model of steer-by-wire system

Since the driverless vehicle cancels the steering wheel module, the SBW system can be divided into steering actuator components, rack and pinion components, and left and right steering wheel components. As shown in Figure 2, the steering actuator components consists of the steering motor and its reducer. The rack and pinion assembly refers to the rack and pinion steering gear. And left and right steering wheels components refer to the left and right steering knuckles and their steering wheels. In this modeling process, the transmission gap between the steering motor and the steering wheels is ignored.

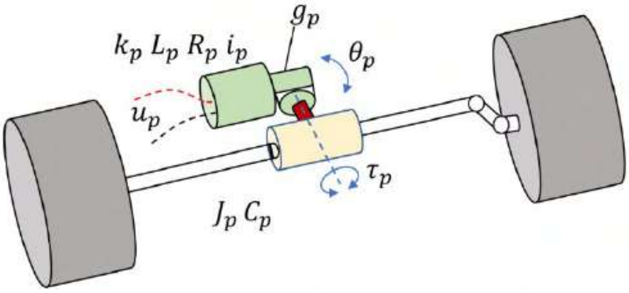

Figure 2 The front wheel steering model structure diagram

The steering actuator components is composed of a steering motor and a reducer. The steering motor is generally a permanent magnet synchronous motor. This motor can be well used in the steer-by-wire system to accurately adjust the steering angle of the vehicle, and then adjust the steering of the vehicle; most of the matched reducers are worm gear reducers, which can change the direction of the steering execution motor while ensuring reduce speed and increase torque, so that the axis of the steering motor and the rack axis are vertically distributed, which can greatly reduce the layout space of the steer-by-wire system along the longitudinal direction of the vehicle, and eliminate the interference of the steer-by-wire system and the suspension, which is called a cross steering gear. The dynamic equation of the steer-by-wire actuator components composed of a permanent magnet synchronous motor and a worm gear reducer can be expressed as formula (1).

$$T_s = J_s\ddot{\theta}_s + B_s\dot{\theta}_s + T_r \tag{1}$$

Where T_s is the electromagnetic torque of the steering motor, J_s is the rotor moment of inertia of the steering motor, B_s is the viscous damping coefficient of the steering motor, θ_s is the rotor angle of the steering motor, T_r is the torque acting on the rack by the steering motor, and shown as formula (2). K_s is the torsional stiffness of the steering motor, X_r is the rack displacement, g_s is transmission ratio of the rotation angle of the motor and the displacement of the rack is executed for the steering, and r_p is the radius of the steering pinion.

$$T_r = K_s(\theta_s - X_r g_s / r_p\ ) \tag{2}$$

The rack and pinion assembly consists of a steering pinion and a rack, as shown in Figure 3. And the dynamic equation can be expressed as formula (3).

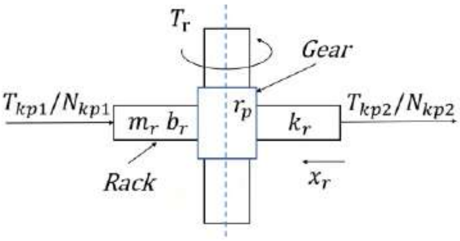

Figure 3 The structure diagram of rack and pinion

$$m_r\ddot{x}_r + B_r\dot{x}_r + k_r x_r = \frac{T_r}{r_p}\eta_p - \frac{T_{kp1}}{N_{kp1}}\eta_n - \frac{T_{kp2}}{N_{kp2}}\eta_n \tag{3}$$

Among them, m_r is the rack mass. B_r is the rack viscous damping coefficient. The k_r is the rack stiffness. The x_r is the rack displacement. $N_{kp1}$and N_{kp2} are the rack to left and right steering knuckle arm transmission ratios. The $\eta_p$and η_n are the steering forward transmission efficiency and reverse transmission efficiency respectively. K_{kp1} and K_{kp2} are the torsional stiffness of the left and right steering wheels around the kingpin respectively. θ_{FW1} and θ_{FW2} are the rotation angles of the left and right steering wheels. T_{kp1} and T_{kp2} are the moments of the left and right steering wheels acting on the kingpin, shown as formula (4) and (5).

$$T_{kp1} = K_{kp1}\left(\frac{x_r}{N_{kp1}} - \theta_{FW1}\right) \tag{4}$$

$$T_{kp2} = K_{kp2}\left(\frac{x_r}{N_{kp2}} - \theta_{FW2}\right) \tag{5}$$

The left and right steering front wheel components are composed of left and right steering knuckles and steering wheels, as shown in Figure 4. The dynamic equation can be expressed as formula (6) and (7).

$$J_{FW1}\ddot{\theta}_{FW1} + B_{kp1}\dot{\theta}_{FW1} = T_{kp1} - T_1 \tag{6}$$

$$J_{FW2}\ddot{\theta}_{FW2} + B_{kp2}\dot{\theta}_{FW2} = T_{kp2} - T_2 \tag{7}$$

Among them, J_{FW1} and J_{FW2} are the moment of inertia of

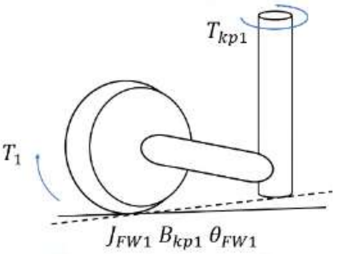

Figure 4 The steering wheel structure diagram

the left and right steering wheels around the kingpin respectively; B_{kp1} and B_{kp2} are the viscous damping coefficients of the left and right steering wheels around the kingpin respectively; T_1 and T_2 are resistance moment, which are respectively acted on the left and right steering wheels by the ground.

B. Simulink model of steer-by-wire system

According to the dynamic equation of the rack and pinion assembly, the basic module provided by Simulink is used to establish the simulation model of the rack and pinion assembly as shown in Figure 5.

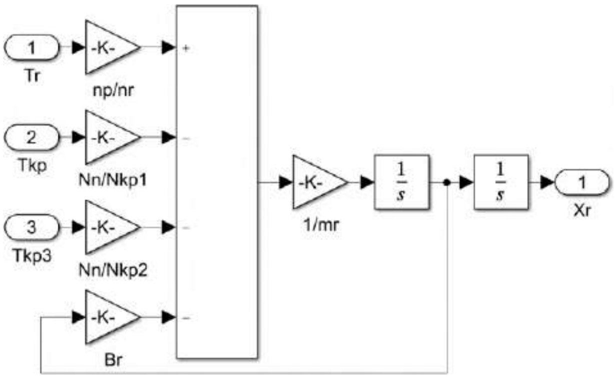

Figure 5 Simulation model of rack and pinion

According to the left and right steering front wheel assembly dynamics equation, the basic module provided by Simulink is used to establish the left and right steering wheel assembly simulation model as shown in Figure 6 and 7.

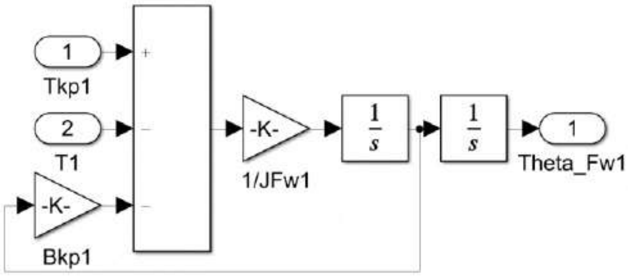

Figure 6 Left steering wheel simulation model

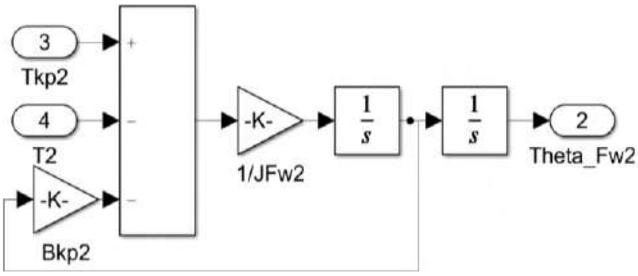

Figure 7 Right steering wheel simulation model

The parameters required for the rack and pinion simulation model and the steering wheel simulation model found above are shown in Table I below.

TABLE I THE STEERING MECHANISM PARAMETER TABLE

Parameter	value	Parameter	value
Steering pinion radius $r_p(m)$	0.0088	Rack quality $m_r(kg)$	5
Steering shaft stiffness $K_c(N\cdot m/rad)$	98	Reverse efficiency $\eta_n(\%)$	65
Forward efficiency $\eta_p(\%)$	75	Rack viscous damping coefficient $B_r(N\cdot s\cdot m^{-1})$	312
Steering kingpin torsion stiffness $K_{kp1}(N\cdot m/rad)$	39951	Rack stiffness $K_r(N/m)$	2.588 $\times 10^8$

According to the dynamic model of the steering motor, the machine module that has been packaged by Matlab/Simulink is used to establish the steering motor simulation model. The relevant parameter settings are shown in Table II below.

TABLE II THE STEERING MOTOR PARAMETER TABLE

Parameter	value	Parameter	value
Rotor moment of inertia $J_s(kg\cdot m^2)$	0.006	Armature inductance $L_s(mH)$	0.00029
Rotor damping $B_s(N\cdot s/m)$	0.0017	Back electromotive force constant $K_{se}(V\cdot s/rad)$	0.06
Torsional stiffness of motor shaft $K_s(N\cdot m/rad)$	121	Torque coefficient $K_{sT}(N\cdot m/A)$	0.086
Armature resistance $R_s(\Omega)$	0.068	Coefficient of viscous friction of motor $B_m(N\cdot s/rad)$	0.01

C. Control model of steer-by-wire system

The motor adopts a three-closed-loop PID control strategy, and the inner loop is current loop tracking control, the middle is speed loop tracking control, and the outer loop is angle tracking control. The motor three-closed-loop control system is actually based on the basic double-closed-loop control, adding a position loop. The double-closed loop can be regarded as a speed control module, and the position regulator will determine the difference between the given position signal and the actual position detection signal. The setting is the speed setting of this control module, so that the motor accurately follows the position setting. The greater position deviation, the greater corresponding speed setting.

Because the PID regulators of the position loop, speed loop and current loop are involved in the paper, in order to reduce the system response overshoot and system response time, the parameters of the three PID regulators are adjusted. This paper sets the input signal to two steps signal, first set the regulator to pure P adjustment. Since most position control does not allow overshoot, adjust the initial parameters of the position P regulator from 500. When K_p=500 is set, a certain amount of overshoot appears in the system response, indicating that the value of K_p is too large, and then the value of K_p is reduced to make the system response result meet the requirements. The value of the position I regulator is the same. The final adjustment result is shown in Figure 8, and the stator three-phase output current is shown in Figure 9. The position loop K_p=250, K_i=0.

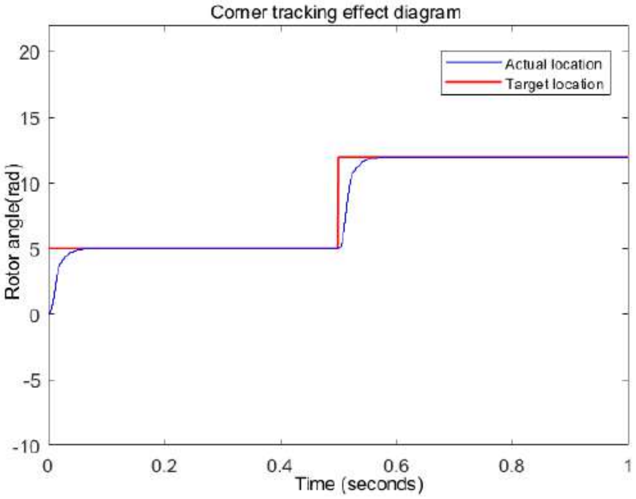

Figure 8 Location tracking result diagram

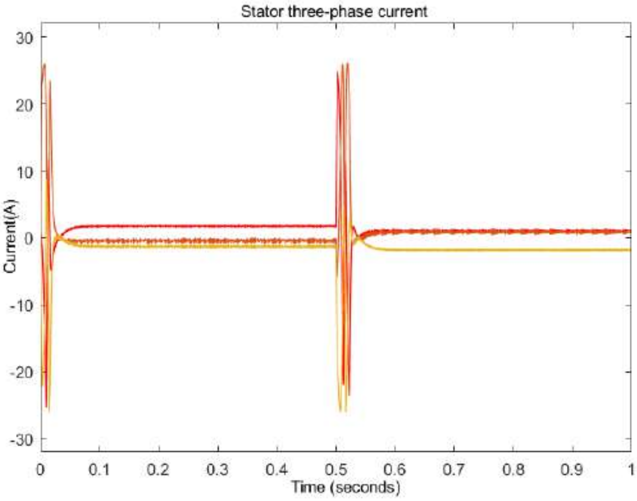

Figure 9 Stator three-phase current output diagram

III. SIMULATION AND RESULTS

The Matlab/Simulink simulation model of the front wheel steering module is embedded into the vehicle model of the Carsim software, instead of the traditional steering system, to obtain the SBW vehicle co-simulation model, as shown in Figure 10. The input of Carsim software are the steering angle of the left and right steering wheels, and the output are the steering resistance torque of the steering wheels and the vehicle state parameters. The vehicle model in Carsim software selects its own B-class vehicle, and some vehicle parameters are shown in Table III.

Figure 10 Matlab/Simulink simulation model

In order to verify the accuracy of the co-simulation model based on the Carsim-Simulink software, the double-line change condition that best reflects the vehicle path tracking

TABLE III THE VEHICLE PARAMETERS TABLE

Parameter	value	Parameter	value
Vehicle length(mm)	4323	Moment of inertia around Z axis $I_z(kg \cdot m^2)$	1523
Vehicle width (mm)	1765	Front wheel track B_f(mm)	1480
Vehicle height (mm)	1660	Rear wheel track B_r(mm)	1475
Vehicle quality m(kg)	1274	Front axle load $F_{Zf}(N)$	7600
Distance from center of mass to front axle l_f(mm)	1010	Distance from center of mass to rear axle l_r(mm)	1550
Rear axle load $F_{Zr}(N)$	4950	The height of the center of mass of the vehicle h(mm)	650
Wheelbase L(mm)	2560		

characteristics is chose for the simulation test to verify the SBW car simulation model and the traditional car with the same vehicle parameters in the Carsim software model. The angular transmission ratio of the SBW system adopts the transmission ratio of the traditional car model in the Carsim software and is set to a fixed value of 20. The simulation results are shown in Figures 11 and 12.

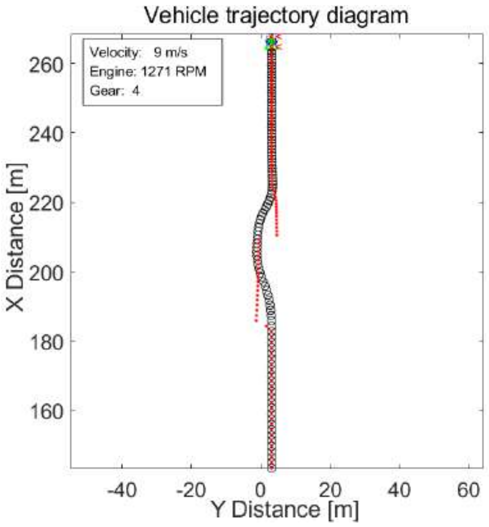

Figure 11 The vehicle trajectory of steering diagram

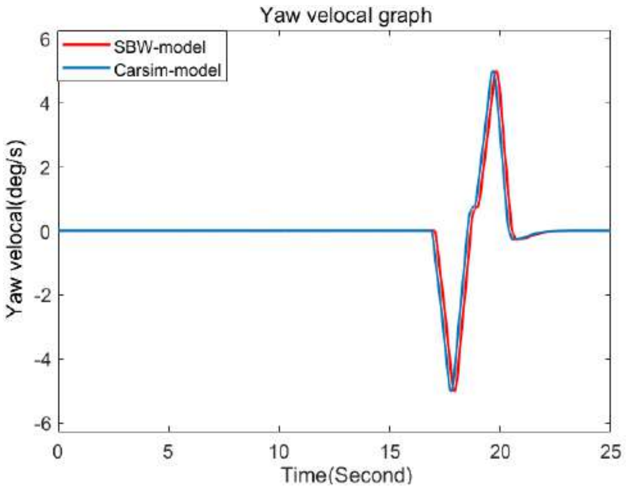

Figure 12 The yaw rate diagram

IV. CONCLUSION

By establishing the dynamic model, simulation model and three closed-loop control strategies of the motor for the steer-by-wire system, the Carsim and Simulink co-simulation platform is finally built. It can be seen from Figure 12 that the yaw rate response of the SBW car model under the double-line-change test conditions lags behind the front wheel angle of the Carsim car model by about 0.15s, but the peak values of the two are not much different, and the curve change trend is the same. The angle tracking error is no more than 8%, which shows that the SBW vehicle model and the three-closed-loop motor control strategy established in this paper also have good angle following characteristics under the two-line change test conditions, and can accurately reflect the dynamic characteristics of the vehicle.

***Abstract* -- COVID-19 is spreading at an unprecedented pace around the world. It has now spread to over 200 countries around the world. CoVID-19 mathematical modelling is often useful for strategic decision making in highly populated countries like India to gain some understanding of the epidemic's future. The prediction of an outbreak has become more difficult as the pandemic scenario of COVID-19 cases has grown. We hope to forecast the effects of COVID-19 in India by gaining a better understanding of its lifecycle in various Indian states. From historical data of verified COVID-19 cases, we are attempting to forecast potential COVID-19 cases and active cases.. For the prediction of COVID-19 we are implementing Susceptible-Infected-Recovered (SIR) model and FB-Prophet model for time series analysis. SIR modelling is more intuitive and explainable, but requires a lot of trial and error and assumptions. The FB-Prophet prediction process is simple and accuracy is also better compared to SIR modelling. In this model we are trying to understand the spread of COVID-19 in the ten most affected states of India (as on 9th December 2020) using publicly available state-wise time series data of COVID-19 patients. In this paper, we discuss how such continuous and unparalleled factors lead us to design intricate models, as It's time to use data-driven, mathematically proven models with the ability to tune parameters dynamically and automatically over time.**

Keywords— COVID-19, prediction, SIR model, Facebook Prophet.

I. Introduction

The CoVID-19 coronavirus outbreak started in Wuhan, China, and has quickly spread around the world. The outbreak of this virus has been deemed so dangerous by the World Health Organization (WHO) that it was declared a pandemic disease on March 11, 2020 [1, 2]. Because of its rapid spread, this pandemic disease is posing a serious threat to people's health and safety all over the world. Regardless of how advanced the healthcare system is, every nation has limited medical services. The most commonly used method for containing the spread of the novel corona virus has been social distancing. The first COVID-19 positive case in India was discovered on January 30, 2020, in Kerala. The Indian government also imposed a full nationwide lockdown on the 25th of March 2020, which lasted for 21 days and was extended until the 31st of May 2020, in order to minimize the number of people infected and slow the virus's spread. Fever and cough are the most common infection symptoms. Other signs and symptoms include chest pain, sputum production, and a sore throat. There were 10,689,527 reported cases of COVID-19 in India from January 3 to 4:35 p.m. CET on January 27, 2021, with 153,724 deaths. [3] Lockdown 2.0 was implemented from April 15th to May 3rd, 2020. During Lockdown 3.0 and 4.0, which lasted until May 30, 2020, the government divided all districts into three zones based on virus spread - green, red, and orange - with applied relaxations [4]. The number of people visiting hospitals declined over time as a result of the national lockout, which included quarantine, social distancing, hand washing, school closures, curfews, mask wearing, and other measures.The government declared that the lockdown would be lifted on May 30, 2020, with the exception of the containment areas, where the lockdown would be extended until June 30, 2020. Every month from June 1, 2020, to January 31, 2021, there were eight unlock steps imposed, each focusing on how restrictions could be relaxed in a staggered manner while keeping an eye on the pace of progress in reported cases. This model calculates the parameter values for India, and then extracts the trend and uncertainty from the available data to make a forecast. Predictive models can help to do this by predicting the number of COVID-19 cases in the future.

II. Materials

As listed in our References column, we gathered data from regular bulletins that are published online in various websites. The details we gathered included the number of regular positive cases, total cumulative cases, recovered cases, deaths, and active cases, among other things. We used the Kaggle [5] dataset for our research and review, which contains data derived from various official sources.

III. ANALYSIS AND FORECASTING

A. Covid Cases:

1. State wise Confirmed Cases:

Fig.1 shows the confirmed cases between 30th January, 2020 to 9th December, 2020 (a total of 315 days). Here we can see

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

that maximum confirmed cases are noted in Maharashtra followed by Karnataka, Andhra Pradesh, Tamilnadu then Kerala.

.

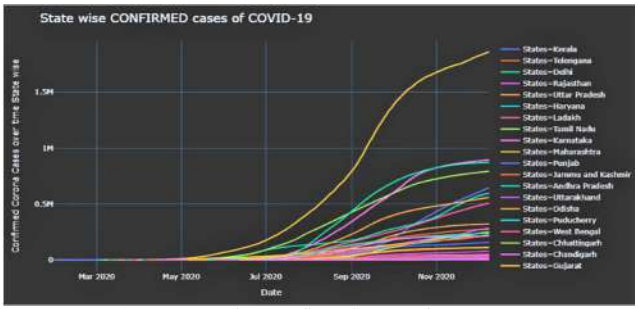

Fig. 1. State wise Confirmed cases of COVID-19

2. State wise Recovered cases:

Fig.2 shows the State wise Recovered cases. Here we can see that maximum Recovered cases are noted in Maharashtra followed by Andhra Pradesh, Karnataka, Tamilnadu then Kerala.

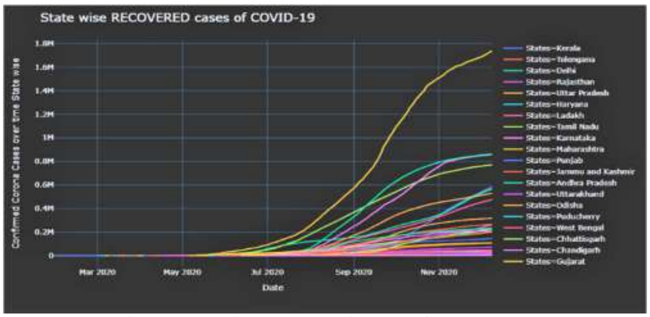

Fig.2. State wise Recovered cases of COVID-19

3. State wise Deceased cases:

Fig.3 shows the State wise Death cases. Here we can see that maximum Recovered cases are noted in Maharashtra followed by Karnataka, Tamilnadu then Delhi.

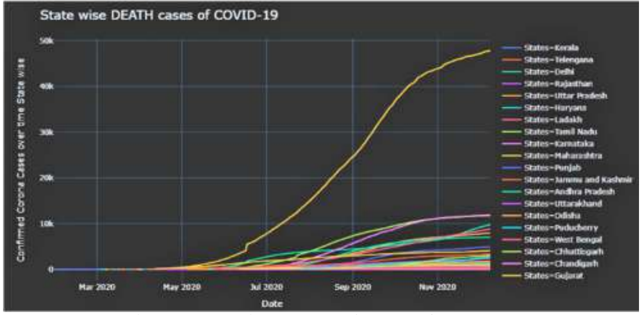

Fig. 3. State wise Deceased cases of COVID-19

4. Reported Cases in India over time

Fig.4 shows the details of cases related to COVID-19 in India. We can observe that the percentage of deceased cases are very less, compared to the total Confirmed cases were around 9.7 million and total recovered cases were around 9.2 million on the 9th of December 2020.

There were a total 141.3k deaths during the same time. The total active cases reached around 383.86k during first week of December 2020 and was maximum on 18th of September 2020 were around 1.01 million.

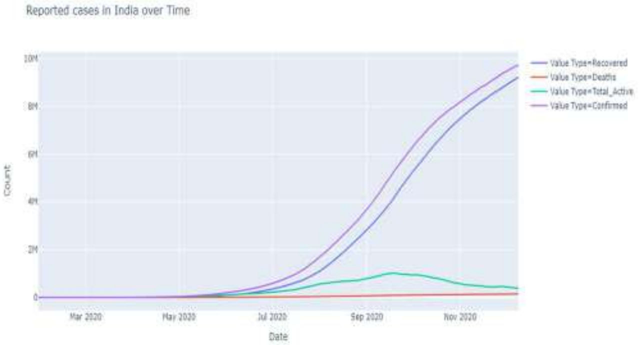

Fig. 4. Reported cases in India

5. State of Patients in India

Fig.5a Shows the percentage of Confirmed, Recovered and Deaths related to COVID-19. We can see that total Confirmed cases are around 51.2%, Recovered cases are around 47.9% and 0.88% Deaths. State wise data can be seen in Fig. 7, Fig. 8, Fig 9.

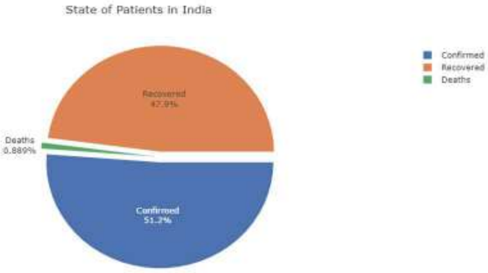

Fig. 5a State of Patients in India

6. COVID-19 CASES IN PERCENTAGES

FIG. 5B, FIG.5C, FIG.5D SHOWS STATES THAT HAD MAXIMUM IMPACT OF COVID-19.

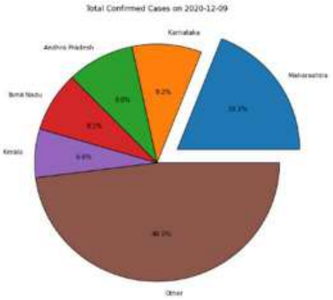

Fig. 5b. Percentage of Confirmed cases

From the above figure we can see that out of Total number of confirmed cases across India, Maharashtra has 19.1% followed by Karnataka with 9.2%, Andhra Pradesh with 9.0%, Tamil Nadu with 8.1%, Kerala with 6.6%.

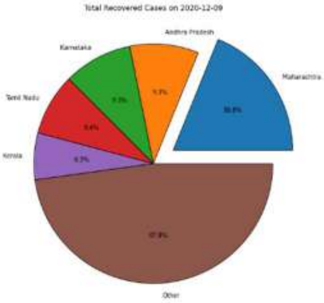

Fig. 5c. Percentage of Recovered cases

From the above figure we can see that out of Total number of Recovered cases across India, Maharashtra has 18.8% followed by Andhra Pradesh with 9.3%, Karnataka with 9.3%, Tamil Nadu with 8.4%, Kerala with 6.3%.

From fig.8 we can see that out of Total number of Deceased cases across India, Maharashtra has 33.8% followed by Karnataka with 8.4%, Tamil Nadu with 8.4%, Delhi with 6.9% and West Bengal with 6.2%.

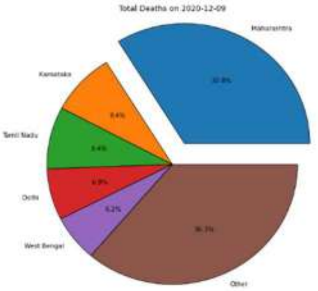

Fig. 5d. Percentage of Deaths

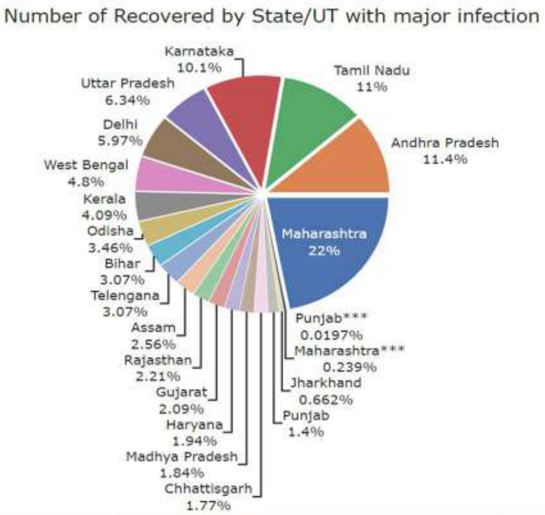

Fig. 6. Recovery cases Percentage for each state

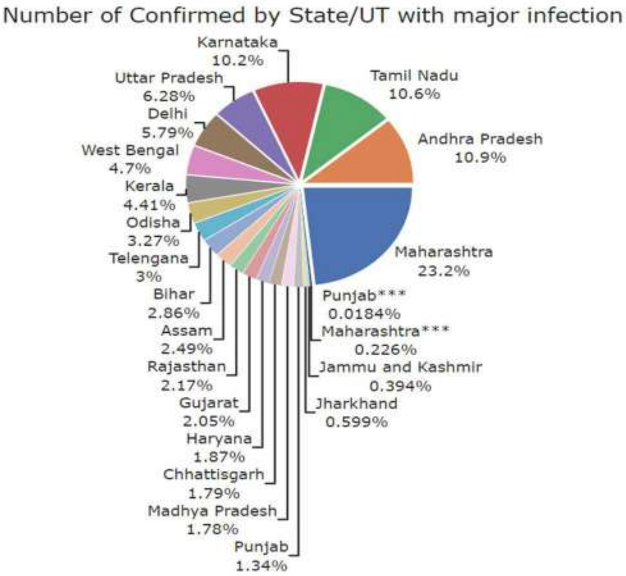

Fig. 7. Confirmed cases Percentage for each state

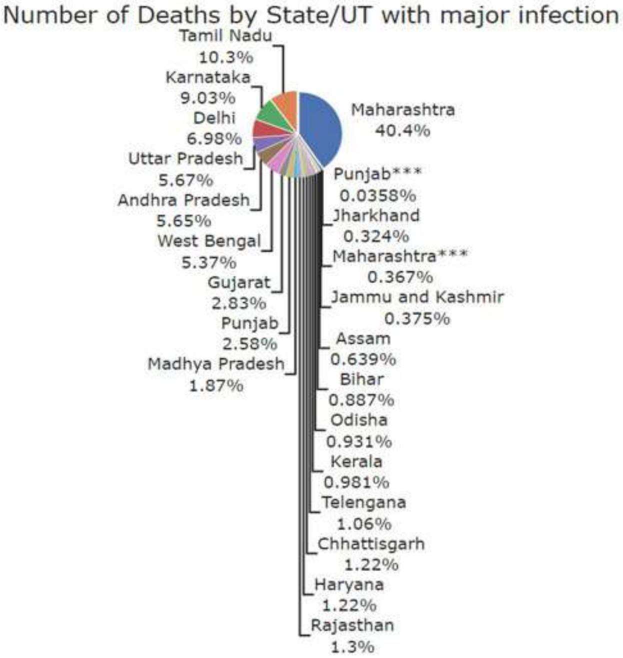

Fig. 8. Death cases Percentage for each state

7. Effect of Lockdown

Fig.9 shows During lockdown, Covid-19 has an effect. As seen in the graph below, there was an increase in reported cases during the Lockdown time, but the number was kept under control. There were 218 confirmed cases on March 25th, and 21.1k confirmed cases by May 31st, the end of the lockdown. However, we can see that once the lockdown in India was lifted, the number of confirmed cases increased exponentially. We reached the 1 million mark in just a few days, on September 12th.

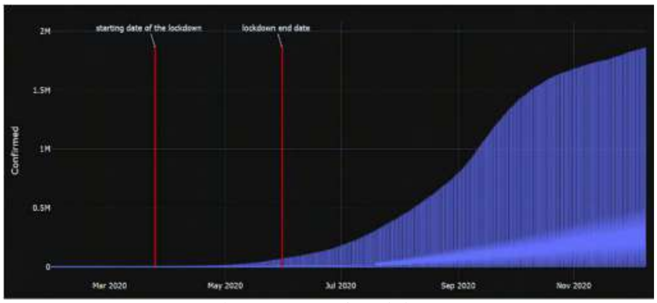

Fig.9. Impact of Lockdown

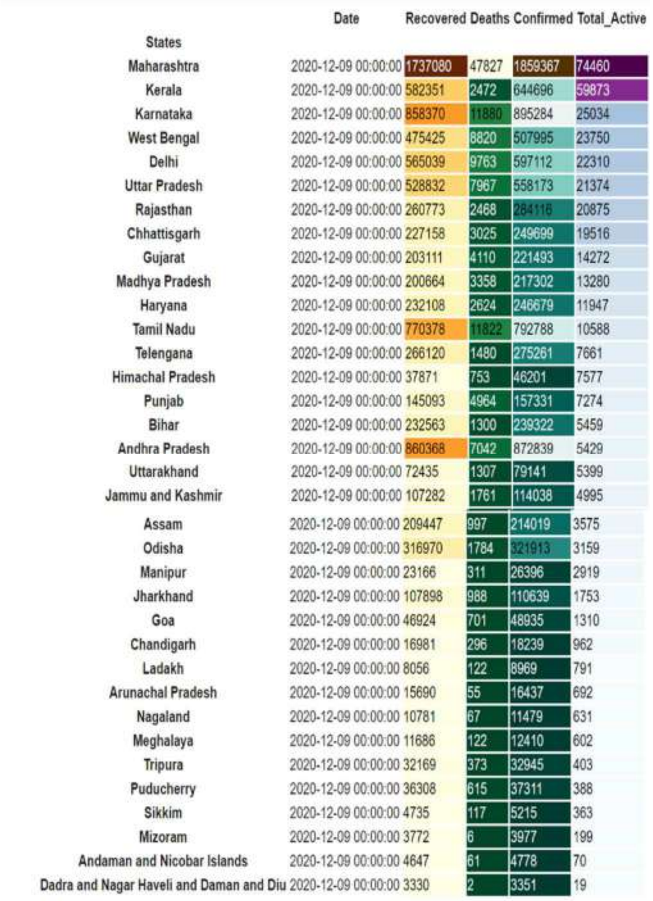
8. Total Active Cases

Fig.10 Shows state wise data of covid-19. We have calculated total active cases for each state on the latest data.

Total Active cases = Total Confirmed – (Total Deaths + Total Recovered)



States	Date	Recovered	Deaths	Confirmed	Total_Active

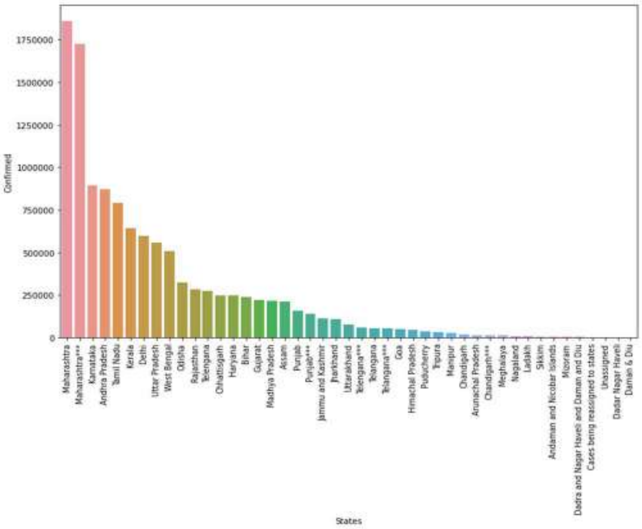

Fig.11. State wise Confirmed Cases

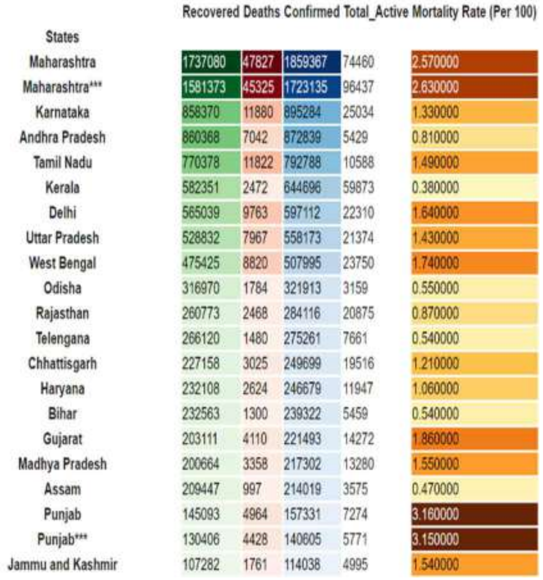
9. Mortality Rate

After its discovery, the COVID-19 virus has spread rapidly throughout the world, with cases registered in 210 countries (till 10:39 GMT on April 26, 2020). The data obtained showed over 2.4 million confirmed cases of CoViD-19.[13] Higher mortality rate (15%) was found in Algeria, Belgium (13.95), Italy and United Kingdom (13%) and Netherland (11.35%). Lower mortality rate was found in countries Qatar 0.17%, Singapore 0.2%, United Arab Emirate 0.6%, and Australia 0.97. The WHO updates and shares these statistics on a regular basis, and as of April 28th, it had issued ninety-seven reports giving country wise details of number of cases.

A strong positive correlation r=0.9, n=56 was observed between reported cases and deaths, indicating that disease spread raises the risk of death due to overcrowded hospitals, limited medical facilities, and other environmental factors. COViD-19 had already begun to spread before preventive steps were implemented. [14] Countries that responded quickly suffered less than countries that were unconcerned in the early stages of the pandemic. Another explanation for the pandemic was that since 80 percent of CoViD-19 cases are mild or asymptomatic, symptom-based disease management is difficult and ineffective.

The recovery versus deceased ratio was estimated, and the data revealed that in Singapore, Qatar, and Thailand, recovery was 68, 59, and 35 times higher than death.The ratio of deceased to recovered was found to be lower in the United Kingdom (0.03), the Netherlands (0.08), Ireland (0.16), and Norway (0.21). [13]In contrast to CoViD-19 prevalence, a previous study found that community acquired pneumonia cases were prevalent in males from lower socioeconomic groups who were illiterate and lived in rural areas.[14] Patients recoveries are significantly correlated with the number of cases (r = 0.63, n = 56), indicating that recoveries increase as the number of cases increases. The potential factors involved in recovery could be a strong immune system among the population, good dietary habits, and early treatment, as well as a Bacillus Calmette-Guerin (BCG) vaccination policy in some countries, which showed fewer cases than non-BCG vaccinated nations. [16]

To measure the Mortality Rate, divide the number of people who have died by the total number of active cases in the population, then multiply by 100.
In the fig.12 we can see the calculated Mortality rate on cases related to COVID-19 in India.



States	Recovered	Deaths	Confirmed	Total_Active	Mortality Rate (Per 100)
Maharashtra	1737080	47827	1859367	74460	2.570000

Fig.12. Mortality rate

IV. METHODOLOGY AND RESULTS

From the above analysis, we can conclude that if we want to know the impact of COVID-19 in India, it is essential for us to understand Mortality rate. Mortality rate is an important parameter for the fight against the Global Pandemic.

We devised the following method for estimating the number of positive cases, recovered cases, and active cases in order to estimate and forecast the recovery rate.
1) Examine the data and determine the pattern.
2) We'll try to explain the Susceptible, Recovered, Infected Individuals phenomenon using the SIR model.
3) Using Prophet to fills the existing gaps in generating fast reliable forecasts.

In our case, we used the SIR model to figure out the pattern of positive cases and the number of recovered cases. We also experimented with Time Series analysis and prediction model Facebook Prophet.

a. SIR modelling

The standard SIR model divides the entire population into three compartments, namely,

- *Susceptible individuals,* S: These are those individuals who are not infected but may become infected in the future. A person who is susceptible to infection may become infected or remain susceptible. If the virus spreads from its origins or new sources emerge, more people will become infected, increasing the susceptible population for a time (surge period).
- *Infected individuals,* I: These are those individuals who have already been infected with the virus and can now pass it on to those who are susceptible. A person who has been infected will stay infected and be removed from the infected population to recover or die.
- *Removed/Recovered individuals* R: These are those individuals who have recovered from the virus and are thought to be resistant, or who have died as a result of the virus.

The disease dynamics are then solved and the model is propagated using a series of ordinary differential equations. The equations for the corresponding equations are as follows

$$dS/dt = -\beta SI \tag{1}$$

$$dI/dt = \beta SI - \gamma I \tag{2}$$

$$dR/dt = \gamma I \tag{3}$$

N is the total number of people in the population.

The rate of change of infected population (dIdt) (dIdt) depends on two primary factors:

1. The number of people falling ill, and

2. The number of people recovering.

The number of people who become ill is determined by the degree of contact between the infected and susceptible populations, and is related by the constant β, which stands for the transmission/infection rate and βSI represents the number of susceptible individuals that become infected per day. γ is the rate of recovery. γI is the number of infected individuals that recover per day; 1/ γ is the infectious period i.e., the average duration of time an individual remains infected. the average amount of time that a person is infected. The reproductive number R0, which represents the average number of secondary infections produced by one infectious person in a fully susceptible population, is an important quantity in any disease model. The total (constant) population size is denoted by the letter N. Regarding the SIR model,

$$N = S + I + R \tag{4}$$

$$R0 = \beta N / \gamma \tag{5}$$

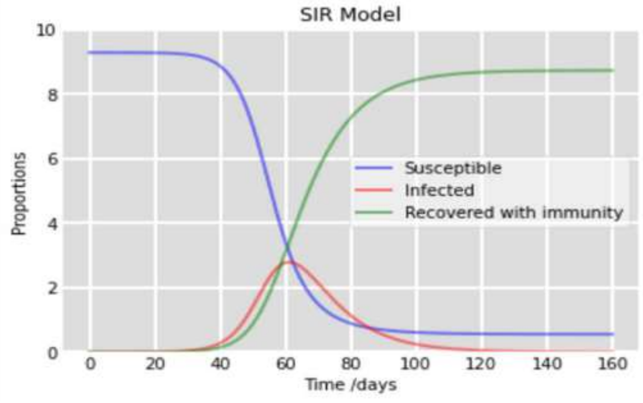

Fig.13. SIR modelling

We used trial and error and visual analysis to try to match the data to the SIR model. The parameters: initial susceptible population, infection rate (beta), and recovery rate (gamma) are manually calibrated through trial and error to match the data as closely as possible, resulting in the graph shown below in. Fig.12. The SIR model is used to simulate the susceptible, infection and removed cases from 9th December, 2020 for next 160 days until 18th may, 2021. From Fig.12 we can observe that the infection cases will reduce to zero by June- July, 2021, if there are no second wave of infections.

b. Facebook Prophet - Time series analysis:

Prophet is a procedure for forecasting time series data based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality, plus holiday effects. It works best with time series that have strong seasonal effects and several seasons of historical data [7].

Advantages of prophet are:

-Prophet makes it much more straightforward to create a reasonable, accurate forecast.

-Prophet forecasts are customizable in ways that are intuitive to non-experts.

Prophet is open-source software released by Facebook’s Core Data Science team. It is available for download on CRAN and PyPI. We use Prophet, a procedure for forecasting time series data based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality, plus holiday effects. It works best with time series that have strong seasonal effects and several seasons of historical data. Prophet is robust to missing data and shifts in the trend, and typically handles outliers well.

By building a base model both with and without changing the seasonality-related parameters and additional regressors, we can create a week-ahead forecast of verified COVID-19 cases using Prophet, with specific prediction intervals.

Predicting daily Death cases using FB-Prophet (Base Model):

FB-prophet prediction of death/ Morality cases and their trend.

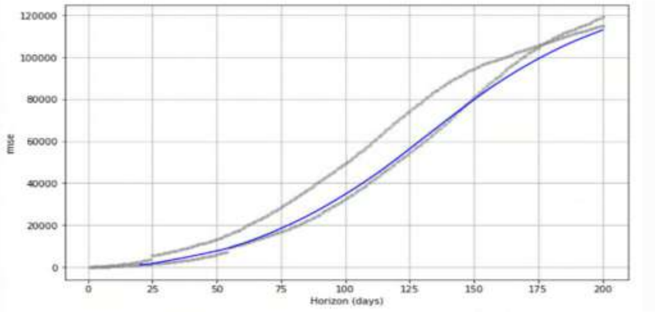

Fig.16a. RMSE plot for FB-Prophet(death)

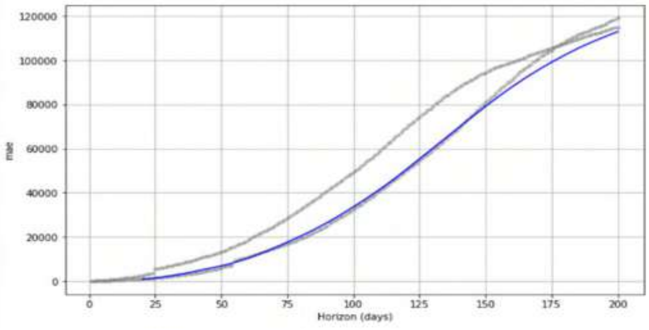

Fig.16b. MAE plot for FB-Prophet(death)

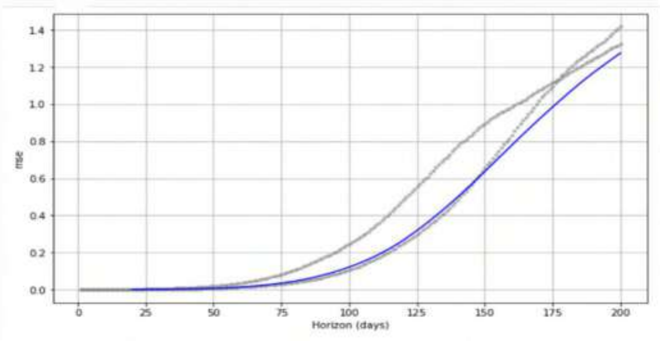

Fig.16c. MSE plot for FB-Prophet(death)

V. DISCUSSION AND CONCLUSION

With data analytics and data mining, information and communication technology aid in decision-making based on historical data. The amount of data available is massive, and extracting information and creating an interesting pattern from the accumulated data is a difficult task. With the current data on confirmed, recovered, and death across India for a long period of time, it is possible to predict and forecast the near future.

The country's epidemic was primarily caused by the movement of people from various foreign countries to India. With the current data on confirmed, recovered, and death across India for a long period of time, it is possible to predict and forecast the near future.

The country's epidemic was primarily caused by the movement of people from various foreign countries to India. The rate of recovery increased while the rate of transmission decreased. As a result, the value of the basic reproduction number decreased, flattening the COVID-19 epidemic spread curve.

Similarly, the percentage of people who remained susceptible after the infection had passed has decreased, and this should be checked in the near future. Furthermore, the peak percentage value of infectious people decreased and showed better results.

In the case of India, additional strict governmental interventions should be carried out, and, of course, pandemic cases can be drastically reduced by raising awareness among the local population. SIR modelling is more intuitive and explainable, but it requires a great deal of trial and error as well as assumptions.

The FB-Prophet prediction process is simple that is why FB-Prophet predictions can be used for quick and accurate prediction of daily COVID-19 positive and active cases. Investigations have been made on the issue of COVID-19 pandemic spread in India in the current challenging scenario. Trend knowledge has been observed with the help of recovery rate and case load rate obtained for the data available.

The various strategies implemented as lockdown; quarantine of population have played a significant role in reducing the risk of spread of epidemic.

This study predicts that when the case load rate gets lesser than recovery rate, there after COVID-19 patients would start to decline.

***Abstract*— Narrowband bandpass Filter plays an important role in modern wireless communication systems specially in the sub 6GHz space. In many cases, transmitted and received signals must be filtered at a certain center frequency with specific bandwidth limitations asper specifications. This research article represents the principle of microwave filter design, fabrication, and performance evaluation of bandpass filter design using the fundamental hairpin resonator structure. It is proposed to design a fifth-order Chebyshev bandpass filter with center frequency at 2.01 GHz using two different FR4 and Arlon 25N substrates separately. The simulated designs are implemented using the full-wave electromagnetic solver Genesys and fabricated on both substrate materials. We observed the accurate and reasonable filter parameters like return loss and insertion loss S11, S21 in both simulation and measurements. The design specifications bandwidth of400MHz, (-30dB, -1.4dB) and (-20dB, -2.5dB) of return, insertion losses were obtained respectively on Arlon 25N, FR-4 materials respectively. The designed filter has multiple potential applications for 4G LTE bands.**

Keywords*— *Bandpass filter, Microwave Filter, Genesys Simulator, return loss, insertion loss, Hair pin resonator.

I. Introduction

Microwave filters are unavoidable components in various electronic systems at various frequencies across the electromagnetic spectrum, like mobile radio, satellite communication transceivers, and Radar. Due to advancements in the technological world of electronics, mainly in Communications, fully integrated filters for high-frequency applications are now receiving great interest worldwide [1]. The usage of microstrip devices in the design of microwave systems and integrated circuits have gained huge popularity for the last two decade due to its compactness, cost-effective and ease of design, and further microstrip can operate in a wide range of frequencies.

Many researchers have presented numerous equations for the analysis and synthesis of microstrip devices, but with the advent of various full-wave electromagnetic simulators like high-frequency structural simulator (HFSS), Zeland IE3D, CST Microwave Office, the design of microwave structures has become simple and challenging. So far, scientific society has resulted in many advanced designs in microwave filters and antennas using microstrip structures [2]-[4].[12]. The purpose of this article is to design and analysis the simulated and fabricated bandpass filters as per specifications needed for various applications like LTE, GSM, S-band mobile transceivers, etc., with minimum return loss and attenuation of 15 dB and 3 dB respectively. Here the design of the fifth-order Chebyshev bandpass filter prototype microwave filters is carried by using the Hair Pin Bend microstrip technique. The synthesis is more convenient and smoothly done by the hairpin bends. The circuit performance is simulated and optimized using the full-wave electromagnetic simulator Genesys developed by Agilent technologies for the intended circuit fabrication. The designed filters were fabricated on the two different types of substrate material, FR4 and Arlon 25N material, with a dielectric constant of 4.4 and 3.38, respectively which are readily available in the market and a high tolerance for electromagnetic noises.

The performance of filters by hairpin bend structures on both substrates is compared in term of scattering parameters Sll and S22, the Arlon 25N microstrip filter design results in low loss condition compared with FR4, and it shows that Arlon 25N has produced a better performance for the microstrip filter design. The filter design presented in this paper can be extended to the filter bank design in the future. The following chapter presents the design and analysis procedure for the proposed bandpass filters. Here, the individual filter's design is done with the futuristic aim to filter banks such that a single device is applicable for multiple advanced applications [6]-[7].

II. Filter Design

There are various procedures in designing the microwave filters, like the image parameter method and insertion loss method. The insertion loss method with coupled line microstrip, stripline filter design is easy for the design and fabrication; further, the parallel-coupled lines give a bandpass response. The selected parallel-coupled transmission-line filter in microstrip, stripline technologies provides bandpass and bandstop filters with required bandwidth up to 20% of centre

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

frequency [8]. Due to their relatively weak coupling, this type of filter has narrow fractional bandwidth. Instead, it has desired advantages such as low-cost fabrication, easy integration, and simple designing procedures. Design equations for the coupled line parameters such as space-gap between lines and line widths and lengths are readily available in the literature. The model prototype of the width and lengths of the parallel-coupled line is demonstrated in figure 1. We could calculate the line's length and widths to design the filter from the existing literature [9]-[10]. The characteristic impedance based on the calculated width and height for the given material is provided in Equation.1.

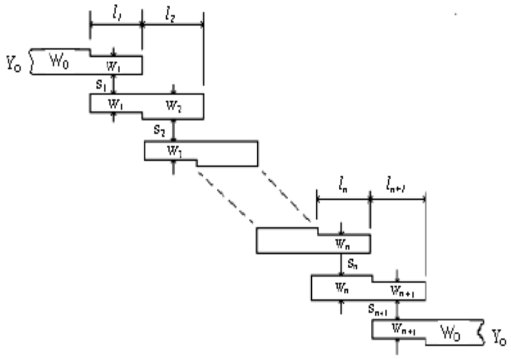

Figure 1: Parallel coupled line filter with parameters.

$$Z_0 = \begin{cases} \dfrac{60}{\sqrt{\epsilon}} \ln\left(\dfrac{8d}{W} + \dfrac{W}{4d}\right) & \dfrac{W}{d} < 1 \\ \dfrac{120*\pi}{\sqrt{\epsilon}\,(\frac{W}{d}+1.393+0.667\ln(\frac{W}{d}+1.414))} & \dfrac{W}{d} \geq 1 \end{cases} \qquad (1)$$

III. HAIRPIN STRUCTURE

Among various techniques available for bandpass microstrip filters in parallel-coupled lines, the Hairpin structural filter design is preferred. The concept of the hairpin filter is the same as parallel-coupled half-wavelength resonator filters [11]. The advantage of hairpin filter over end-coupled and parallel-coupled microstrip realizations is the optimal space utilization. This space utilization is achieved by folding the structure as the half-wavelength long resonators. The design of the simple half-wavelength resonator is shown in figure .2, and the corresponding bandpass filter layout design using multiple hair-pin resonator structures is in figure.3, where α gives the values of the slid angle, and the small slid angle leads to greater coupling between the resonators in figure .3.

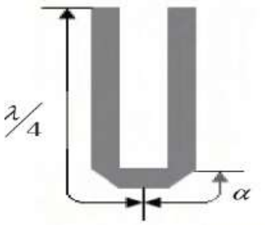

Figure 2: Illustration of a single Hairpin resonator structure.

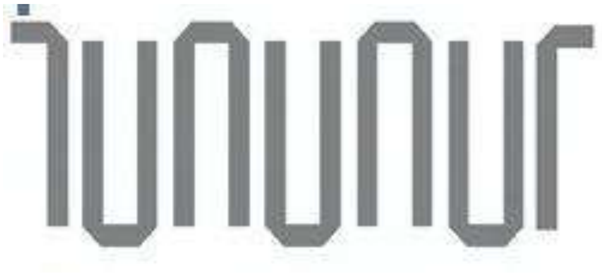

Figure 3: Hairpin filter layout.

IV. DESIGN SIMULATION

Many full-wave and half-wave Electromagnetic simulators are available in the market like Zeland IE3D, High-Frequency Structural Simulator (HFSS), CST Microwave office, etc. Here in this research article, the design of the bandpass filter is done in the Genesys full-wave simulator from the Agilent technologies. The Genesys simulator enables to design of circuits composed of schematics and electromagnetic (EM) structures from an extensive electrical model database and then generates layout presentations for the designs. The design's output will be in a wide variety of graphical forms based on the analysis needed. The advanced tunable tool in this simulator enables us to tune or optimize the designs, and the changes reflect immediately in the layout according to the given filter specifications. The designers can observe the effects of the test signals before investigating in hardware prototypes. The Genesys simulation design procedure consists of the following tasks in the design environment:

- Creating projects to organize and save the designs.
- Creating system diagrams, circuit schematics, and EM structures.
- Placing circuit elements into schematics.
- Placing system blocks into system diagrams.
- Creating and displaying output graphs.
- Running simulations for schematics and system diagrams.
- Tuning simulations to optimize the design in terms of the space.

- Creating layouts.

The final design in the simulation layout for the proposed filters is shown in figure.4, here extreme ends in both filters are input and output ports and it was designed for port characteristic impedance of 50 Ω which is common standard value in any electromagnetic designs. There are **five half wave resonators** in each design which indicates the fifth-order filter. The fifth-order Chebyshev proposed filter gives more precise cutoffs frequencies (sharp transitions between passband and stopband frequencies) than the popular and simple Butterworth filters.

Figure 4: Simulator filter layout for two-different fifth-order bandpass filters.

V. FILTER FABRICATION

In modern technology there are advanced semiconductors machines for the fabrication of many electronic devices. This section gives detail explanation about the processes involved in the fabrication of microstrip circuits using printed circuit board technologies. The following are the basic steps involved in actual fabrication process of microstrip line bandpass filter fabrication.

- Preparing the mask
- Creating a photo resist pattern
- Etching the unwanted copper material
- Housing for the microstrip
- Soldering the edges for the input and output terminals.

The fabrication is done in this research article on both substrates Arlon 25N and FR-4 substrate materials. The substrate characteristics were mentioned in the Table.1. The width and lengths were calculated from the literature in such a way that it matches for the 50 Ω characteristic impedance of the input and output ports of the 2-port network and the corresponding values are represented in the Table 2. The proposed filters were designed assuming the center frequency of the bandpass filter is at 2010MHz which is the 4G LTE band (example: TDD, band 34, FDD, band 1 etc.).

Material Parameter	**FR4**	**Arlon 25N**
Dielectric Constant	4.60	3.38
Loss Tangent	0.011	0.0022
Metal Thickness	1.42 mil	1.6 mil
Substrate Height	59 mil	20 mil

Table.1: Substrate material characteristics.

S.No	**Parameter**	**Arlon 25N**	**FR-4**
1	Length (mm)	23.1	20.5
2	Width (mm)	1	2.56

Table.2: Hairpin structure length and width values of Arlon 25N & FR-4 substrates.

The sample design of the filter after the due fabrication is as shown in figure.5 & figure.6 with Arlon 25N and FR-4 substrate materials, respectively. Here the input and output ports are matched to the standard characteristic impedance of 50Ω. The real-time fabricated filter parameters are measured and obtained by using the 3.6 GHz R&S Network Analyzer, and the analysis of the simulated and measured parameters are explained in the next section.

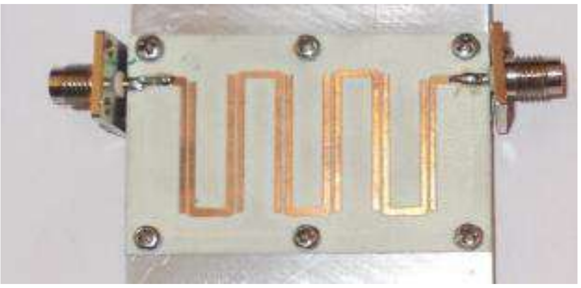

Figure 5: Fabricated fifth-order bandpass filter with Arlon N25 substrate.

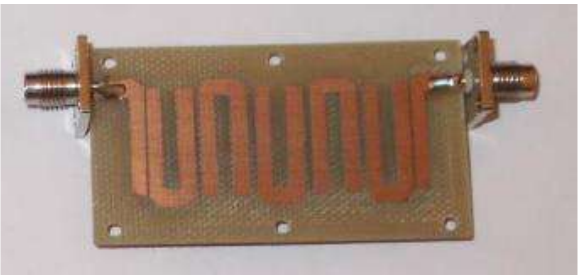

Figure 6: Fabricated fifth-order bandpass filter with FR-4 substrate.

VI. RESULT ANALYSIS

The fabricated filters were tested using the R&S Network Analyzer of 3.6 GHz capacity. The Insertion loss (S21) and Return losses (S11) of each fabricated filter has been observed and recorded in the Table 3. The filter parameters are observed that these filter characteristics are of required standards like low insertion loss in passband, high attenuation in stopband whereas it has high return loss in passband. The simulated filter response for the Arlon 25N and FR-4 substrates are mentioned in figure.7 and figure.8, respectively. The measured filter responses are mentioned in the figure.9 and figure.10, respectively. Clearly, the results from simulations and measurements indicate a low insertion loss in pass band. Losses in case of bandpass filters with Arlon 25N substrate material and FR4 substrate material are compared in Table.3.

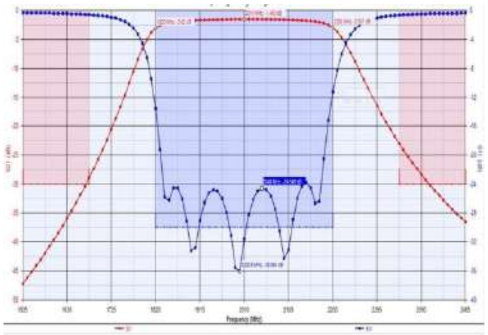

Figure 7: Simulated bandpass filter Response with Arlon 25N substrate.

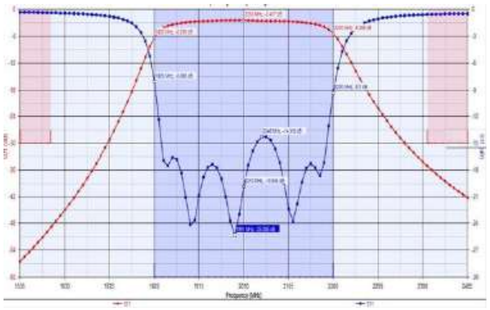

Figure 8: Simulated bandpass filter Response with FR-4 substrate.

S. No	Parameter	FR-4 Filter	Arlon 25N Filter
1	S11 (dB)	-14 to -25	-24 to -36
2	S21 (dB)	-2.5	-1.4

Table 3: Fabricated filter measurements (return loss and insertion loss) for each substrate.

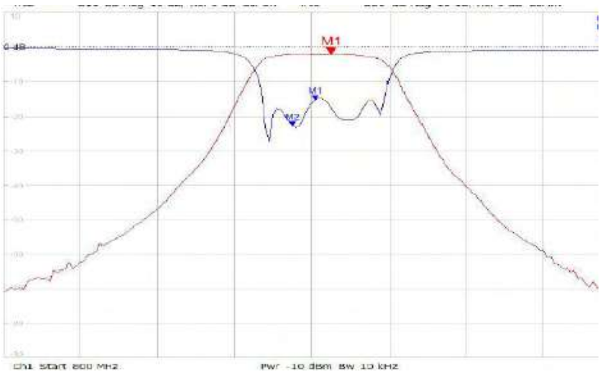

Figure 9: Measured bandpass filter characteristics with the Arlon 25N substrate.

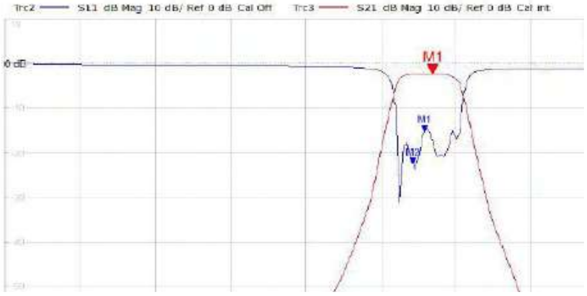

Figure 10: Measured bandpass filter characteristics with the FR-4 substrate.

VII. CONCLUSIONS

The successful simulated and fabricated bandpass filters with Arlon 25N and FR4 substrates are comparable and are found to be close enough (98%) with the provided specifications, further they exhibit the nearly 90% elimination of unwanted signals in the respective bands. Use of hairpin structure results to obtain the desired characteristics for a filter with line coupling and reduced size. Finally, Arlon 25N microstrip filter design shows low insertion loss and high return loss in the passband compared with FR4 filter design for the proposed specifications interims of insertion loss and return loss. The designed bandpass filter has the potential applications in 4G LTE band application as filters specially for the central frequency of 2.01GHz like TDD band 34 and FDD band 1. The design of multiple filters with different center frequencies and specifications (like bandwidth, insertion loss, return loss in the passband and attenuation in the stopband) can be implemented on a single substrate either on Arlon 25N or on FR-4 substrate such that it can be a filter bank which helps the multiband radio wave applications in future.

***Abstract*— The learning process requires specific methods to achieve effective and efficient learning goals. Learning methodology is a way of carrying out activities between educators and students when interacting in the learning process. One of the learning methodology methods is the demonstration method, which using objects or other teaching materials at the time of teaching. Students expected can understand the correlation between microprocessors and memory practically is one of the main goals in the microprocessor lectures. This research aims to help the learning process in the microprocessors lecture by designing and implementing the teaching aid of the "Microprocessor Interconnection with Memory" module. This aid demonstrates an input and processes it into output in the form of lit LED using the 80C88 Microprocessor. The test results of this aid obtain an average of 75.34% by using the Mean Opinion Score (MOS) method.**

Keywords—* *Teaching aid, microprocessor, memory read, memory write, qualitative analysis.

I. Introduction

The media of learning can be in the form of trainers or teaching aids. A trainer is a learning medium that forms kit equipment to simulate material in teaching and learning activities so students can understand [1]. Conventional ways to teach microprocessor and microcontroller are commonly based on simulators. In practical such approach will not always effective due to the complexity of the microprocessor components [2]. One of the courses in the Telecommunication Engineering Program at Telkom University is the Microprocessor course. This course talks about microprocessors, microcontrollers, and microcomputers.

The microprocessor is a computer electronic central processing unit (CPU) made from mini transistors and other circuits on top of a semiconductor integrated circuit. The course typically comprises of lectures and laboratory work. The laboratory gives students the opportunity to use software for the programming part of the course and linking the output to the hardware. It is essential that the students know how to operate the functionality of both part [3]. In this research, the authors made a learning media in the form of trainers or teaching aids using an Intel 80C88 microprocessor, Dual In-line Package (DIP) Switch, and several Light Emitting Diode (LED) that help students to understand the material about microprocessor interconnection with memory.

II. Basic Theory

A. Numeral System

The numeral system is a method that represents a quantity with a symbol. In the digital world, there are only two voltage levels that indicate a value. The two voltages are 0 Volt and +5 Volt. Therefore, the base-2 numeral system or binary numeral system can express those two voltage levels, which use only two symbols. These two symbols are 0 represents a 0 Volt and 1 represents +5 Volt [4].

B. 80C88 Microprocessor

A microprocessor is an integrated circuit or IC in the form of a Very Large-Scale Integration (VLSI) chip component that can execute commands sequentially in the form of a program and carry out counting, reasoning, and digital control operations. An 80C88 Microprocessor has 8 bits of the data path and 20 bits of address path [5].

The microprocessor course in Telkom University still uses 8088 as the main reference for CISC (Complex Instruction Set Computer) with comparison to DLX processor for RISC architecture [6] and this teaching aid is focused on 8088 microprocessors.

Fig. 1 is the pin configuration of the 80C88 microprocessor [5].

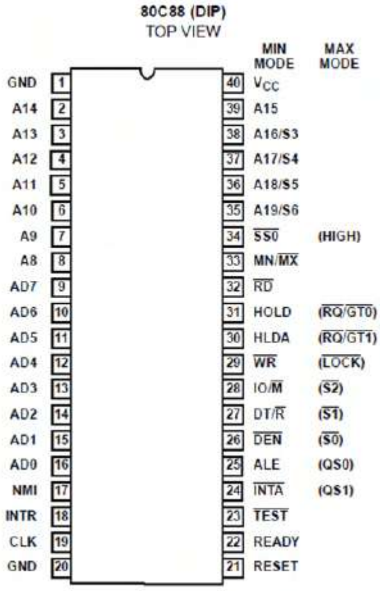

Fig. 1. Pinout of microprocessor 80C88 [5]

The Work Process of The 80C88 Microprocessor

While carrying out an instruction, the 80C88 microprocessor performs 3 stages of processing as follows [7]:

1. Instruction Fetch (IF)

IR ← [CS+IP]. The process begins with the pickup of new instruction from memory to IR.

- Control Unit (CU) translates the register contents of CS and IP, then determine the location of a new instruction in the memory.
- CU sends the translated CS and IP contents to memory via the address bus.
- CU sends a Mem-READ signal to indicate the memory that the CU wants to read the data.
- In response to the Mem-READ signal, the memory returns the data stored at the cell memory specified by the CU on the data bus (1 byte wide)
- CU reads the contents of the data bus and places it on the IR.

2. Instruction Decode/ID.

CU translates the new content from the IR to find out the instructions wanted. It uses the help of the instruction table in the Instruction Decoder.

3. Execution/EX

CU will carry out one of three functions depending on the results of the translation of the instructions, including:

- Arithmetic or Logical Operations
- Data transfer
- Control

C. Memory

Memory is a tool or medium that is used as a storage medium for data information or instructions and can be issued again. There are two types of memory, including [8]:

1. Volatile, is a memory that stores information as long as there is a power supply source (uninterrupted). Example: Random Access Memory (RAM).
2. Non-Volatile, a memory that can store memory for a long time even when the power supply source is cut off. Example: Read Only Memory (ROM), magnetic disk, magnetic core, magnetic tapes, hard disk, etc.

Interconnecting microprocessor with memory

The work process of reading data by the microprocessor from memory including:

1. The microprocessor prepares the address of the data to be read.
2. The microprocessor sends a read signal to memory.
3. After receiving the read signal, the memory looks for the desired data by the microprocessor according to the address given.
4. The data is sent by memory to the microprocessor.

The work process of writing data by the microprocessor to memory including:

1. Microprocessor prepares the address where data will be written.
2. The microprocessor prepares the data to be written.
3. The microprocessor sends a write signal to memory.
4. After receiving the write signal, the memory will read the data that has been given by the microprocessor and put it according to the predetermined address.

D. Mean Opinion Score

Mean Opinion Score (MOS) is an assessment obtained from listening to a voice directly, this scoring system is subjective [9]. The following is a table of MOS values used in this research.

TABLE I. MOS VALUES

No	Quality	Value
1	Excellent	5
2	Good	4
3	Fair	3
4	Poor	2
5	Bad	1

III. SYSTEM PLANNING

A. Block Diagram

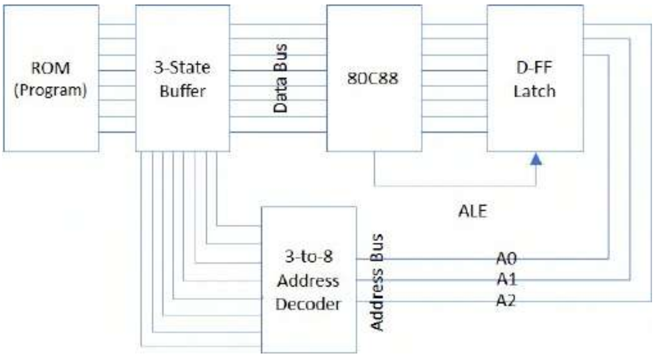

Fig. 2. Block diagram for the teaching aid

Fig. 2 shows that the 80C88 Microprocessor is connected to the D-FF Latch. D-FF is activated using the ALE pin. This D-FF functions to separate the Address bus from the data bus of the 80C88 microprocessor. If the ALE pin is active (condition 1), then the address bus line is active, while the ALE pin is not active (condition 0) then the data bus is active. The data bus line is connected to a 3-state buffer output. In this trainer, the input of the 3-state buffer is the program the DIP Switch. In this DIP Switch, the program inputted to or from the memory register. DIP Switch is used to replace ROM. This makes it easier for users to use this teaching aid, because if you use DIP Switch, the user will immediately program it. If using ROM, then the ROM must be removed to enter the program / instruction to be executed. To activate the 3-state buffer, use a 3 to 8 decoder. The input of this decoder is A0 - A2 and the output of this decoder is connected to 3 state buffer pins. the 80C88 microprocessor only uses a clock generator in the form of a push button because there is no minimum clock frequency.

B. Component Specification

TABLE II. COMPONENT SPECIFICATION

No	Component Name	Qty	Description	Figure
1	Microprocessor 80C88	1	8-bit CMOS Microprocessor	

2	74LS373N	1	8-bit D-Flip flop	
3	74HC138N	1	Decoder 3 to 8	
4	DIP Switch 8 bit	4	8 SPST	
5	74HC541N	8	Octal buffer	
6	LED Lamp	16	3mm	7	Resistor 330 Ohm	16	¼ W	
8	Resistor 10k Ohm	32	¼ W	
9	Push button	1		
10	USB Socket	1	Female, type A	11	Single copper cable		Multi colour cable to represent each functionality	
12	USB to USB Cable	1	Male – Female	

C. *System Design*

1. Separating address bus with data bus using D-FF

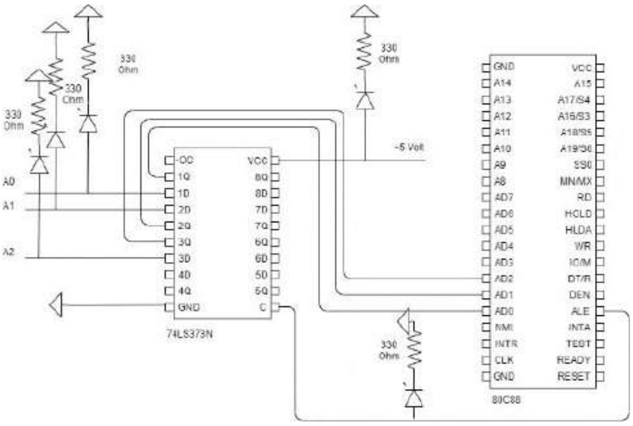

Fig. 3. Schematic diagram to separate data bus and address bus from 80C88 using 74LS373N

Fig. 3 shows interconnection of 80C88 microprocessor with IC 74LS373N. This schematic only uses 3 address line, which is A0, A1, and A2 since we only use 4 DIP Switch to replace the ROM (while A2=0) and to access 4 other bytes from Static RAM (while A2=1). Thus, we connect pins AD0 - AD2 to IC 74LS373N, which will provide the address bus output (A0 to A2). Microprocessor connection with the 74LS373N IC using the ALE pin. If the ALE pin is active (condition 1), then the address bus line is active, while the ALE pin is not active (condition 0) then the data bus is active. Connect the address bus with the LED and each led is connected to a 330 Ohm resistor. The ALE pin is given an LED indicator so that the user knows when the ALE pin is active or inactive. The VCC pin is also given an LED indicator so that the user knows the IC has been given a voltage.

2. Connecting DIP Switch to data bus

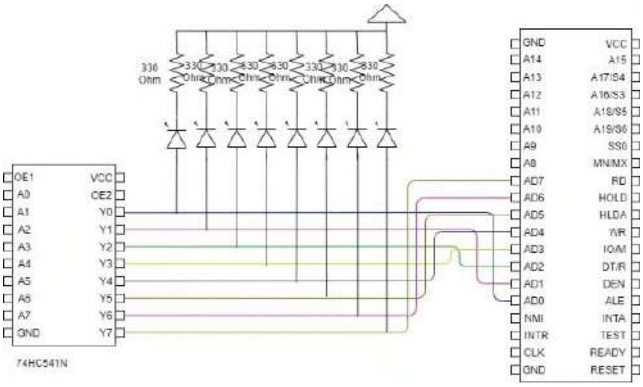

Fig. 4. Connecting DIP Switch to data bus using 74HC541N

Fig. 4 shows interconnection of 80C88 microprocessor with IC 74HC541N. The output 3-state buffer (IC 74HC541N) is connected to the microprocessor data bus (AD0 - AD7). In this schematic we use four IC 74HC541N, each for one DIP Switch. Each component is connected to the data bus. Connect the data bus to the LED. The LED is also connected to a 330 Ohm resistor which is connected to GND.

3. Control bus of 80C88

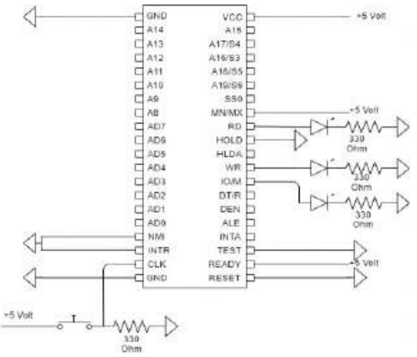

Fig. 5. Control bus used from 80C88

Fig. 5 shows the control signal on the 80C88 microprocessor. On the RD pin, an LED is connected to determine whether the RD signal is active or not (RD signal is active low). The WR pin is also given an LED indicator to find out the status of WR signal, whether it is active or not (WR signal is active low). Because the RD pin and WR pin are active low, if they are active it provides 0 Volt, while inactive it provides +5 Volt. The IO/M pin is also given an LED indicator to provide the status of access, whether 80C88 is accessing memory or I/O. The CLK pin is given a push button to replace the clock generator. The MN/MX pin and READY pin are connected to +5 Volt, while the HOLD pin, TEST pin, RESET pin, NMI pin, INTR pin, and GND pin are connected to ground. VCC pin is connected to +5 Volt to provide power to 80C88.

4. Replacing ROM with DIP Switch to store program

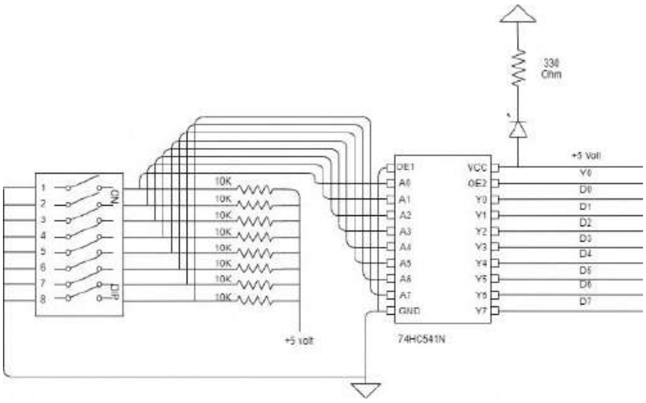

Fig. 6. Schematic for DIP Switch to store program with 74HC541N to connect with data bus

Fig. 6 shows the DIP Switch interconnection with the IC 74HC541N. One side of the DIP Switch is connected to the ground, while the other side is connected to 74HC541N and thus connected to data bus with 10 kOhm pull-up resistor.

5. Address decoder for DIP Switch using 3-to-8 decoder 74HC138

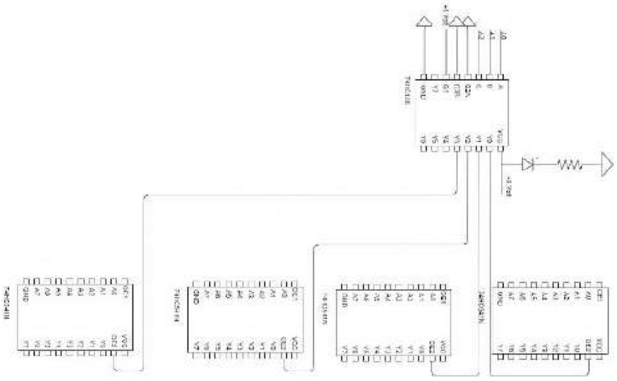

Fig. 7 Schematic of address decoder using3-to-8 decoder 74HC138

Fig. 7 shows interconnection between the 74HC138 and 74HC541N decoders. The input of this decoder is A0 - A2. With the output to be connected to the 74HC541N. This creates a binary combination. Each binary combination will activate each of the 75HC541N to connect one DIP Switch at a time.

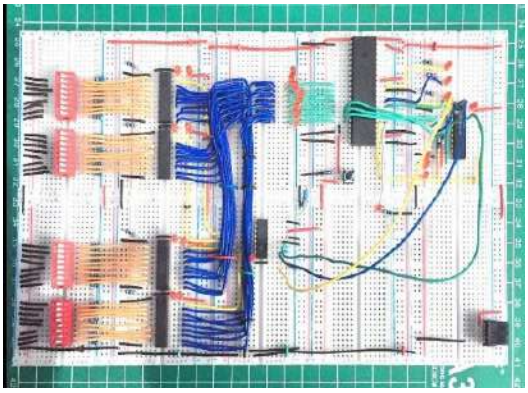

Fig. 8. Layout of teaching aid for microprocessor

Fig. 8 shows that the 80C88 microprocessor, along with all components in the teaching aid, is activated using a USB power supply. LEDs are installed in the address bus line, data bus, read signal, write signal and IO / M signal. The LED serves as an indicator of which path is active. From this path, it can be seen which memory address the information and data entered is pointing to. When inputted information, the information will be read by the 80C88 microprocessor. The information will be processed by the 80C88 microprocessor and will be output in the form of an LED. The illuminated LEDs are analyzed by the user from various aspects, namely the data bus LED, the address bus LED, the write signal LED or the read signal.

IV. ANALYSIS AND RESULT RESEARCH

This research conducted tests on several respondents who had different backgrounds. These criteria include:

- First Respondent: Senior Undergraduate Student of Telecommunications Engineering, Telkom University.
- Second Respondent: Junior Undergraduate Student of Computer Engineering, Telkom University.
- Third Respondent: Senior Undergraduate Student of Informatic Engineering, Telkom University.
- Fourth Respondent: Senior Undergraduate Student of Telecommunications Engineering, Telkom University.
- Fifth Respondent: Magister Undergraduate Student of Electro Engineering, Telkom University.

A. Testing The Microprocessor Trainer

In this test, 2 operations were performed, namely the write to memory operation and the reading from memory operation.

- The reading from memory operation

Table VIII - Table XII show that the test results of 5 respondents have a different number of clocks. The results of the read signal or write signal show the same results. The visual aid also when displaying the program inputted on the bus data LED is also not sequential and not the same for each respondent.

- Subjective Testing

This research uses three MOS parameters to conclude that the teaching aid can help students to have more understanding on how the microprocessor 80C88 works. The three parameters are:

1. aesthetic based on the shapes, colors, and neatly assembled
2. easy to use based on the worksheet provided
3. completeness based on the compliance with the syllabus

The formula to identify whether the teaching aid is beneficial for students is: if more than 51% respondents state that the teaching aid is easy to use, and if more than 51% respondents state that the worksheets were comply with the syllabus, and if more than 51% respondents state that the teaching aid has simple shapes, colors, and are neatly assembled.

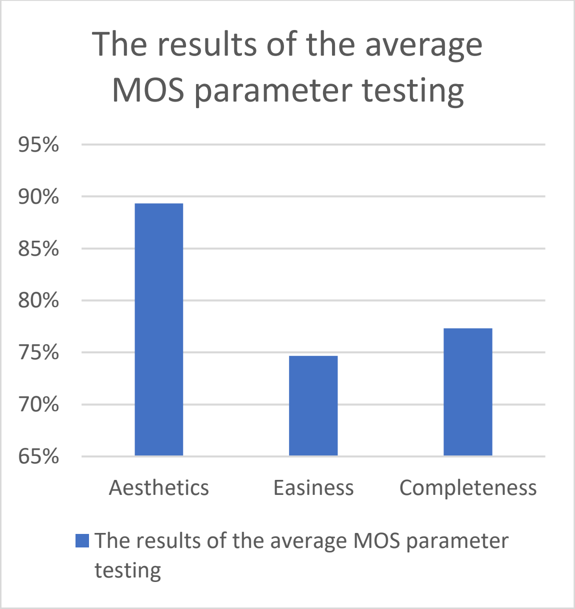

Fig. 9. Control bus used from 80C88

Fig. 9 is the result of the quantitative tests using three MOS parameters. Fig. 9 shows that the MOS test results are based on the assessment aspects that have been submitted to respondents. The average MOS test results were obtained based on the assessment aspect, namely the aesthetic aspect of 89.33%, the easy-to-use aspect of 74.67%, the completeness aspect of 77.33%.

V. CONCLUSION

The conclusion of this research is the trainers are functioning correctly and effectively to improve students' understanding of the "Microprocessor Interconnection with Memory" module. The test results of the props are in accordance with the expected parameters. The test results with the MOS parameter get an average value of more than 51% for each respondent. The average MOS test results were obtained based on the assessment aspect, namely the aesthetic aspect of 89.33%, the easiness aspect of 74.67%, the completeness aspect of 77.33%.

It is recommended that this trainer use RAM memory so that data can be stored in memory. The trainer is still in breadboard form, so the component cannot hold it in the socket. Therefore, the author suggests designing PCBs for microprocessor trainer.

ACKNOWLEDGMENT

Authors are grateful to Renesas Electronics Corporation (https://www.renesas.com) for providing the microprocessor 80C88, giving the opportunity to implement this teaching aid to support microprocessor course at Telkom University.

***Abstract*—Lightning is responsible for both human and economic loss but its prediction remains challenging. We seek to find a lightning prediction model in South Africa that uses historical lightning-flash data only. This type of prediction model is cost-effective, easy to interpret and may be used for real-time forecasting. We evaluated and compared three popular time-series machine learning techniques on their ability to predict the number of Cloud-to-ground lightning flashes in South Africa for three-hours ahead. These models are the Auto Regressive (AR), Auto Regressive Integrated Moving Average (ARIMA) and the Long-Short-Term-Memory Recurrent Neural Network (LSTM) models. We used historical lightning data from the South African Lightning Detection Network during 2018. Our prediction model parameters were AR(lag=8), ARIMA (AR lag=8, integrate=0, MA lag=2) and LSTM (2x50 layers, activation=ReLU, optimizer=adam) and models were minimized for Root Mean Square Error but evaluated based on Mean Absolute Percentage Error (MAPE). We used a 70%/30% Train-test split. The AR and ARIMA models performed comparably with a MAPE of 15312 and 15080 respectively. The LSTM Model outperformed considerably with a MAPE of 3705. Although the LSTM model outperformed, predictions errors in absolute terms were still high. This paper highlights the usefulness of non-parametric predictions models for lightning prediction.**

***Index Terms*—lightning forecast, univariate, Long-Short-Term-Memory Recurrent Neural Network, weather forecasting, ARIMA, autoregressive**

I. Introduction

Lightning is responsible for both human and economic loss. It is estimated that 264-people on average die from lighting strikes in South Africa every year [4]. Further, lightning is responsible for about twenty-percent of all outages of electrical distribution in South Africa [5]. Knowing when lightning will occur, will help reduce human loss and assist in planning for expected lightning damage.

Lightning is an electrostatic discharge that results in a spectacular display of electromagnetic radiation and a pressure-wave called thunder [1]. There are between 30-to-100 lightning strokes every second on earth [2]. Seventy-five-percent of these lightning strikes originates and ends in the clouds; this is termed cloud-to-cloud lightning [3]. The remaining twenty-five-percent of lightning originates from the cloud and discharges to the ground; this is called Cloud-to-Ground (CG) lightning.

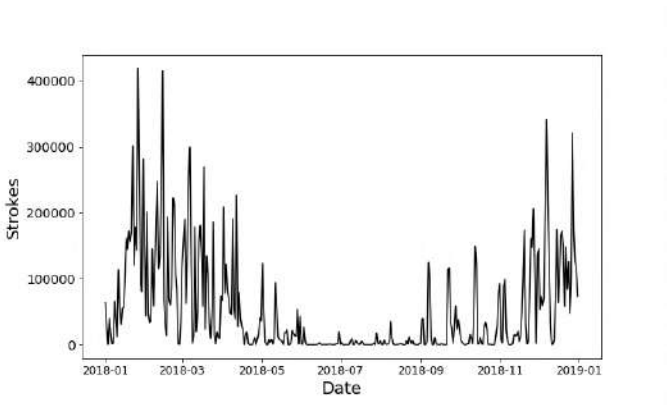

Fig. 1. Number of Lightning Strokes per day in South Africa during 2018.

Although lightning is familiar and well-researched, its prediction remains challenging. Recent academic studies have focused on using Numerical Weather Prediction (NWP) data to build a weather model for lightning forecasting. NWP models attempts to use mathematical models of the atmosphere and oceans to predict the weather based on current weather conditions. NWP model data is the culmination of sophisticated and complicated weather modeling often using supercomputers that relies on weather stations for data.

A lightning prediction model based only on actual historical lightning would be advantageous. A model based only on historical time-series would be cost-effective and can be used for real-time forecasting. Three common machine learning models for univariate time-series models are the Auto Regressive (AR), Auto Regressive Integrated Moving Average (ARIMA) and Long-Short-Term-Memory Recurrent-Neural-Network (LSTM) models.

The AR model is a linear predictive modeling technique. The model predicts future values based on past values of the same series by using the AR parameters as coefficients [14]. The ARIMA model also uses this concept but builds on it by including moving average error and integrated components.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

The moving average component indicates that the regression error is a linear combination of error terms whose values occurred contemporaneously and at various times in the past [10]. Moving average component removes non-determinism or random movements from a time series. The integrated component assists to make the data stationary if required.

The LSTM RNN Model is a type of artificial recurrent neural network (RNN). Unlike standard feedforward neural networks, RNN has feedback connections. LSTM models have a unit called a cell that is composed on an input gate, an output gate and a forget gate. The cell remembers values over arbitrary time intervals and the three gates regulate the flow of information into and out of the cell. LSTM networks are well-suited to classifying, processing and making predictions based on time series data since there can be lags of unknown duration between important events in a time series.

Our aim is to compare and evaluate the short-term (three-hours) lightning predictive ability (number of flashes) of the AutoRegressive model, ARIMA model and the LSTM Recurrent Neural Network model using historical CG lightning flash data only. Doing this will lower the cost of lightning prediction and allow for real-time lightning prediction. Time-series univariate analysis have been applied in various datasets; although their accrual is limited, they are easy to implement and often provide a decent approximation for predictions.

Our study will contribute to current literature. This is the first time a LSTM RNN model has been applied to historical lightning data events from the SALDN dataset to evaluate its effectiveness against other common autoregressive techniques. This study will set the foundations of a more accurate lightning forecast model that will also incorporate weather data variables [15].

II. Methodology

Dataset Historical Cloud-to-ground Lightning Data in year 2018. The South African Weather Service established and maintains the South African Lightning Detection Network that records mainly CG lightning strikes [11]. The network currently consists of 24 Vaisala lightning sensors. The SALDN can detect lightning with a location accuracy of approximately 0.5km and an estimated detection efficiency of 90% over most of South Africa [12]. Our dataset had just under 20 million lightning observations that was grouped for every thee-hourly. Data was scaled using with a feature rand between 0 and 1.

Train/test Split. We trained the models using 70% of data and predicted the remaining 30%. For the year, this corresponds to training dates between 1 Jan 2018 to 12 Sep 2018, and testing dates between 13 Sep 2018 and 31 Dec 2018. All negative test predictions were considered as zero, as it is impossible to have a negative number of lightning strikes.

Test for stationery. The AR and ARIMA models require the historical time-series lightning data to be stationary in nature. We used the Augmented Dickey-Fuller test to test for stationary data. The test results indicate a test statistic of t = 5.96 with a p-value of 2.03×10^-7 (p <0.05). This indicates that we can reject the null hypothesis that the data in non-stationary.

A. Machine Learning Models

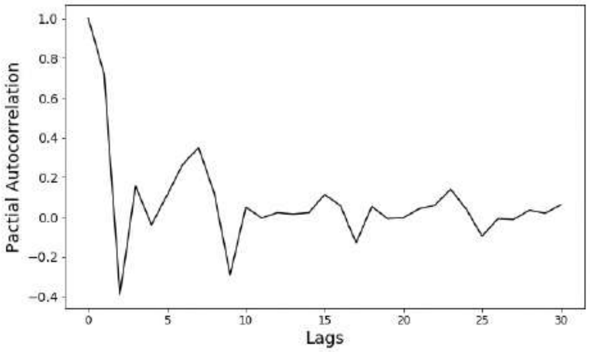

Fig. 2. Partical AutoCorrelation Function with SALDN Historical Lightning Data. The graph indicates a lag value of 8 is inclusive.

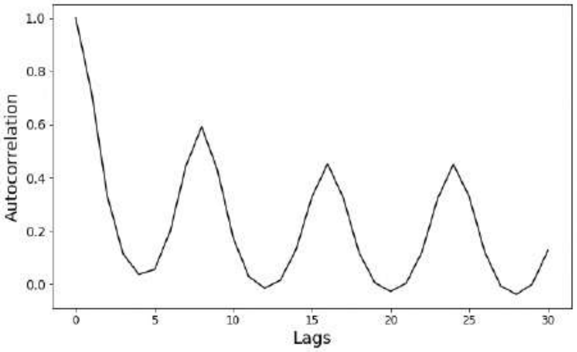

Fig. 3. AutoCorrelation Function with SALDN Historical Lightning Data. The graph indicates a lag value of 1 is optimal.

AutoRegressive Model. The general equation for the AR model is as follows:

$$X_t = c + \sum_{i=1}^{p} \phi_i X_{t-1} + \epsilon_t,$$

where p indicates number of lag steps, ϕ_i are the parameters of the model, c is a constant and ε_t is white noise. We used a lag value based on the Partial-Auto-Correlation-Function 2, which corresponds to a lag value of eight. The AR model from the Scikit-learn library of Anaconda Python v2019.10 was used. The Ordinary Least Square (OLS)/MSE error was minimized.

ARIMA Model. ARIMA is a popular class of autoregressive models that builds on the AR. model. In addition to AR component, the ARIMA model makes data stationary and also incorporates the dependency between an observation and a residual error from a moving average model applied to lagged observations.

Given a time series data X_t where t is an integer index and the X_t are real numbers, This defines an ARIMA(p,d,q) process with drift $\frac{\delta}{1-\sum \phi_i}$,

$$\left(1-\sum_{i=1}^{p}\phi_i L^i\right)(1-L)^d X_t = \delta + \left(1+\sum_{i=1}^{q}\theta_i L^i\right)\varepsilon_t,$$

where L is the lag operator, the α_i are the parameters of the autoregressive part of the model, the θ_i are the parameters of the moving average part and the ε_t are error terms.

Our ARIMA model is optimized with an AR value of 8, Integrated value of 0, and MA value of 2. The AR parameter is taken from Fig. 2. The MA value of 1 is taken from the Auto-Correlation-Function of Fig. 3. An integrated value of 0 is used as the data is stationary. The ARIMA model from the Scikit-learn library of Anaconda Python v2019.10 was used. The Ordinary Least Square (OLS)/MSE error was minimized.

LSTM Recurrent Neural Network Model. Long Short-Term Memory Recurrent Neural Network. As mentioned earlier, LSTM is a special kind of RNN with additional features to filter recurrent data that is well-suited for time-series data forecasting. Our network has two dense network layer of fifty units followed by one dense layer with an activation function of rectified Linear Unit (ReLU) to reduce negative forecast values. We ran the model for 200 epochs; Fig 4 indicates that 200 epochs are sufficient minimize loss. The LSTM Keras module version 2.3.1 was used for LSTM RNN Network.

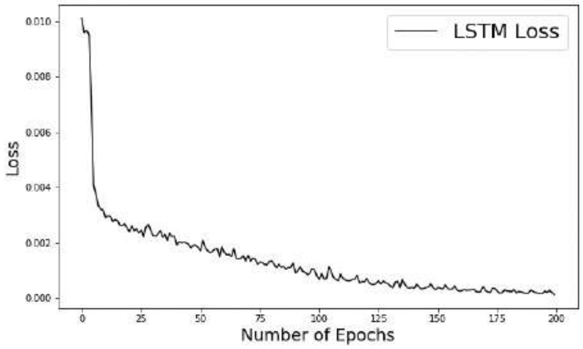

Fig. 4. Loss Function of LSTM RNN Model.

Limitations. Our data only processed one year of historical lighting data; this data should have seasonality which will improve prediction power.

III. Results

A graphical summary of the predicted values versus the actual data is shown in Figures 5, 6, and 7. The AR and ARIMA models performed comparably similar with MAPE values of 15312 and 15080 respectively. The RMSE values were 8579 and 8301 respectively I. The LSTM model had MAPE and RMSE values of 3705 and 9426, indicating it had outperformed AR and ARIMA considerably.

TABLE I
Prediction Model Error Values

Model	MAPE Value	RMSE Value
AR(p)	15312	8579
ARIMA	15080	8301
LSTM	3705	9426

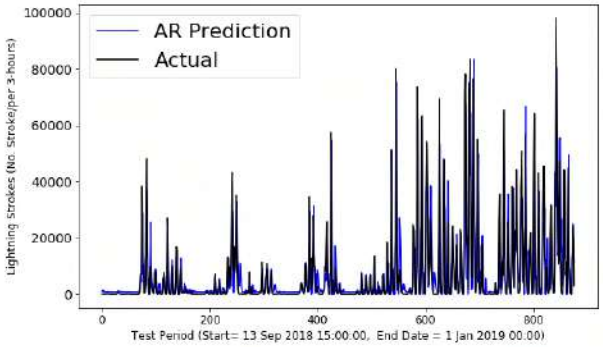

Fig. 5. AR Prediction Model Results vs. Actual Flashes.

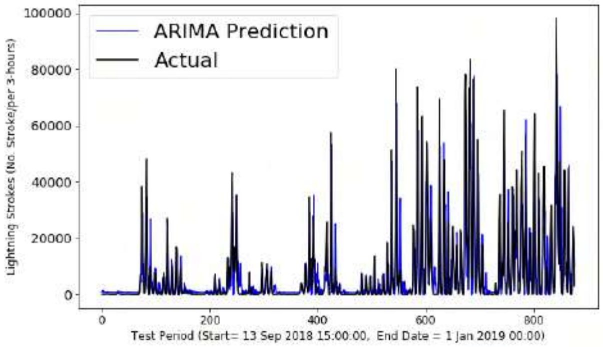

Fig. 6. ARIMA Prediction Results vs. Actual Flashes.

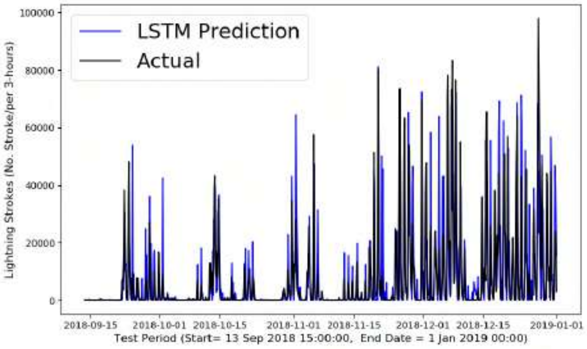

Fig. 7. LSTM RNN Prediction Results vs. Actual Flashes.

A graphical summary of the predicted values versus the actual data is shown in Figures 5, 6, and 7. The AR and ARIMA models performed comparably similar with MAPE values of 15312 and 15080 respectively. The RMSE values were 8579 and 8301 respectively I. The LSTM model had MAPE and RMSE values of 3705 and 9426, indicating it had outperformed AR and ARIMA considerably.

TABLE II
RESULTS OF AR COEFFICIENT AND INTERCEPT

Lag	AR Coefficients
AR Lag 1	0.9479
AR Lag 2	-0.5274
AR Lag 3	0.2505
AR Lag 4	-0.1218
AR Lag 5	0.0615
AR Lag 6	-0.127
AR Lag 7	0.3206
AR Lag 8	0.0702
Intercept	0.0054

TABLE III
RESULTS OF ARIMA COEFFICIENT AND INTERCEPT

Lag	ARIMA Coefficients
AR Lag 1	0.2063
AR Lag 2	-0.0816
AR Lag 3	0.1331
AR Lag 4	-0.0736
AR Lag 5	-0.0054
AR Lag 6	-0.019
AR Lag 7	0.0936
AR Lag 8	0.4647
MA Lag 1	0.7489
MA Lag 2	0.3323
Intercept	0.0456

Table II shows that the first lag value has the highest correlation compared to other lag steps for the AR model. Table III indicate the Moving Average Lag 1 values have the highest correlations actual data.

IV. DISCUSSION

In this study, we evaluated the AutoRegressive, ARIMA and LSTM models to forecast the number of lightning strikes for a period of 3-hours into the future. The AR and ARIMA performed comparably, and the LSTM considerably outperformed all models based on MAPE values (Table I).

Our study is not directly comparable with recent lightning prediction studies. The most recent study to investigate same-day lightning prediction in South Africa is by [11]. In this study, the authors found an AUC ratio of 90% using a stepwise logistic regression mode. But the study predicted the occurrence of a lightning strike occurring rather than the quantitative number of lightning strikes.

Numerous studies have found that LSTM models outperform AR and ARIMA models in forecasting using univariate time-series data [6], [7]. Even with weather series data [8], [9]. Reference [6] found the average reduction in error rates obtained by LSTM was between 84 - 87% when compared to ARIMA indicating the superiority of LSTM to ARIMA for various time-series data. Reference [8] found LSTM models performed about 20% better than ARIMA to predict wind-speed based on MAPE.

LSTM RNN models have several advantages over linear regression models but does not provide explanatory ability. Firstly, LSTM models are able to perform more complex functions than regression models. Secondly, they are able to analyses data with less restrictions such as the stationary requirement of data in regression models. The fact that LSTM models outperform autoregressive models indicates that lightning is non-parametric in nature and involves numerous dependencies. A limitation of neural network models is that they do not provide an understanding of how the results arises.

Recommendation for future studies. We believe that LSTM prediction accuracy can improve if we used a larger dataset to incorporate seasonal trends. This should increase predictive accuracy as lightning is seasonal. If we want an more accurate but data-intensive model, Numerical Weather Prediction parameters can also incorporated into the LSTM model. To gain a better understanding on the factors that influence lightning density, we suggest using a non-parametric machine learning techniques,

V. CONCLUSION

In this study, we predicted the number of lightning strikes for a three-hour period within South Africa. We found that the LSTM RNN model significantly outperforms AR and ARIMA models based on MAPE values. But all models still have relatively high error rates. This study indicates that lightning is better predicted using non-parametric techniques to due its nature. Future models may focus on using non-parametric modelling to better understand and predict lighting.

ACKNOWLEDGMENT

This work is based on the research supported in part by the National Research Foundation of South Africa (Grant number: 121835 and 98244). The authors would also like to thank The South African Weather Service, specifically Morné Gijben and Andrew van der Merwe, for the use of the SALDN data.

The support of the DSI-NICIS National e-Science Postgraduate Teaching and Training Platform (NEPTTP) towards this research is hereby acknowledged. Opinions expressed and conclusions arrived at, are those of the author and are not necessarily to be attributed to the NEPTTP

Abstract*—Speech emotion recognition is an important part of the human-computer interaction process, which has been receiving more attention in recent years. However, although a wide diversity of methods had been proposed in decades, these approaches still cannot improve the performance. The main reason for the low accuracy of emotion recognition system is how to effectively extract emotion-oriented features. In this paper, we propose a novel autoencoder architecture, two-stream emotion-embedded autoencoder, to extract deep emotion feature. The input is projected to two latent representations in our method. One of them is meant to learn the best representation of the input which contains all information of speech; whereas the other is used to capture emotion-independent information. Next, the difference between two latent representations is considered as the deep emotion feature. Furthermore, the deep emotion feature is concatenated with global acoustic features obtained by openSMILE toolkit. Finally, based on the concatenated feature vector, fully connected network is adopted to conduct emotion classification. Besides, to improve generalization of our method, a simple data augmentation approach is applied. IEMOCAP that is a publicly available and highly popular databases is chosen to evaluate our method. Experimental results demonstrate that the proposed model achieves significant performance improvement compared to other speech emotion recognition systems.

Keywords—speech emotion recognition, two-stream autoencoder, emotion embedding

I. Introduction

In human speech interaction, people convey the underlying intent of speech through paralinguistic characteristics such as emotions, intonations and styles. Since human emotions help us to understand each other better, speech emotion recognition (SER) has gradually become a significant research interest. This technology has promising prospects and plays an important role in natural language understanding. For example, robots, mobile services and call centers. Recognizing these paralinguistic characteristics can help intelligent systems understand user intention and further improve the user experience. In this paper, an algorithm that analyzes the human emotions in speech with deep learning algorithm is proposed.

Recognizing human emotions from speech are a complex task. The main challenges are as follows: 1) due to their abstraction, human emotions may be treated as noise and discarded in many current speech recognition methods. 2) generally speaking, human emotion in a long utterance can only be detected in some specific moments [1]. Many previous works mainly focused on selecting speech acoustic features that can distinguish different emotion such as statistical features and prosodic features. Finally, basic machine learning algorithm (e.g., hidden Markov model (HMM) [2], Gaussian mixture model (GMM) [3], support vector machine (SVM) [4]) are utilized for SER. Recently, deep learning (DL) algorithm have made noteworthy progress in image processing field. Therefore, DL algorithms, such as Recurrent Neural Networks (RNNs) and Convolutional Neural Networks (CNNs), are also introduced into speech signal processing. The automatic extraction of useful features from speech signals by Deep Neural Networks (DNNs) has become a very powerful technique. Prior researchers used DNNs has demonstrated that DL has the most promising results compared with traditional algorithms.

Encouraged by the recent success of autoencoder structure [5] with deep unsupervised learning, and the idea of word embedding [6] in natural language processing (NLP), a novel autoencoder architecture, two-stream emotion-embedded autoencoder, is proposed to improve both learning and generalization capacities of SER system. Our modified autoencoder method projects the input to two hidden spaces. One of them is meant to learn the best representation of the input which contains all information of speech; whereas the other is used to capture information that is related to human emotions. Emotion embedding layers in our method can allow the model to efficiently learn a priori information from the ground truth. Besides, instance normalization (IN) [7] is introduced into autoencoder. In emotion classification stage, the deep emotion feature extracted by modified autoencoder and IS10 [8] feature set obtained by openSMILE toolkit [9] are fused for SER task. Finally, we evaluate our suggested SER model on IEMOCAP dataset and it achieves 71.86% recognition results. In the comparative analysis, our system shows outperformed recognition performance.

The rest of this paper is organized as follows. Section II describes the related algorithm of the autoencoder. Section III presents our proposed novel algorithm in detail. Section IV shows the experimental details and database. Section V demonstrates the experimental results.

II. Related Work

SER is considered a challenging task in human-computer interaction domain. In the early stage, several SER approaches attempted to use handcrafted speech features and low-level descriptors (e.g., fundamental frequencies, pitch, prosody, voice quality) to train classic machine learning models. Recently, increasing attention has been drawn to the study of the DNNs. However, there are two major issues observed in SER domain: (1) insufficient amount of labelled speech data, (2) the difficult of extracting emotion-oriented features from audio.

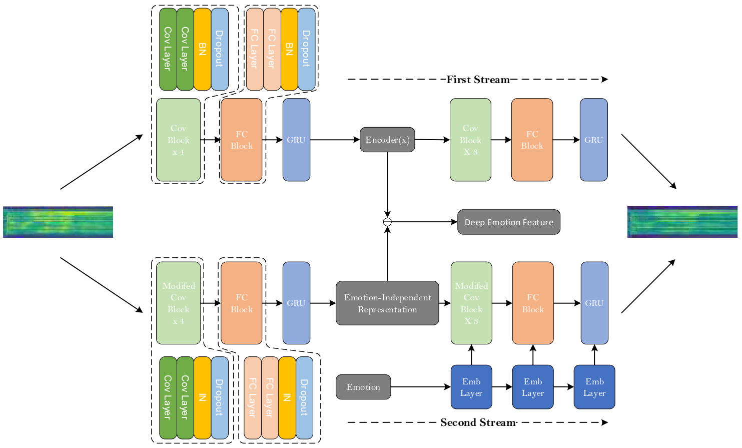

Fig. 1. The framework of two-stream emotion-embedded autoencoder.

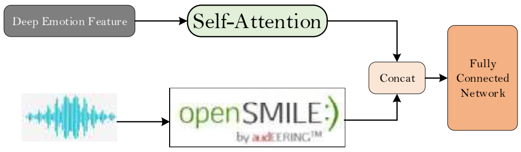

Fig. 2. The framework of emotion classification network.

To address the scarcity of training data, multiple methodologies were implemented in many works. Generally speaking, there are three approaches to solve this obstacle. (1) Collecting and annotating new data. However, it is expensive and time-consuming to create a big enough dataset. (2) Data augmentation. It is a most common method that has been widely used in DL field. (3) Transfer learning. This method is a popular research problem in DL that focuses on storing knowledge gained while training one model and applying it to another task. It has been successfully applied in various domains [10][11]. A major assumption in transfer learning is that the training and future data must be in the same feature space and have the same distribution. However, the mismatch between the dataset in SER field is a common problem. This is the reason why transfer learning has not further improved the accuracy of SER system. In this paper, a simply data augmentation method is applied for proposed SER algorithm.

In recent years, to strengthen the capability of feature extraction, autoencoder structure with unsupervised learning have been proposed. With the successful application of autoencoder, there is an increasing trend in most work to use it. Autoencoder is an unsupervised learning model used to reconstruct the input with minimum reconstruction error. Basic autoencoder has one input layer, one hidden layer and one output layer. Autoencoder first maps the input vector to the best latent representation through a non-linear layer and then this representation is mapped back to output layer, which purpose is to reconstruct input vector. If the number of hidden layers is greater than one, the network is considered to be deep. Many previous works directly utilized the latent representation learned by basic autoencoder for SER tasks. For instance, [12] proposed a deep autoencoder based on a multilayer perceptron for SER. Arghya Pal et al. [13] proposed deep dropout autoencoder based multilayer perceptron. Moreover, autoencoder was also applied to extract the bottleneck features for dimensionality reduction in [14] and [15]. Finally, the features extracted by autoencoder were utilized to train some machine learning algorithms, such as SVM and long short-term memory (LSTM).

Furthermore, denoising autoencoder (DAE) are also investigated in SER field to extract more robust features. The major difference between DAE and traditional autoencoders is that DAE is trained to recover from corrupted inputs. Inspired by the motivation behind this, Sayan Ghosh et al. [16] explored stacked DAEs, the deep structure of DAE, for representation learning. In addition, Zixing Zhang et al. [17] proposed a memory-enhanced recurrent denoising autoencoder (rDA). Experiment results have shown that this method can achieve significantly performance improvement.

In aforementioned methods, the purpose of autoencoder is to learn a lower-dimensional distributed representation of the input data directly. However, many researchers have also explored many modified autoencoder network. To reduce the discrepancy between the training and test set, shared hidden-layer autoencoder (SHLA) was proposed to learn common feature representations shared across them in [18]. Besides, Zefang Zong et al. [19] proposed a novel framework named multi-channel auto-encoder (MTC-AE) on emotion recognition. MTC-AE contains multiple local DNNs based on different low-level descriptors with different statistics functions that are partly concatenated together. It allows the model to consider both local and global features simultaneously. Pengcheng Wei et al. [20] proposed an algorithm based on autoencoder, denoising autoencoder, and sparse autoencoder. The first layer of the structure is based on a denoising autoencoder which purpose is to learn a hidden feature with a larger dimension, and the second layer employs a sparse autoencoder to learn sparse features.

Obviously, even if such methods can further improve the performance of SER, the high-level features learned by reconstructing input mainly contain the content information rather than emotion-oriented feature. Moreover, these above-mentioned works do not consider the significance of a priori knowledge. To address this problem, we design a new autoencoder architecture, two-stream emotion-embedded autoencoder, to increase the modeling capacity. In our model, we impose a constraint, emotion embedding, on decoder stage. Emotion embedding layers in our method lead the model to efficiently learn a priori emotion information from the label, which allows autoencoder focus more on deep emotion feature during reconstruction process.

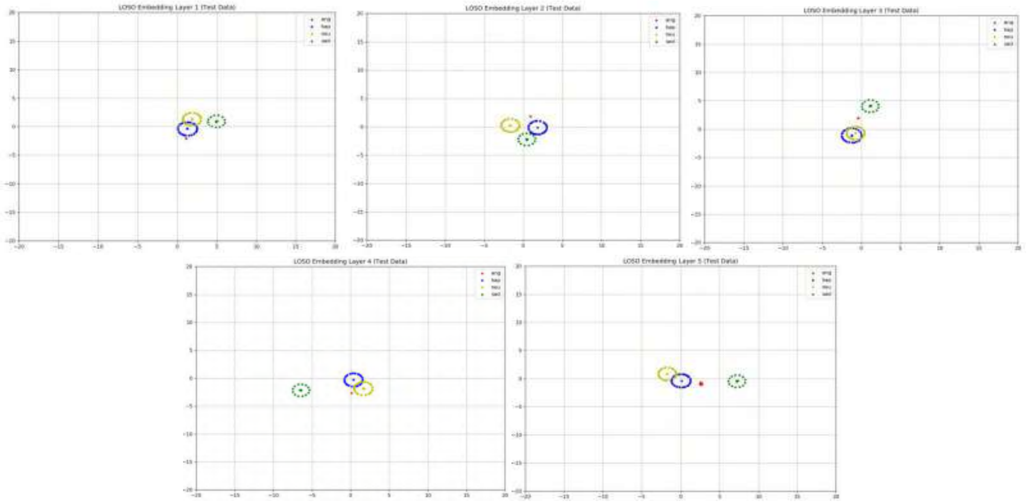

Fig. 3. T-SNE visualization of emotion embedding on IEMOCAP (LOSO).

III. Proposed Method

In this section, we describe our proposed method. There are three parts including input speech feature, two-stream autoencoder with emotion embedding and emotion classification network. Fig. 1 depicts the model framework, which includes two autoencoder paths, an emotion embedding path, and an emotion classification net. Let us consider that a dataset with N labelled samples $D=\{(x_1,y_1),(x_2,y_2),\ldots,(x_N,y_N)\}$ and M unlabeled samples $\{(x_{N+1}),(x_{N+2}),\ldots,(x_{N+M})\}$, where x_i is denoted as the i-th acoustic feature sequence of speech sample and y_i is the emotion label corresponding to x_i. $y_i \in \{1,2,3,\ldots,K\}$, and K is the number of emotion categories.

A. Input Speech Feature

1) Log magnitude spectrogram: Spectrogram is a useful feature for analysis of speech and audio signals. Many previous researches are performed in the spectral domain rather than in the original time domain. The reason is that the magnitude spectrograms of audio signals tend to be highly structured in terms of both spectral and temporal regularities [21]. It is easier to deal with many problems by processing magnitude spectrograms than directly processing time-domain signals. In fact, magnitude spectrograms have been employed in many speech processing fields including audio separation and speech synthesis systems [22][23]. In this paper, log magnitude spectrogram is utilized to input our model, and the detailed spectral analysis was the same as the previous work [24].

2) IS 10 feature set: We utilize openSMILE [9] toolkit to extract statistics feature which was used in the INTERSPEECH 2010 Paralinguistic Challenge [8]. The open-source media interpretation by large feature-space extraction (openSMILE) toolkit is a modular tool for signal processing and machine learning applications. It can flexibly extract the features of signals and is mainly used for audio signal feature extraction. 1582-demensional feature vector is generated by extracting 38 kinds of LLDs and applying 21 statistic functions in this work. Details about these features can be found in [8]. In the emotion classification stage, it is concatenated with the deep emotion feature obtained by autoencoder.

B. Two-stream Autoencoder with Emotion Embedding

In this part, we interpret the complete scheme of our modified autoencoder in detail, as shown in Fig. 1. In this letter, due to the 2D representation of spectrogram, our proposed autoencoder is mainly based on a CNN. To further remove redundant information that is not related to human emotions and obtain robust deep emotion feature, the input is projected to two hidden representations. The first path in our model is a basic autoencoder network which consists of three blocks: convolution blocks, fully connected blocks and gated recurrent unit (GRU) [25]. In the second path, emotion embedding is introduced into the autoencoder. Additionally, in our method, we replace batch normalization (BN) [26] with IN in our network. BN is one of the most common components in many CNNs, and it can reduce the internal covariate shift during training process. The key difference between BN and IN is that the latter applies the normalization to an individual sample instead of a whole batch of samples. Generally, IN is mainly used in the style transfer field, for instance, image style transfer [27]. Many existing works disclose that IN learns features that are invariant to appearance changes, such as colors, styles, and virtuality, while BN is essential for preserving content related information [28]. We consider that human emotion is a kind of style features. To this end, we introduce IN into our autoencoder network, which purpose is to lead model to attract more attention to features related to emotion.

In the encoder process, the network is trained to map an input x to two latent representations: $encoder(x)$ (the first stream), $encoder_{EI}(x)$ (the second stream). EI donates emotion-independent. In the decoder process, the decoder network in the first path is trained to reconstruct input directly, as shown in (1). However, the decoder in the second path is equipped with the emotion embedding path, leading the model to efficiently learn a priori emotion information from the label. The main contribution of emotion embedding is that we expect that the projection can capture the emotion-independent information of the utterance. In this path, the decoder is trained to generate x' which is a reconstruction of x from $encoder_{EI}(x)$ given the emotion label y, as shown in (2).

$$x' = decoder(encoder(x)) \tag{1}$$

$$x' = decoder(encoder(x), y) \tag{2}$$

The mean absolute error (MAE) is used as the reconstruction loss since it generates a sharper output than the mean square error [29], as shown in (3).

$$L_{AE}(\theta_{Enc}, \theta_{Dec}) = \sum_{(x,y)\in D} \|x' - x\|_1 \tag{3}$$

Where θ_{Enc} and θ_{Dec} are the parameters of the encoder and decoder respectively.

Finally, the deep emotion feature is considered as:

$$emotion\_feature = encoder(x) - encoder_{EI}(x) \tag{4}$$

C. Emotion Classification with Feature Fusion

In the classify process, classification network takes the output of two-stream autoencoder and learns the links between it and the emotion label, as shown in Fig. 2. The output is fed into the self-attention [30] layer firstly, and the details of attention layer is same as the previous work [30]. With the attention mechanism, the network can focus more on emotion-oriented information of speech utterance.

Moreover, while the progressive downsampling of CNNs provides strong capability in local context modeling, Runnan Li et al. [31] believed that the temporal structure of speech that is highly related to emotions will gradually be lost in the downsampling process [32]. To overcome this problem, we concatenate the deep emotion feature extracted from attention layer and acoustic features obtained by openSMILE toolkit. These features contain global information of speech. Finally, the concatenated feature vector is fed into the fully connected network for emotion classification.

The emotion classification network takes $emotion\_feature$ as input and outputs the predicted emotion class. The classifier is trained to minimize the negative log-probability, as shown in (5).

$$L_{EC}(\theta_{Att}, \theta_{Cla}) = \sum_{(x,y)\in D} -\log P_{EC}(y \mid emotion\_feature) \tag{5}$$

Where θ_{Att} and θ_{Cla} are the parameters of the attention layer and classification network respectively.

During the training process, the object function of our network is a joint function decided by both reconstruction error and the negative log-probability:

$$\begin{aligned} L_{Total}(\theta_{Total}) = L_{AE1}(\theta_{Enc1}, \theta_{Dec1}) \\ +\lambda_1 L_{AE1}(\theta_{Enc1}, \theta_{Dec1}) + \lambda_2 L_{EC}(\theta_{Att}, \theta_{Cla}) \end{aligned} \tag{6}$$

where λ_1 and λ_2 are constant controlling the weighting between encoder path and classify path.

IV. Experiment

A. Data augmentation

Currently, there are two common problems about dataset in SER field: 1) the typical inherent mismatch between the dataset, 2) the difficulty in creating corpora. Generally, due to different emotion annotation schemes, the distribution of data between different datasets is often mismatch. In addition, high data collection often come with high annotation costs. Therefore, data augmentation has been proposed as a method to generate additional training data. In [33], Navdeep Jaitly et al. proposed a method named Vocal Tract Length Normalization for data augmentation. In [34], authors superimposed clean audio with a noisy audio signal. In LVSCR tasks [35], they have applied speed perturbation in their work. Besides, the use of an acoustic room simulator [36] and generative adversarial networks (GANs) [37] have been also proposed for data augmentation. However, aforementioned approaches all operated on the raw audio itself, rather than the spectrogram. In [38], D. S. Park et al. proposed a simple and computationally cheap method for data augmentation, which directly acted on the log mel spectrogram and did not require any additional data. Three deformations of spectrogram were chosen in their work: time warping, frequency masking and time masking. More generally, many works have demonstrated that data augmentation techniques have achieved state-of-the-art performance in ASR. In this paper, to not lose local context information of the speech signal, we randomly sampled 128 frames of log magnitude spectrogram with overlap. It means that 128 consecutive time steps $[t, t+128)$ is termed as a training sample, where t is chosen from a uniform distribution $[0, T-128)$, and T is the length of log magnitude spectrogram.

B. Dataset

To investigate the performance of the proposed method, a publicly available and highly popular database, namely the Interactive Emotional Dyadic Motion Capture (IEMOCAP) [39] is chosen as source set. IEMOCAP was collected by SAIL lab at USC, USA, and it consists of 5 sessions. It has 10 professional actors (5 male and 5 female) acting in two different scenarios: scripted play and spontaneous dialog. This corpus has approximately 12 hours of audiovisual data, including video, speech, motion capture of face, text transcriptions. Each interaction has been segmented into sentences that are labeled by at least 3 annotators. In this paper, we used four emotion categories: angry, happy, sad and neutral. Note that, like many previous works, Happy and Excited in the original annotation were merged into one class: happy. Only the audio signals were used in the experiments.

C. Experiment Setup

Since there are 10 speakers in IEMOCAP and each session consists of 2 speakers, leave-one-speaker-out (LOSO) cross-validation were applied in our experiments, so that there is no speaker overlap between the training and test data. Moreover, 10-fold cross-validation strategies were also used to evaluate the proposed method.

For performance comparison, we utilize unweighted accuracy (UA) [40], which have been used in several previous emotion challenges. Weighted accuracy is the accuracy over all testing utterances in the dataset. It is quite a good measurement in this case since the class distribution is imbalanced.

We used sampled log magnitude spectrogram as the inputs. We trained the network using Adam optimizer with $lr = 0.0001, \beta_1 = 0.9, \beta_2 = 0.999$. The model was trained for 40 epochs on the dataset. All the experiments were performed using an Nvidia GTX 1080Ti with 11 GB memory.

V. Results and Analysis

A. *Impact of emotion embedding*

In this part, the IS10 feature set is combined with the traditional machine learning algorithm SVM (IS10+SVM) to serve as a comparison baseline. Moreover, to verify that our modified autoencoder (TSAE+EE) can efficiently improve SER performance, contrast experiments are performed on two different models (OSAE, TSAE).

TABLE I. The Impact of Emotion Embedding

Method	**Two Stream**	**Emotion Embedding**	**UA**	
			10-fold	**LOSO**
IS10+SVM	--	--	--	58.6
OSAE	×	×	69.98	65.46
TSAE	✓	×	69.43	65.18
TSAE+EE	✓	✓	**71.86**	**66.23**

Table I shows the performance of different classifiers on the IEMOCAP speech database. For 10-fold cross-validation, the UA obtained with the proposed method is improved by 1.88% and 2.43% compared with OSAE and TSAE, respectively. For LOSO cross-validation, the UA obtained with TSAE+EE is improved by 7.63%, 0.77% and 1.05% compared with IS10+SVM, OSAE and TSAE, respectively. Moreover, we can find that OSAE and TSAE have similar performance. This is because two streams in TSAE are mutually independent. In summary, the performance of SER is further improved by introducing emotion embedding.

B. *Visualizing the Emotion Embedding Using T-Distributed Stochastic Neighbor Embedding (t-SNE)*

T-SNE is an algorithm developed for visualizing multidimensional data, based on the idea of dimensionality reduction. We visualize the emotion embedding of our modified autoencoder model by t-SNE. There are five emotion embedding layers in decoder network, and they are trained to map an emotion to a 512-dimensional representation. T-SNE was then used to reduce the dimensions to only two for a 2D plot, as shown in Fig. 3. From Fig. 3, we can clearly see the separation between " ang" and "sad". Such result is expected since there are obviously different characteristics between them. However, we can also see that it is not clearly separated between "neu" and the other three emotions. One possible explanation is that low energy state of emotion "neu" do not have salient characteristics compared with the other emotions. Meanwhile, we can find the fact that "ang" is easily confused with "hap" due to the reason that the anger and happiness emotions correspond to high activation.

In summary, experimental results demonstrate that our proposed autoencoder naturally learn useful emotion representations from the label, and the training process discovers the intrinsic attributes that are necessary to solve the emotion recognition.

C. *Proposed method on IEMOCAP*

Table II clearly shows that the proposed method, two-stream emotion-embedded autoencoder, offers an improved performance in SER compared to previous studies. From the results of Table II, we can see that the highest accuracies obtained by the proposed method are 71.86% and 66.23% on IEMOCAP.

TABLE II. Performance Comparisions on IEMOCAP

Method	**Validation Setting**	**UA**
[41]	10-fold LOSO	64.2
[42]	10-fold LOSO	62.8
[43]	10-fold LOSO	59.54
[44]	10-fold	68.8
Proposed Method	10-fold LOSO	**66.23**
Proposed Method	10-fold	**71.86**

VI. Conclusion

In this paper, we designed a novel autoencoder network, two-stream emotion-embedded autoencoder. In modified autoencoder, the first stream is a basic autoencoder which purpose is to learn the best representation of speech. In second path, we combine both autoencoder and emotion embedding and replace BN with IN. The emotion embedding path focus on learning strong emotionally information from label. In emotion classification process, IS10 feature set was fused with the deep emotion feature from autoencoder. Experimental results with one publicly available corpora show that the proposed algorithm further enhances the classification accuracy.

***Abstract*—In heterogeneous networks, vertical handover plays a major role in providing seamless connectivity to the mobile users that are passing through different network access technologies and connecting to different point of network attachments. A mobile node scans all of its interfaces to find a suitable network with which it can connect. However, scanning of a large number of networks requires a huge amount of energy thereby the mobile node drains the battery very fast. The Media Independent Handover (MIH), which was introduced by IEEE, to facilitate seamless and energy efficient handover of mobile nodes across heterogeneous networks. The MIH Information Service (MIIS) offers a variety of criteria and services that can be used to avoid network scanning. But sometimes scanning avoidance leads to inconsistent handover, that is, increased handover failure rates. Thus, an optimal network scanning procedure, which can maintain a consistent handover and should consume the energy as least as possible is required. Our proposed work incorporates two additional functional units into MIH – one is responsible for making an optimal network scanning decision (it could be either full scanning, partial scanning, or avoid scanning) and other one is responsible for computing handover decisions by taking both network conditions and user preferences into account. In the second functional unit, we have introduced a utility function based TOPSIS algorithm that computes the handover decisions. Whereas, in principle, MIH users make the handover decision. Almost all of these existing methods suffer from severe ping-pong effect, unnecessary handovers, handover failures, and excess energy consumption due to inaccurate scanning method and ineffective network choice, whereas the performance analysis of our proposed work indicates that the suggested scheme performs better and consumes less amount of energy than existing works.**

***Index Terms*—Vertical Handover, Heterogeneous network, IEEE 802.21, MIH, Energy, TOPSIS, Utility Function**

I. Introduction

Heterogeneous networks [1] have been designed to include several access technologies of diverse forms aimed at providing better network coverage and capacity to mobile users. A mobile node should use an enhanced mobility management technique to make use of the access technologies in best way for meeting it's requirements [2]. Due to better handover management, a mobile user can retain its connectivity while switching from one point of network attachments to other [3]. As the handover takes between different access technologies, it is called as Vertical Handover. From now on, handover refers to Vertical Handover. Since handover consumes a lot of resources for managing it, hence it can greatly impact the overall efficacy of the networks unless managed aptly.

In order to serve multiple web applications in heterogeneous systems, next-generation communication systems must integrate multiple network interfaces (NICs) [4]. The usage of multiple interfaces opens up various ways to overcome many of the limits of transmission networks and provide numerous exciting new opportunities like Resource Sharing, Bandwidth Aggregation, Mobility Support etc. Using multiple interfaces at the same time a mobile node can extend the communication across the interfaces that reduce the risk of an interruption of communication. The increase in numbers of network interfaces and emergence of various standards, leads to compatibility issues and consumes excess energy during handover [5, 6]. IEEE 802.21 [7], a standard for Media Independent Handover (MIH), was developed to address these challenges. The handover protocol proposed in this standard is capable of communicating with all types of IEEE 802.x networks and other mobile networks (non-IEEE) like LTE, GSM etc. [8]. It fits in between Layer 2 and Layer 3. The central and logical entity of MIH known as, MIH Function (MIHF), operates as an intermediary layer between top and bottom layers, whose primary purpose is to manage the transfer of commands and data between various devices participate in the decision-making and the execution of handover process. MIHF offers three types of services to handle a seamless handover between various technologies. They are Media Independent Event services (MIES), Media Independent Command services (MICS), Media Independent Information services (MIIS). These services enable users of MIHF to obtain information relating to handover process, and to send commands to L2 Layer or to the network. The events created in L2 layers are transferred and delivered to MIHF, asynchronously, whereas the commands and data produced by request/response method are delivered synchronously. The MIIS is used to enable the mobile node to carry out a handover procedure without any network scanning [9]. As the MIIS includes the Information Elements (IE) that incorporates the network attributes, in compliance with the norm, the mobile node can conduct a handover instead of using any scanning procedure. In real scenarios, the updation of IE happens after a complete scanning procedure. If a mobile node is carried out a handover process by avoiding any scanning process then it fails to deliver the IE update notification to the Information Server (IS). This suggests that the information about the network and the IS are not consistent, which could lead to handover failures. Consequently, scanning is required or not required can be determined. During the network discovery process of handover, the mobile terminals conduct the total network scanning procedure by continuously activating all network interfaces. The energy usage of a given mobile node directly depends on the number of network interfaces it uses [10]. The existing network scanning methods are of the following types: Always active scheme (conventional method), periodic scanning, and adaptive scanning [11]. Always Active scheme performs better in terms of handover delay, but it fails to address the issue of energy efficiency. Periodic scanning [9] is another network scanning approach, where a mobile node scans the neighbouring network periodically over a time frame. In order to conserve energy, a mobile node enters into an idle slate when scanning process is not carried out which prevents vertical handover decisions from being taken in real time. Therefore, the existing approaches may not be suitable for heterogeneous networks. Different algorithms based on the IEEE 802.21 architecture have been reported by various researchers in order to solve and optimise the problem of vertical handover. Such algorithms are categorized into many groups

978-1-6654-4067-7/21/$31.00 © 2021 IEEE

[12] such as: RSS based, distance based, cost function based, utility function based, multi attribute decision making (MADM) based etc. Utility function-based algorithms are widely used to define the mobile node's degree of satisfaction with the various functionalities provided by network technology [13]. The contributions of the paper are outlined as follows:

1) An efficient vertical handover is proposed to minimize the energy consumption of a mobile node by improving the network scanning process of MIH protocol.
2) Although the complete scanning procedure for the heterogeneous network is very heavy, the objective of our approach is to limit or avoid the number of scans on each NIC with a purpose of ensuring lower energy usage. Here we have considered a heterogeneous network consisting of numerous access points and base stations, and suggested an optimal network scanning approach intended to make the network very energy-efficient.
3) This work also employees a partial scanning method which is based on application's priority level to speed up the scanning process and reduced energy consumption by minimizing unwanted scans.
4) In our proposed handover technique, the handover decisions are computed by taking both network conditions and user preferences into account. To take care of user demands along with handover consistency, a hybrid approach of utility function and TOPSIS is considered in this work.

The remaining portion of the paper is organized as follows: Section II includes Related Work. Section III describes the Proposed Methodology. In Section IV, the Performance Analysis of our proposed handover technique is discussed using the simulation results along with simulation settings. Section V lastly concludes this paper.

II. Related Works

A) *Energy Efficient Handover Techniques*

In heterogeneous network the transmission ranges of most of the point of attachments are overlapped due to their random deployments which leads to higher interference and packet loss rate. The co-existence of point of attachments often lead to unnecessary energy consumption even at the time of low traffic condition as the communication systems does not have an uniformity in terms of energy usage relative to traffic loads. For example, even though these nodes are in idle condition, they continue to consume considerable amount of energy [14]. Here some earlier study has been carried out on the channel scanning method. Moon et al. [15] suggested a scanning method, focused on Received Signal Strength (RSS) and dwell time. This method extends the scanning period when the dwell-time time is sufficiently long and the RSS is enough for communication. Many studies mentioned MIH for energy consumption purposes [16, 17] but most solution approaches only referred to the life-span of mobile node batteries while the actual energy usage of the system was ignored. The authors of [16] suggest a fuzzy logic-based algorithm that involves multiple criteria for network selection. This work gives a good QoS and encourages the mobile nodes to utilize low energy power. The authors in [17], proposed an algorithm in which network scanning is carried out by considering channel coherence time to conserve MN battery life. In Ref. [18], the MIIS is used to handle the scanning process. The goal of the suggested approach is to reduce energy consumption by minimizing the number of network scan. Xenakis et al. [19] proposed a context aware vertical handover framework to reduce energy consumption in MN. Liu et al. [20], suggested an energy-efficient handover method in which they used IEEE 802.21 MIIS for information gathering. In their work, handover is triggered only when power consumption level, RSS, and cost exceeds a predefined threshold. Although conventional network scanning techniques are improving the accuracy of the scanning performance they consume a lot of energy. In this context, the periodic [21, 22] and adaptive scanning mechanisms [23] were proposed.

B) *Network Selection using Hybrid Algorithms*

Current research [24, 25] suggests a number of vertical handovers schemes focused on MADM approaches for selection of the best target network. The hybrid approach of Simple Additive Weighting (SAW) and Analytic Hierarchy Process (AHP) was used widely in order to make network selection judgments [26]. In [26, 27], the authors formulated the problem of network selection using two approaches named as AHP and Multiplicative Exponential Weighting (MEW). The TOPSIS is extensively used by many researchers to rank the available networks [28, 29]. Even though AHP approach is generally used to assign weights to decision criteria, limitations remain in this method. For this purpose, the authors in [30] have suggested an improved TOPSIS algorithm to rank the alternatives using ANP to assign weights to criteria. As a result, it gives better performance than conventional approaches. Authors in [31, 32], have proposed a hybrid algorithm that uses MADM approaches and utility function to solve the network selection issue where the utility functions is useful in describing the required application specifications and evaluate the state of network resources. Another smart network selection technique based on utility function and MADM approaches was introduced in Ref. [33]. The suggested approaches helped the mobile nodes to choose appropriately a network to connect and reduced the number of ping-pong effects significantly.

III. Proposed Methodology

A. *Problem Formulation*

The network consisting of N base stations, S mobile nodes, each mobile node is assumed to have K number of interfaces and running M different applications on each interface. Before triggering a handover, the network scanning process go on to search for a network which suits well to the requirements of the application which is currently running on the mobile node.

The objective of our work is to minimize the energy consumption of the mobile node due to unnecessary scanning and maximize user preferences during network selection. Mathematically, the objective function is explained as follows:

$$Minimize \quad P_{total} = \sum_{i=1}^{S} (P_{HO})_i \tag{1}$$

Where, P_{total}: Total power consumption due to network scanning, $(P_{HO})_i$: Power consumption of the mobile node due to i^{th} handover, S: The number of handovers.

B. *Solution Approach*

We have introduced two functional units in the existing MIH architecture which will minimize total energy consumption and maximize user satisfactions of the mobile nodes after a handover takes place. Our proposed energy efficient vertical handover framework is illustrated in Figure 1. The functional units are Energy Consumption Unit (ECU) and Handover Decision-making Unit (HDU).

The purpose of ECU unit is to reduce the unnecessary network scanning during a handover process. Sometimes scanning avoidance leads to inconsistency in handover process and increases handover failure rates whereas excess network scanning increases energy consumption in the system. So, an optimal network scanning procedure is introduced here to minimize overall energy consumption.

HDU unit is responsible for taking handover decisions. This unit not only takes handover decisions but also maintains user satisfactions and helps in meeting requirements of the mobile nodes. For this purpose, we have used the idea of utility functions. Finally, a hybrid approach of TOPSIS and utility function is proposed to take handover decisions.

C. Energy Efficient Vertical Handover in Heterogeneous Networks

1) Energy Consumption Unit (ECU)

The proposed solution approach is relying on IEEE 802.21, a latest IEEE standard which allows the continuity of service between heterogeneous networks like IEEE 802.x, 3GPP and 3GPP2. In order to minimize the energy consumption of mobile nodes, here we have used the Media Independent Information Service (MIIS) to handle the network scanning procedure. MIH offers the MIIS to enable the mobile node to conduct a handover process by avoiding network scanning [34]. Though the MIIS gives the IE, which includes relevant information related to network, as per the norm, the mobile node can conduct a handover even without performing any scanning process. Initially, the most important concept of the MIH is the reduction of network scanning using MIIS. The data provided by the MIIS are not always relevant because the updation period of the IE is not consistent and there are also not any representatives appointed to perform the duties of updating the IEs. In the real scenarios, the values of IE are updated after a complete scanning phase. When a mobile node conducts a handover by avoiding the scanning phase, then it is unable to transmit the updated value of IE to the Information Server (IS). So, the system information's are not accurate and valid. As a result, there appears a consistency issues between the system and IS which leads to handover failure.

The working procedure of ECU is shown in Figure 2. It's role is to decide the necessities of scanning process in the network. That's why the mobile node always conducts the complete scan process of the network and as a result it works against MIH's main objective. Thus, the criteria for evaluating whether to scan or skip needs to be established. Therefore, in this context, a new functional entity called the Energy Consumption Unit (ECU) has been introduced. The objective of the ECU is to limit the amount of network scans, which is the initial objective of the MIH. The ECU assists the overall minimizing process of the network scanning towards the chosen network.

Once the mobile node is alerted by the Connection Going Down (CGD) signal, it realizes that the handover mechanism needs to be carried out soon, so, the mobile node requests Information Elements (IE) to the information server (IS) of MIH (All networks are expected to have an access connection to the IS). After receiving the request message, IS then delivers the appropriate IE to the mobile node. When the mobile node obtains the IE, the ECU of the node retrieves the message and produces the membership degree. To verify the validity of the values of IEs, we provided two Time fields to the IE which helps to validate the IE data. It is restored with its initial values, whenever the data is modified. The MIHF conducts the task of network selection using the IE obtained and informs to the ECU. The ECU then measures the consistency of the preferred network. By using the outcome of the consistency checking process, it will determine whether to perform or skip the network scanning phase to trigger the handover process.

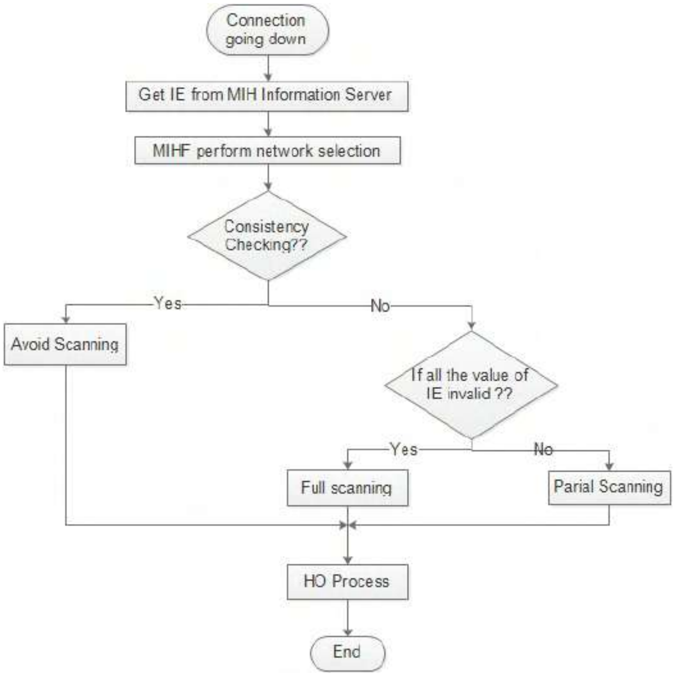

Fig. 2. The Working Procedure of ECU

- Consistency Checking Unit:

It checks whether the IE values are valid to use or not. It uses a fuzzy theory based mechanism [35] to measure consistency level of IE values. The scheme uses a Normal Distribution Function with mean 1.0 and standard deviation 0.4 as per Ref. [35]. With the help of input value and membership function we get the membership degree. If the value of membership degree is higher than the threshold value then the consistency of the value is still preserved.

- Network Scanning:

In this section, various types of scanning mechanism are explained that we have considered throughout the handover process by taking consistency level into account. After going through validity checking process, if all the IE values are consistent then the mobile node ultimately avoid the scanning process. Secondly, If some fields of IE values are valid i.e., partially valid, having some basic network related parameters, e.g., Service Set Identifier (SSID), location etc., then the mobile node goes for partial or fast scanning method, where, network scanning is performed only for the chosen network (not for all enabled networks).

a) Application's Priority-based Scanning Method

It actually falls under the category of partial scanning method. It is expected to have various applications operating on a single interface. During this, for each interface the mobile node is allocated with various time slots for scanning, which is based on the importance of applications that are running on the mobile node at that time. Usually, a higher prioritized application requires a lot of energy relative to a lower one. A mobile device typically has various applications including conversational (e.g., VoIP, video telephony, video game), streaming (e.g., watching multimedia), interactive (e.g., web surfing) and background class (e.g., WWW, emails) [36]. While travelling through heterogeneous wireless networks, each interface of a mobile device uses various types of applications. When an interface uses a prioritized application, then that will become the first choice for scanning. The application's importance level in terms of their priority is described in Table 1. Algorithm 1 describes the partial scanning method. According to algorithm, when a mobile device detects a high prioritized application then the node proceeds to scan that interface. Before the maximum time limit expires if that interface identifies a suitable target network then that time mobile node proceeds to scan a different interface having second prioritized application. Likewise, every interface executes their scanning processes. Finally total power consumption during partial scanning is calculated by adding each interface's power consumption in one scan time together.

TABLE I
APPLICATION'S PRIORITY VALUES

Various Applications	Priority Level
Conversational Class (e.g., VoIP, video telephony, video game)	High=1
Streaming Class (e.g., watching multimedia)	
Interactive Class (e.g., web-surfing)	Low=0
Background Class (e.g., news, WWW, Emails, file transfer)	

Algorithm 1: Partial Scanning Method

```
Input: M, K, $t_{inf}$=0, $t_{max}$=0, $p_{scan}$=0, $p_{inf}$
//M:Number of applications, K:Number of interfaces, $t_{inf}$:Interface scanning time, $t_{max}$:Maximum scanning time, $p_{scan}$:Power consumption during total interface scanning, $p_{inf}$:Power consumed by an interface in one scan time
Output: Scanned networks
// P:Priority, // inf:Interface
 $high \leftarrow inf1$;
 for $inf = 1$ to $K$ do
     if $(P[inf] > P[inf-1])$ then
         $high \leftarrow P[inf]$;
     end
     $inf$++;
end
while $(t_{inf} < t_{max})$ do
    $Scan(high)$; // Scan the interface having highest prioritized application.
    $p_{scan} = p_{scan} + p_{inf}$;
    if $(Scan(high) == finish)$ then
        Scan the interface having $2^{nd}$ highest prioritized application
    else
        $t_{inf}$++;
    end
end
```

b) Full Scanning Method

Lastly, if all IE values are inconsistent/invalid then complete network scanning process is conducted. Here complete scanning means all the enabled target networks are scanned. The total power consumption due to network scanning throughout a simulation having multiple handover process is calculated as follows:

$$P_{Total} = \sum_{i=1}^{H} P_{FS} \cdot (N_{FS})_i + \sum_{i=1}^{H} P_{PS} \cdot (N_{PS})_i \tag{2}$$

$$P_{HO} = P_{FS} \cdot N_{FS} + P_{PS} \cdot N_{PS}$$

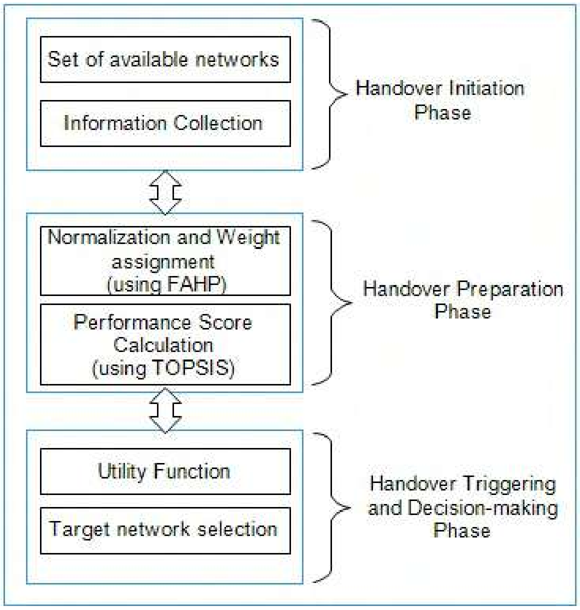
$$P_{FS} = P_{AP} \cdot t_{real\_scan} \cdot N$$

$$P_{PS} = \sum_{inf=1}^{K} p_{inf}$$

Where, P_{Total}: The total power consumption due to network scanning, P_{HO}: Power consumption due to a single handover, P_{FS}: Power consumption due to full scanning, P_{PS}: Power consumption due to partial scanning, N_{FS}: Number of full scanning, N_{PS}: Number of partial scanning, P_{AP}: Average received power of different access technologies involved, t_{real_scan}: The actual scanning time per scanning period, K: Number of interfaces, H: Number of handovers, p_{inf}: Power consumed by an interface in one scan time.

2) Handover Decision-making Unit (HDU)

HDU is divided into three phases as shown in Figure 3.



Set of available networks
Information Collection
Handover Initiation Phase
Normalization and Weight assignment (using FAHP)
Performance Score Calculation (using TOPSIS)
Handover Preparation Phase
Utility Function
Target network selection
Handover Triggering and Decision-making Phase

Fig. 3. Handover Decision-making Unit (HDU)

- Phase1: This phase is known as handover initiation phase. After the completion of network scanning phase, the mobile node gathered necessary information (e.g., network, terminal, and service related information) about the networks. Handover decisions are taken using these information.

- Phase2: This phase is called preparation phase of handover where all necessary steps are carried before triggering of actual HO process. Here, we have considered multiple decision criteria to make handover decision seamless and consistent. Fuzzy AHP (FAHP) is used to find the relative weights of decision criteria. Then the performance score of the networks is evaluated using TOPSIS algorithm.
- Phase3: Lastly this is called the decision-making phase of handover process. With the help of utility function and network performance score (which is calculated in Phase 2), the appropriate target network is decided for a seamless handover process.

The core element of this unit is an integrated module consisting of TOPSIS and utility function. TOPSIS usually picks the BS having highest solution score as the target node, irrespective of whether the user or the system requirements are fulfilled or not. Here the user or system demands and requirements are clearly neglected. To avoid these shortcomings, utility function is used along with TOPSIS to avoid the abnormalities created during the network ranking process. TOPSIS is used to aggregate multiple parameters and finds the relative closeness to the ideal solution or performance score. Then the utility function is used to rank the networks by using the above performance score. Here utility function measures the degree of satisfaction when MN travels from one Point of Attachment (PoA) to other.

The complete procedure of Utility Functions based TOPSIS method is described as follows:

- The conventional TOPSIS algorithm is used to distinguish the alternatives by ranking them. Then as a result, the highest ranked alternative is known as the best option for handover. But here we have not considered the highest ranked network as the target one. We only use TOPSIS for calculating the performance score of all the networks. We avoid the last step i.e. the ranking step of TOPSIS [37]. First the decision matrix with dimension m×n is constructed to compare available networks using different parameters. Then, the value in each cell of decision matrix is normalized. After that a weighted normalized decision matrix is created. The positive as well as the negative ideal solutions (optimal best and worst values) are evaluated. Then the deviation from the optimal solutions for each BS is determined. Finally, the performance score or the relative closeness to the ideal solution is measured.
- After measuring the performance score of the networks using TOPSIS then Utility function is used to rank the networks. The utility functions is useful in describing the required application specifications and evaluate the state of network resources. Here we have used exponential utility function to identify the appropriate target network. This is described below [38]:

$$\begin{cases} u(x) = \alpha * [\frac{1}{1+e^{-a(x-b)}} - \beta] \\ \alpha = (1+e^{ab})/e^{ab} \\ \beta = \frac{1}{(1+e^{ab})} \end{cases} \tag{3}$$

Where, x: Relative closeness to the ideal solution (computed in TOPSIS algorithm), a: value of anti-ideal solution, b: value of ideal solution.

IV. Performance Analysis

A. Simulation Settings

To facilitate our illustration, we consider a heterogeneous network scenario consisting of twenty BSs, three access technologies: LTE, WLAN, and WiMax and five MN. Table II contains all the simulation parameters. This framework is implemented in MATLAB. The decision criteria used in this work are grouped as, Network related: RSS, bandwidth, security, network condition, network performance, time to trigger, delay, QoS, velocity; Terminal related: power; Service related: cost, quality factor. FAHP is used to assign the relative weights to these criteria. We have used Empirical Hata propagation model since it is a widely used pathloss model along with all four traffic classes: Conversational, Streaming, interactive and Background traffic class. The Random waypoint mobility model is used in the proposed work to represent the behaviour of mobile nodes in the heterogeneous network. It is a widely used network mobility model [39]. In this model a node is arbitrarily selected at any point to reside or move with a certain probability. When it is decided to move, the direction and speed are randomly chosen.

TABLE II
Simulation Parameters

Parameters	Values
Area of interest(A)	80 x 80 m^2
Total no of nodes(N)	20
Transmitter Power (PT)	43dBm
Transmitter gain (GT)	18dB
Receiver gain (GR)	-1dB
Loss due to Transmitter (LT)	3dB
Loss due to Receiver (LR)	8dB
Pathloss Type	Urban/Sub-urban Hata model
Number of MS	5
Simulation Time	100s
MS Height	1m
BS Height	40m/50m
MS Speed	5-10(m/s)
Threshold value of Bandwidth	1800MHz

B. Result Analysis

In order to make the simulation more accurate, we ran the simulation 10 times and averaged the results. We didn't concentrate on the energy usage of a single node, but rather the entire network's energy consumption. An Optimum energy-efficient vertical handover is being achieved by employing an energy efficient scanning process and user requirements-based handover decision mechanism. Here the mobile node scans the neighbouring networks using the ECU employed in MIH. ECU, as described in Figure 2, decides whether to scan or skip. The suggested scanning method is compared with conventional, periodic and adaptive scanning schemes. Figure 4 shows the total energy consumption comparison between proposed and

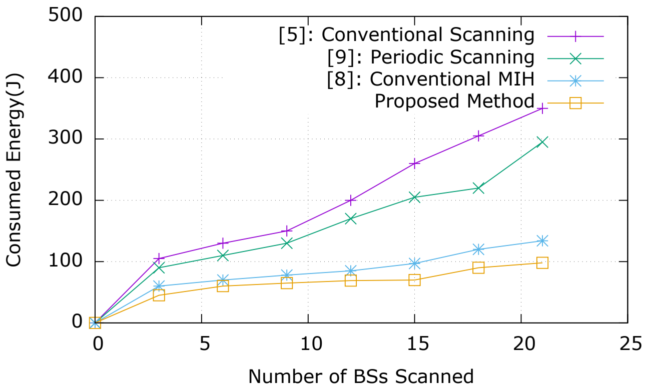


Fig. 4. Comparison of Consumed Energy versus Number of Base Stations

other existing scanning techniques. As a result, the proposed scheme considerably decreases the total energy consumption, occurred due to network scanning process. Figure 5 shows the comparison of network scanning rate between conventional MIH and our proposed method. Simulation results indicate that the proposed scheme lowers network scanning rate profoundly. Due to inadequate scanning technique, the existing schemes suffers from increased unnecessary scanning rate. The conventional technologies scan all the neighbouring networks at the time of handover which ultimately requires a huge amount of energy. There are certain applications which demands continuous connections across heterogeneous networks. So, the proposed technique gives more attention to the highest priority applications as compared to others. This often eliminates repeated handovers, which ultimately saves substantial amount of energy. Figure 6 shows the comparison of unnecessary handovers, where the proposed scheme performs very well as compared to the conventional MIH standard because our work considered a hybrid handover decision algorithm which avoids the occurrences of unnecessary HOs. The proposed work maintains a good balance between energy consumption and user requirements. Figure 7 shows the comparison of handover failure rate by considering all traffic classes. As a result, our suggested scheme is superior than TOPSIS and utility function algorithm. Figure 8 displays the average ping-pong rate versus all traffic classes. We observed that the hybrid approach of TOPSIS and utility function based algorithm can effectively minimizes the ping pong effect than other algorithms. This figure illustrates that the utility function-based TOPSIS outperforms the traditional TOPSIS. As a result, we conclude that introducing the utility function with TOPSIS will improve efficiency for various types of services.

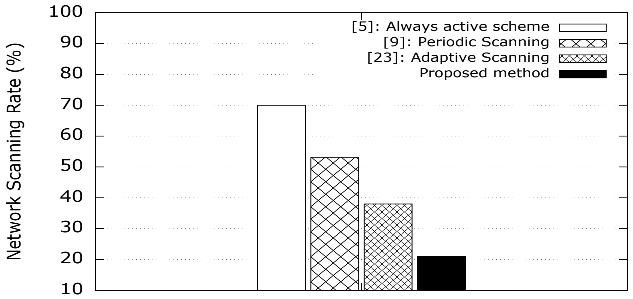

Fig. 5. Comparison of Network Scanning Rate

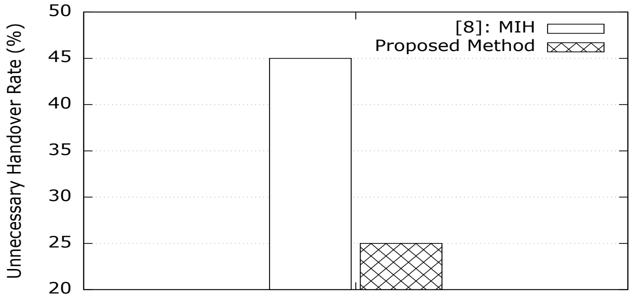

Fig. 6. Comparison of Unnecessary Handover Rate

V. Conclusion

To ensure smooth and seamless connectivity and to allow the optimal use of available network resources, it is essential to improve the performance of vertical handover in heterogeneous network in terms of unnecessary handovers and handover failure rates. With this in mind, an energy-efficient improved vertical handover technique is proposed in this work. This work introduces an energy efficient scanning scheme for IEEE 802.21 protocol that considers two functional units ECU and HDU to minimize network scanning process as well as meeting user requirements. MIH Information Server offers quick and energy-efficient channel scanning outcomes to the mobile nodes. Now a days, multiple applications are running on a mobile device at a given point of time with different priorities level. The proposed scheme scans the interfaces according to their priority of applications thus avoiding the scanning of entire interfaces which ultimately reduced the energy consumption. From the simulation result, it is confirmed that the suggested TOPSIS and utility function-based hybrid approach lowers the handover failure rate and ping-pong effect for all types of traffic classes. Thus the proposed work reduced the energy consumption while maintaining user preferences and their demands. This work may be further enhanced by proposing a prediction and forecasting based handover scheme for better quality of experience of users.

***Abstract*—The wide range of applications and advantages offered by the Internet of Things has attracted every sector to deploy it in their environment to exploit its advantages. The deployment of devices manufactured by different manufacturers in an Internet of Things environment has also opened the doors for threat actors to launch variety of attacks by exploiting the vulnerabilities present in these devices. The miniaturized size of most of the devices offers a very less space to incorporate the security elements. Healthcare sector has greatly benefited from the growth of Internet of Things. The COVID-19 pandemic has further highlighted the role of Smart Healthcare applications in the future. Deployment of life saving devices with limited security features make them one of the critical sector that needs more attention. The impact of a vulnerability exploited in smart healthcare devices can even be life damaging. In this work, the security challenges faced by smart health devices are analyzed and the necessary measures to be taken to improve the security are suggested.**

Keywords— Attack, Healthcare, Internet of Things (IoT), Security, Vulnerability

I. Introduction

Internet of Things (IoT) is a network of different physical devices that are connected to each other through different communication mechanisms. The surge in growth of IoT is evident in almost every sector and it has minimized the gap between the Information technology (IT) and Operation Technology (OT). The ability to operate with varied type of devices with varied operational features has made them an indispensable part of every sector. IoT has also taken the healthcare sector and the number of Smart Healthcare applications are on the rise [1, 2]. The growth in wearable technology coupled with the increase in device connectivity technologies like RFID, 5G, WBAN, Bluetooth, Wi-Fi and other evolving standards have greatly contributed to the progress of Smart Healthcare [3, 4]. It has reduced the complexity involved in the collection and analysis of data from patients located in remote areas. It has become a boon to both the medical practitioners as well as patients who need continuous monitoring. The beneficiaries list of smart healthcare applications even extend to insurance companies as the entire patient history can be accessed with ease [5].

The COVID-19 pandemic had an impact on the economy of many sectors but IoT has helped many sectors to survive the pandemic period and Smart Healthcare is one such critical sector that has grown strong during the pandemic period [6]. As in the case of all IoT devices, smart healthcare application devices are also vulnerable to attacks. The size of the devices and their mode of operation has limited the ability to add more security features to the device. The critical and sensitive nature of the data used in smart healthcare make them a favourite attacking ground for attackers. As these devices are involved in life saving applications, security is an indispensable ingredient in such applications [7] In this work, the impact of IoT in smart healthcare and the major devices that are used in healthcare applications are analysed in detail. It also explores the major cyber security challenges faced in the deployment of such lifesaving networks. Proactive measures are also suggested to ensure the security of smart healthcare networks.

The reminder of this work is structured as follows. Section II presents the various elements involved in Smart Healthcare. Section III gives a brief overview on the stakeholders of Smart Healthcare. Section IV presents the widely used smart healthcare devices. Section V discusses the cyber security challenges present in smart healthcare. Section VI presents the best practices and proactive measures that can be taken to secure a smart healthcare network. Finally, conclusion is provided in Section VII.

II. Smart Healthcare Elements

There are three main elements present in IoT based smart healthcare networks. They are Data collection and Pre-processing, Data storage and Processing and Data analysis. An overview of the elements involved in smart healthcare is presented in Fig.1.

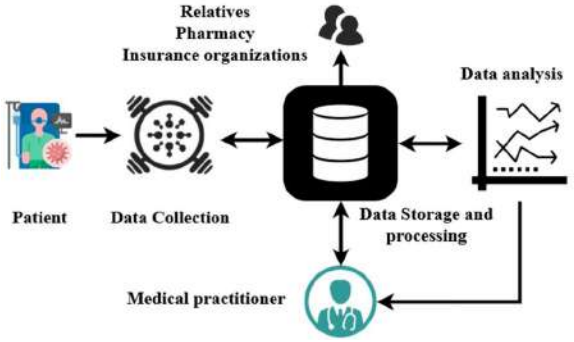

Fig. 1. Smart Healthcare elements

A. Data Collection and Pre-processing

Sensors, detectors, or monitors collect the information from the patient. Sensors will be present in the wearable devices at the patient end, in case if the patient is located in a remote place. If the device is not wearable, the patient may be present at locations where the devices are available to transmit the information to the network. Data collection transceivers present at the patient end may either transmit the data immediately or it may process the data and send the processed data to the data storage centre. However, the data will be converted into a form suitable for transmission. For security reasons, in most cases, the information will be pre-processed for encrypting the data before transmission [8].

B. Data Storage and processing

Information collected from the patient will be received by the data storage centre. In most cases, it could be a cloud storage medium. The data will be then be processed and it will

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

be transmitted in accordance to the user who needs access to the data. The format of the data will be varied in accordance to the accessing person. Data sent to the medical practitioner may not be the same data that will be sent to the relatives. The data storage medium will receive the feedback of the medical practitioner and it will send the necessary data that has to be sent to the concerned people. Depending on the information type, it may send the data to the patient, hospital, relatives, insurance agencies or any other relevant person defined in the network.

C. *Data analysis*

The data analysis will be done by the medical practitioner or by the research team that will analyse the response of the patient to the treatment provided to him/her. The data can also be used for behavioural analysis and for different research purposes. It can also be used to forecast the health condition of the patient.

III. Stakeholders of Smart Healthcare

Smart Healthcare is beneficial not only to the patient and the medical practitioner. But it is also useful to different stakeholders of Smart Healthcare [9]. In this section, the stakeholders of Smart Healthcare presented in Fig. 2 are discussed in brief.

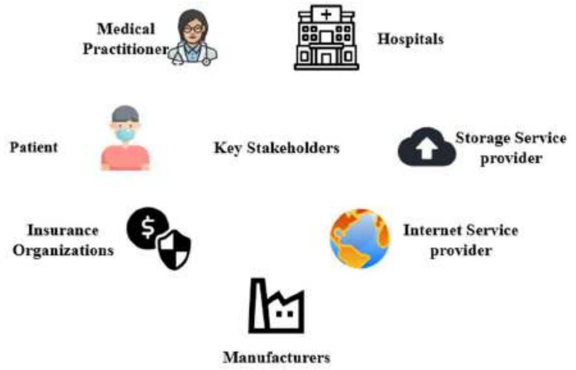

Fig. 2. Stakeholders in Smart Healthcare

A. *Patients*

The rise in wearable technologies and miniaturization of critical monitoring devices with high speed connectivity features have increased the rise of Smart Healthcare applications used by patients. Constant monitoring is made possible with these applications and the deployed smart devices are useful to alert the doctors, patients and their relatives, in case of any fluctuation in their regular body functioning. It has helped to predict and prevent health problems. Even in cases of emergency cases, the time gap between any health incident and the initial treatment has got dropped.

B. *Medical practitioners*

The constant supply of patient data from the smart devices helps the practitioners to constantly monitor the progress and response to the treatment provided to the patient. It offers the flexibility to the practitioners to change their treatment in accordance to the progress made by the patient. Practitioners also have better access to patients' history as they are readily available anytime and anywhere.

C. *Hospitals*

Hospitals provide the platform to most of the critical healthcare monitoring cases. Hospitals play a key role in monitoring the location of patients. They also monitor the performance and operation of critical devices. In addition to that, pharmacy inventory and the need for medicines can be generated based on the information received from the practitioners and patients. It will also help to acquire critical medicines and equipment well in advance before an emergency arises.

D. *Storage service provider*

Data storage is one of the important elements in Smart Healthcare system. Transmission, storage and retrieval of data have to be done effectively. As most healthcare applications require continuous monitoring, the volume of the data will be large and it requires a proper storage and retrieval mechanism. In addition to that, to perform a complete analysis on the data of the patient, the data must be available anytime and anywhere for analysis to the authorized users.

E. *Insurance organizations*

Insurance claims can be made more transparent as the entire data of the patient will be available for analysis and documentation. It can also help them to make the risks associated with the health of the patients. Insurance organizations also can track the progress made by the patient and adherence to treatment guidelines.

F. *Manufacturers*

The important stakeholder in Smart Healthcare system is the manufacturer. The smart health device performance is crucial to determine the efficiency and security of the network. The device must have secured connectivity features and also it should have better performance, in terms of power consumption and information processing capabilities. The manufacturers must comply with the standards setup by the regulatory bodies and legal agencies.

G. *Internet Service Providers*

Internet Service providers determine the communication platform for communication between the devices and the storage medium. Integration of dedicated IoT communication protocols along with the standard communication channels are on the rise. This will increase the security and connectivity of IoT devices.

IV. Smart Healthcare devices

COVID-19 pandemic has increased the deployment of Smart Healthcare devices and it is likely to develop in the post-pandemic era. The Smart Healthcare devices can be classified as wearable devices, implantable devices and clinical devices. Wearable devices can be worn by the patient and it can be removed even by the patient. Implantable devices are placed inside the body of the patient and it requires the help of medical practitioner to place or remove it from the body. Clinical devices will be present only at places where assistance will be provided by medical experts, such as MRI and X-Ray machines. The devices must comply with the CIA triad. A few of the major devices used in Smart Healthcare are presented in Fig. 3.

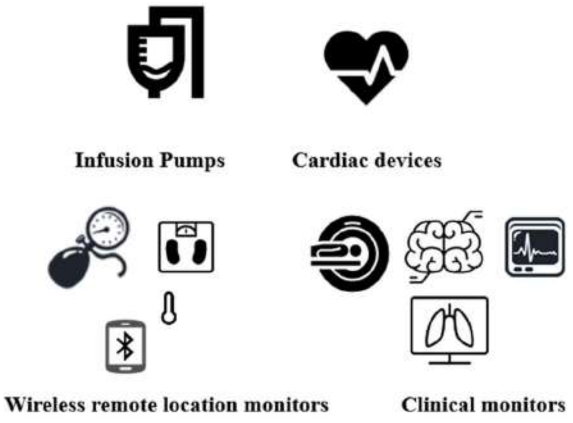

Fig. 3. Smart Healthcare devices

A. *Infusion pumps*

Infusion of medical fluids and monitoring the progress of the fluids can be done through the infusion pumps. Infusion pumps can be controlled remotely and it can be used to infuse multiple doasages at multiple places inside the body. This controlled infusion without any large scale surgery has reduced the complexity and expenses of several critical treatments. Insulin can also be infused through such pumps.

B. *Cardiac devices*

Programmable implantable cardiac devices can be used to monitor the performance of the heart. These devices will be continuously monitored and any change in the performance of the heart will be immediately intimated to the physician and the concerned authorities.

C. *Wireless monitors*

Devices such as blood pressure monitors, thermometers and heart rate detectors monitor the patient performance at periodic intervals and the progress of the patient will be monitored on a regular basis. These devices are generally connected to the mobile phone of the patient mostly through Bluetooth communication and by using dedicated apps. In some cases, cameras are also used to monitor the health condition of the patient.

D. *Clinical monitors*

Devices such as MRI, CT scanners, X-ray, lasers, surgical devices, ventilators, dialysis machines, ECG, EEG and other such similar devices which are deployed in hospitals or clinics are also connected to the IoT environment to track the continuous progress of the patients [10]. They are also used to analyze, process and interpret the data for better diagnosis.

V. Cyber Security Challenges in Smart Healthcare

Health information of a person is a very sensitive information and attacks on gathering such data have taken a steep rise after the COVID-19 pandemic. Attacks are launched by threat actors through multiple means to gather the patient related information. Since the smart devices carry vital data about the health, the attackers target such devices as they are more vulnerable.

Attackers can exploit the vulnerabilities that can be present in any layer, such as application layer, network layer or perception layer [11]. If the attacker gains access to control these live saving devices, such as infusion pumps or cardiac devices, the impact can be even life damaging. Even a small change in the dosage of drugs, or a Denial of Service (DoS) attack can result in death of patients with critical diseases.

A. *Device size and Power limitations*

The devices in most of these applications are too small and they have very few features for security. Incorporation of security features increases the size of the device and it limits the addition of security features to the smart healthcare devices. In addition to that, these devices are battery powered and loading them with too many features can affect the battery life of the device. The size also limits the use of stronger encryption mechanisms to transmit and receive the data.

B. *Software Update*

The devices may have vulnerabilities and if the devices are not updated with the patches, the device will remain vulnerable to be exploited by an attacker. Software update of Smart Healthcare devices are complicated since some critical devices cannot stop its operation even for few seconds. In case of Zero day attacks or if no patches are available for the vulnerability, it is difficult to replace the implanted devices. The attacker can also exploit any device that is connected in the network. In a hospital environment, multiple devices can be connected and they can be outdated. An attacker can exploit such systems and intrude into the network.

C. *IT-OT gap*

The healthcare industry has less IT experts to handle IT related incidents compared to other sectors. Hence, the sector has limited ability to handle incidents or attacks. The limited resources available with them increases the risks associated with the device. The networks maintained at the hospitals lack proper cyber security experts in most cases and hence, there is always a possibility of cyber threat in such vulnerable networks. The famous Wannacry ransomware attack was one such attack that exploited systems located at hospitals [12].

D. *Network connectivity failure*

The availability of Internet is the backbone for any IoT system. Patients with critical diseases need to stay in Internet connected areas for continuous monitoring. A small lapse in the connection, can turn crucial in some cases.

VI. Proactive Measures

As Cyber security is a key issue in Smart Healthcare, the following proactive measures can be taken to improve the security level of the Smart Healthcare networks.

A. *Deployment of cyber security experts*

Sufficient number of cyber security experts must be deployed at hospital and Smart Healthcare networks to regularly monitor, update and protect the connected devices in the network. This will try to reduce the IT-OT gap in a Smart Healthcare environment. The hospitals must be equipped with expert teams and also with proper incident response procedure to handle incidents.

B. *Inventory maintanence*

The IoT network must have an inventory of all the devices connected to the network. Their behaviour must be continuously monitored including the traffic and connections made by them. A Vulnerability database must be developed and it must be updated with the latest vulnerability reports related to the products used in the network and the corresponding devices must be updated with the suitable patches released by its vendors.

C. Compliance

The devices must be tested before deployment for compliance with the security standards such as ISO/IEC 82304, ISO/IEC 62304 and other relevant health products standards [13]. The devices must be tested for the ability to do security update. The data collection and distribution must comply with the legislative terms and conditions.

D. Secure update

Update should be allowed from authorized IPs and any connection made with unauthorized IPs must be considered as a malicious traffic. Connection attempts for security update must be made only through specific ports and the ports must be closed once the update is completed. Communication must be done only with whitelisted IPs.

E. Product security

The network must be formed as much as possible by using devices manufactured by the same manufacturer and the manufacturer must try to reduce the use of third party products in their design to reduce the risk of supply chain attacks. The default password of the devices must be changed before deployment in to the network. It is always preferable to deploy specific application based devices in a healthcare environment instead of third party general purpose IoT devices.

F. Network segmentation

Microsegmentation can be done to lock the critical devices from any unauthorized access outside the network. It has to be ensured that the devices in the network are loosely coupled and hence, failure of one device may not affect the overall performance of the network.

G. Data Integrity

The data that is stored in the storage medium must be made accessible only to the authorized user and all the information must not be made available to the users. The device must gather only the required information and it must be ensured that it do not gather any unnecessary information [14]. Periodical backup of data must be made to mitigate any unprecedented attack.

H. Security audit

Third party audits must be conducted periodically on the network and the vulnerabilities present in the networks must be assessed. Devices which cannot be updated with patches must be replaced with new devices.

VII. Conclusion

Smart Healthcare offers many advantages such as rapid diagnosis, improved decision making and proactive treatment. Cyber security is a key ingredient in such networks. But most of the Smart Healthcare networks are vulnerable to attacks due to several factors. In this work, the elements involved in Smart HealthCare networks and the cyber security challenges associated with them are analysed. The proactive measures that can be taken to improve the security of Smart Healthcare networks is also presented. The provided proactive measures can be used as best practice guidelines for developing a secure Smart Healthcare environment.

***Abstract*— One of Indonesia's companies engaged in investment management is PT PNM Investment Management (PNMIM). Entering the digitalization era, PNMIM intends to use an information system in web and mobile-based applications, currently known as fintech, making it easier for investors to conduct mutual fund transactions online. This application is known as SiJAGO. However, in the first quarter of 2020, it did not achieve the launch of SiJAGO to the public. The impact of not achieving the launch of SiJAGO to the public will be affected the adaptive competition in technological development. Besides, the investment that PNMIM has spent for constructing the SiJAGO development project will be hampered by meeting several targets from the top management of PNMIM. This research is to identify the criteria and success factors for Information Technology (IT) projects in application development in the financial sector industry (FSI) in the era of digital transformation. The SLR analysis and expert judgment results show ten criteria and 18 factors (grouped into five categories) of IT project success, using the waterfall life cycle, using PMBOK® guidelines in analyzing each process. In the subsequent development of SiJAGO, PNMIM, and IT vendors, SiJAGO developers can focus on the criteria and factors that can support IT project development's success.**

Keywords*— *IT projects, information technology, application implementation, fintech, CSF, Critical Success Factors, Systematic Literature Review, SLR, expert judgment

I. Introduction

Investment is a common thing at this time, the commitment to several funds or other resources carried out at this time, intending to obtain several benefits in the future [1]. One of the fastest-growing investment products today is mutual funds. Mutual funds have turned into an investment product of choice for people who want to invest and cannot separate the increasing facilities and ease of investing. One of Indonesia's companies engaged in investment management is PT PNM Investment Management (PNMIM). PNMIM is a group of PT Permodalan Nasional Madani (Persero). PNMIM runs its main business in investment management, especially mutual funds and other managed funds, in the form of discretionary funds, business advisory, and corporate finance, both private and state-owned companies.

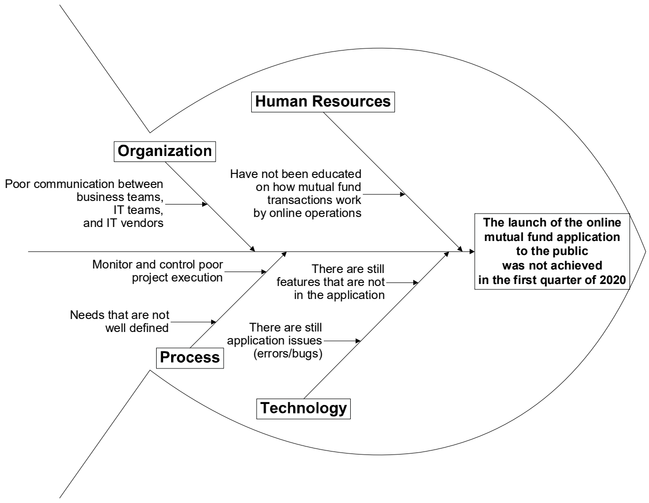
Entering the digitalization era, PNMIM intends to use an information system in web and mobile-based applications that can make it easier for investors to conduct mutual fund transactions online, known as financial technology (fintech). The implementation of an online mutual fund application development project, starting now referred to as SiJAGO, begins with submitting a request for proposal (RFP) document to an Information Technology (IT) consulting vendor. The RFP lists PNMIM's expectations regarding the SiJAGO development project, among them: (1) launching SiJAGO to the public in the 1st quarter of 2020, (2) 40,000 SiJAGO users when the application launched to the public in the first year. The SiJAGO development project began with a kick-off meeting between PNMIM and IT vendors. The SiJAGO development project's life cycle uses the waterfall life cycle and application development using the most common life cycle in IT, namely the Systems Development Life Cycle (SDLC). Planning, analysis, design, implementation, maintenance, and support are the five primary SDLC phases [2].

The implementation of SiJAGO implementation was three months late from the set schedule. After the implementation phase is carried out or known as go live, public users cannot directly use SiJAGO, the process related to licensing and SOP (Standard Operating Procedure) requirements issued by the Financial Services Authority (OJK) [3]. The condition impacts the delays of PNMIM's plan to launch SiJAGO to the public in the first quarter of 2020. Furthermore, PNMIM proposed additional features for SiJAGO development to the IT vendor. In the Software Maintenance Life Cycle, this process is called a modification request [4]. The addition of features to this application is considered a new project for application development and also carried out the System Integration Test (SIT) and User Acceptance Test (UAT) phases. In both stages, the application's issue findings into the ticket system of JIRA, the recapitulation of JIRA data in the SIT and UAT phases showed 49% of application bugs and 51% of change requests from users.

The fishbone diagram in Fig 1 illustrates the causes of the problems on the previously described exposure. Describe the causal relationship of various aspects and root causes that affect the failure to reach the public release of SiJAGO in the 1st quarter of 2020. It can be concluded that this condition is

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

a risky thing, especially since SiJAGO is a transaction tool that will be accessed at any time by the user. The company engaged in the financial sector industry (FSI) and transforming into the digital era cannot tolerate transaction errors due to technological factors. The condition will have an impact on customer perceptions and also on the increasingly competitive FSI competition. Therefore, it encourages analyzing the factors that can affect IT projects on application development at FSI.



Human Resources
Organization
Poor communication between business teams, IT teams, and IT vendors
Have not been educated on how mutual fund transactions work by online operations
The launch of the online mutual fund application to the public was not achieved in the first quarter of 2020
Monitor and control poor project execution
There are still features that are not in the application
Needs that are not well defined
There are still application issues (errors/bugs)
Process
Technology

Fig. 1. *Fishbone Diagram of Root Problems Identification*

A survey was conducted by The Standish Group from 2012 to 2016 for all software projects around the world. The Standish Group also identifies the success rate of IT projects on that period [5] as follows:

- 36% of projects are successful (the project was delivered on time, on budget, and will all features).
- 27% of projects are challenged (the project was eventually delivered but either over budget, not on time, or not fully completed).
- 17% of projects are unsuccessful (nothing was delivered).

Furthermore, the survey results based on project resolution based on the industry for projects in the financial sector showed that projects in the project criteria were victorious by 29%, on challenging project criteria by 55%, and on project criteria for failing by 14% [5].

In previous research literature studies, not many focuses on IT projects' success factors on application development at FSI in the era of digital transformation or those that focus on implementing fintech applications. Furthermore, this research question is, what are the criteria and factors for IT projects' success in application development in the FSI in the era of digital transformation. Furthermore, the research is structured as follows: Part II describes a literature review related to the topic. Section III describes the methodology used for this research. Section IV reports the results and analysis of findings. Section V concludes and provides recommendations for further research on this research area.

II. LITERATUR REVIEW

A. IT Project

The IT projects are activities to build or implement IT-based service products, an organization's investment. Will be expecting to return the spent value of the time, money, and resource [2]. Information systems projects require resources with different expertise to work together to create software products, including systems analysts, software programmers or developers, testers, system installers, trainers, and other specialized skills [6].

B. IT Project Success Criteria

The success criteria for IT projects have different variations; the criteria for the success of IT projects that are used as a reference source in this research are [2], [6], [7], [8], [9], and [10]. The results of the analysis of the six references are described in Table I.

TABLE I. IT PROJECT SUCCESS CRITERIA

Criteria	Reference					
	[2]	[6]	[7]	[8]	[9]	[10]
Cost	√		√	√		√
Communication						√
Quality			√		√	√
Process		√				
Risk			√	√		√
Scope	√	√	√	√		√
Stakeholder		√			√	√
Resource		√		√	√	√
Time	√		√	√		√

The results of the analysis of six references obtained nine success criteria for IT projects. Furthermore, interviews were conducted with the teams involved in the SiJAGO development project, both from PNMIM and from IT vendors, to obtain validation and insight for research. The interview results showed that they agreed, and there was no revision of the nine success criteria for the IT project. The PNMIM team and IT vendors' interviews indicated that these nine factors were essential criteria for project success. The interviewee also conveyed that these nine factors are essential for the SiJAGO project, related to the collaboration between PNMIM and IT vendors. The communication factor becomes the determinant of the project's success. The Stakeholder factor is also important because any decision regarding the SiJAGO project requires stakeholder approval.

C. Critical Success Factor (CSF)

Since 1960 the success factor concept has been studied; D. Ronald Daniel introduced the origin of the success factors' concept [11]; first developed and refined into CSF in 1961 [12]. Daniel highlighted the importance of the factors that determine organizational success in addressing the risk of data overload. CSF is the key to information system design [13]. Several essential factors in management information systems have a positive and sustainable influence on a company's success; using these factors, competitive advantage can be realized [12].

CSF could prioritize an organization's strategic planning to support the CSF to achieve a competitive advantage with concentrate the resources. There are usually three to ten influential CSFs to determine the success of a project [14]. The CSFs are considered a powerful and applicable method used to address many of the challenges of implementing IT in several domains [15]. There is no differentiation of CSF for business models in general and fintech specifically. Moreover, the fast-paced and positively changing environment naturally demands a continuous observation of the critical factors. The dynamic development of the fintech field creates a need for future investigations [16].

D. Systematic Literature Review (SLR) for CSF in IT Project

This section is carried out at the literature research stage to find out the literature on the research results that have been done regarding CSF application implementation, especially in the FSI. The literature research is carried out a systematic literature review (SLR) using the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analysis) model approach. The PRISMA model approach was used to eliminate excess factors in the literature [17]. The protocol used in the PRISMA model approach in this research is as follows:

1) *Identification*, literature searches were conducted on online databases with large repositories for IEEE Xplore, Elsevier (SCOPUS), ScienceDirect, and Springer Link. First, inclusion and exclusion criteria are determined to filter the search results. Inclusion criteria: literature published between 2015 and 2020, written in English, published in international journals and conferences, which conduct evaluation or analysis of CSF IT projects for implementation or application development in the FSI or digital transformation. Exclusion criteria: literature not related to presentations/opinions/papers, not focused on IT, related to IT projects but did not describe CSF, not published as proceedings of international conferences or international journals.

2) *Keyword*, literature search using keywords: ("project *" OR "implementation *" OR "information technology project *" OR "project management" OR "IT project implementation") AND ("financial technology" OR "financial sector" OR "fintech "OR" digital transformation "OR" case study") AND ("critical success factor * "OR" success factor * "OR" CSF"). The search results obtained are as follows: IEEE Xplore found 98 kinds of literature, Elsevier (SCOPUS): found 84 literature, ScienceDirect: found 53 literature, Springer Link: found 69 pieces of literature.

3) *Screening*, at this stage, a selection is made from the search results by looking at the title's suitability, abstract, and keywords previously identified. The total number of articles obtained in this section is 20 articles.

4) *Eligibility*, this section is done by reading in full to determine the article will be included in the next research that matches the eligibility criteria. The total number of articles obtained in this section is seven articles.

5) *Included*, in this section, five articles are selected that best fit the predetermined criteria.

E. CSF in IT Project Application Implementation

This section describes the CSF mapping of five previous types of research, which was obtained from the literature analysis in Part D, namely: [18], [14], [19], [20], [21]. In the five previous research literature, the research was conducted using the same framework, namely The Project Management Body of Knowledge (PMBOK®) [10], to analyze CSF in this research.

CSF is grouped based on factors and sub-factors, according to [18] and [14]. There are six-factor groupings and thirty-nine sub-factors of project success. Thirty-nine sub-criteria for project success were analyzed with the same characteristics, impacts, and risks on the development of SiJAGO. The results of these analysts obtained nineteen subfactors.

TABLE II. MAPPING OF PREVIOUS RESEARCH CSFS

Factor	Subfactor
Organizational	Communication
	Evaluation Progress
	Management Commitment and Support
	Management Leadership
	Relationship with Third Party
	Strategic Planning
Project	Project Control and Monitor
	Project Management
	Project Performance
	Project Planning and Requirements
	Project Risk
	Project Duration
Project Manager	Project Manager Experience
	Project Manager Formal Power
	Project Manager Skill
Project Team	Team Commitment and Participation
External Environment	Rules and Regulation
	Subject Matter Expert (SME)
	Tren

III. RESEARCH METHOD

This research uses qualitative and quantitative research methods (mixed methods) to draw more robust conclusions, provide a greater diversity of different views, and enable researchers to simultaneously answer confirmatory and exploratory questions, verify, and generate theories simultaneously [22]. In this research, the research strategy was carried out using a case study using a single case. Case study research is a form of qualitative method that has a robust approach to information systems research. Case studies are used both for confirmatory purposes (theory testing) and for exploratory purposes (theory building) [22]. The case study uses a single case because it is unique and essential, fulfilling all the conditions for testing the existing theories. Furthermore, single-case case studies can be generalized to various other conditions [23]. Research with the case study method seeks to examine the subject under research as much data as possible.

A. Instruments and Data Sources

In this research, the research instrument was related to qualitative research's basic principles, namely, data triangulation. A more nuanced picture of the situation can be obtained through data triangulation and increases the findings' reliability and validity [22]. Triangulation involves using more than one data source and collection methods to confirm the research data's authenticity, analysis, and interpretation [24]. Data triangulation in this research was carried out by interview, observation, and literature research. There are two types of data sources taken, namely primary data and secondary data. Primary data from this research were obtained from interviews obtained directly from informants or research objects. Secondary data is obtained from written documents and other things related to this research.

B. Data Collection Technique

Data collection was carried out using a technical triangulation approach. Triangulation is defined as a data collection technique that combines various data collection techniques and existing data sources [25]. Technique triangulation itself means that researchers use different data collection techniques to get data from the same source. Researchers used participatory observation, interviews, and documentation for the same data source.

- Observation, participant observation is carried out because researchers participate in doing what data sources do [25]; observation is also carried out directly at the PNMIM organization.
- Interviews were conducted with PNMIM's VP Retail Business Development & Customer Relations and PNMIM Information Technology & General Affairs Operations, two PNMIM business user teams, two IT vendor project managers, and two IT vendor application maintenance teams.
- The documentation source is from conducting studies on documents related to SiJAGO development projects. The source is from (1) kick-off meetings, Functional Specifications Document (FSD) containing SiJAGO functional specifications, (2) Technical Specifications Documents (TSD) containing SiJAGO system technical specifications, (3) Minutes of Meeting (MoM) documents, (4) JIRA ticket data, and (5) sign-off documents.
- Expert judgment, as part of an interview using a Likert scale, to seven application development project management experts.

IV. RESULT AND ANALYSIS

This section describes the results of semi-structured interviews with seven IT project management experts for application development. The interview is related to the SiJAGO development project. It is associated with assessing the criteria and success factors of the IT project in application development, described in sections B and E.

A. Expert Profile

The seven experts' selection was based on experience criteria in application development project management, especially in the FSI, and had attended IT project management training. Six experts work at the IT vendor company that does the development of SiJAGO, one person outside the IT vendor organization. Two of the seven experts have the Project Management Professional (PMP) certification. Table III describes the profiles of the seven experts.

TABLE III. EXPERT PROFILE

Expert Code	**Position**	**Company**	**Project Management Experience (years)**
P1	Chief Executive Officer (CEO)	IT Consultant	>15
P2	Head of Professional Delivery Services	IT Consultant	>10
P3	Head of Project Management Officer (PMO)	IT Consultant	>8
P4	Head of Wealth Management	IT Consultant	>6
P5	Project Manager (have PMP certification)	IT Consultant	>5
P6	Project Manager	IT Consultant	>5
P7	Head of Financial Solutions Group (have PMP certification)	Telecommuni cation Consultant	>10

B. Expert Judgement Interviews

Interviews with experts were conducted for two days, 07 - 08 January 2021, through virtual meetings media. At the time of the interview, the experts were presented with a list of criteria and success factors in IT projects in application development. The assessment was carried out using the survey.ui.ac.id site, with the link https://survey.ui.ac.id/955715. The scale used to rate responses to the criteria and success factors is a five-Likert scale from strongly disagree. Besides, each expert is also given the option to add criteria and success factors for IT projects that are not yet on the selection list.

C. Expert Judgment Results for IT Project Success Criteria

The results of the assessment carried out by experts are described in Table IV. The criteria proposed will be used in this research if the experts' average scale value is more significant than three. Next, a discussion was held regarding the assessment given by these experts.

TABLE IV. EXPERT JUDGMENT RESULTS FOR IT PROJECT SUCCESS CRITERIA

Criteria	**P1**	**P2**	**P3**	**P4**	**P5**	**P6**	**P7**	**Average**
Biaya	2	1	4	3	5	4	4	3,29
Communication	4	4	5	5	5	5	5	4,71
Quality	5	4	5	4	5	4	5	4,57
Process	5	4	5	4	5	5	5	4,71
Risk	4	2	4	3	5	5	4	3,86
Scope	5	4	4	3	5	5	4	4,29
Stakeholder	5	4	4	5	5	4	5	4,57
Resource	5	1	4	4	5	4	5	4,00
Time	4	1	4	4	5	4	5	3,86

Four experts provide additional criteria from the proposed. P1 provides additional commitment from the entire project team to support the IT project's success; these related discussion results are acceptable to add to the IT project success criteria. P3 adds lessons learned and expert judgment for the success criteria of IT projects. However, after further discussion, these criteria had the same meaning as the Project

Performance factor, so the proposed criteria from P3 were not included.

P6 provides handover to maintenance entry as criteria. However, from the discussion results, these criteria are more appropriately included in one of the sub-factors of IT project success, the Project factor. P7 adds business direction and government regulations as the success criteria for IT projects. The proposed business direction criteria have the same meaning as the Strategic Planning sub-factors on Organizational factors from the discussion results. Table IV shows that the Communication and Process criteria have the highest value in the Average column, followed by Quality and Stakeholders, and Scope and Resources in the next sequence.

None of the criteria has a mean value below three, although P2 assesses one for the criteria Cost, Resources, and Time. From the interview results with P2, it was revealed that the criteria for Communication, Process, Quality, and Stakeholders have the most crucial role in the success of the project, while other criteria are supporting factors. From the interviews with other experts, on average, they have the same opinion that these nine criteria are critical in IT projects' success.

D. *Expert Judgment Results for IT Project Success Factor*

Similar to Part B, this section describes the assessment results conducted by experts for IT projects' success factors. The criteria proposed will be used in this research if the experts' average scale value is more significant than three. Next, a discussion was held regarding the assessment given by these experts.

TABLE V. EXPERT JUDGMENT RESULTS FOR IT PROJECT SUCCESS FACTOR

Factor	Sub Factor	P1	P2	P3	P4	P5	P6	P7	Ave-rage
Organiza-tional	Communication	4	4	5	5	5	5	4	4,6
	Evaluation Progress	3	4	4	5	5	4	5	4,3
	Management Commitment and Support	4	3	5	4	5	5	5	4,4
	Management Leadership	4	3	5	5	5	4	5	4,4
	Relationship with Third Party	3	4	4	5	5	5	4	4,3
	Strategic Planning	4	4	4	5	5	4	5	4,4
Project	Project Control and Monitor	5	2	4	5	4	4	5	4,1
	Project Management	5	2	5	5	4	4	5	4,3
	Project Performance	4	2	4	4	4	4	5	3,9
	Project Planning and Requirements	5	2	4	5	5	5	5	4,4
	Project Risk	4	2	3	4	5	5	4	3,9
	Project Duration	5	2	3	4	5	4	3	3,7
Project Manager	Project Manager Experience	4	4	3	4	5	4	5	4,1
	Project Manager Formal Power	3	5	3	4	5	3	4	3,9
	Project Manager Skill	4	4	3	5	5	3	5	4,1
Project Team	Team Commitment and Participation	5	4	3	5	5	5	5	4,6
External Environment	Rules and Regulation	4	4	3	4	5	3	5	4,0
	Subject Matter Expert (SME)	4	4	4	4	5	4	5	4,3
	Tren	3	4	3	3	5	2	4	3,4

Four experts add to the success factors of an IT project. P1 proposes the Project Management Maturity (PMM) level as an additional success factor for IT projects; this is in line with the literature, which explains that the higher the PMM level, the higher the success rate [26]. The type of industry is a supporting factor related to PMM and organizational performance; it also explained that the service sector, especially the IT industry, has benefited the most from high PMM rates [27]. Furthermore, P1 describes the project team's roles and responsibilities in understanding its goals and objectives. The discussion results revealed the Project Team factor could add to the team's roles and responsibilities. P3 provides additional factors related to team knowledge; the discussion results revealed that these factors could be added to the Project Team factor. Furthermore, P7 provides additional factors related to the technology used, but these factors have the same meaning as the discussion's knowledge team factor. Organizational factors in communication and project team commitment and participation are the factors that have the highest average. On the other hand, the Project factor in duration and the External environment factor in the trend are the factors that have the lowest average value.

E. *Analysis*

From the results of interviews with project teams from the PNMIM organization as well as from IT vendors, document observations, literature studies using SLR, as well as the results of interviews and assessments conducted by experts, then an analysis regarding the criteria and success factors of IT projects in application development in the most suitable FSI in the digital transformation era.

Fig 2 outlines the criteria and success factors for an IT project. In the IT project success criteria, eight criteria are obtained from [10]; the PMBOK® guide defines the project success criteria: cost, communications, quality, risk, scope, stakeholder, resource, and time. Process criteria are obtained from [8], which explains that process performance is related to project completion on time and within budget. Commitment criteria are criteria added by expert judgment; project success should not be separated from all parties' commitment and activities in the project.

The factors and sub-factors of IT project success were obtained from SLR and expert judgment. There are five factors and eighteen subfactors, three of which are included in the expert judgment. The following describes an explanation for each of the success factors of an IT project.

Fig. 2. *Structure of Success Criteria and Factor for IT Project Application Implementation in Digital Transformation Era*

1) Organizational: this factor is used by literature [14] and [20], projects are the primary way to create value and benefits in organizations, organizational leaders must be able to manage with tighter budgets, shorter schedules, scarcity of resources, and changing technology with fast [10], also added by experts that the role of the organization for IT projects in the FSI has an important role related to cooperation and communication.

2) Project: this factor is found in all SLRs used in this research; the experts added the handover to the maintenance sub-factor, with the reason that if the user has used the IT project, minimal bug maintenance is one of the success factors of IT projects.

3) Project Manager: three SLRs use this factor as the success of IT projects, [14], [19], [21], and also explained in discussions with experts that the ability of project managers to handle a project at FSI in the era of digital transformation has challenges separately to be able to communicate with all parties to align business needs with the technology used.

4) Project Team: this factor is found in all SLRs used in this research; the experts add sub-factors Understand the goals and objectives of the project and Team Knowledge; the reason for adding these two factors is because the team's understanding and ability in IT project are one of the factors that can support success IT project.

5) External Environment: two SLRs use this factor as the success of IT projects, [14] and [19], which were also described in discussions with experts; in Indonesia, the regulatory authority at the FSI is regulated by the government, in this case, the OJK.

V. CONCLUSION

This research is to identify the criteria and success factors for IT projects in application development at FSI in the digital transformation era, with a case study of SiJAGO development in PNMIM organizations. It is hoped that in the subsequent development of SiJAGO, PNMIM, and IT vendors as SiJAGO developers can focus on the criteria and factors that can support IT project development's success. The results of discussions with experts at FSI, the Subject Matter Expert (SME) factor has an essential role in the success of the SiJAGO project. Organizations that will transform a business that was initially done manually to digital need an SME regarding the processes and rules that must be carried out.

The organization is a factor that is no less important in IT projects' success, in communicating and collaborating with third parties, such as banks or payment gateway vendors. The rules and regulation factor are a factor that cannot be ignored in IT projects at FSI because the development of financial technology, otherwise known as fintech, must follow the rules and regulations of the Indonesian government, in this case, the OJK.

This research is limited to IT projects' criteria and success factors in application development at FSI with the SLR method and expert judgment. As a criterion and success factor for IT projects at FSI in Indonesia, it cannot be used as a reference because it only represents the fintech field. Expanding the scope of IT project research in other fields and CSF ranking can improve further research quality. The parties involved in project work can prioritize strategies in project management.

***Abstract*— The Arctic has a unique resource potential. Many countries around the world are ready to explore this territory for mineral exploration. This circumpolar region has been covered with many summer ice for a long time. Recently, due to global warming, the amount of ice in the Arctic has decreased significantly, but still, it is pretty enough to make it difficult for navigation. Delivery of extracted minerals in this region is possible only by sea transport. For navigation in the Arctic, icebreakers or ice-class vessels are required. In the manufacture of such ships, welds are most often used. For the seams not to oxidize during welding, it is necessary to carry out this process by blowing the seam with inert gas, for example, carbon dioxide. The method of selecting the parameters of a gas jet is very complex. Our work's theme is the impact of a submerged jet with a shield during metal welding for Arctic use. We have created a mathematical model that simulates various operation modes and chooses the optimal one.**

Keywords—computer, modeling, welding, gas, shield, Arctic

I. Introduction

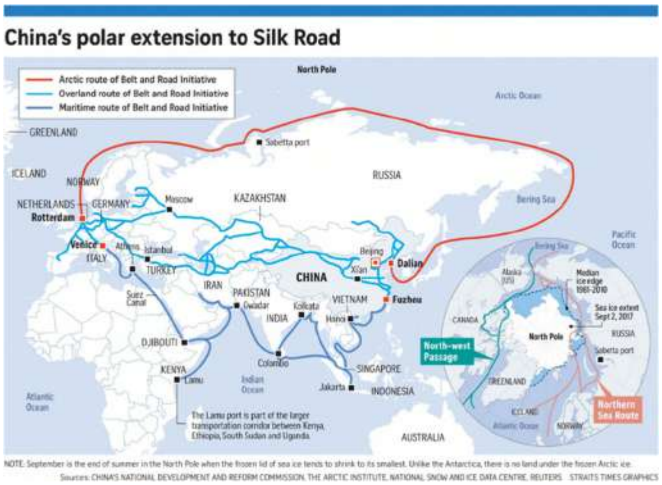
The territories adjacent to the Arctic zone occupy a special place in the system of strategic national interests of circumpolar countries in economy and transport, environmental protection, innovation, defense, and geopolitics. This region's unique resource potential allows, subject to the formation of a particular system of state regulation of the economy, to ensure dynamic, sustainable development of both the Arctic regions and the country.

Minerals produced in the Arctic, their reserves and forecast reserves explored in the 20th century, constitute the main part of the circumpolar region countries' mineral resource base. According to calculations of the U.S. Geological Survey, the last pantry of the Earth contains 30 % (47 trillion cubic meters) of the world's natural gas reserves, 13 % (90 billion barrels) of oil, 9 % of coal, as well as significant volumes of metals (uranium, copper, titanium, silver, gold) and other rare minerals (diamonds, graphite). In addition to its resource potential, which has yet to be clarified, the Arctic opens up new opportunities in the field of transportation [1]. For example, the sea route from Asia to Europe through the Arctic waters is average two times shorter than the route currently used through the Suez Canal.

Long-term forecasts of the circumpolar region countries' economic development show that the total forecast estimate of recoverable hydrocarbon resources of the continental margin of the Arctic Ocean made by Academician I.S. Gramberg is about 110 billion tons of fuel equivalent. This significantly exceeds the reserves of the continental margins of each of the Earth's oceans.

The mined minerals can only be delivered by sea transport. Because the Arctic Ocean is almost constantly covered by ice fields [2], shipping in the Arctic is risky. Over the past decades, the summer ice cover in the Arctic has significantly decreased. Some scientists make predictions about global warming, which may substantially reduce ice fields and ice thickness so much that navigation in this region will be possible for non-ice class ships.

Simultaneously, facts and more pessimistic forecasts suggest some reduction in ice thickness in the Arctic and the possibility of organizing navigation. For example, the government of the People's Republic of China has adopted a document "China's Arctic policy" [3], which proposes to add a "blue economic corridor" linking China and Europe through the Arctic Ocean to the 21st century Maritime Silk Road (Fig. 1).



China's polar extension to Silk Road

NOTE: September is the end of summer in the North Pole when the frozen lid of sea ice tends to shrink to its smallest. Unlike the Antarctica, there is no land under the frozen Arctic ice.

Fig. 1. The maritime silk road of the 21st century.

The Suez and Panama canals' capacity, which currently carry the main flow of maritime traffic, is limited. This fact requires a

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

search for other short and safe ways of cargo transportation. In addition to the best-known shipping routes, there are two different routes in the Arctic: the "Northwest Passage" (Fig.2, red line), the "Middle (Polar) Passage" (Fig. 2, green line), and the "Northeast Passage," which has a safer component, the "Northern Sea Route" (Fig. 2, turquoise). (Fig. 2, turquoise line). These transport corridors, which allow the transport of goods from Asia to Europe and back, and the delivery of energy resources, are shorter than traditional transport corridors. The route from China to Western Europe along the NSR is about 8,100 nautical miles long. The way through the Suez Canal is 2,400 miles longer. If you go around Africa, you need to add more than 4 thousand miles.

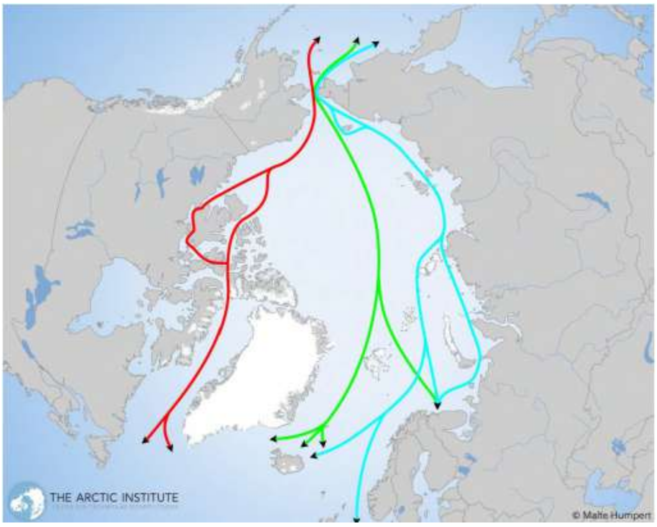

Fig. 2. Arctic shipping routes.

However, the use of these transport corridors affects states' geopolitical security, some of whose zones of influence extend along these transport corridors (Fig.3). Geopolitical security describes the extent to which international relations (both pan-Arctic and global) are cooperative or contradictory; and the level to which political tensions can affect demand for and access to Arctic resources, militarization efforts, and, ultimately, maritime operations. Instability in some regions affects fuel prices and has a direct impact on naval logistics and planning. Also, control of sea lanes (i.e., protecting shipping lanes worldwide is a costly undertaking) affects maritime transport in the Arctic region.

This key factor involves the complex role that energy prices play in increasing maritime operations' profitability in the Arctic. On the one hand, the entire naval industry is strongly affected by high fuel prices and the resulting increase in operating costs. On the other hand, the fossil fuel sectors are driven by increased profitability as the oil per barrel price rises. While high bunker fuel prices encourage the use of trans-Arctic routes, the extent to which Arctic routes are used in practice depends on inevitable tradeoffs in transit times: the need to reduce speed in ice-covered areas may tip the scales in favor of alternative, traditional maritime routes. While this factor is related to the critical factor "Global Economic Trends," it highlights the importance of energy price trends in creating economic incentives to increase or decrease activity in the Arctic region.

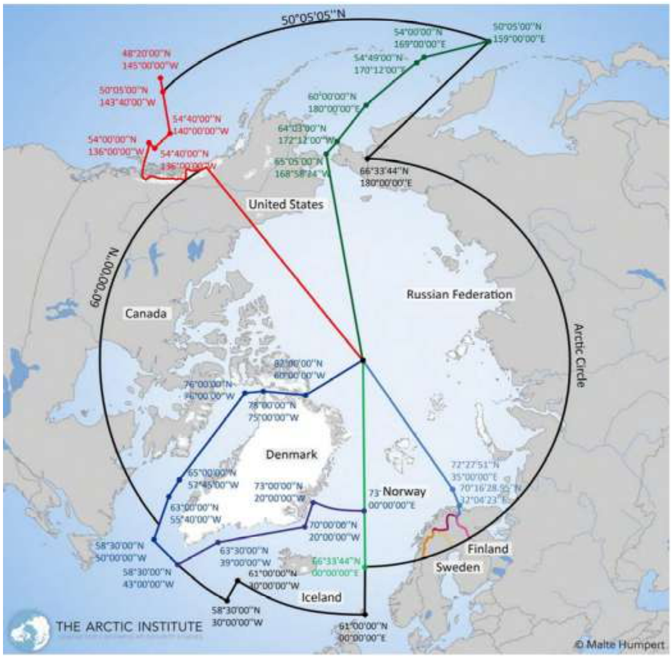

Fig. 3. Distribution of zones of influence among countries.

Increased activity in the Arctic region concerning navigational safety is impossible without the countries that will use the Northwest and Northeast Passages with an icebreaker fleet. For polar nations, icebreakers are strategic to national sovereignty and crucial in opening up safe waterways for other shipping to supply northern indigenous communities, explore resources and study climate change.

For the construction of icebreakers, it is necessary to have high-quality metal welding. In arc welding under the circumpolar region's harsh conditions, the weld metal is formed from molten metal. Despite the short duration of the metal in the liquid state, it has a detrimental effect on the weld's quality. The contact of the molten metal with air leads to the oxidation of the metal and nitrogen and hydrogen dissolution. This contributes to the appearance of pores and cracks in the welded seam, reduces the seams' plasticity, and reduces the structure's efficiency.

Protection of the welding zone from atmospheric air is a condition for ensuring high-quality welds in all arc welding methods. Gas-shielded welding is one of the most common types of welding. It is widely used in all industrial countries globally since it makes it relatively easy to mechanize technological processes. We have already considered this issue in the works [4,5]. In this paper, we will consider modeling the collision of a flooded nozzle scene.

II. THEORETICAL STUDY

When the welding torch is positioned at an angle to the surface to be welded, the gas shielding zone configuration undergoes some changes: the burner angle α plate and the burner symmetry axis. According to [6], in the range of angles,

$\alpha < 25^0$ the protection zone's size practically does not change. At angles, $\alpha > 25^0$ $\alpha \approx 55^0 - 65^0$. At curves, the $\alpha > 70^0$ effectiveness of the gas protection is completely compromised. If the length of the protection zone is denoted by b, then the function b/DZ within $15^0 < \alpha < 65^0$ can be approximated by the following expression:

$$\frac{b}{D_3} = 1 + 0{,}2 \cdot \left(\frac{\alpha}{65}\right)^2 \tag{1}$$

Following [6], let us outline an approximate solution for the impact of a flooded turbulent jet with a boundless plane surface. Schematically, the jet flow is divided into three regions (Fig.): 1) a free jet, 2) a jet turning zone, and 3) a jet flowing over a solid surface.

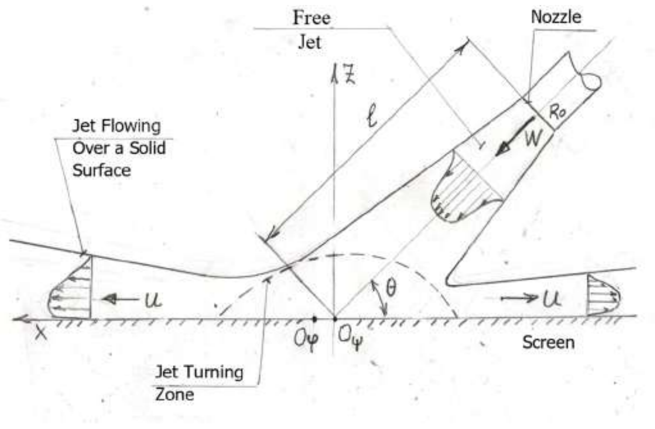

Fig. 4. Distribution of zones of influence among countries.

The calculation scheme is based on experimental data characterizing the flow in each of these areas. Experiments have shown that the static pressure on the jet axis up to the turning zone practically does not differ from the pressure on the free flooded jet's axis, i.e., up to the turning zone, the flow parameters obey the laws of the free plane. The turning zone's flow is characterized by a significant change in pressure and a large curvature of the current lines. This zone has a transverse size on the order of the free jet's diameter before it comes into contact with the screen. Measurements of static pressure on the screen at different angles of impact of the plane with the screen θ showed that outside the turning zone, it is close to atmospheric, and at the exit from this zone does not exceed 3% of the velocity head in the free jet at the entrance to the turning zone. The jet's flow area, flowing on the screen surface, is characterized by constant pressure, almost equal to atmospheric pressure. The movement of liquid in this zone has a radial character, and the center of flow O_Ψ is the point of intersection of the axis of the free jet with the plane of the screen.

The line of maximum velocity in the jet above the screen surface corresponds to the exit from the turning zone and is close to a circle. Thus, the flowing jet flow is realized as if it spreads from a cylindrical circular source of variable height b*. The center of this source O_φ is displaced relative to the point O_Ψ by a distance (Fig.5). The results of measuring the vertical velocity distribution at different screen points showed that the relative velocity profiles u^0 in the close point coordinates z^0 are similar. The velocity profile is well described by Schlichting's formulas [7].

$$u^0 = \left(1 - \xi^{1,5}\right)^2 \text{ωηερε}\ \xi = \frac{z - \delta}{b\ - \delta} \quad \text{ατ}\ z \geq \delta$$

$$u^0 = \left(z / \delta\right)^{0,1} \ \text{ατ}\ z \leq \delta \tag{2}$$

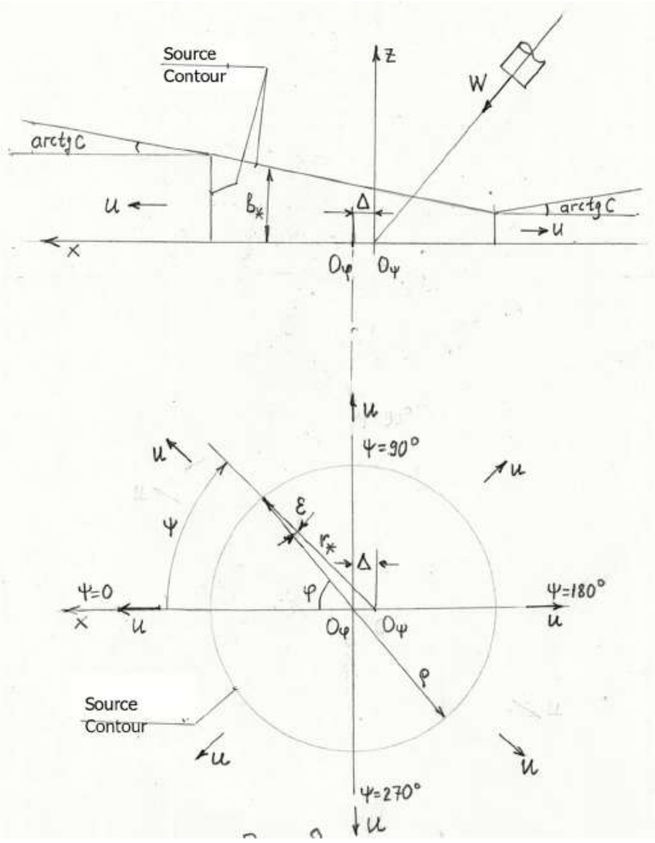

Fig. 5. Jet spread pattern.

Here δ is the thickness of the boundary layer; b is the thickness of the jet. Let's denote by $l^0 = l / R_0$, where l is the distance from the exit section of the nozzle to the screen, measured along the jet's axis, R0 is the radius of the nozzle. Experiments have shown that for all values of parameters and θ l^0 the thickness of the boundary layer along the screen is approximately 5 to 10% of the flowing jet's thickness. With distance from the center of propagation, $O_\Psi\ \psi$), increases linearly:

$$\frac{b - b_*(\psi)}{r\ - r_*(\psi)} = C \tag{3}$$

Where are $b_*(\psi), r_*(\psi)$ some initial values of the jet thickness and radius. It follows from the experimental data that the angle of inclination of the boundaries of the flowing jet concerning the screen's plane is equal to arctg C and does not depend on the impact angle θ and the angle ψ of. The velocity at the source outlet is constant and equal to u_{m*} . The outflow occurs in the direction of the radii drawn from the point O_Ψ . According to the experimental data, it is possible to assume that the circular source's upper base is a plane that makes some angle with the plane of the screen. In this case, the height of the formations of the circular source, depending on the direction of propagation, will be expressed by the relation:

$$b_* = A + B \cdot \cos\varphi \qquad (4)$$

The angle φ differs from the angle by the value $\varepsilon\ \psi$, depending on ψ . The radius of the cylindrical source ρ R* when approaching the screen. Thus, to determine the flow at the exit from the turning zone, it is necessary to find three geometrical parameters A, B, Δ , which depend on the angle of impact of the jet with the screen plane θ and the shape of the longitudinal velocity profile in the free plane before the turning zone, and one kinematic parameter u_{m*} , which depends on the value and distribution of velocity W in the free jet at the entrance to the circular source. The laws for the free plane determine the jet parameters before the turning zone. This is justified because the screen's presence does not significantly affect the flow in the jet up to the turning zone. Assume that the flow rate and kinetic energy of the flow are conserved during the turning process since the turning zone is short and there are no significant energy losses. With this in mind, we can write that

$$\int_{t^*} \int_0^{b^*} u \cos\varepsilon \cdot dz dt = \int_{s_0} W ds$$

$$\int_{t^*} \int_0^{b^*} u^3 \cos\varepsilon \cdot dz dt = \int_{s_0} W^3\ ds \qquad (5)$$

where

ε - is the angle between the radius vectors and $r_*\ \rho$, drawn in the plane of the screen from points and O_φ , respectively O_Ψ, t_* - the boundary of the circular source, b_* - the height of the formations of the cylinder, z - coordinate axis normal to the plane of the screen, s_0 - cross-sectional area of the free jet at the entrance to the turning area. The left parts of the above equations represent the flow rate and kinetic energy at the liquid exit from the turning zone, and the right parts represent the same values in the jet when approaching the turning zone. Assume that the velocity profiles do not depend on the angle φ , that is, $u_*(z^0) = u_{m*} \cdot f(z^0)$ where $z^0 = z / b_*$, $W_*(R^0) = W_{m*} \cdot f_0(R^0)$ where $R^0 = R / R_*$.

Then the flow and energy equations can be converted to the following form:

$$\int_0^1 f(z^0) dz^0 \int_{t^*} b_* \, u_{m*} \cos\varepsilon \cdot dt = 2\pi \cdot R_*^2 \int_0^1 f_0(R^0) R^0 \cdot W_{m*} dR^0$$

$$\int_0^1 f^3(z^0) dz^0 \int_{t^*} b_* \, u^3{}_{m*} \cos\varepsilon \cdot dt = 2\pi \cdot R_*^2 \int_0^1 f_0{}^3(R^0) R^0 \cdot W^3{}_{m*} dR^0 \qquad (6)$$

where

R is the radial distance from the axis of the free jet to an arbitrary point, R_* - boundary radius of the free plane before the turning zone, W_{m*} - maximum speed (on the axis) in the aircraft before the turning zone, u_{m*} - is the maximum velocity at the outlet of the annular source, which does not depend on the angle of φ . If we take out and u_{m*} W_{m*} flow and energy, we obtain:

$$u_{m*} = \alpha \cdot W_{m*}$$

$$\alpha = \{ \int_0^1 f_0{}^3(R^0) R^0 dR^0 \cdot \int_0^1 f(z^0) dz^0 \}^{0,5} \cdot (\int_0^1 f_0 (R^0) R^0 dR^0 \cdot \int_0^1 f^3(z^0) dz^0)^{-0,5} \qquad (7)$$

To find the parameters A and B, characterizing the height of the cylindrical source, we will use the conditions of conservation of flow and momentum projection on the screen's plane. Let us write down the equations of conservation of flow and momentum projection, taking into account the similarity of velocity profiles:

$$\int_0^1 f(z^0) dz^0 \int_{t^*} b_* \cdot u_{m*} \cos\varepsilon \cdot dt = \int_0^1 f_0(R^0) R^0 dR^0 \cdot \pi R_*^2 \cdot W_{m*} \quad ,$$

$$\int_0^1 f^2(z^0) dz^0 \int_{t^*} b_* \, u^2{}_{m*} \cos\phi dt = \cos\theta \cdot (\int_0^1 f^2{}_0(R^0) R^0 dR^0 \cdot \pi R_*^2 \cdot W^2{}_{m*}) \cdot$$

Converting these ratios, we obtain

$$2\rho \int_0^\pi (A + B\cos\varphi)\cos\varepsilon \cdot d\varphi = \frac{\beta}{\alpha} s_0 \qquad ;$$

$$2\rho \int_0^\pi (A + B\cos\varphi)\cos\varepsilon \cdot \cos\phi \cdot d\varphi = s_0 \cdot \cos\theta \cdot \frac{\gamma}{\alpha^2} \quad .$$

Here

$$\beta = 2(\int_0^1 f_0 (R^0) R^0 dR^0) \cdot (\int_0^1 f(z^0) dz^0)^{-1}$$

$$\gamma = 2(\int_0^1 f_0^2(R^0) R^0 dR^0) \cdot (\int_0^1 f^2(z^0) dz^0)^{-1} \qquad (8)$$

Let us express $\cos\psi$ as a function of the angle and φ Δ . From the geometric diagram of the reversal (Fig.5), we can derive the relation $\cos\varepsilon = \dfrac{\rho + \Delta\cos\varphi}{\sqrt{\rho^2 + 2\rho\Delta\cos\varphi + \Delta^2}}$.

Using these relations and neglecting the change compare $\cos\varepsilon$ to $\cos\psi$, we obtain the flow and momentum equations, respectively, in the following form:

$$A\left(l_0 + \Delta^0 l_1\right) + B\left(l_1 + \Delta^0 l_2\right) = \frac{s_0\beta}{2\rho\alpha}$$

$$A\left(l_1 + \Delta^0 l_0\right) + B\left(l_2 + \Delta^0 l_1\right) = s_0 \cdot \cos\theta \cdot \gamma \cdot \frac{1}{2\rho\alpha^2}$$

Here $\Delta^0 = \dfrac{\Delta}{\rho}$, $l_j\left(\Delta^0\right) = \displaystyle\int_0^{\pi} \frac{\cos^j\varphi \cdot d\varphi}{\sqrt{1 + 2\Delta^0\cos\varphi + {\Delta^0}^2}}$, where j = 0, 1, 2. (9)

Dependencies ca $l_j(\ \Delta^0\ )$ be obtained by numerical integration. Calculations have shown that at $A \approx \dfrac{s_0\beta}{2\rho\alpha\left(l_0 - \Delta^0 l_1\right)}$ $0 \le \Delta^0\ \le 0{,}85$. This formula is simplified:

$$A \approx \frac{s_0\beta}{2\rho\alpha\pi} \qquad (10)$$

This result means that the turning area's average height is almost independent of the angle θ at which the jet collides with the screen. Let us determine the fourth unknown - the value of Δ^0 . By analogy with an ideal fluid, let us assume the integral form about conservation of the flow rate in the angle element before and after the turn. Shows the jet section before the turning zone and the section at the base of the annular source. Drawing in the bottom of the cylinder's plane through the point O_Ψ the line a-a, perpendicular to the axis X, we divide the liquid flow into two parts. Since the issue O_Ψ is the quasi-source of the jet, all of the fluid to the right of a-a will move to the right, and the liquid to the left of this line will move to the left. In the jet's cross-section s_0 at a distance Δ_* from the plane's axis, it is also possible to draw a line $a_* - a_*$ perpendicular to the axis X, which similarly divides the flow in the jet. Let us assume by analogy with the theory of an ideal fluid that the distances Δ and are Δ_* proportional to the radii of the corresponding circles $\dfrac{\Delta}{\rho} = \dfrac{\Delta_*}{R_*} = \Delta^0$. Based on the adopted flow diagram, write the flow rate balance. The flow rate of gas flowing from the turning area is equal to $G_* = \displaystyle\int_\lambda^\pi \rho \int_0^{b*} u(z)dzd\omega$, where $\omega = \pi - \varphi$, $\lambda = \arccos\Delta^0$. Since $b_* = A - B\cos\omega$ it makes sense to represent G_* as a sum of $G_* = G_{*1} + G_{*2}$. Here $G_{*_1} = A\displaystyle\int_0^\rho u(\omega)dr\int_\lambda^\pi d\omega$, $G_{*_2} = -\displaystyle\int_0^\rho u(\omega)dr\int_\lambda^\pi B\cos\omega d\omega$.

The flow rate of gas flowing into the turning area is equal to $G = G_1 + G_2$, where $\sigma = \Delta^0 / \cos\omega$ $G_1 = \displaystyle\int_\lambda^\pi\int_0^{R_*} u(R)\cdot R \cdot dR \cdot d\omega$ $G_2 = \displaystyle\int_0^\lambda\int_0^\sigma u(R)\cdot R \cdot dR \cdot d\omega$

From the comparison of these relations, it follows that $G_1 = G_{*_1}$, and since $G_* = G$, and $G_2 = G_{*2}$ or else: $\displaystyle\int_0^\lambda\int_0^\sigma u(R)\cdot R \cdot dR \cdot d\omega = -\int_0^\rho u(\omega)dr\int_\sigma^\pi B\cos\omega \cdot d\omega$.

Converting this expression and neglecting the change in $\cos\varepsilon$, we obtain equality of costs through the unshaded part of the sections: $B\sqrt{1 - {\Delta^0}^2} = \dfrac{R_*^2 \cdot W_{m*}}{\rho \cdot u_{m*}}\left(\displaystyle\int_0^1 f\left(z^0\right) \cdot dz^0\right)^{-1} \cdot \int_0^\lambda\int_0^\sigma f_0\left(R^0\right)R^0 dR^0$.

Because of the difficulties in calculating the integral in the right-hand side of this equality, we considered two limiting cases corresponding to triangular and rectangular velocity profiles at the turning area entrance. It turned out that in a wide range of values of the jet's angle of impact with the screen, the following dependence is well performed $\Delta^0 = \cos\theta \cdot (\ 2\displaystyle\int_0^1 f_0\ \left(R^0\right)R^0 dR^0\ )^{0{,}5}$. This formula can be used in the field of $0 \le \cos\theta \le 0{,}7$. The valuecan be obtained either by numerical integration or by extrapolation using the condition for large values. Using the results obtained above and introducing the notation

$$A^0 = \frac{k \cdot A}{R_*},\ ,B^0 = \frac{k \cdot B}{R_*}\quad k = \frac{\rho}{R_*} \qquad (11)$$

Let us write out the final formulas for calculating the parameters of the ring source:

$$A^0 = \frac{\beta\pi}{2\alpha\left(l_0 - \Delta^0 l_1\right)}\ \text{ορ}\ A^0 \approx \frac{\beta}{2\alpha}\ \text{ιφ}\ \Delta^0 < 0{,}6$$

$$B^0 = \frac{-A^0\left(\Delta^0 l_0 + l_1\right) + 0{,}5\pi\cos\theta \cdot \gamma\alpha^{-2}}{\left(l_2 + \Delta^0 l_1\right)} \qquad (12)$$

The value of the coefficient k is an experimental constant and is equal to 1.5. To calculate the propagation of the jet over the screen, we will use the empirical fact of its boundaries' straightness at a constant angle of inclination to the screen surface for propagation directions. Consider the motion of a fluid element in cylindrical coordinates O_Ψ , z, r, ψ . Let us write down for the selected elementary volume of fluid the equation of change of momentum: $\int_0^{b_1} u_1^2 dz_1\, dL_1 = \int_0^{b_2} u_2^2 dz_2 dL_2 + (\ T_1 - T_2 + T_3)$, $b_1 = (r - r_*)C + b_*$, $b_2 = (r + dr - r_*)C + b_*$ $\quad dL_1 = rd\psi$, $dL_2 = (r + dr)d\psi$ where b is the height of the element, S1, S2 are the areas of the first and second faces of the component, respectively, T1 is the friction force on the bottom edge adjacent to the screen, T2, T3 - friction forces on the side faces of the element.

The action of the pressure forces is mutually balanced. After estimating the magnitude of the equation terms, we conclude that friction forces in total give no more than 5% of the importance of the change in momentum. This makes it possible to neglect the friction forces. Given the similarity of the velocity profiles and discarding the terms of the second-order of smallness, we finally obtain the differential equation $du_m^2 \cdot r[(r - r_*)C + b_*] = -u_m^2[(2r - r_*)C + b_*]dr$. Integration of the equation is performed under the boundary condition: $u_m = u_{m*} = \alpha \cdot W_{m*}$ $r = r_*$.

The result is that

$$u_m^2 = \alpha^2 \cdot W_m^2 \cdot \frac{r_*}{r} \cdot \left[1 + \frac{Ck}{A^0 + B^0 \cos\varphi} \cdot \frac{r_*}{R_*} \cdot \left(\frac{r}{r_*} - 1\right)\right]^{-1} \qquad (13)$$

Values and $\cos\varphi$ ρ are determined from geometric considerations

$$r_* = \rho \cdot \left(\sqrt{1 + \Delta^{0^2} \sin^2\psi} + \Delta^0 \cos\psi\right)$$

$$\cos\varphi = -\Delta^0 \sin^2\psi + \cos\psi \sqrt{1 + \Delta^0 \sin^2\psi} \qquad (14)$$

It follows from these formulas that at sufficiently large r, the value of the maximum velocity at an arbitrary point of the screen weakly depends on l and is determined only by the angle of impact of the jet with the screen. If the screen is located within the initial section of the plane ($l^0 = l / R_0 \leq 9$), then

$$W_{m*} / W_{m0} = 1 ; R_* / R_0 = 1 + k_1 l^0 \qquad (15)$$

If the screen is placed on the central part of the jet ($l^0 \geq 9$), then

$$W_{m*} / W_{m0} = k_3 l^0 ;\ R_* / R_0 = k_2 l^0 \qquad (16)$$

Here $k_1 = 0{,}14$; $k_2 = 0{,}22$; $k_3 = 12{,}4$. When determining the velocity profiles at the entrance to the turning zone $l^0 \leq 9$, we need to know the ordinate of the inner boundary of the mixing zone R_1 , which is found from the ratio

$$(R_0 - R_1) / R_0 = 0{,}08 \cdot l^0 \qquad (17)$$

When calculating the values of α , β , γ the importance of integrals $\int_0^1 f_0^{\,n}(R^0) R^0 dR^0$ for the initial section of the jet is calculated by the formula:

$$\int_0^1 f_0^{\,n}(R^0) R^0 dR^0 = 0{,}5(R_1^0)^2 + (1 - R_1^0)^2 \cdot \int_0^1 f_0^n(\eta)\eta d\eta + (1 - R_1^0) R_1^0 \int_0^1 f_0^n(\eta) d\eta \qquad (18)$$

Here $R_1^0 = R_1 / R_*$, $\eta = (R\ - R_1)/(\ R_* - R_1\ )$. The Schlichting formula describes the velocity profile at the source outlet

$$f_0(\eta) = (1 - \eta^{1,5})^2 \qquad (19)$$

To describe the velocity profile for further propagation of the jet through the screen, the Schlichting profile with boundary layer in mind is used

$$u^0 = \frac{u}{u_m} = (1 - \xi^{1,5})^2 \ \text{ατ}\ b \geq z \geq \delta ;$$

$$\text{ατ}\, u^0 = (z / \delta)^{0,1} \ z \leq \delta \qquad (20)$$

where b is the thickness of the jet flowing on the screen,

δ - is the thickness of the boundary layer in the jet flowing over the screen $\xi = \frac{z - \delta}{b\ - \delta}$.

III. RESULTS OF COMPUTER MODELING

The results of calculations using the obtained formulas are shown in Fig.6-7. Unfortunately, the solution given here is only marginally applicable to protective jets since it satisfactorily describes the flow only in the jet's flowing part. The size of the protection zone DZ of interest to us in this theory can be estimated very approximately by the value of the conditional source's radius ρ . The solution consists of the following main stages:

1) Selecting the computational domain

2) Setting the equations of the mathematical model

3) Setting the initial and boundary conditions

4) Setting the computational grid

5) Carrying out a numerical calculation

6) Viewing and analyzing the results obtained

The calculation was carried out using the FlowVision-HPC software package [8], which is designed for numerical modeling of three-dimensional laminar and turbulent, stationary, and unsteady liquid and gas flows.

The software package is based on the finite volume method, high-precision difference schemes, effective numerical methods, and reliable mathematical models of physical processes.

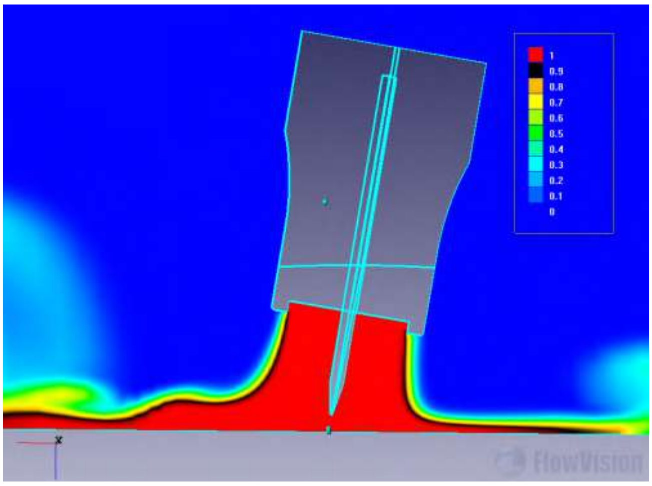

Fig. 6. Carbon dioxide concentration in the section plane.

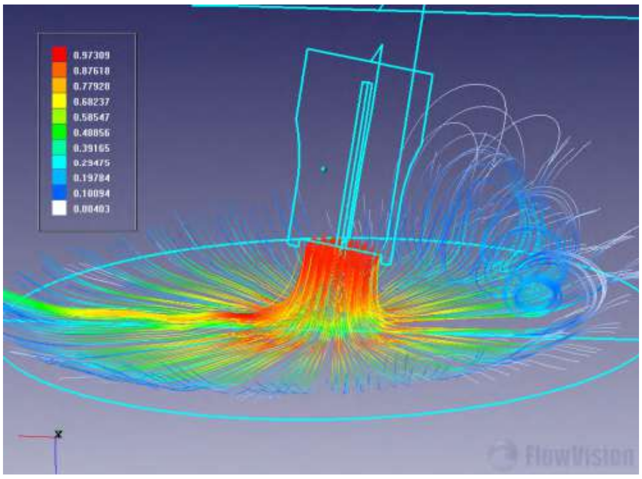

Fig. 7. Streamlines.

An experiment at the Joint Stock Company "Production Association 'Northern machine-building enterprise" has shown the proposed model's relatively high efficiency.

IV. CONCLUSION

The wide range of shielding gases used makes this method widespread concerning metals to be welded and their thickness. The main advantages of the considered welding method are as follows:

- high quality of welded joints on a variety of metals and their alloys of different thicknesses, especially when welding in inert gases due to low waste of alloying elements;
- the possibility of welding in various spatial positions;
- no operations for filling and cleaning flux and removing slag;
- the ability to observe the formation of a seam, which is especially important in mechanized welding;
- high productivity and ease of mechanization and automation of the process;
- low cost when using active shielding gases;
- the ability to weld at different ambient temperatures, which is very important in the Arctic.

This welding method's disadvantage is the complex process of adjusting the welding location, pressure, and direction of shielding gas supply. To eliminate this drawback, we created a mathematical model and implemented it in the FlowVision program. An experiment at a shipbuilding plant showed reasonably high efficiency of the proposed model.

***Abstract*— The world is globalized day by day so the demand of automated machine has increased rapidly. In restaurant or offices, factories, homes, hospitals, automation robot holds a significant contribution. In this paper we have designed and implemented a smart automated system using over head crane. As the proposed system is overhead type so it needs no extra space in the ground. Most of the smart restaurants in the world are using line following robot to serve food to customer. The installation cost of line following robots is high. For this reason, it's difficult for developing countries to build a smart restaurant. So, we have designed a smart system for serving at restaurant by using overhead crane, which is cost effective. Also due to the ongoing Covid-19 epidemic, the restaurant business is in recession. With this proposed system, it is possible to provide food directly from the kitchen to the customer's table while maintaining social distance and following hygienic rules.**

***Keywords*—PIC16F72 microcontroller; ULN2003 Motor Driver IC; IR LED; LM7805 Voltage Controller; LM2576 DC-DC Converter; Covid-19.**

I. INTRODUCTION

Automation control is the use of different control systems for running devices, such as machines, processes in plants, boilers and heat treating ovens, switching on telecommunication networks, steering and stabilizing ships, aircraft and other applications and vehicles with limited or decreased human interference. A mobile robot is a software-controlled system that uses sensors and other technologies to recognize and move around its surroundings. The use of mobile robots makes the complex and laborious tasks easy, reduces human error, increases efficiency, and enables continuous work without taking rest. We have made a frame work that is an overhead wheel based system which works with relay, IR sensor and microcontroller PIC16F72. The restaurant has been divided into a certain number of row and column sections through IR sensor. The table on which the food will be served in any row and column section of the restaurant will be calculated by the microcontroller PIC16F72. The overhead crane will collect food from the kitchen and serve it at the designated table.

II. LITERATURE RIVIEW

There have been a number of studies on smart restaurant serving in the past. Automated Restaurant Service Program Using a Robot Line Follower has developed a system on automated food serving [1]. This project can be used to maintain a restaurant to take orders and serve the same route the follower robot allows also travels with a particular course. This direction perhaps a black belt on a white frame or a white belt on a black frame, but it may be transparent to the magnetic field. This route utilized for this venture was a black one on a white frame. With the help of IR sensors, this route had tracked, also this sensor readings were utilized to operate the engine operator that was mounted over this robot which was the main reason for the robot motion.

To communicate between the robot and the customer, NRF transceivers were used. A. Jain et. al. developed a system in which robot's first task was to move around the room to find collectible locations, i.e. tables [2]. Once a table has been set up by a computer, the job is to collect the various objects on the table.

The robot was designed to identify and collect the table below. N. Malik et. al. from Moradabad Institute of Technology Moradabad in India designed a robot which were designed in such a way that they can greet the visitor, order and sever the food to the customer [3].

R.Poonguzhali et. al. from Periyar Manniammai Institute of Science and Technology designed a Wheeled Robotic System in which the LCD, Keypad and Bluetooth modules were the basis for the menu bar [4]. By using the automated menu bar to place the order the customer needs. This order was transmitted via the communication network to the kitchen and reception. Then the Waiter robot will transport food to the customer from the kitchen.

Ademola Abdulkareem et. al. from covenant university, Ota ,Nigeria developed smart autonomous mobile robot [5]. When customers arrive, they have to press the button to

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

refresh themselves. The LED at the start point and the LED at the junction from which the robot moves to work towards the table will glow as the button is pressed (switch is on). The robot began after a black line when it got a white light when it turned left or right and served the refreshmentaccordingly. Upon working, the returning black line route will lead again and arrive at the starting position.

M. Asif et. al. from Riphah International University, Islamabad designed a line following waiter robot which provides the client with adequate restaurant service [6]. If a person wants to place an order, he or she can call the robot simply by pressing a switch on his desk. The whole device made use of RF technology.

Afsheen Salmiya et. al. designed a self-sufficient waiter robo in which a waiter based on robotic technique was planned and implemented for a two-room office [7]. The waiter robot was built to accept requests from the kitchen boy via android applications, collect food / drinks (max600grams), travel to the destination (the individual sending the request) and return to the place of origin after delivery of the requested food / drinks.

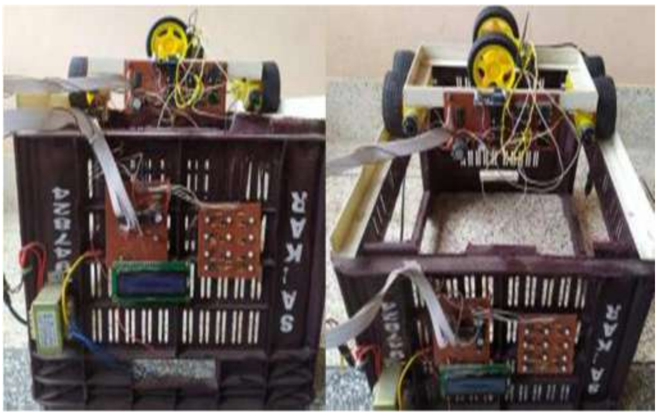
The goal is to develop a small-scale robot called the Serving Robot, which can aid in the development of robotic assistance technologies. A robot that acts as a personal assistant should be able to help in a variety of settings, whether it is a research lab, a clinic, or even at home.

- Effective and effective jobs as we do with robots:
- Reduces customer waiting time.
- One-time system investment.
- Work can be easier and can reduce labor costs.
- When customers place their own orders, the number of waiter staff may be reduced.
- Procedures are carried out with accuracy and high repeatability.
- Serving food to the customer while maintaining social and safe distance due to Covid 19 pandemic.

Considering the previous work, we have seen that each of them has basically used Line following Robot, which is very expensive. Perhaps it is better for developed countries to bear the cost. But it is difficult for developing countries to bear this high cost and also need a certain amount of space allocated for restaurants that are using line following robots. If there is any kind of involuntary obstruction in that space, the robot needs more time than the allotted time, which is undesirable for the restaurant business. In addition, the perimeter of the restaurant needs to be enlarged for the installation of robots and lines. On the other hand, for an overhead system doesn't require extra space to set up, so the restaurant has the potential to be economically viable and make the restaurant environment more attractive by setting up the required number of tables. So, a smart restaurant using overhead crane has been developed at a very low cost to keep pace with the developed world.

III. SYSTEM OVERVIEW

This prototype is microcontroller and relay based. Also IR sensor will play important role in this project.



(a) Front view (b) Top view

Fig 1. Implemented Prototype of Smart Food Service.

In this system we mainly used PIC16F72 microcontroller, ULN 2003 motor driver IC, IR LED, Liquid Crystal Display (LCD),LM7805 voltage regulator,LM2576 DC-DC Converter, Gear Motor, Limit Switch, Resistor, Capacitor, Diode. "Fig.1." shows the implemented prototype of smart food serving using overhead crane.

In this prototype, we have designed a total number of nine tables and one kitchen which is separated by four rows and three columns with the help of IR sensors. "Fig.1." shows the implemented prototype of smart food serving using overhead crane. The block diagram of proposed project is shown in "Fig.2."

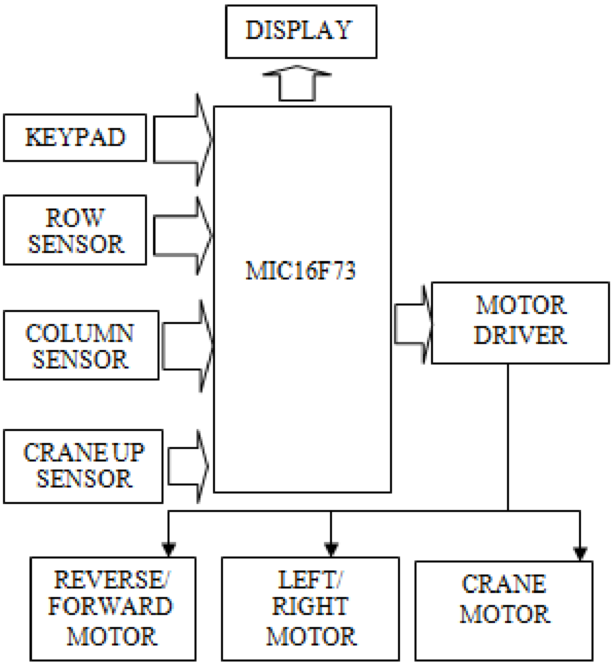


Fig 2. Block diagram.

There are total seven motors which have been used in the overhead crane, of which four motors are used to move the overhead crane to forward /backward direction, two to the right/left direction and one to up/down for collecting food from the kitchen and serving food at the designated table. After activating the system in the initial state, any table will be selected with the help of push button. Different analog voltages are generated due to the use of different resistors with push button. Converting analog voltage to digital voltage through ADC , microcontroller will Calculate the row and column number for the table. “Fig.3.” shows the flow chart of the proposed system.

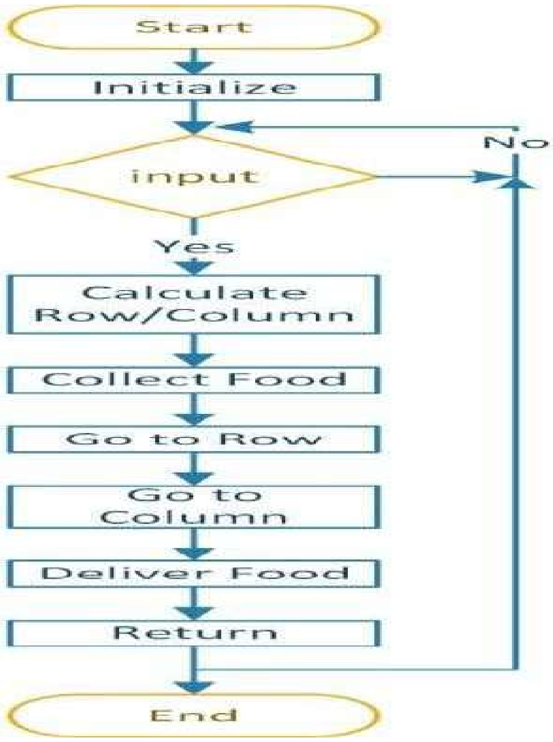

Fig 3. Flow chart.

There are seven motor connected to ULN 2003 motor driver which is connected to port C of microcontroller. Crane up /down motor connected to pin number 13 and 14. Forward/backward motor connected with 15 and 16 number pin and right/left direction motor connected to 17 and18 number pin of PIC16F72 “Fig.4.” shows the circuit diagram.

In order to serve the food, we use row sensors and column sensors in port A, port B and port C. After pressing any key, the microcontroller will measure the row and column number, then the crane will down when pin number 14(RC2) will be high. After collecting the food, the crane will up when pin number 13(RC1) will be high. It will go up until the crane limit or pin number 23 goes high then it will go forward. In this situation pin number 15 (forward direction) will high to go to row with the aid of row sensor Again the crane will go down to deliver the food and after serving it will go up and go back to middle position with the aid of right/left motor. Suppose the crane is in the left position, so it needs to go right direction to go to middle point that means pin number 17 (right direction) will high. After reaching middle point it will go back to the kitchen, for this purpose pin number 16 will high. “Fig.5.” shows the structure of over head crane.

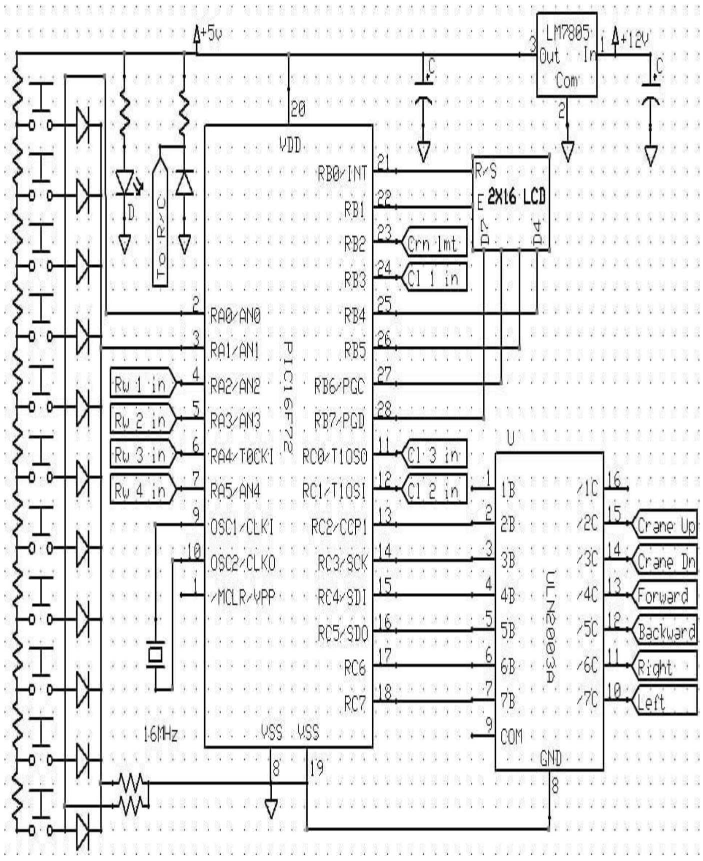

Fig 4. Circuit diagram.

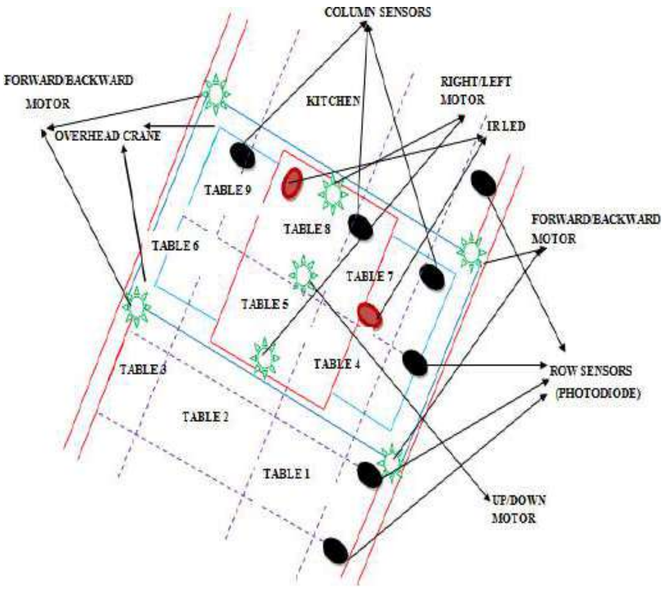

Fig 5. Structure of overhead crane.

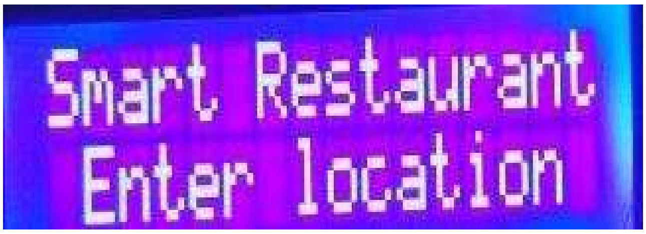
IV. WORKING MODE AND RESULT ANALYSIS

The output of the system is shown in "Fig.6." to "Fig.9."



Smart Restaurant
Enter location

Fig 6. When turn on the device then it needs location.

A. *Initial State of working mode*

When we turned on the device then microcontroller send the information in main circuit and main circuit transfer the information to microcontroller circuit. Then it needs location. The program selects the row and column for different tag. Then the information is collected by touch switch then motor driver circuit will be activated. ."Fig.6." shows when we turned on the device, it needs location.

Then location will display either yes or no to confirm the table number which is shown in "Fig.7."

B. *Serving state of working mode*

When the information is sent, microcontroller software selects the row and column then photodiode can detect row and column because the PIN structure provides quick response time. PIN photodiodes are mainly used in high-speed applications and then it will collect food from the kitchen area. After taking food from kitchen, it would reach table number 1 and serving food. In the same way, we will assign a location to the number 2 table and that it is getting ready to serve. Same process it will serve food table number 3, 4, 5, 6, 7, 8 and 9. "Fig.8." shows the collecting food from the kitchen.

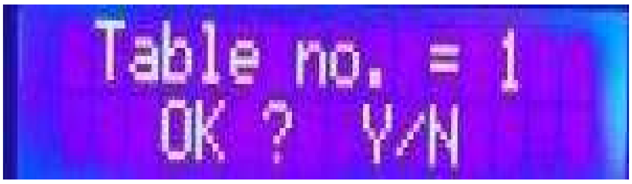


Table no. = 1
OK ? Y/N

Fig 7. Location will display either yes or no to confirm the table number.

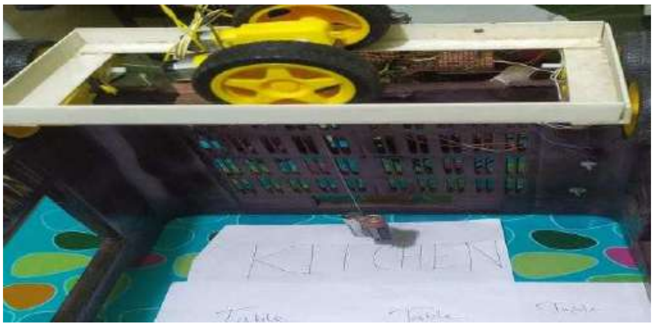

Fig 8. Collecting food from the kitchen.

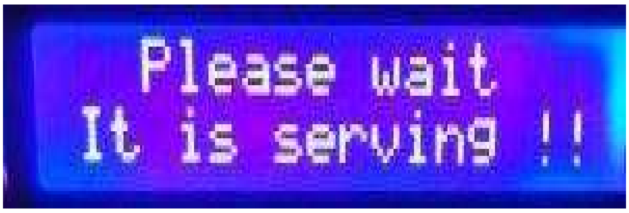
The crane will go to row and column with the help of IR Sensor. The IR sensor is composed of two parts, the circuit emitter and the circuit receiver. This is known collectively as a Photo-Coupler, or Opto-Coupler. The emitter is an IR LED and the detector is a photodiode of the IR. The IR photodiode is sensitive to the IR light produced by an IR LED. The resistance to the photodiode and the output voltage change in relation to the received IR light. That is the IR detector 's basic operating theory, at last running the gear motor. "Fig.9." shows getting ready to serve food and then it delivers the food to the customers. After delivering the food, it will go back to the kitchen automatically and waiting for the next order.



Please wait
It is serving !!

Fig 9. Getting ready to serve.

V. COST ANALYSIS

If we consider the 1st month (when the system is set up): Installment Cost = (1700+920) Tk = 2620 Tk

Variable Cost = (60+60) Tk = 120 Tk Total Cost = Installment Cost + Variable Cost

= (2620+120) Tk

= 2740 Tk = 34.25 USD

There is no installment cost after the 1st month and the overall cost is just the variable cost.

Table 1. COST CALCULATION OF THE PROPOSED SYSTEM

Cost	Equipment Description	Amount (Tk)
Installment Cost	Overhead Crane &Frame Cost	1700/-
	Additional Equipment Cost	920/-
Variable Cost	Motor, Wheel, Wire & LCD Cost	60/-
	Additional Cost	60/-

VI. CONCLUSION

The idea of delivering food using a robot is not old but there are a number of technical challenges to address. It would be the cost involved first. To convince people that this automated food delivery system is workable, the point is that people should actually compare the cost of hiring a worker and purchasing a robot. It is therefore essential to keep costs down. The proposed project is an idea to keep pace with the developed world at low cost. The system can also be used in addition to restaurants, parks, offices, hospitals or market places which will help to continue activities while maintaining social distance in the ongoing Covid-19 epidemic in the current world.

***Abstract*—This work presents a step forward solution for solid waste collection using an adequate IoT-based practical monitoring platform. The system is designed to assist Algerian municipalities in collecting solid waste by monitoring the fullness status of outdoor bins. The solution framework is based on (1) wireless sensor nodes connecting the (2) intelligent bins to the (3) monitoring station by sending the bins filling level status for analysis in order to control the waste in real-time and avoid bins over-filling. This process leads to an improvement in waste management via bins collection-based route optimization process. With the proposed solution, the benefit would be the timely-efficient waste collection, operating costs and gas emissions reduction, and preserve the environment from pollution with future prediction of waste generation.**

***Index Terms*—Municipal solid waste, IoT, Intelligent bin, Gateway, Route optimization, Monitoring platform.**

I. Introduction

A. Motivation

Nowadays, the volume of Municipal Solid Waste (MSW) production is increasing very drastically and become a major challenge for governments and countries due to unprecedented population growth, industrial and urban expansion, and changes in the consumption habits and lifestyle of urban populations [1] [2]. According to worldwide studies, the annual production of solid waste is expected to reach approximately 3.40 billion tonnes by 2050, or an approximate cost of 635.5 billion USD for municipal waste management [3]. Additionally, waste generation in large cities has increased rapidly over the past two decades. Furthermore, 85% of the total MSW management budget is spent on waste collection and transport [3].

Several studies have indicated the direct link between the increase in waste production and the difficulty of its management by traditional solutions, which leads to an inadequate mechanism of collection, disposal, and mismanagement of waste in cities resulting in a deterioration in the citizen' quality of life and economic losses. Thus, solid waste management has become a major issue for the authorities responsible for the lack of satisfactory solutions.

B. Algerian situation regarding waste management

In general, urban population growth and the average standard of living are the main factors contributing to large-scale waste generation [4]. In the Algerian situation, a significant increase in the rate of solid waste production of nearly $0.93\ kg/person/day$ [5] due to several factors, such as the economy has evolved steadily over the past two decades, the regular increase in population (44.18 millions, 2020) [6], improved financial resources, an increased level of consumption of community life and more people are turning to city life.

Currently, the waste collection in Algerian context is based on a static and passive model, carried out once a day by a mechanical pressurized truck with a capacity of 7 to 10 tons which is lifted, transported, and emptied mechanically. There are several fixed waste collection points (bins) in a residential area that make up the truck visit sequence, where they are all collected in one way. In such a model, the capacity of collection trucks is not used at the limit, and several bins are overflowing as in Figure 1. As with other emerging countries, an effective solution for Algerian solid waste management has become the urgent need to replace the conventional way in which municipalities manage waste collection.

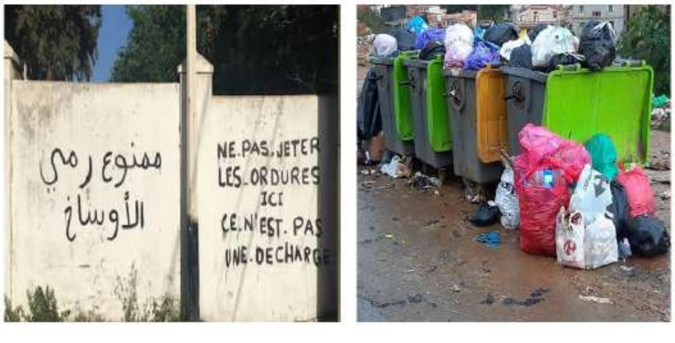

Fig. 1. MSW collection points in a residential area (over-filling).

This work is financially supported in part by the DGRSDT (Direction Générale de la Recherche Scientifique et du Développement Technologique) and CDTA (Centre de Développement des Technologies Avancées), Algeria, as part of Socio-Economic Projects (SEP) 2019-2021. (Project Code: I-Bin, $N°07/CDTA/DGRSDT$).

Therefore, a technology-based solution would be the best option and could reduce the effort of the workforce involved in the waste collection by adopting smart bins alerting that send alerts for collection. This can be achieved by using a combination set of modern information technologies that provide necessary data [7] (sensor network, databases) and algorithms for intelligent dynamic routing as shown in Figure 2(b) instead of the traditional method of Figure 2(a). The application of technology in environmental waste management will have major benefits [8] in particular: (1) improve waste collection services, (2) optimize resources and routes for drivers, (3) minimize collection costs, (4) reduce carbon emissions and enhance environmental quality.

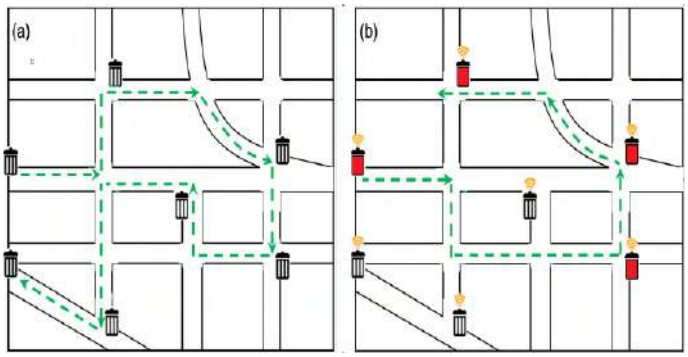

Fig. 2. Waste collection plan (a) static model vs. (b) dynamic model [9].

II. Literature survey

There are many waste management systems proposed to deal with different kinds of challenges existing with current waste management systems in smart cities [10]. In terms of adopting capacity, weight, temperature, humidity, and chemical (C-W-T-H-Ch) sensors, various models have been proposed as in [11]–[14]. The authors in [11] introduced a MSW management platform that exploits information from recycling collection based on IoT technology, and which serves as a model for waste collection introduced in Wuhan. The research findings help city authorities to effectively use the information produced at every step of the waste collection process and ultimately achieve the goal of the smart cycle.

Authors in [12] proposed a dynamic optimization model for solid waste recycling based on material recycling and dynamic optimization. The work represents a significant development of a dynamic decision model that includes state variables and is compatible with the quality of the waste in each bin on a daily basis by (1) controlling the variables, thus determining the quality of collected materials, (2) determining the routes of each waste-truck to reduce the total costs of collection. Furthermore, the decision model is integrated into a decision-support system that is activated with a Geographic Information System (GIS). The demonstration of the concept and its efficiency was carried out as a case study in the municipality of Cogoleto in Italy. A significant advantage has been obtained by improving waste collection 2.5 times more than the current estimated policy.

A monitoring system for solid waste bins and trucks that are activated by Radio Frequency Identification (RFID) and Information Communications Technology (ICT) has been proposed in [13]. The work provides an integrated system for efficient waste collection by adopting Global Positioning Systems (GPS), GIS, and cameras to design an intelligent container and truck surveillance system by introducing an integrated theoretical framework based on hardware engineering and an inference algorithm, in which the model includes a database that stores information about garbage containers and trucks. In addition, data is collected and used via a monitoring system for effective planning and routing using an advanced Graphical User Interface (GUI) which includes real-time images processing, graphical analysis, waste estimation, and container information. Experimental results prove the stability and high performance of the proposed monitoring system.

Proposed in [14], a prototype for monitoring solid bins with an energy-efficient detection model; this research expands [11] by describing a system that responds online when waste is thrown into the bins. The system architecture is based on three levels, (1) the lower one includes the sensors integrated into the bins while the energy-efficient model detects and transmits the measurements to (2) the intermediate level, which includes a gateway that stores and transmits data from the bins to the control station, and (3) the top level stores and analyzes the data for later use. This system is able to reduce truck operating costs and pollutant emissions by providing collected data to the Decision Support System (DSS) which includes dynamic routing of waste collection.

Related works on waste collection containers for content estimation and collection optimization based on capacity, weight, temperature, humidity, and pressure (C-W-T-H-P) sensors are discussed below. Authors in [15] designed and implemented an appropriate urban SWM system based on the amount and variety of waste prediction via adopting measures to correlate waste capacity with residential population and consumption index at different seasons of the year. The system prepared and tested in the Pudong New Area, Shanghai (People's Republic of China) includes an intelligent container and sensors to exploit the data used in further statistical inference processes.

In [16], the authors propose a collection monitoring model for early detection and evaluation of waste through sensitized bins. This research goes from [17] to the description of a new application for monitoring MSW, based on distributed sensor technology and GIS. This system has specific monitoring requirements related to the rapid increase in the rate of waste generation, the model tested and evaluated in Pudong, Shanghai.

In addition, an energy-based model has been proposed to improve solid waste collection in [18], which is applied in a large urban area. The research extends [16] by providing three dynamic scheduling and routing models which have been enhanced by the improvement of paths. A model is proposed in [19] to analyze the impact of solid waste Source Segregation (SS) intensity on fuel consumption as well as collection costs. The work provides an assessment of the fuel consumed and an analysis of the costs of solid waste collection. A simulation model is also integrated to calculate the time spent, the capacity of waste collected, and the fuel consumption for a specific waste collection channel.

Moreover, a Web-GIS system has been proposed in [20] to improve the viability of selective MSW collection in developed and transient economies; issues related to the implementation of the proposed model were also discussed. The model is critically evaluated through two scenarios, (1) two European case studies, where Web-GIS systems in Italy were the best examples of selective collection optimization, and (2) two case studies outside Europe, this scenario achieved 80% efficiency of waste source separation in the recycling purposes.

The Smart-M3 platform was examined and exploited by [21] to model smart planning and monitoring of urban solid waste management by leveraging IoT technology. The authors seek to solve the problem of waste collection by integrating the context of heterogeneous interconnected devices and by sharing data involving a large part of the urban population. They stated the benefits for service providers and users can achieve significant cost savings, while users enjoy Quality of Service (QoS).

Furthermore, many researchers are integrating RFID on a large scale for tagging and identification as part of solid waste collection infrastructure [10]. Authors in [22] proposed RFID and weight-sensor technology as part of the intelligent real-time waste collection system. Weight measurement processes are integrated into the proposed real-time waste collection system; the work ended with an application that leverages RFID data and weight sensors to define an automatic Waste Identity, Weight, and Stolen Bins Identification System (WIWSBIS).

A further effort by [23] who proposed real-time traceability data based on a multi-objective waste collection model supported by various IoT mechanisms to implement an efficient and innovative waste collection routing model. The authors declared that knowing the real-time data related to trucks and the actual level of the bins allows a dynamic routing and scheduling plans. The framework is integrated with an innovative dynamic routing model using real-time traceability data from an Italian city of $100,000$ inhabitants. The model has been tested and validated by simulation; while an economic feasibility study is also being carried out.

In [24], authors proposed an automated bin level detection system by using an advanced image processing approach integrated with ICTnd a camera for bin level detection. The system is evaluated by training and testing features extracted by Gray-Level Cooccurrence Matrix (GLCM) with Multilayer Perception (MLP) and K-Nearest Neighbor (KNN) classifiers. The authors stated the robustness of their system and the ability to apply it at different types of level detection of waste and bins under various conditions.

A. Contribution

This article describes an integrated smart solution developed for solid waste collection to support the current waste collection practices in Algerian municipalities (static model) and responds to the lack of a real-time monitoring system (dynamic model). The solution consists mainly of two modules, (1) monitor system receives the fill level of the outdoor bins measured using sensor node, reported via cellular networks (GPRS) to the platform known as I-Bin Platform, providing the (2) waste collector module with a route map allowing a truck management system and drivers to focus on routes containing most bins with optimum fill levels for collection. Most contributions concerning the proposed solution are: (1) Design and deploy real-time IoT sensor node (ability to measure the bin's capacity). (2) Design a new platform (I-Bin Platform) for data collection and analysis for smart management. (3) Integration and real-time testing of the developed system.

Furthermore, recycling is one of the most efficient ways to manage waste that is environmentally friendly. Among MSW recycling, authors in [25] proposed a real-time robust identification system for polyethylene terephthalate (PET) plastic using a probabilistic approach to model the color, size, and distance of the adjacent tape to differentiate between PET and non-PET plastic materials.

This article is organized as follows. Literature review of relevant works are highlighted in Section II. The examined methodology includes a theoretical framework, system architecture, and physical designs are presented in section III. System setup and implementation are given in section IV. Results and performances with brief limitations are discussed in section V. Conclusions and future work are provided in section VI.

III. Methodology

The effective design methodology for a real-time solid waste management system uses specific hardware, IoT devices, and programming tools, where the methodology is divided into different parts: (1) theoretical framework, (2) system architecture, and (3) physical design based soft-decision algorithms.

A. Theoretical Framework

Figure 3 illustrates the theoretical framework for remote monitoring of bins filling level, using IoT technologies to prevent waste overflow via municipal authorities notification of waste collection manner and times. Main actors involved: smart bin, monitoring system, and collector truck for disposal.

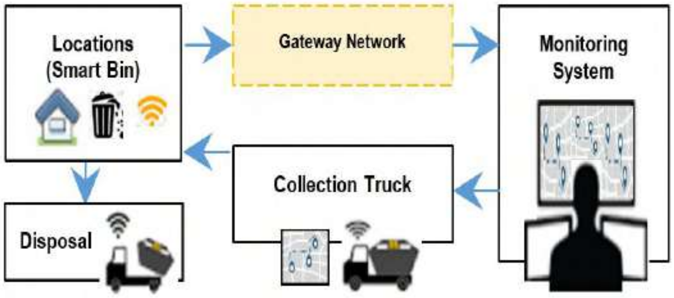

Fig. 3. A theoretical framework to remotely monitor the bins.

The smart bin located in the intended location (house, mosque, hospital, school, etc.) will be registered in the central system. The bin's cover will be embedded with an integrated circuit board for a real-time waste data sensor. The sensors equipped with a cellular network as a gateway to transfer the bins' fill level status to the central database of the system. The monitoring system manager browses and retrieves the information processed for waste collection and transportation; then, it determines the optimal path for truck drivers to collect and dispose of waste.

B. System Architecture

Three main parts from the lower-tier (sensor node) to the upper-tier (control station) through the middle-tier (gateway) represent the system architecture as shown in Figure 4. The sensor node (smart bin) collects the waste status and communicates with the gateway, which is an aggregation layer and message broker providing linking and transmission capabilities to the control station (end-user), which contains a server to store collected data from smart bins located in the city streets, in addition to a processing module for data computing and routing optimization.

Fig. 4. Main part of the system architecture.

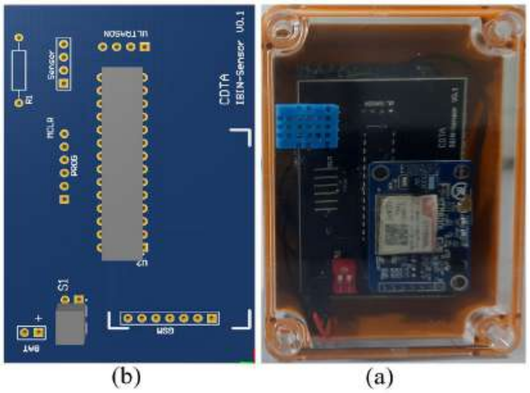
C. Physical Design

Physically, the designed system is based on three main parts:

1) Senor node: consists of sensors, micro-controller, network interface, and power supply attached to the bin cover for data collection and transmission.

- *Sensors*: composed of three types, (1) the HC-SR04 ultrasonic sensor to measures the bins fill-level. (2) the DHT-11 model for temperature and humidity sensing inside and surrounding the bin, helping to predict incoming fires or unwanted events.
- *Micro-controller*: memory and processing requirements, minimum power consumption, and low-cost are factors to consider when selecting a micro-controller. The PIC18F2550 considered as a good enough choice to receive and transmit data from sensors to the server, respectively via a network interface card and Internet services, and is more cost-effective.
- *Network interface*: quad-band GSM/GPRS network expansion module (SIM800L V2.0) with an internal antenna is used to send sensed data over GPRS to the remote web server application.
- *Battery*: Currently, rechargeable batteries ($5V$) are used to power the first prototype. But wireless technology, sensor data, and transmission rates are directly affected by energy consumption, which leads to considering solar energy charging for future use.

Figure 5 depicts the integrated circuit and sensing node that sends and transmits the information to PIC via a specific protocol to coordinate and control signals.



(b) (a)

Fig. 5. Sensing node, (a) PCB model along with (b) physical design.

2) Gateway: receives sensed data from multiple bins, where PIC collects the data from the sensors and sends it to the gateway via TCP/IP using MQTT protocol through the GSM/GPRS module. A broker running on the server, to receive all data and route it to the appropriate NoSQL database for storage. Rule engines will be used for data analysis and display to end-user dashboard.

3) Control station: called I-Bin platform, developed and contains a central server that hosts the database and retrieves the data received from the gateway. The central server hosts a web application-based GUI that monitors bin status and user's interaction with the system. This data can be used by the control station to power programs such as data analysis, optimization engines, and routing and planning applications. The control station basically consists of three components that work together as a processing unit:

- *Storage unit*: all data collected and information received (sensor measurements, location, etc.) from different sensors will be stored in the NoSQL database in an organized manner to be processed for future uses such as predicting filling level and periodic planning of waste collection.

- *Analysis unit*: this is an algorithm-based computation unit that helps to (1) calculate the best bins location with respect to crowd and waste generation ratio in an outdoor area, (2) calculate the distances to optimize the truck's routing paths, (3) scheduling and forecasting tasks for waste collection (4) statistical analysis for further use.
- *Visualisation unit*: provides visual display and tracking services to the end-user, including (1) real-time bins status, (2) optimized routing paths, sub-system, and panels designed for trucks, employees, and tasks management based on updated information.

IV. System setup and implementation

A. Deployment site

Calibration and setup regarding the proposed I-Bin platform for the practical waste collection began with the site selection. Figure 6 illustrates Google map of Baba Hassen city, Algeria, chosen as deployment site for testing and examining the solution. It is a municipality in the capital Algiers (area: $8.75\ km^2$) and a suburb in northern Algeria. The city's population was $23,756$ according to 2008 census [26].

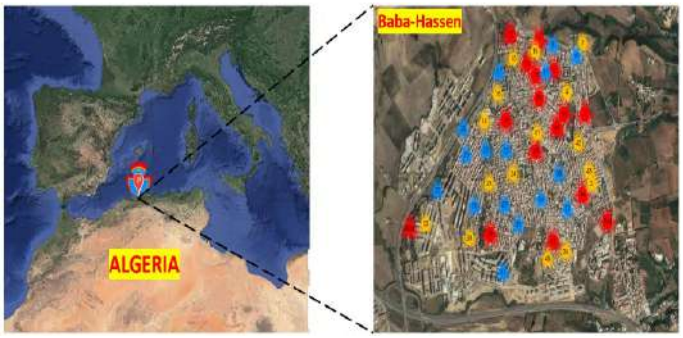


Fig. 6. Deployment site, Baba Hassen city in Algiers, Algeria.

B. Bin layer: Fill levels setting

As shown in Figure 7, the state in the bins was calibrated and monitored according to the three filling levels as follows:

- *Bin-Low Level* (*BLL*): this level defined as an initial step, bins are empty or emptied during the allotted time.
- *Bin-Half Level* (*BHL*): this level defined as a new status of bins to predict their filling time, useful for estimating the waste cost of trucks in terms of time and fuel.
- *Bin-Full Level* (*BFL*): this level reflects the overcapacity of the bins, which requires alerting the authority and truck drivers for the collection time.

The three fill-level for bin monitoring were examined with two different calibration modes:

- *Adjust-Calibration* (*Adju-Calib*): when the user selects this mode on the panel platform, the filling level will be arranged as indicated in Table I (first row).

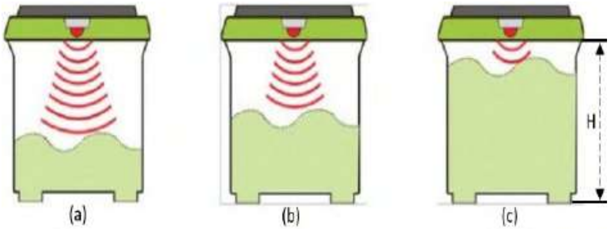

Fig. 7. Ultrasonic fill level sensor, (a) BLL, (b) BHL, and (c) BFL.

- *Adaptive-Calibration* (*Adpt-Calib*): when the user handles this mode, regardless of the status of high-level and low-level bins, the level will be controlled manually via the control panel slider to required values in Table I (second row).

TABLE I
Level bin and calibration setting modes

Mode types	Fill levels setting		
	BLL	***BHL***	***BFL***
Adju-Calib	$BLL \leq \frac{H}{3}$	$\frac{H}{3} < BHL \leq 2 \times \frac{H}{3}$	$2 \times \frac{H}{3} < BFL$
Adpt-Calib	$BLL \leq Th$	$Th < BHL \leq 2 \times Th$	$2 \times Th < BFL$

H=Bin Height. Th=Setting Index (Threshold)

C. Data Layer: Device and gateway work-flow

Figures 8 (a) and (b) are flowcharts and data layer structures used for operating principles and gateway networks and include key elements and logical decision-making processes. Clearly shown the way of real-time detection of bins status, device activity, gateway, and their intra-communication. In short, after turning on the device, the micro-controller will start reading the data from the sensor and send it at regular intervals through a gateway that receives it and transmits it to the server. All data is stored in the database and required data is visualized in real-time.

D. User layer

At this point, end-users manage the waste monitoring and collection process through the I-Bin web platform which includes real-time system monitoring and waste collection modules.

1) System Monitor: in short, the system administrator is the end-user that is able to monitor the current state of the entire system by adding, updating, and removing smart bins from the central system. In addition to providing mapping of the current waste situation, statistical data and various analysis can be performed on historical data provided to the municipality in order to make important decisions regarding updates to the waste management policy.

2) Waste Collector: this unit for users collects targeted bins according to the shortest optimized path. The unit's purpose is to guide and improve the collection path, unlike the static path model that collects every bin, whether full or not. The waste collection can be done quickly, efficiently, and

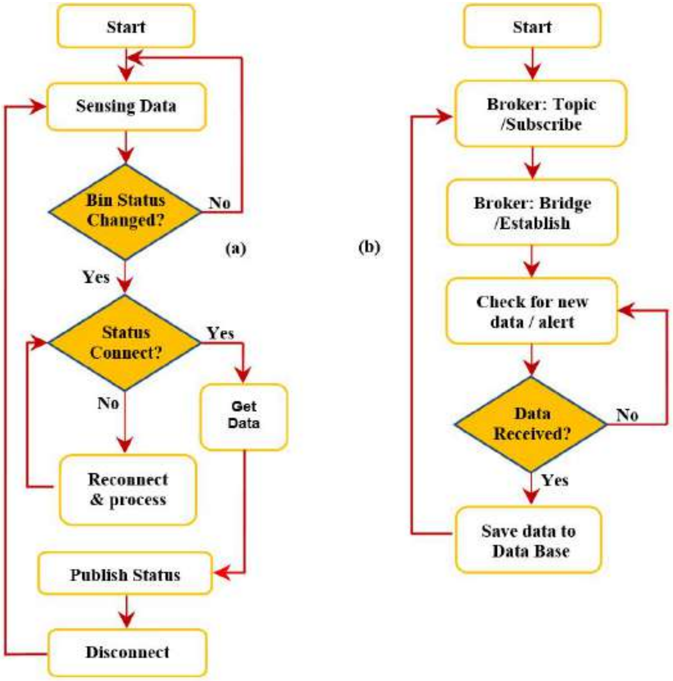

Fig. 8. Workflow of (a) sensing device and (b) gateway.

inexpensively only when the truck is able to perform collection based on the shortest way. In this step, the platform introduces a Dynamic Routing Model (DRM) to the waste collector for waste collection. The DRM carried out in two different stages, (1) DRM-Pattern Mining and (2) DRM-Optimal Routing.

a) DRM-Pattern Mining: for the purpose to extract a pattern function reflecting the distribution of the bins by analyzing the data fill-level and determine when the bins are full or nearly full. This process permits collecting the maximum amount of waste and gives more time to fill the bins. This can be achieved in two different ways: Pattern-A (pick only fully bins), and Pattern-B (pick medium and fully bins) according to Variable Assessment References (*VAR*) computed from equation (1). BFL and BHL reflect number of the daily collected bins with fully and medium filling levels respectively, from $9:00\ p.m.$ to $9:00\ a.m.$ with one-hour interval.

$$\begin{cases} VAR = \frac{\sum(BFL_i)+\sum(BHL_i)}{\sum Bin_i} \times 100 \\ \\ Adopt\ Pattern_{(A)} \quad if\ VAR \geq 50\% \\ Adopt\ Pattern_{(B)} \quad if\ VAR < 50\% \end{cases} \tag{1}$$

b) DRM-Optimal Routing: for the purpose to reduce waste collection path, this step adopted A-Star (A*) search algorithm [27] [28] using either pattern (*A* or *B*) extracted from the previous step to optimize and approximate the shortest path in real-time situations. In addition, two basic aspects can be achieved: (1) determine the optimal path between different sites; (2) estimate time or set of times when a particular route is to be performed.

V. Results and Discussions

A similar case study is shown in Figure 9. Baba Hassen city map was examined to collect the fill level of the 50 bins placed in different places, and the colors indicate the packing capacity of the bins: yellow, blue, and red indicating low, medium, and full levels, respectively.

A. I-Bin platform

This is a web-based monitoring platform provides to the end-user a real-time screening status of bins and fill-level, its sensing data, and amount of waste collected tagged with indicated three different colors. Shown in Figure 9 is the control panel from the I-Bin platform, displaying information such as bin ID, fill-level, date and time, and details including sensor node coordinates, temperature, humidity, and current battery power are retrieved and displayed in the status tool.

The progress bars appear and show the recent fill-level bins status. All this data stored in the database will be further used to optimize the waste collection path. The results returned by the calculation process appear visually in the *Panel Map* with additional settings tool includes VAR index measurement, algorithms for VAR-based routing, and pattern mining (*A* or *B*) for finding the shortest path and alternates routes in real-time. All these data are stored in the database and will be used further to optimize the waste collection route.

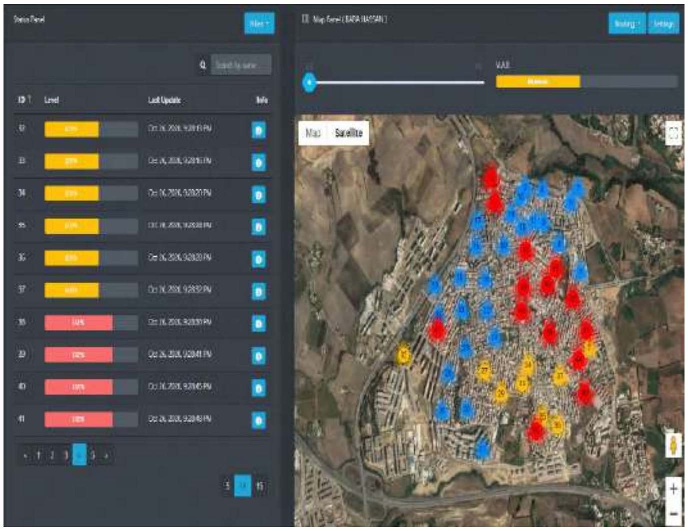

Fig. 9. Control panel from I-Bin platform with bins distribution and their waste fill-levels status, blue (low), yellow (medium), and red (full).

B. Event processing

The waste collection managed dynamically with timely-based updates. The waste truck visits and collects the specified bins only when it receives alerts from the sensors of outdoor bins within a specified period of time or according to the VAR index setting. Figures 10 and 11 represent the results of the optimized waste collection route of the targeted bins when employing the VAR index with both patterns (*A*) and (*B*) respectively. In this instance, the truck speed was set to

20 km/h when is weightless and otherwise at 80 km/h. Due to traffic rules and truck capacity restrictions, each bin pick-up and unload with a specific estimated time.

In short, Figure 10 shows the optimal extraction of the roadmap for waste collection using pattern (A) as in equation (1) with alerts indicator of $VAR \geq 50\%$. In this case, only the filled bins (red color) send an alert for collection and emptying. Waste collection process and truck expenses cost (C_i) was calculated with setting of $C_i = [20\ Km/h,\ 7.08\ Km,\ 1h31m]$, reflects the truck's speed, estimated distance, and additional estimated-time (E-Time++) respectively, and i indicates the number of routes generated for bins collection. On the other hand, Figure 11 illustrates the waste to be collected according to the optimal route extracted using pattern (B), with equation (1), and alerts index $VAR < 50\%$. Both filled and half-filled bins (red and yellow colors) were alerted for collection and emptying. In this case, $C_i = [20\ Km/h,\ 11.55\ Km,\ 1h44m]$ was obtained as the waste-collection cost and expenses.

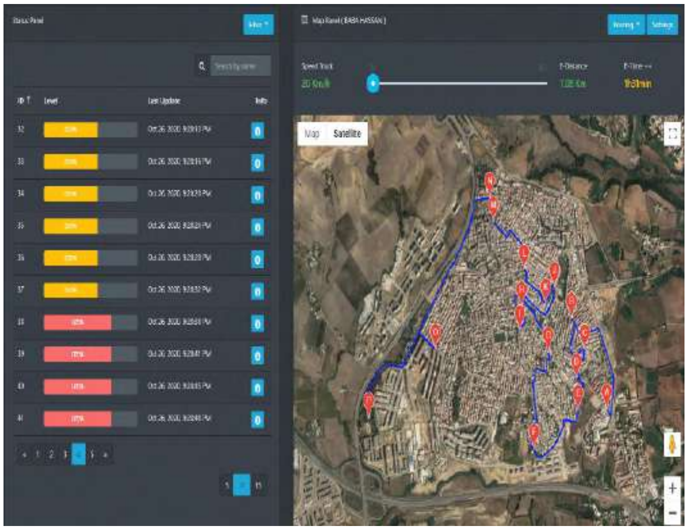

Fig. 10. Control panel from I-Bin platform, DRM-optimal route map through Pattern-A.

From the above, waste collection via DRM roadmap based on pattern (B) required more expense in terms of distance and time consumption compared to pattern (A). Meanwhile, using pattern (B) improves the efficiency of the collection in terms of number of bins collected daily, resulting in further improvement of waste collection and monitoring. In order to effectively monitor and collect accurate data in real-time and help reduce operating costs, the optimal route can be set auto mode to alert for waste collection based on VAR measurement. Moreover, the optimal routing can also be set manually according to the needs of waste management user.

C. Dynamic Scheduling

Besides the above, the added value is also the developed model for dynamic routing and prior planning that helps in dynamic scheduling and better system management. In addition to specifying a time or set of times when a certain route is run, the dynamic planning system provides three subsystems, related to personnel, trucks, and tasks to support collection, management, and reducing waste costs.

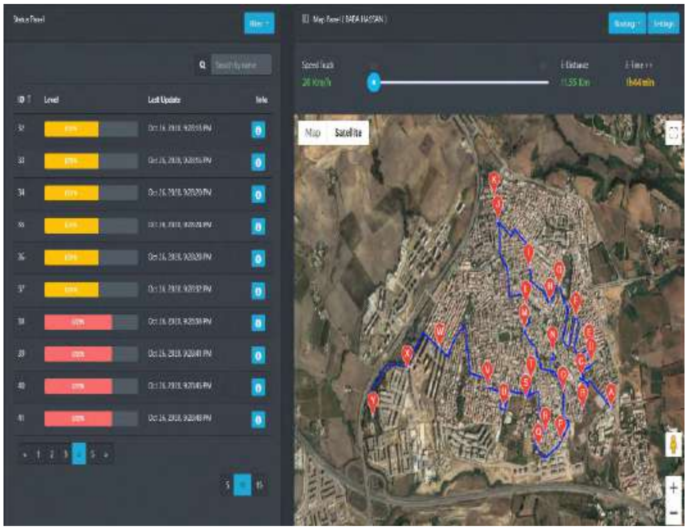

Fig. 11. Control panel from I-Bin platform, DRM-optimal route map through pattern-B.

So far, hardware implementation is the critical challenge with many issues such as (1) scarcity of various high-quality components required, (2) real-time fault reading has emerged with many components of detection, (3) the system tested and limited to only 50 bins, and more challenges will arise when it comes to managing more bins, (4) IoT-enabled technology directly affected by power consumption, prompting consideration of enabled solar charging for future use.

VI. Conclusion

This article discussed practical IoT-enabled monitoring solid waste management system to be implemented in the city of Baba Hassen (Algiers), combines the use of outdoor bins with remote fill level sensor technology for triggering of smart collection when outdoor bins are full or almost. The waste level in each bin sensed and transmitted to a central management platform can be accessed remotely in any web browser to perform the collection process. The system provides route details to the collection truck fleet management system, allowing drivers to focus on routes with most bins of optimum fill levels for collection. Using the I-Bin platform, city authorities can now explore avenues for smart waste management using the power of technology, resulting in cost reduction for waste management, automation, and optimization of daily activities, simultaneously improving services and avoiding bins overfilling on street. Future work includes; (1) seamless integration of smart bins with a cloud-based web application in order to avoid delays in the internet service of mobile operators, and (2) develop mobile apps through which citizens can report incidents and locations of illegal or abandoned waste.

***Abstract*—Real-Estate rent prediction in housing market analysis plays a key role in calculating the Rate of Return - a salient index used to evaluate real-estate investment options. Accurate rent prediction in real estate investment can help in generating capital gains and guaranty a financial success. In this paper, we carry out a comprehensive analysis and study of seven machine learning algorithms for rent prediction, including Linear Regression, Multilayer Perceptron, Random Forest, KNN, Locally Weighted Learning, SMO, and KStar algorithms. We train new model for the US territory, including three house types of single-family, townhouse, and condo. Each data instance in the dataset has 21 internal attributes (e.g., area space, price, number of bed/bathroom, rent, school rating, so forth). A subset of the collected features selected by filter methods for the prediction models. We also employ a hierarchical clustering approach to cluster the data based on two factors of house type, and average rent estimate of zip codes. The empirical results suggest that the rent prediction models based on lazy learning algorithms lead to higher accuracy and lower prediction error compared to eager learning methods.**

***Index Terms*—housing analytics, applied machine learning, rent prediction, data mining**

I. Introduction

Real estate rent prediction has a key role in calculating the Rate of Return- a measure used to evaluate the performance of an investment in the housing market. Rate-of-Return can measure the quality of a real estate investment over a time-period and has two important factors: *Net Present Value and Future Value*.Proper rental property investments can lead to a successful and profitable Rate of Return over time. However, such ventures can be very risky due to miscalculation or inaccuracy of algorithms used in rent prediction. Applying machine learning algorithms to perform house rent prediction is not a novel trend. Lambert and Greenland [1] investigate eager learning methods like Multi- Layer perceptron, and bagging REP trees to estimate the rental rate for both the land-owners and students interested in renting a place close to a university campus. The training set contains two property types: *i)* apartment and *ii)* condo. The coverage area of the training set is limited to three distant zip codes surrounding a university campus. The input features entertained in this work include proximity to university campus, apartment appliances (like Cable TV) and dimensions, the length of the apartment contract, and the date of the residence's constructions. The study reports bagging REP trees as the best rent prediction algorithm. However, the proposed global learning-based solution can generate a biased model due to the skewed data set, all located surrounding a university campus.Machine learning models can be used in social sciences [2]–[4] [5] [6] and provides more view about peoples opinion about housing market. Transfer models can provide more powerful insight about house price prediction [7]–[9]

Machine learning models have advanced applications in health [10]–[12], cyber security, computer hardware [13], [14] and computer science [15]–[17] [18], [19]and business [20], [21]. In the previous studies, the prediction models for real estate rent/price prediction are very generic and they don't differentiate according to the house type and/or zip code [22]–[24]. For instance, a generalized prediction model is proposed by [25] for city-wise scope of data, to predict rent and house prices. However, this can lead to inaccurate predictions. Rent behavior is different, even for the real estate properties which are in the same state/city or a close geo-spatial proximity from each other. For instance, the zip codes 22066 and 20190 are neighbors but they show a very different behavior in terms of the average rent price. In addition, statistical data shows that house type parameter affects the rent price due to internal factors like area space, number of bed/bathrooms, HOA fee, community factors, so forth.

The average rent price for a zip code depends on internal factors (like house type, number of bedroom/bathrooms, house price, area space, other) and external factors. In fact, external factors like crime rate and school ratings corresponding to a zip code impact the price of rent and are deal-breakers for many real estate investors [26]. In this paper, internal house properties as well as external attributes like walk score, transit score, crime rate, and school rating are entertained. Walk score indicates the errands that can be accomplished on foot or those that require a car to nearby amenities. Transit score indicates the connectivity (i.e., proximity to metro), access to jobs, and frequency of service [27]. Crime score indicates the rate of violent and non-violent incidents related to a zip code [28].

In the past studies, the impact of eager learning methods for real estate rent/price prediction has been investigated [1]. In general, unlike eager learning methods, lazy learning (or instance learning) techniques aim at finding the local optimal solutions for each test instance [29], [30]. Friedman, Kohavi, and Yun in [29], and Homayouni, Hashemi, and Hamzeh in [30] store the training instances and delay the generalization until a new instance arrives. Another work

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

carried out by Galv´an et al. [31], compares memory-based (or locally) learning vs neural network methods, and report the superiority of memory-based (i.e., lazy) learning method over Neural Network approach using multiple data sets of UCI machine learning data set repository, including Iris, Diabetes, Sonar, Vehicle, car, and balance. In this study, the two lazy learning algorithms, namely Integer Part and Atomic Radios outperformed eager learning algorithms, namely SMO and Naive Bayes algorithm. Our work is inspired by these research explorations.

We collected a Zillow data set of 600K real estate properties in Virginia State. In addition, transit score, walk score, and crime rate are collected from information sources like alltransit.cnt.org, walkscore.com, and crimereports.com respectively. Transit parameters entertained in the data collected from AllTransit data source clearly indicates the proximity to metro as a significant parameter in determining the transit score of a location.

The data set consists of three house types: *town-house*, *single family*, and *condo*. This study is motivated by the need to build models with respect to house type and zip code. To deal with the sparse (i.e., thin) data in every zip code, we divided the data set according to house type, and then applied K-means clustering to generate subsets of instances within zip codes with similar average rent prices. The clustering method uses the similarity measure of *average-rent* to compute the distance between the data points. The data samples in each cluster is later used to train a rent prediction model.

In this work, we study the impact of several machine learning methods on this data set by performing a comparative analysis of lazy vs. eager learning methods. We report the empirical results to show the superiority of lazy learning algorithms over eager learning methods in real-estate rent prediction for each house type and a subset of zip codes with similar average rent prices. We examine the performance of Linear Regression (LR), SMO, Multilayer Perceptron (MLP), and Random Forest (FR) algorithms (eager/globally-based learning) against KNN, locally weighted learning (LWL) and K-star (K*) algorithms (lazy/memory-based learning), using three performance evaluation metrics: i) R-squared , ii) Mean Absolute Error (MAE), and iii) Area Under ROC Curve (AU-ROC). The target variable is the rent price and the evaluation metrics show the variance between the predicted target variable and the actual rent price.

Our rent prediction algorithm uses a salient subset of data set attributes, which is determined during feature selection using Principal Component Analysis technique (PCA). PCA technique filters out unwanted features based on each house type (i.e., single family, town house, and condo), and independent of the learning algorithm applied on the data.

For imputation, we removed the observations with many missing attributes as the proportion of these instances to the entire data set was less than 3%.

The remainder of this paper is structured as follows: In section II related work is discussed. We describe the data set used in this paper for analysis in section III. Section IV describes our methodological framework including data preprocessing, data exploration and feature selection, building prediction models, and model evaluation. In section V, experiments and results are discussed. Finally, section VI gives the conclusion.

II. Related Work

Real estate rent/price prediction using machine learning techniques has already been studied in several works [22]–[25]. In [32], PSO-SVM algorithm is used for real- estate price prediction. In [33], [34], spatiotemporal dependencies between housing transactions is used to predict future house prices. However, this approach is limited by spatial autocorrelation, since the degree of similarity between observations is not solely based on the distance separating them.

Some of the previous work focus on hedonic price models as a method of estimating the demand and value in the housing market and determination of house prices [35], [36]. In these studies, rather than internal and external house features, economic submarkets are used in the prediction model which are defined in terms of the characteristics of neighborhoods or census units. In [22] a sample size of 200 houses of all house types in New Zealand were used in a hedonic price model and an artificial neural network (ANN) model, and shows that the eager method ANN outperforms the hedonic model. The problem with the hedonic approach is disregarding the differences between the properties in the same geographical area.

Park and Bae in [37] determine the house sales trends of the US housing market subject to the Standard & Poor's Case-Shiller home price indices and OFHEO which is the housing price index of the Office of Federal Housing Enterprise Oversight. The authors used and compared the classification accuracy of four methods C4.5, RIPPER, Naïve Bayesian, and AdaBoost, where RIPPER algorithm outperformed others.

We are now at the age where people in different fields are hacking their way into machine learning. Machine learning techniques have become available as commodities which can be used to perform prediction and classification tasks in various domains like real-estate rent/price prediction. Bin Khamis and Kamarudin in [20] compared the efficacy of the eager learning method Neural Network (NN) against the hedonic model Multiple-Linear Regression (MLR), and showed that NN outperforms MLR. However, Galv´an et al. in [5], reports the superiority of lazy learning methods over NN.

According to [38], eager learning methods can sometimes lead to suboptimal predictions because of deriving a single model that seeks to minimize the average error over the entire data set, whereas lazy learning can help improve prediction accuracy. While our study is inspired by [31], [38], we take our analysis to the next level, by comparing the impact of eager and lazy learning algorithms in the prediction accuracy of the generated models with respect to each house type and a subset of zip codes with similar average rent prices. We use a two- layer clustering technique, and a subset of internal and external real-estate property factors.

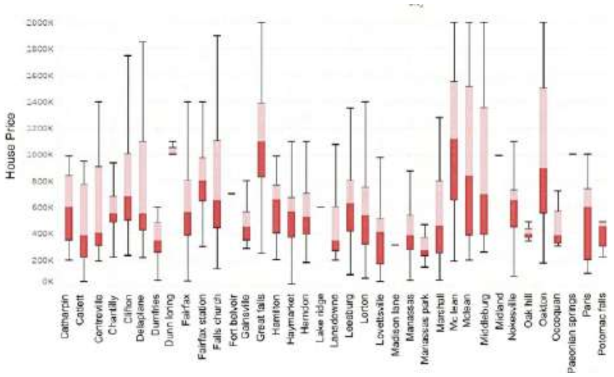

Fig. 1. House Price Distribution

III. Data set description

There are variety of housing data sources in the real estate market. Zillow API [39] delivers home details including historical data on sales prices, year of sale, tax information, number of bed/baths, so forth, for the US territory. In this paper, we used the Zillow API to collect a data set of residential housing data for the state of Virginia. The size of this data set contains about 4000 housing property records (including townhouse, single-family, and condo) with 21 attributes. In addition, external attributes, namely walk score, transit score, and crime rate are collected.

We collected transit score data from AllTransit data source [27]: their dataset is collected from 824 agencies, and it includes 662K stop locations and 13K routs. Transit and walk scores are collected per household, while crime rate is obtained for each zip code , normalized by the number of people living in that area [40] using Selenium tool with Python. Crime score data was normalized using Dickson method [40] indicated by equation (1):

$$Incident_{norm} = \frac{CrimeIncidents}{population} * 100,000 \tag{1}$$

We obtained zip code-wise population by collecting data from *www.moving.com*.

IV. Methodology

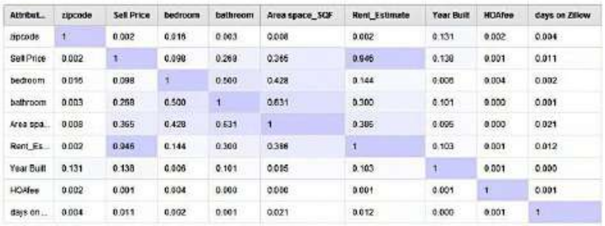
A. Data Preprocessing

One of the rudimentary principles in calibration of machine learning models when dealing with a biased data is to re-sample the data to balance them [41]. Some of the areas have much higher densities compared to other areas. To normalize the data, we re-sampled the data in zip codes with higher house prices due to their crowded density relative to the zip codes with lower house prices.

For imputing the missing values of external attributes, we used K-means clustering and KNN. The distances between data points is calculated with respect to each cluster centroid.

To reduce the dimensionality of the data set and enhance the generalization of the model, we perform feature selection by applying PCA (principle component analysis) to all 21 attributes of the data set. However, before applying PCA, attributes are normalized based on Min-Max Normalization, using equation (2):

$$X_{norm} = \frac{X - X_{min}}{X_{max} - X_{min}} \tag{2}$$



Attribut...	zipcode	Sell Price	bedroom	bathroom	Area space_SQF	Rent_Estimate	Year Built	HOAfee	days on Zillow

Fig. 2. Correlation matrix based on house features

B. Data Exploration

Figure 1 shows house Price Distribution for the state of Virginia We analyzed the correlations between various variables of the data set to identify the co-linearity between the variables. Discovering co-linearity between the data set variables and the target variable yields valuable insights about the dependent variables that affect the rent price. Figure 2 illustrates the co- linearity between the data set attributes in the VA data set. Since zip code is a nominal attribute, there is no collinearity between zip code and rent price. Also, there is a strong dependency between rent and internal attributes like number of bed/bathrooms, area space, year, and sale price. In addition, there is a correlation between average rent price and urban planning parameters (external attributes) of walk/transit-score and crime-rate. The general trend indicates a positive correlation between average rent and walk/transit score, and a negative correlation between the average rent and crime rate across multiple zip codes.

We hypothesize that there is a rent prediction model for every house type within a zip code/similar zip codes. To test this hypothesis, we carry out the following analysis:

Prior to attribute selection, to obtain a suitable representation of the data set, we apply PCA (principle component analysis) to the 21 data set attributes. The attributes consist of ZipID (a unique id for each house in the Zillow API), Number of bed/baths, floor size (the area of the house based on SQF), latitude and longitude (geographical location of each house), year built (the year of house construction), status (house type), zip code, house features (facilities in a house described by owner), estimated rent (basic amount of rent price for each house used as a class label in the prediction task), so forth.

Since zip code and house type are nominal attributes, there is no collinearity between the rent price and these two attributes.

C. Feature Selection

To identify important attributes, we apply PCA (principle component analysis) - which is a well-known and studied method- on three subsets of data samples, each subset covering a different house type across all zip codes in the state of Virginia. This is illustrated in Figure 3.

unlike town house and condo, features like HOA fee, walk score, and transit score show a very low variance for single family instances. The higher variance of transit score, especially for condos, explains the outpacing of median appreciation rates of condos compared to single family detached-houses in large metropolitan areas [42]. Number of bedrooms is found to be an important feature only when house type is single-family or town-house. Next, unlike town-house instances, average school rating is discovered to be an important feature for both single-family and condo instances. This can be explained due to sparsity of school rating for town-house instances in our data set. In our future work, we will employ data mining techniques to obtain this information for town-house instances.

We validated the above mentioned strategy by training our models based on a data set including all house types, and then based on each house type. We discovered that the latter approach leads to relatively higher accuracy and lower prediction error.

D. Data Clustering

First, we cluster the housing data set based on house type and zip code attributes, to eventually learn a model for each cluster. However, we observed that the some of the clusters are very sparse with the number of instances below 100, which could immensely affect the ability to train the prediction models [43], [44]. To increase the density of the training samples and facilitate the accuracy of prediction models at the same time, we carried out a different strategy, first, we divided the data set into three groups based on the house type attribute. We refer to these groups as status-clusters. Next, we calculated the average rent for every zip code in each status-cluster. Furthermore, we applied K-means clustering to cluster the content of each status-cluster based on the average-rent. Using this clustering technique, we increased the density of the training samples.

1) Problem Formulation: Given a $status - cluster_j$,$i = (sf, th, co)$ where sf=single-family, th= town-house, and co=condo with a set of observations $(o_1, o_2, \cdots, o_m)$ where each observation is a d_i dimensional vector, K-means clustering partitions the observations into $n(n = k, h, gs.t., n \ll m)$ sets S.

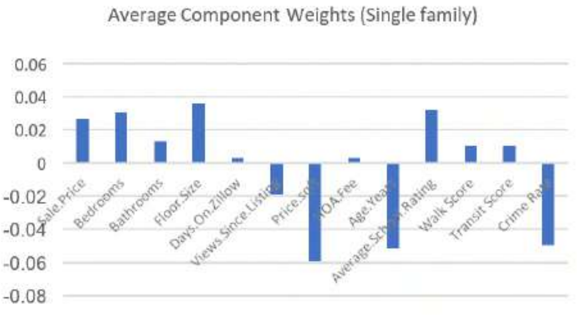

Fig. 3. The PCA plot for single family

Clustering the data points according average-rent implies organizing instances of similar zip codes inside the same cluster, e.g., cluster s_j. The next task is to train a model for each cluster s_j: $s_j \rightarrow Learner \rightarrow f_j$, such that f_j is a rent prediction model. In this study, we build rent prediction models with respect to each house type and a subset of zip codes with similar average rent prices, using two eager and two lazy learning algorithms.

2) Data Partitioning: In our experiments, we use 10-Fold Cross-Validation to partition the training data set into 10 equal parts. During each round of 10 iterations, we repeat the prediction by using one of the 10 parts as test data and the other 9 parts as training data to create a prediction model. Next, we select the model with the best accuracy. We then evaluate the rent prediction model on the test data set that covers 30% of the entire Virginia housing data set collected from Zillow website.

The important attributes determined during feature selection are used as input of the above-mentioned models to predict the target variable *rent price*.

E. Model Evaluation

The key comparison measure used for regression analysis and model evaluation described in this section uses three different measures: i) Mean Absolute Error (MAE), ii) R-squared, and iii) Area Under the Receiver Operating Characteristics curve (AUROC or AUC). MAE measures the accuracy of the prediction models over the test data set. R- squared (or the coefficient of determination) is a quadratic statistical scoring rule which shows how close the actual target data are to the fitted regression line. R-squared is used in the paper to show the variance between the predicted target variable and the actual rent price. Hence, the lower MAE and the higher R-squared, the better our model fits the data. The ROC curve [45] is a graphical technique to visualize the performance of prediction models and selecting the best model based on their performance. AUROC measures the accuracy of a prediction model. Based on these evaluation metrics, we calculate and compare the efficacy of the produced rent prediction models for seven machines learning algorithms MLP, RF, LR, SMO, LWL, KStar, and KNN based on the hierarchical clustering . For KNN's combination function, we used simple unweighted voting for K=3, based on Euclidean distance. The comparison of MAE and R-squared is illustrated in figure 4 and figure 5.

V. Experiments and Results

This section discusses the result of our experiments carried out to evaluate and compare the performance of MLP, RF, LR, SMO, LWL, KStar, and KNN algorithms. According to table I, KStar algorithm outperforms the other algorithms. KStar shows the lowest variations(R-squared) and highest accuracy (MAE) compared to other algorithms tested in this work. Based on the overall measure of the fit of the model, we compare the best of eager methods with that of lazy methods. Among the eager methods tested, LR and RF show the highest accuracy, and LR shows the lowest variance (R-squared),

TABLE I
MACHINE LEARNING MODELS PERFORMANCE

Algorithm	**Single-Family**			**Town-House**			**Condo**		
	R-squared	***MAE***	***AUROC***	***R-squared***	***MAE***	***AUROC***	***R-squared***	***MAE***	***AUROC***
MLP(eager)	1373.4	410	0.865	150.4	105.4	0.913	218.8	152.4	0.896
RF (eager)	543.2	322.7	0.924	250.48	109.7	0.937	525.1	109.3	0.914
LR (eager)	497.004	294.1	0.853	119.230	83.37	0.941	156.9	112.7	0.891
SMO (eager)	1114.76	342.02	0.881	234.06	98.02	0.891	178.2	254.1	0.746
LWL (lazy)	489.6	299.2	0.951	146.96	98.1	0.951	260.3	121.4	0.905
KStar(lazy)	150.0	91.7	0.971	86.4	49.3	0.981	194.3	103.2	0.965
KNN (lazy)	167.0	321.065	0.89	140.00	97.15	0.912	101.1	110.78	0.907

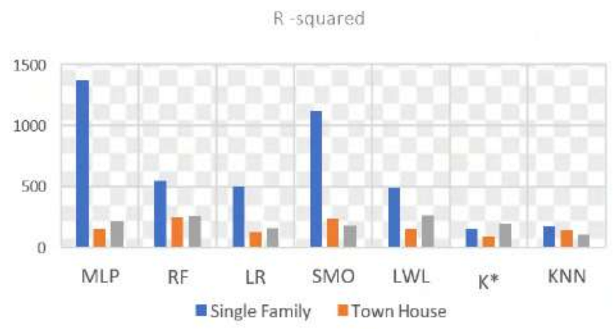

Fig. 4. Model performance for single family and townhouse

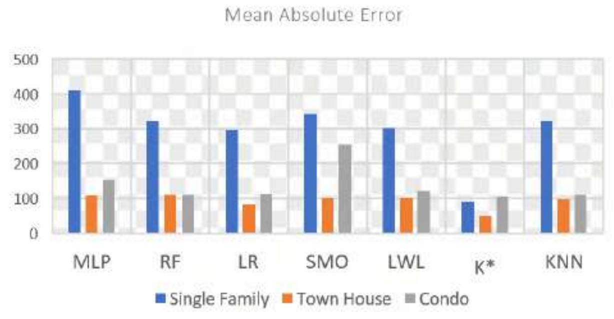

Fig. 5. Comparison of Model performance

while KNN and KStar show the minimum variance among the lazy methods. In addition, KStar shows the highest accuracy compared to other ML methods tested in this work. In fact, KStar algorithm decreased the prediction error by 69%, 41%, and 8% for single-family, town-house, and condo respectively, compared to LR method. Also, KStar decreased the prediction error by 71%, 55%, and 5% for single-family, town-house, and condo respectively, compared to RF method.

Finally, KStar decreased the prediction error by 71%, 49%, and 6.8% for single-family, town-house, and condo respectively, compared to KNN method. Based on figure 5 the low variations of MAE measure across different algorithms for the town-house records compared to single-family and condo is happening due to skewness of the data set: the number of single-family properties, and then condo, dominate the data set compared to town-house records, which indicates the skewness of the data set. In addition, according to Table I, AUROC for KNN and LWL are very close, while eager version of SMO shows the lowest AUROC among other examined algorithms. The results show that KStar regression model provides the best fit, and lazy learning methods overall, outperform the eager methods. All algorithms perform relatively well when it comes to the town-house data.

This result can be explained due to insufficient data in terms of internal/external features, and the number of observations. For instance, the single-family houses with the rent price above $9K in cities like Fairfax and Gainsville are very sparse and listed as "home-office by the owner to rent to doctors; these houses are rented as "home-office" with the medical equipment inside the rental property. We observed that for town-house records, the performance of the learning method LR is very close to KNN lazy learning method.

VI. CONCLUSION

Eager learning methods build a prediction model using the entire training set which is later used on the test instances to evaluate the performance of the model. While eager learning methods tend to extract the general properties of data and minimize the global error, lazy learning methods select the most appropriate samples in the learning process, and minimize the local error.

Based on our experimental study in the domain of real-estate, well-known Lazy learning methods can surpass eager learning algorithms in rent prediction problem for each house type (single family, town-house, and condo) in our housing data set. We examined KStar, KNN, and locally weighted learning models as the well-known representatives of lazy learning methods, and compared them with MLP, LR, SMO, and Random Forest eager learning algorithms. The results indicate that the behavior of eager learning methods can negatively affect the generalization capability of these models.

Given that deep learning methods work well on high dimensional data, we plan to employ natural language processing tools to extract metadata from property owner comments in Zillow website, and increase the number of attributes. We also plan to investigate the prediction accuracy of deep learning models like Neural Network.

***Abstract*—Link prediction is an important task in many domains, including health sciences, biology, recommender systems, social networks, and many more. It is one of the problems residing within the intersection of knowledge graphs and machine learning. Link prediction aims to discover unknown links between entities in a graph using various techniques. However, due to the size of knowledge graphs today and their complexity, it is a challenging and time-consuming task. In this work, we present RegPattern2Vec, a method to effectively sample a large knowledge graph to learn node embeddings, while capturing the semantic relationships between graph nodes with minimum prior knowledge and human involvement. Our results show that the link prediction using RegPattern2Vec outperforms related graph embedding approaches on large-scale and complex knowledge graphs.**

***Keywords*—knowledge graph, link prediction, machine learning**

I. Introduction

Today, knowledge graphs (KG) are gaining popularity in many domains. KGs can be stored and represented using standardized vocabularies, including Resource Description Framework (RDF), Web Ontology Language (OWL), and various graph databases that are rapidly gaining popularity, nowadays. Today, KGs often are very large and represent vast amounts of actionable data and researchers and computing practitioners have turned to graph data mining to leverage the KG data even further.

Recently, machine learning (ML) has been gaining popularity due to numerous successful applications in many different domains, including graph mining [1], image and video processing [2], [3], text mining [4], reinforcement learning [5], and many others. It is also applicable to data mining of KGs. Software systems can automatically discover interesting patterns in KGs, while not being explicitly programmed to achieve that task. There are various types of learning algorithms, such as supervised and unsupervised learning, reinforcement learning, and many more. Classification and clustering are some of the most popular algorithms for machine learning on KGs. Experts take advantage of different algorithms to create recommendation systems for social media networks, entertainment libraries, find similarities in bibliographic networks, and many more.

KGs in nature are similar to Heterogeneous Information Networks (HIN) [6], where a variety of node and/or relation types between are used to represent data. This diversity of types provides benefits for learning, as compared to Homogenous Network, where types of nodes and relations are uniform. Finding appropriate methods to capture this extra information and use it in ML algorithms is a significant challenge.

Another major area, in the intersection of machine learning and KGs, is KG completion and, more specifically, link prediction. This problem has two aspects: predicting the missing links. KGs are usually populated automatically using variety of internal and external resources and due to the incompleteness of those resources, there might be some known links that are missing in populated KG. Here, one task of machine learning methods is to find those missing links and suggest that there should be connections between them.

As the graph analytics techniques are computationally expensive, especially on large graphs, researchers often aim to reduce the dimensionality of a graph into a low dimensional space. Graph embedding aims to preserve the structure of the graph while representing it as low dimensional vectors [7].

Based on [7], there are six different categories to generate vectors from a graph. These include matrix factorization, deep learning, edge reconstruction-based optimization, graph kernels, generative models, and hybrid models. In this work, we use a deep learning approach, in which random walks are used to sample the graph. This approach is based on a family of models from Natural Language Processing (NLP) called word2vec [8]; we specifically use the modified version of skip-gram model [9] in producing the vector embeddings. Skip-gram attempts to find the semantic similarity between words in a context by learning a meaningful representation for each word used in sentences in a corpus or documents. The main intuition is that we can discover the meaning of a word by understanding other words appearing close in a sentence. In the basic word2vec approach, the algorithm accepts a sentence and considers a window, usually of size 5 to 10, around the word of interest (center word) and generates training examples for a simple Neural Network (NN) with one hidden layer. The training examples are pairs of the center word and each of the words within the window size (context words). Then it trains the Neural Network to maximize the probability of a context word, given a center word. Then, the

weights in the trained network are used as embeddings for each word in the corpus dictionary.

In this paper, we adopted this NLP method to our novel graph flattening approach using regular expressions to produce vector representation for the nodes in the graph. We formulate the link prediction as classification problem, using a model trained on the vector embeddings of the pairs of nodes connected by the link of interest. Our method, which we call RegPattern2Vec, shows high accuracy and discovers interesting possible links between unlinked nodes in the graph.

II. RELTED WORK

Past research includes several approaches to capturing the semantic relationship between graph nodes. Matrix factorization-based methods generate embeddings by factoring the matrix that represents the relations between nodes [10]. The matrix can be an adjacency or a Laplacian matrix, among other methods. Another technique that is used to generate vector embeddings, is Graph Kernels. Graph kernels are a measure of similarity of pairs of graphs. For example, [11] uses graph kernels for subtrees and similarity of instances in the original graph by counting common structures. Intuitively, vector embeddings of nodes with similar structure in a subtree are closer to each other.

Generative models are also popular as a graph representation learning method. The generative and discriminative models play the minmax game, where the generator approximates the connectivity of a graph and a discriminator calculates the probability of edge's existence. They are used to perform link prediction and node classification [12]. Finally, we discuss two approaches that can be classified as Deep Learning (DL) methods. DLs using random walks, such as metapath2vec [9], and DLs not relying on random walks [13] and [14], utilizing other techniques for computing vector embeddings. Whether employing minimization of Margin-Based Ranking Loss for entities or constructing a multilayer graph with structural similarity of all nodes in level of hierarchy, their goal is to translate the graph to a low dimensional space, where it can be used for applications such as link prediction or node classification. It is worth mentioning that there are other techniques such as using Convolutional Networks [15] and Autoencoders [16], which we do not discuss in this section because they fall into an entirely different type of methods. Generally, most GCN approaches suffer from scalability problems when the graph is large and dense due to the number of parameters and so are impractical to use. Therefore, different type of approach with a smaller number of parameters and hyperparameters will be required to large KGs such as approaches to sample the graph and learn representation in more efficient way, which will be discussed next.

Since in our method we rely on deep learning using random walks, we will focus on similar approaches in greater detail. As the computation of all possible walks on a graph is computationally expensive, researchers tend to choose random walks on the graph using some probability distribution. This would be sufficient for walks on homogenous networks. However, in heterogeneous networks with multiple types of nodes and edges, we need to differentiate types of nodes/edges when selecting the next node. Metapath2vec++ [9] is an approach that considers a fixed path of node types, which is called a meta-path. For instance, on a DBLP computer science bibliographic dataset [17], the meta-paths APA, APVPA, and OAPVPAO were chosen, where A represents the author, P paper, O the organization, and V the venue. These meta-paths are used to bias the random selection of the next node with the appropriate type in a random walk. Although some results of automatically discovering meta-paths have been published [18], usually domain experts are needed to choose the meta-paths of their interest for random walks. A domain expert should fully understand the KG organization. Although some tools for a KG schema discovery exist, such as KGdiff [19], due to the complexity of KGs and the hierarchy of concepts in them, it becomes difficult and time consuming to create appropriate meta-paths. Their selection should consider several aspects, e.g., the problem we want to solve (node classification, clustering, etc.), either the selected subgraph or the whole KG, and the meta-path coverage within it (number of nodes that can be reached using meta-paths/meta-graphs). Although the meta-path approaches on HINs were often used for various tasks, they are not useful for capturing more complex relations among entities. Each type of node must be explicitly defined or the meta-path does not capture the variation of attributes linked to the nodes. [20] proposed meta-graphs, which in a nutshell are meaningful combinations of meta-paths. For instance, if there are two meta-paths as APA, AVA, a possible meta-graph would be A-[P/V]-A. The use of meta-graphs as constrained to random walks was tested in [21], but the choice of meta-graphs where they can improve the overall model poses another challenge. To overcome these weaknesses, we introduce RegPattern2Vec, where a regular expression guides the random walks to sample sequences of nodes in a more efficient way, especially for large KGs. where other methods fail due to the lack of scalability. The embeddings produced by our representation learning captures all of the necessary characteristics of each node to be used for high accuracy link prediction.

III. PRELIMINARIES AND PROBLEM DEFINITION

In this section, we first introduce some preliminary concepts and then define the problem of Link prediction on KGs using Random Walks constrained by Regular Expressions. As of this writing, a single, commonly accepted definition of a knowledge graph does not exist, yet, and many researchers provide their own definitions. A good analysis is of KG definitions has been presented in [22], [23]. Here, we will use graph-based definition.

Knowledge graphs. A knowledge graph (KG) is a directed graph $\mathcal{G}: (\mathcal{V}, \mathcal{E})$ whose nodes $v_i \in \mathcal{V}$ are entities and edges $e_i \in \mathcal{E}$ are relations connecting the entities. Edges, usually referred to as triples of the form (v_i, e, v_j), represent some type of semantic dependence between the connected entities. Nodes have an associated type mapping function $\phi : \mathcal{V} \rightarrow \mathcal{T}$, where $\mathcal{T}$ denotes a node type, while edges have an associated type mapping function $\varphi : \mathcal{E} \rightarrow \mathcal{R}$ where $\mathcal{R}$ denotes a relation type set.

Given a knowledge graph G, an edge with a relation type R connects source nodes of type S and target nodes of type T defines a meta edge $S \xrightarrow{R} T$. A set of all such meta edges for G is called a *schema graph* (sometime referred to as *meta-template*). In fact, schema graph is a directed graph defined over node types $\mathcal{T}$, with edges from $\mathcal{R}$, denoted as $G_S = (\mathcal{T}, \mathcal{R})$ [24].

Knowledge graphs are often represented as RDF [25] datasets, where nodes (entities) and relationships are represented using Uniform Resource Identifiers (URI). Nodes and relationships have assigned types, given as URIs, as well. Furthermore, these types may form type hierarchies. RDFS [26] is often used to define a schema for an RDF knowledge graph. Knowledge graphs are closely related to Heterogeneous Information Networks (HIN). In HINs, object (node) and relationship *types* both contain more than one element, that is, there are multiple labels for graph nodes and multiple labels for edges. In case that type sets are singletons, the Information Network is called a Homogeneous Information Network (all nodes in the network are of the same type and all edges are of the same type).

Despite the obvious similarity of KGs and HINs, there exist important differences between them. An important distinction is that in HINs, a relation of type $R \in \mathcal{R}$ uniquely determines the types of source and target nodes that can be connected by the relation R. In knowledge graphs, however, a relation of type R may connect nodes of many different source types and target types. Many other differences KGs and HINs exist, but they are not important for the research presented in this paper.

It has been shown that the results of various graph-embedding tasks are sensitive to the selection of a specific meta-paths [27]. In this paper, we propose a method of using regular expressions as a specification of a wide range of semantic relationships to be incorporated in random walks.

Regular Patterns on KGs. Let G be a knowledge graph, $G = (\mathcal{V}, \mathcal{E})$, with a node type mapping function $\phi : \mathcal{V} \rightarrow \mathcal{T}$ and an edge type mapping function $\varphi : \mathcal{E} \rightarrow \mathcal{R}$. A Regular Pattern on G is a regular expression (pattern) [24] *r* formed over either set $\mathcal{T}$ or $\mathcal{R}$ as the alphabet.

We will not formally define regular expressions, since they are commonly used in computing, today. Briefly, a regular expression defines a set of strings (sequences, or words) over an alphabet; it defines a regular set [24]. We assume a standard format of regular expressions used in many programming languages today, for example in Python [28]. Here, we will only use a subset of possible regular expression constructs, including the concatenation, the alternative (**|**), repetitions of zero or more times (the Kleene star *****), one or more times (+), specified number of times ({n, m} n through m, and {n,} at least n), and the complement matching [^xy] (any symbol other than x or y). Note that a meta-path, as defined in the metapath2vec algorithm [9], can be regarded as a regular expression over $\mathcal{T}$ (or $\mathcal{R}$) since it can be regarded as a concatenation of node (or relation) types placed on the meta-path (again, a relation in HINs uniquely determines the source and target node types and vice-versa).

As an example, given node types $T_i \in \mathcal{T}$ in a KG, we could formulate a variety regular patterns over node types, for example, $T_1\ T_2\ T_3$, $T_1\ (T_2 \mid T_3)\ T_4$, $(T_1 \mid T_2)\ T_3$+ T_4, any many others. Similarly, given edge types $E_i \in \mathcal{R}$ in a KG, we could create regular patterns over edge types, such as $[\text{^}R_1]\ R_2\ R_3\text{*}\ R_4$ or $R_1\ (R_2 \mid R_3)\text{*}\ R_4$. Intuitively, a regular pattern defines a set of node (or edge) type sequences (a regular set), which we use to bias random walks on a KG to follow semantically relevant data.

Many knowledge graphs utilize complex hierarchies of node (entity) types such as Yago[29], DBpedia[30], and NELL[31]. Consequently, defining regular patterns based on node types is impractical, as they would require costly type inference (node types in actual sampled walks could be subtypes of those included in the defined regular pattern). Hence, using regular patterns on edge types may be a better choice.

In this paper, we focus on link prediction and so we rely on a specific general format of regular patterns for biasing the random walks. Assume that given a KG, we need to predict an edge (*h, r, t*), where h, t $\in \mathcal{V}$, r $\in \mathcal{E}$, $\phi(h) = H$, $\phi(\text{t}) = T$, and $\varphi(\text{r}) = R$. If the KG has a simple (non-hierarchical) structure of node types, our expression pattern can be based on node types and have a general format $\boldsymbol{H[\text{^}T]\text{+}\ H\ T}$. However, in a KG with a large node type hierarchy, we use edge-based patterns with the general format of $\boldsymbol{[\text{^}R]\{2,\}\ R}$. That is, at least 2 edges with relation types different than the one to be predicted followed by the edge relation type to be predicted.

The intuition behind the above regular (expression) pattern formats primarily comes from the observations of meta-paths and meta-graphs, where the similarity of two nodes is calculated based on the number of paths between them that follow a specific meta-path [32]. While some works [9], [21], [33] use symmetric meta-paths to calculate similarity between nodes of the same type, others [34] use more complex meta-paths for a different types of nodes. RegPattern2Vec follows the latter idea of finding the similarity of nodes with different types, but meta-paths and meta-graphs must be explicitly designed by domain experts and each such meta-path needs to be used in a separate experiment. In general, individual meta-paths cannot capture all possible semantically relevant connections between the nodes of interest. RegPattern2Vec, due to its use of regular patterns cover a large set of meta-path-like connections and takes advantage of a multitude of such semantic connections in one experiment.

We can explain the RegPattern2Vec using a simple example shown in Fig. 1. The graph contains 4 different relations: R1, R2 R3, and R4 (red, green, blue and yellow, respectively). The link that we want to predict is R2. Following the regular pattern, [^R2]{2,}R2, we have R1, R3, R4 ∈ **[^*R2*]**. An example walk following the pattern is $a1 \xrightarrow{R1} c1 \xrightarrow{R1} a2 \xrightarrow{R2} d1$. The intuition is that if we found two nodes (a1 and a2) where they link to another common node (c1), they are semantically related and node a1 might have the relationship R2 to d1, as well, which is useful for the link prediction task.

In the example nodes a1 and a2 have two common nodes b1 and c1 and plus the above path, $a1 \xrightarrow{R4} b1 \xrightarrow{R4} a2 \xrightarrow{R2} d1$ is also allowed based on the regular pattern. It is possible that the intermediate nodes have a relationship with other nodes, such as nodes c1, c2, and c3. These links might be considered as loops within the same type of nodes. If the nodes are the same or different type, a regular pattern can find such path and there is hyperparameter to control number of such possible loop. If this parameter is 1 the path $a1 \overset{R1}{\rightarrow} c1 \overset{R3}{\rightarrow} c2 \overset{R1}{\rightarrow} a3 \overset{R2}{\rightarrow} d2$ is allowed and if it was 2, a walk from node c1 can reach node c3 and the path $a1 \overset{R1}{\rightarrow} c1 \overset{R3}{\rightarrow} c2 \overset{R3}{\rightarrow} c3 \overset{R1}{\rightarrow} a4 \overset{R2}{\rightarrow} d3$ is also permitted. Here, a1 and a2 are more similar than a1 and a4 but it can be beneficial to capture those paths, as well. By this logic, a random walk constrained by a regular pattern can reach different paths to capture more links within the graph, if necessary.

IV. RegPattern2Vec

RegPattern2Vec relies on random walks to produce graph embeddings. Random walks on knowledge graphs are constrained to those matching a defined regular pattern.

A. Random Walks

Random walks in RegPattern2Vec are designed to sample an arbitrary number of walks. Their number can be controlled by parameters, such as "walk length" and "number of walks" (per starting node). Even though the knowledge graphs we use are defined as directed graphs, here, we treat them as undirected. We do this to be able to sample paths from all possible paths according to a defined distribution. Having an undirected knowledge graph and a regular expression pattern, a random walk can be started from any instance of the starting edge (or node) type in the pattern.

A regular pattern is converted to an equivalent Deterministic Finite Automaton (DFA) *M* [24] with the same input alphabet as the one used in the regular expression pattern definition. We will not introduce a formal definition of a DFA here but simply state that a DFA has a finite set of states, an input alphabet, a transition function δ, a starting state, and a set of final states. In our case, the state transition function is defined as δ: S×$\mathcal{R} \rightarrow S$ (or δ: S×$\mathcal{T} \rightarrow S$) and specifies state transitions based on edge (or node) types, depending on the regular pattern expression. We assume that δ is a partial function and for some states, transitions on some relation (or node) types may be undefined. We use the transition function δ of *M* to define the probabilities of node selections in our random walks.

It is obvious that if we repeat the walk from each node, we will discover more paths as the node might link to multiple nodes, which are allowed based on the regular pattern. We will call this parameter "number of walks". We will discuss how to choose the parameter and analysis of their impacts in the next section. As in each step there might be multiple choices, randomization will help the random walk to select a next node in each step. In the scale-free networks, where the degree distribution follows the power law, some nodes, often referred to as hubs, have high number of incoming/outgoing edges. It seems that such nodes would dominate the random walks as they have a higher probability of being reached when the next node selection follows the normal distribution. As the frequency of nodes appeared in the walk is the key point of representation learning, we bias the walks while using a regular expression pattern and its equivalent DFA *M*, using the formula below:

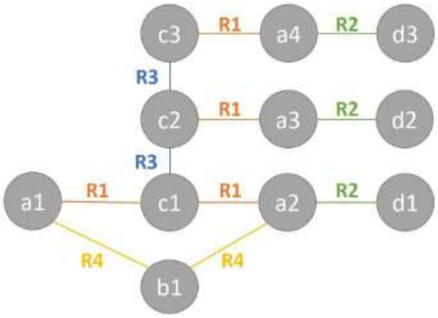

Fig 1. Illustration of random walks using regular expression.

$$P(v^{i+1} \mid v^i, M) = \begin{cases} \dfrac{\frac{1}{|N_{v^{i+1}}|}}{\sum_{v \in N_{v^i}} \frac{1}{|N_v|}} & (v^i, r^i, v^{i+1}) \in \mathcal{E}, M \text{ is in state } s_i \text{ and} \\ & \quad \delta(s_i, \varphi(r^i)) = s_{i+1} \\ 0 & (v^i, r^i, v^{i+1}) \in \mathcal{E}, \text{but } \delta(s_i, \varphi(r^i)) \text{ is undefined} \\ 0 & (v^i, r^i, v^{i+1}) \notin \mathcal{E} \end{cases} \quad (1)$$

(1)

Here, $|N_v|$ is the of degree of node v, v^i indicates the current node and $v^{i+1} \in N_{v^i}$ is the next candidate node, where N_{v^i} is the entire neighborhood of node v^i. Furthermore, s_i is the current state of *M*, that is, after processing the sequence of edge types $\varphi(r^1)\ldots\varphi(r^i)$, and *M*'s transition function from state s_i on edge type $\varphi(r^i)$ is defined and leads to state s_{i+1}. We can easily create a similar formula using a DFA *M* with node types, instead of relation types, as shown in (1). By fine tuning the previously mentioned parameters, this probability distribution will be sufficient to reach as many node as possible (of reachable nodes) to be included in walks, which results in more accurate vector embeddings.

B. Representation Learning

RegPattern2Vec converts the graph into the sequences of nodes and, from this point, we treat the nodes as words in sentences, as produced by random walks. These sentences are used as input to a model, similar to the one used in metapth2vec++ [9], for generating node embeddings. This model is an improved version of the original skip-gram model, as it takes into consideration types of edges (nodes). This allows the embeddings to capture the similarity of edges (nodes) based on their types (often considered as classes) along with their appearance of closely connected nodes, as required by the pattern.

C. Link Prediction

RegPattern2Vec formulates Link Prediction in KGs as a classification problem. Each existing link (or edge) of interest is represented as a vector of real numbers and is treated as a positive example for training the model. We can combine two vectors using Hadamard product and used the resulted vector as features for machine learning algorithm with label as positive. As the negative examples are typically not included in knowledge graphs, we create combinations of pairs of nodes that are not connected by edges in the graph and use them as negative examples, which as a common approach in the published research in this area. RegPattern2Vec uses an element-wise multiplication of vectors as the combination operation, which transforms the pairs of nodes to another space. These examples are used to train a classification model, such as Logistic Regression, which can be used for link prediction.

V. EXPERIMENTS

A. Datasets

In our experiments, we used two popular datasets, YAGO39K [35] and NELL [5]. YAGO39K contains a subset of the YAGO knowledge base [29], which includes data extracted from Wikipedia, WordNet and GeoNames. This subset contains 123,182 unique entities (nodes) and 1,084,040 edges, using 37 different relation types. A histogram of relation type distribution in the YAGO39K dataset is shown in Fig. 2. NELL is a knowledge graph mined from millions of Web documents and contains 49,869 unique nodes, 296,013 edges, using 827 relation types. In contrast to the Heterogeneous Information Networks, both datasets include many edges with the same relation type connecting nodes with many source types and/or many target node types.

B. Link Prediction Experiments

Following the work on link prediction on the YAGO dataset [35], we chose three different relation types namely *isLocatedIn*, *isCitizenOf*, and *isLeaderOf*. Based on the relation to be predicted, we split the KG data, as reported in Table 1. We need to extract some number of edges from each of the three types into three different test sets for three different tasks. To do so, we utilized minimum spanning tree to capture the minimum number of nodes that can be added to the test set while having the nodes in the training set. It is necessary, because our method requires that the node exist in the training data, although the node does not necessarily need to have the edge of interest in the training set. However, it can have other relations with other types of nodes. So, for each task, we extract the maximum number of edges of interest from the graph as the test set, while the remaining edges of interest and instances of other relations are combined to form the training data. We have already discussed how to use the edge of interest in creating the training data with positive and negative examples for a binary classification model. We can follow the same process to make examples for testing in order to evaluate the performance of our method.Following the work described in [5], we chose two relations *CompetesWith* and *playsAgainst* for our link prediction experiments with the NELL dataset. The cited work reported the best metapaths used to predict these relations and used these metapaths for comparison. We performed a similar process (as described above) in order to split the data into a train and test sets.

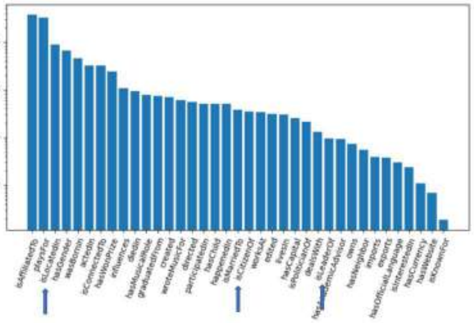

Fig 2. Distribution of relation types in the YAGO39K dataset.

TABLE 1. STATISTICS OF SPLIT OF DATA FOR DIFFERENT EXPERIMENTS

	isLocatedIn	isCitizenOf	IsLeaderOf
Train Set Graph	1,039,499	1,080,570	1,083,079
Train set edges	44,542	3,128	855
Test set edges	44,541	342	106

C. Performance

Having approximately a balance training set we train a logistic regression for binary classification. We evaluate our model using 10-fold cross-validation and test it using unseen set that we extracted from the graph.

To evaluate the performance of RegPattern2Vec on YAGO39, we chose metapath2vec as our baseline, shown in Fig 3, to demonstrate that RegPattern2Vec can cover more meta-paths without explicitly defining them and perform better, too. To get the best meta-paths for *isLocatedIn* and *isCitizenOf* relations, we chose the ones that achieved the best scores reported in the literature. However, were not able to find the best metapaths for *isLeaderOf*, and we designed them ourselves. After our experiments, Person $\xrightarrow{\text{isLeaderOf}}$ city $\xrightarrow{\text{isLocatedIn}}$ country $\xleftarrow{\text{isLocated}}$ city was the best meta-path. For example, a leader of state, is specified as leader of cities with the state. That information suggesting the earlier meta-paths to perform better than any other meta-paths. The regular pattern for three aforementioned links were defined as follow:

$$[\hat{}isLeaderOf\{2,\}\,isLeaderOf]$$

$$[\hat{}isLocatedIn]\{2,\}\,isLocatedIn]$$

$$[\hat{}isCitizenOf]\{2,\}\,isCitizenOf]$$

To run the experiments, we kept the same parameter settings for each of the method, when working on a specific relation prediction. The settings included the number of walks from each node, the maximum walk lengths, the Logistic Regression parameters, and the metrics to evaluate their performance.
To select the best algorithm for binary classification we examine two famous and popular algorithms, Logistic Regression and Random Forest, and we tested several experiments with both, and it seems that logistic Regression in our case the best performing method.

Therefore, all the experiments are performed with logistic Regression for evaluation purposes. RegPattern2Vec shown superior performance over metapath2vec method with best meta-paths possible. It is expected that RegPattern2Vec would perform better in link prediction tasks where it can obtain more semantics by exploring different path within the knowledge graph. In the case of the *isLeaderOf* relation, as the data does not contain information useful for predicting this relation, the performance is lower than for other relations.

For the evaluation of RegPattern2Vec on NELL datasets, we chose metapath2vec and used the best meta-paths reported in [5]

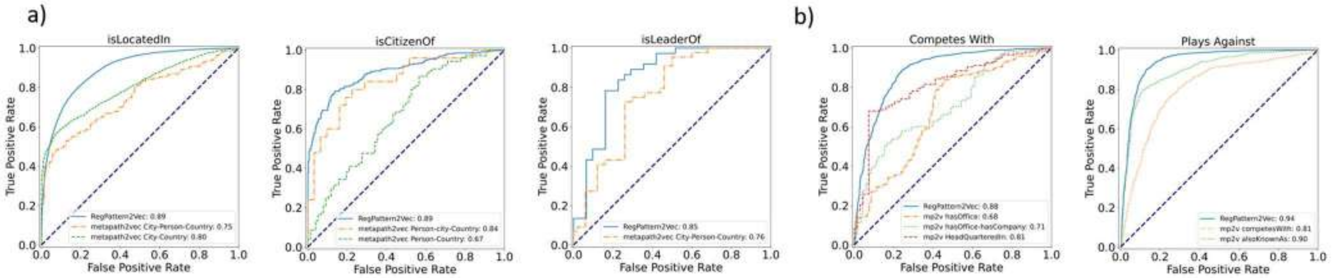

Fig 3. Comparing ROC of RegPattern2Vec with baseline on two datasets. a) Three relations on YAGO39K b) Two relations on NELL

for each of the relations. For *CompetesWith*, there were top five meta-paths. Our experiment showed that *HeadQuarteredIn* performs the best although it was ranked as the third in top 5. And for the *PlaysAgainst* relation, we selected two best meta-paths for evaluation purposes. We used the following regular expression patterns:

$$[\hat{}CompetesWith]\{2,\}\ CompetesWith$$

$$[\hat{}PlaysAgainst]\{2,\}\ PlaysAgainst$$

As shown in Fig. 3, RegPattern2Vec outperforms metapath2vec with different meta-paths for both relations in correctly predicting the unseen links between different nodes. The ROC shows that across most of the threshold the performance of RegPattern2Vec is significantly higher than metapath2vec with different metapaths.

D. Patterns Discovered of Random walk guided by Regular Pattern

Based on the dataset and underlying schema, RegPattern2Vec discovers different patterns in the data and uses them to accurately predict possible links in the KG. Fig. 4 shows the top 30 frequent meta-paths capture with RegPattern2Vec without explicitly specifying them. Although the number of possible relation sequences is very high, especially allowing for repetitions, some of the sequences can be seen frequently, based on the graph and they might significantly influence the vector embeddings. So, it is important to have a way to capture most of the patterns in the graph and consequently all path instances to allow the representation learning model to produce more accurate embeddings. This cannot be achieved by meta-paths as prior knowledge is needed to design each meta-path and they can be easily missed, especially when the schema of KG is unambiguous or not well-defined. Although just the frequency of each pattern in the data does not provide a good measure of how the pattern is important or useful for the link prediction problem, it can provide information about the graph itself and what are the frequent patterns in the graph. Then, the representation learning model can decide how frequent two specific nodes appear in the same context and provide a closer embedding for each of them, based on their local structures and neighbors.

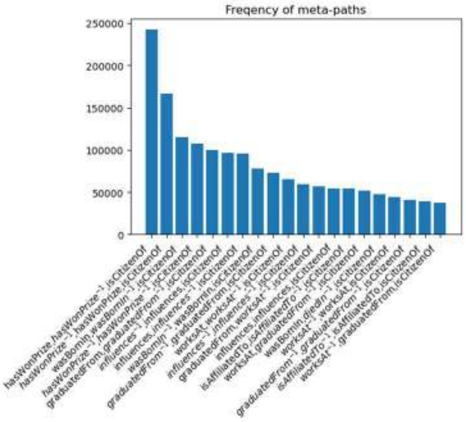

Fig 4. The top 30 most frequent relationship patterns discovered by RegPattern2Vec for *isCitizenOf* relation.

E. Effect of Hyper-parameters

In this section we studied the effect of two important hyper-parameters in the random walks on performance and elapse time namely the number of walk and length of walks. The effect of different choices of these two on the AUC ROC is demonstrated in Fig. 5a for *playsAgainst* relation on NELL dataset. As more nodes are connected to each other, we need to sample more paths by increasing the number of walks or walk length. On the other side, due to the large size of KGs, one of the challenges of learning the embeddings is scalability and efficiency. we showed that increasing the number of walks can improve the performance, as the random walks are able to trace more paths in the data. Fig 5b shows how the increase of this parameter affects the elapsed time of the random walk, in this case when experimenting with the *competesWith* relation on the NELL dataset in two cases of walk length 10, and 100. As demonstrated the elapsed time is linearly related to the hyper-parameters.

VI. Conclusion and Future work

In this work, we presented RegPattern2Vec, where a regular pattern guides the random walks in a knowledge graph to efficiently sample sequences of nodes to learn high quality

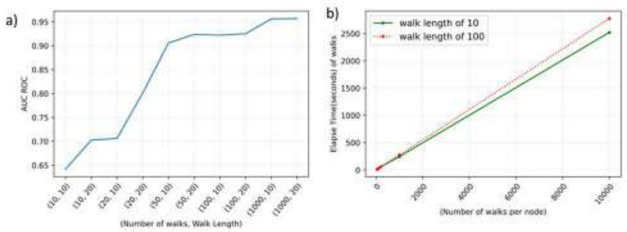

Fig 5. a) Effect of number of walks and walk length on AUC ROC b) Effect of number of walk per node on elapsed time of random walks with two different walk lengths 10 and 100.

embeddings for link prediction. We demonstrated link prediction using relation types, where the schema of knowledge graph is unknown, or node type hierarchy is complex. As a future direction for our work, we want to explore how to bias the random walks to favor the nodes or relations that might contribute more accurate link prediction results. Also, if the most frequent relations found in the patterns of walks would improve the results. We plan to achieve this by automatically tuning the bias score for each type of node (or relation), while training on the graph and checking the link prediction results to adjust the scores. The number of parameters to tune is related to the number of types or relations that we have in KG, which seems to be practical to a model to work with.

***Abstract*— Digital signatures are increasingly used today. It replaces wet signature with the development of technology. Elliptic curve digital signature algorithm (ECDSA) is used in many applications thanks to its security and efficiency. However, some mathematical operations such as inversion operation in modulation slow down the speed of this algorithm. In this study, we propose a more efficient and secure ECDSA. In the proposed method, the inversion operation in modulation of signature generation and signature verification phases is removed. Thus, the efficiency and speed of the ECDSA have been increased without reducing its security. The proposed method is implemented in Python programming language using P-512 elliptic curve and SHA-512 algorithm.**

Keywords—Elliptic Curve Digital Signature Algorithm (ECDSA), Elliptic Curve Cryptography, NIST P-521 Curve, Hash Function, Finite Fields, Inversion in modulation, Python.

I. Introduction

Information security is one of the issues that gain importance with developing technologies. Digital signature is a concept that has a key role in ensuring information security today. It is used in many areas such as health, banking, commerce, internet of things, electronic voting. Digital signatures are used to provide integrity, authentication, and non-denial [1].

ECDSA based on elliptic curve cryptography (ECC) is efficient compared to other signature algorithms such as Rivest Shamir Adleman (RSA) and digital signature algorithm (DSA) [2]. It was first accepted as the ISO standard (International Standards Organization) in 1998 and later the ANSI standard (American National Standards Institute) in 1999 and in 2000 as NIST (National Institute of Standards and Technology) and IEEE standards. It is accepted in international standards makes that is used widely.

ECDSA provides the same security level with smaller key size compared to other signature algorithms [3]. The security provided by RSA and DSA with 3072 bit key size is equal to the security provided by ECDSA with only 256 bit key size. Provides an advantage when resources such as processing power, storage space, bandwidth, and power consumption are limited [2]. Due to this feature, it is suitable for use in many applications such as Internet of Things, sensors, RFID, smartphones [4], smart cards, wireless devices [2].

There are many ECDSA variants in the literature and different algorithms are proposed. Some of the proposed methods want to increase speed, while others want to increase security [5-10]. In the proposed algorithm given in the study, the inversion operation in ECDSA is removed from the signature and signature verification phases without security level reduced. In addition, the multiplication operation is reduced in these phases**.** The inversion operation in modulation is added to the key pair generation phase. Since this phase is in the setup, it does not affect the signature and signature verification phases. Thus, a more efficient and security variant of ECDSA is designed. Designed algorithm as a variant of ECDSA is implemented in Python programming language using the P-521 elliptic curve recommended by NIST.

The rest of this paper is organized as follows. In the second section, hash functions are explained and SHA algorithms are compared. In the third section, ECC and its mathematical operations over finite fields are explained and also group order and elliptic curve discrete logarithm problem (ECDLP) are explained. In the fourth section, the ECDSA is introduced and key pair generation, signature generation and signature verification phases are explained. In the fifth section, the proposed algorithm are designed which is implemented in Python programming language. Finally, in the sixth section conclusions are given.

II. Hash Function

A one-way hash function $H(M)$, takes a variable length message, and produces a fixed length hash value h. Regardless of the length of the message M, even terabyte in size, the output value h is always fixed length. The message M cannot be found from the hash value h, denoted as one-way property. In this way, reverse engineering is not possible. This process is defined as follows [11].

$$h = H(M) \qquad (1)$$

The hash function can be used to ensure that the content of message M has not changed. If there is any change in the content, output value h will change. For this reason, it is used to ensure information security in many fields such as digital signature and digital forensic. The hash algorithm must provide to use safely one-way and collision resistant properties. Collision property is that the same output hash value h is produced for different input message values [12]. The collision case is defined as follows.

$$M_1 \neq M_2,\ \ H(M_1) = H(M_2) \qquad (2)$$

There are many different hash functions such as MD (Message Digests) family, SHA (Secure Hash Algorithm) family, RIPEMD (RIPE Message Digest) family, Whirlpool

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

family [17]. The most widely used today is the SHA (Secure hash algorithm) family. The properties of the different SHA algorithms are shown in TABLE I [12].

TABLE I. COMPARISON OF DIFFERENT SHA ALGORITHMS

Algorithm	Message Length (bits) (Maximum)	Block Size (bits)	Word Size (bits)	Hash (bits)
SHA 1	2^{64}-1	512	32	160
SHA 256	2^{64}-1	512	32	256
SHA 384	2^{128}-1	1024	64	384
SHA 512	2^{128}-1	1024	64	512

In this study, the SHA-512 algorithm is used. It is an improved version of the other SHA family [17].

III. Elliptic Curve Cryptography (ECC)

Elliptic curve cryptography (ECC) is a public key cryptography that was discovered independently of each other in 1985 by Neil Koblitz [13] and Victor Miller [14]. For ease of calculation, operations are performed on finite fields. The finite fields used in software and hardware applications may differ. Prime field (F_p) for software applications and binary field (F_{2^m}) for hardware applications are widely used [15]. The equation,

$$y^2 = x^3 + ax + b \ \ (mod\ p) \tag{3}$$

which is known as Weierstrass equation, where a and b are constant integers less than p that is a prime number, and satisfys the following condition.

$$4a^3 + 27b^2 \neq 0 \ \ (mod\ p) \tag{4}$$

Let define an elliptic curve $E(a,b)$ over prime field F_p. The values of a and b in equation (3) are selected as -1 and 0, respectively. $y^2 = x^3 - x$ is shown in Fig. 1.

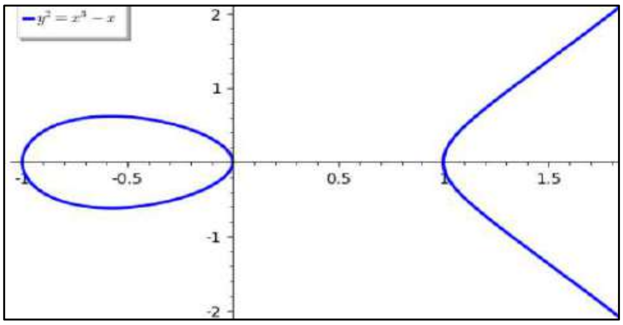

Fig. 1. $y^2 = x^3 - x$

A. Mathematical Operations of ECC

Operations on a finite field are based on the affine coordinate system which each point in the coordinate system is represented by the vector (*x*, *y*). Mathematical operations performed over finite fields are defined below [15].

1) Point addition

Let define two distinct points $P(x_1, y_1)$ and $Q(x_2, y_2)$ on the elliptic curve $E(a,b)$. The point addition calculation is given as follows.

$$R(x_3, y_3) = P(x_1, y_1) + Q(x_2, y_2) \tag{5}$$

- if $x_1 \neq x_2$, then the point addition is defined by

$$x_3 = \lambda^2 - x_1 - x_2 \tag{6}$$

$$y_3 = \lambda(x_1 - x_3) - y_1 \tag{7}$$

where

$$\lambda = \frac{y_2 - y_1}{x_2 - x_1} \tag{8}$$

- if $x_1 = x_2$, the infinity point (O) is obtained.

2) Point Doubling

Let define two points $P(x_1, y_1)$ and $Q(x_2, y_2)$ on the elliptic curve $E(a,b)$, which are equal to each other i.e. $P = Q$. Point doubling can be defined as follows.

$$R(x_3, y_3) = P(x_1, y_1) + P(x_1, y_1) = 2P \tag{9}$$

where

$$P(x_1, y_1) = Q(x_2, y_2). \tag{10}$$

The calculation of the point doubling is given as follows.

$$x_3 = \lambda^2 - 2x_1 \tag{11}$$

$$y_3 = \lambda(x_1 - x_3) - y_1 \tag{12}$$

where

$$\lambda = \frac{3x_1^2 + a}{2y_1} \tag{13}$$

3) Point Subtraction

Let define two distinct points $P(x_1, y_1)$ and $Q(x_2, y_2)$ on the elliptic curve $E(a,b)$. The negative of the point Q can be defined as follows.

$$-Q(x_2, y_2) = Q(x_2, -y_2) \tag{14}$$

The subtraction of two points is given as follows.

$$P(x_1, y_1) - Q(x_2, y_2) = P(x_1, y_1) + Q(x_2, -y_2) \tag{15}$$

4) Scalar Multiplication

Let define any point $P(x_1, y_1)$ on the elliptic curve $E(a,b)$. The scalar multiplication $9P$ can be calculated as follows.

$$9P = 2(2(P+P)) + P \tag{16}$$

5) Inversion

Let *x* be a non-zero element and *y* be the inverse of *x* in modulo *p* (*x*, *y* ∈ F_p). The relation between *x* and *y* is given below.

$$xy = 1 \ (\mathrm{mod}\ p) \tag{17}$$

B. Group Order

Let define an elliptic curve $E(a,b)$ over finite field F_p. The number of points in $E(F_p)$ is called the order of $E(a,b)$ over prime field F_p which is denoted as $\#E(F_q)$ and is equal to n. It must be prime number and satisfy the following equation.

$$nG = O \text{ (infinity point)} \tag{18}$$

C. Elliptic Curve Discrete Logarithm Problem

The security of ECC is based on the difficulty of the elliptic curve discrete logarithm problem (ECDLP). Suppose we know the values of P and Q in Equation (19). Finding the value of k is quite difficult.

$$Q = kP \tag{19}$$

D. Recommended Elliptic Curves

There are elliptic curves recommended by NIST for U.S. Federal Government. Special curves are defined as over prime field F_p and over binary field F_{2^m}. Elliptic curves over F_p are called Edwards curves and Montgomery curves. The prime fields: P-192, P-224, P-256, P-384, P -521, W-25519, W-448, Curve25519, Curve448, E448, Edwards25519, Edwards448. Elliptic curves over binary field F_{2^m} are called Koblitz curves and pseudorandom curves. The binary fields: Curve K-163, Curve K-233, Curve K-283, Curve K-409, Curve K-571, Curve B-163, Curve B-233, Curve B-283, Curve B-409, Curve B-571 [16].

IV. Elliptic Curve Digital Signature Algorithm (ECDSA)

ECDSA was proposed in 1992 by Scott Vanstone which is based on the implementation of the digital signature algorithm (DSA) on the elliptic curves [3]. Its security is based on the elliptic curve discrete logarithm problem (ECDLP). ECDSA consists of three phases: key pair generation, signature generation and signature verification. Let examine these three phases below [3].

A. Key Pair Generation

1. Signer selects a random integer $d \in [1, n-1]$.
2. Compute $Q = dG$ hence $Q = (x_Q, y_Q)$.
3. Signer's public key is Q, and private key is *d.*

B. Signature Generation

1. Signer selects a random integer $k \in [1, n-1]$.
2. Compute $kG = (x_1, y_1)$.
3. Compute $r = x_1 \pmod{n}$. If r =0 then go to step 1.
4. Compute $k^{-1} \pmod{n}$.
5. Compute SHA-1(M) and convert this bit string to an integer h (*Hash*(M)=h).
6. Compute $s = k^{-1}(h + dr) \pmod{n}$. If s =0 then go to step 1.
7. The signature for the message M is (r, s).

C. Signature Verification

1. Verify r and s are integers and r, s ∈ $[1, n-1]$.
2. Compute $w = s^{-1} \pmod{n}$.
3. Compute SHA-1(M) and convert this bit string to an integer h (*Hash*(M)=h).
4. Compute $u_1 = hw \pmod{n}$ and $u_2 = rw \pmod{n}$.
5. Compute $(x_1, y_1) = u_1 G + u_2 Q$, $v = x_1 \pmod{n}$.
6. If $v = r$, the signature is valid, otherwise the signature is invalid.

D. Proof of ECDSA Signature Verification

Let's perform the steps below in order to proof the signature verification.

$$(x_1, y_1) = u_1 G + u_2 Q \tag{20}$$

If kG, hw, rw, w are put in equation (20).

1. $kG = u_1 G + u_2 Q$.
2. $kG = hwG + rwQ$.
3. $kG = hs^{-1}G + rs^{-1}Q$.
4. $kG = hs^{-1}G + rs^{-1}dG$.
5. $k = s^{-1}(h + dr)$.

Thus, signature verification has been proven.

E. Security of ECDSA

The security of ECDSA is based on the difficulty of solving the elliptic curve discrete logarithm problem (ECDLP). Suppose Eva is a black-hat hacker who want to forge our signature. She has domain parameters and our signature (*r, s*). If she gets hold of our private keys *d* and *k*, she can use our signature anywhere. Therefore, we must choose the elliptic curve parameters very carefully in accordance with the international standards.

If Eva starts from the signature (*r, s*) known to everyone, finds the equality between *k* and *d* according to the following equation (21). *h* is calculated by *h*=hash(*M*) and *r, s* are already known.

$$s = k^{-1}(h + dr) \tag{21}$$

$$k = s^{-1}(h + dr) \tag{22}$$

$$kG = (x_1, y_1) \tag{23}$$

$$Q = dG = (x_Q, y_Q) \tag{24}$$

Finding *k* and *d* are very diffucult due to ECDLP. The *k* value must be selected independently for each message when signing multiple messages. If the value of *k* is not selected differently, the value of *d* can be recovered. Suppose we assume the same value of *k* for two different messages. Since the same *k* value is used, *r* value will be the same. The obtained signature will be (r,s_1) and (r, s_2). The hash values h_1 and h_2 obtained for two different messages are different.

$$s_1 = k^{-1}(h_1 + dr) \tag{25}$$

$$s_2 = k^{-1}(h_2 + dr) \tag{26}$$

$$ks_1 - ks_2 = (h_1 + dr) - (h_2 + dr) \tag{27}$$

where

$$ks_1 - ks_2 = (h_1 - h_2) \tag{28}$$

$$k = (h_1 - h_2) / (s_1 - s_2) \tag{29}$$

$$d = (ks_1 - h_1) / r \tag{30}$$

First *k* is calculated form equation (29), then *d* from equation (30). However, this probability is ignored by choosing a random number.

V. Proposed Algorithm and Implementation

In the ECDSA, inversion operation in modulation is performed in both signature generation and signature verification. Inversion operation in modulation is a mathematically difficult operation. For this reason, signature generation and signature verification times are getting longer. The use of ECDSA in many areas depends on the speed of these processes. Security can be increased in ECDSA, but it is difficult to make the algorithm more efficient at the same security level. In the proposed method, the inversion in signature generation and signature verification phases is eliminated with the change in key pair generation algorithm. In the key pair generation algorithm, public key Q is calculated by taking the inversion of randomly selected integer *d*. The proposed method is given below. The computer used has an Intel (R) Core (TM) i7-7500U CPU processor and 8GB of RAM. Algorithms have been run 7 times with the "timeit" command and averaged.

A. Proposed Key Pair Generation Algorithm

1. Signer selects a random integer $d \in [1, n-1]$.
2. Compute $Q = (d^{-1}\, mod\ n)G$.
3. Signer's public key is Q, and private key is *d*.

B. Proposed Signature Generation Algorithm

1. Signer selects a random integer $k \in [1, n-1]$.
2. Compute $kG = (x_1, y_1)$.
3. Compute $r = x_1$ (mod n). If r =0 then go to step 1.
4. Compute SHA-512 *(M)* and convert this bit string to an integer *h* (*Hash(M)=h*).
5. Compute $s = d(k-h)$ (mod n). If s =0 then go to step 1.
6. The signature for the message *M* is (r, s).

C. Proposed Signature Verification Algorithm

1. Verify r and s are integers and *r, s* $\in [1, n-1]$.
2. Compute SHA-512 (*M*) and convert this bit string to an integer *h* (*Hash*(*M*)=*h*).
3. $u_1 = s$ (mod n) and $u_2 = h$ (mod n).
4. Compute (x_1, y_1)=$u_1Q + u_2G$, $v = x_1$ (mod n).
5. If $v = r$, the signature is valid, otherwise the signature is invalid.

D. Proof of Signature Verification

Let perform the steps below in order to proof the signature verification.

1. $s = d(k-h)$
2. $sd^{-1} = (k-h)$
3. $G(sd^{-1}) = G(k-h)$
4. $Gsd^{-1} = kG - hG$
5. $kG = hG + Gsd^{-1}$
6. $kG = hG + sQ$
7. $kG = u_2G + u_1Q$

Thus, signature verification has been proven.

E. Implementation

Firstly, let choose the NIST P-521 (p=$2^{521}-1$) curve over the prime field for implementation. The NIST P-521 domain parameters are shown in TABLE II. Then, let choose a message *M* that is "This is my signature".

TABLE II. NIST P-521 DOMAIN PARAMETERS

- $r = x_1$ (mod n). The signature has been verified.

VI. CONCLUSION

In this study, a more efficient and secure version of ECDSA is designed and implemented. The inversion operation that is included in both signature and verification in ECDSA is an expensive and time consuming operation in modular arithmetic. Execution times (µs) of mathematical operations in different elliptic curves defined on prime fields recommended by NIST are given in TABLE III. Note that inversion operation requires much more execution time than other operations. Please note that the duration of the multiplication is much higher compared to addition and subtraction. Hardware-based applications require more time to perform inversion operation in modular arithmetic than software-based applications.

Based on this challenge, the proposed method only includes inversion operation in the key pair generation algorithm. Since this algorithm is in the set-up phase of the parameters, it will not affect the signature and signature verification time.

TABLE III. EXECUTION TIME (µs) OF MATHEMATICAL OPERATIONS

Operation\Fields	$F_{P_{192}}$	$F_{P_{224}}$	$F_{P_{256}}$	$F_{P_{384}}$	$F_{P_{521}}$
Addition in Modulation	0.221	0.264	0.241	0.244	0.237
Subtraction in Modulation	0.217	0.228	0.223	0.228	0.225
Multiplication in Modulation	0.338	0.408	0.320	0.823	1.02
Inversion in Modulation	3.79	4.4	4.02	5.62	7.34
Point Addition	50.4	52.9	51	54.4	57.9
Point Doubling	64.1	65.8	65.6	69	74.8

Compared to other variants in the literature and ECDSA, the proposed method gives better results due to the shorter times and less mathematical operations. The comparison of the proposed method, ECDSA and other variants by number of operations is shown in TABLE IV. (A.M. : Addition in Modulation, Su.M : Subtraction in Modulation, M.M. : Multiplication in Modulation, I.M. : Inversion in Modulation, S.M. : Scalar Multiplication, P.A. : Point Addition, S.G. : Signature Generation, S.V. : Signature Verification, ⊕ : XOR)

TABLE IV. COMPARISON OF ECDSA AND VARIANTS

Algorithm	Phases	A. M.	Su.M	M. M	I. M.	S. M.	P.A
ECDSA	S.G.	1	-	2	1	1	-
	S.V.	-	-	2	1	2	1
Ref. [5]	S.G.	-	-	4	2	1	-
	S.V.	-	-	1	1	1	-

	S.V.	1(⊕)	-	-	1	2	1
Ref. [8]	S.G.	2	-	3	1	2	-
	S.V.	1	-	1	1	2	1
Ref. [9]	S.G.	2	-	3	1	2	-
	S.V.	-	-	4	1	2	1
The Proposed Method	S.G.	-	1	1	-	1	-
	S.V.	-	-	-	-	2	1

Execution times (milliseconds: ms) of the ECDSA and the proposed method during the signature generation and verification phases are shown TABLE V. The proposed method provides 25% and 18% time advantage in the signature generation and verification phases, respectively.

TABLE V. COMPARISON OF EXECUTION TIMES

Algorithm	Signature Generation	Verification
ECDSA	**48**	**83**
The Proposed Method	**36**	**68**

The proposed method can be used in many software and hardware applications that require speed and security thanks to the features it provides. It is particularly suitable for constraints such as low power, limited memory and computing capacities that exist in areas such as the Internet of Things, which are increasingly becoming important today.

***Abstract*—Due to the low cost and high data transmission speed, the demand for wireless communication systems (WLAN, Wi-Fi) is increasing day by day. Nowadays, high-speed data transmission can be provided to a whole area or a building using WLAN and Wi-Fi systems. Since better performances and efficiency are expected for WLAN and Wi-Fi systems in the future, considering these issues, a Half-wave Dipole Antenna has been designed with an operating frequency of 2.45 GHz (ISM-Band). The antenna has been developed using the Copper (annealed) and the Perfect Electrical Conductor (PEC) material in the CST Studio Suite 2019 Software. After completing the simulation of the antenna, a Return Loss of -31.019 dB has been successfully achieved. A Gain of 2.026 dBi and a Directivity of 2.032 dBi was also achieved, respectively. The antenna's efficiency was determined as 99.70%, which was calculated by using the value of Gain and Directivity. The other obtained performance parameters of the antenna are Surface Current, Bandwidth, etc. Considering all of the above performance parameters, the simulated Half-wave Dipole Antenna will be an ideal option for the WLAN and Wi-Fi systems.**

Keywords*— *Dipole Antenna, Wi-Fi, WLAN, Gain, VSWR, Surface Current, Return Loss, CST.

I. Introduction

In recent times, the improvement of technology has rapidly increased, and the use of the internet has also increased to a significant level in both developed and underdeveloped countries. For the requirement of high-speed data transfer, a variety of wireless networks, such as WiMAX, WLAN, Wi-Fi, etc., plays an important role [1]. WLAN (Wireless Local Area Network) refers to a form of computer network service that uses wireless networking to link multiple devices in a small area to form a Local Area Network (LAN) [2]. Wi-Fi refers to a wireless networking system that connects users to the internet, including computers, handheld devices (smartphones and wearables), computers (laptops and desktops), and other appliances [3]. Wireless communication networks have grown and continue to expand based on many technologies, including 2G/3G. Different types of frequency bands can be used for wireless communication such as Several frequency bands can be used to design the antenna, such as ISM-band (433.05-434.79 MHz, 866-868 MHz, 902-928 MHz, 2.4-2.4835 GHz, and 5.725-5.875 GHz), L-Band (1-2GHz), S-Band (2-4GHz), C-Band (4-8GHz) [4]. The most common frequency band is ISM-Band (2.4-2.5 GHz). Among them, ISM-Band is most commonly used. To have sufficient coverage for potential operating frequencies, modern antennas must comply with the ISM band or wideband requirements [5].

There are different types of antennas such as Monopole, Dipole, Microstrip Patch Antennas, etc., for wireless communication. Performances of these antennas are various according to the dimensions of the antenna and their substrate material. The antenna's size must be small enough to fit inside a wireless networking system with limited space. When it comes to commercial antennas for wireless networking, the most popular antenna is the dipole antenna [6]. One of the benefits of dipole antennas is that they can receive balanced signals essential for wireless communication. The antenna's two-pole nature allows a device to transmit signals from a wide range of frequencies. It also enables the system to resolve signal conflicts without sacrificing transmission efficiency [7]. Low-frequency bands are more preferable because achieving better performances with high frequencies is a big challenge. The drawback of using a high-frequency band is that the path distortion or free space loss is high in this type of band, causing the signal's degradation to interference plus noise ratio (SINR) [8]. This paper proposes to design a half-wave dipole antenna for Wi-Fi and WLAN using the ISM band to achieve a higher Bandwidth and a Return Loss ($S_{1,1}$) to communicate faster.

II. Design and Methodology

A half-wave dipole antenna was designed to operate at 2.45 GHz for improved performance in the Wi-Fi and WLAN Communications Systems genre. The proposed model's geometric orientation in free space was depicted in Figure-1. From the Geometry, it can be seen that the intent of feeding is a distance between the two arms of the antenna, known as the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

feeding gap denoted by g. L indicates the antenna's total length; antenna arm thickness is designated by D. The dipole's radiation resistance is 73 Ohm, which corresponds to the line's impedance [9].

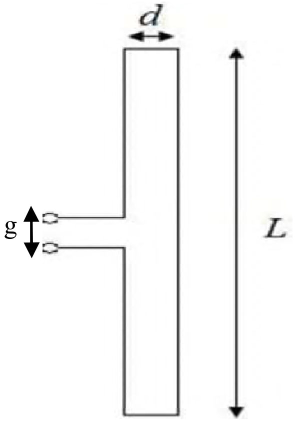

Fig.1. Geometry of the proposed Half-Wave Dipole Antenna

The frequency spectrum is first defined by the maximum and minimum magnitudes of the frequency, which are respectively 1GHz and 10GHz. Then the resonant frequency, *f* = 2.45GHz, was selected. Then the wavelength (λ) was calculated by using the given equation (1) [9].

$$\boldsymbol{\lambda = \frac{c}{f}} \qquad \textbf{(1)}$$

The total length of the antenna was calculated by using the resonant frequency, *f* using the following equation (2) [9].

$$\boldsymbol{L = \frac{143}{f}} \qquad \textbf{(2)}$$

By using the value of the total length, L, the antenna's feeding gap, g was calculated by using the following equation (3) [9].

$$\boldsymbol{g = \frac{L}{200}} \qquad \textbf{(3)}$$

The dipole radius was calculated by using the following equation (4) [9].

$$\boldsymbol{R = \frac{\lambda}{1000}} \qquad \textbf{(4)}$$

Table-I represents the input parameter values of the designed Half-Wave Dipole Antenna.

TABLE I. INPUT PARAMETERS OF THE DESIGNED HALF-WAVE DIPOLE ANTENNA

Input Parameters with their symbols	**Dimensions**	**Unit**
Radius of Dipole (R)	53.74	mm
Length of Feed (F)	10	mm
Length of Dipole (L)	54.64	mm
Input Impedance (Z)	73	Ω
Wavelength (λ)	109.28	mm

III. RESULT ANALYSIS

A. Return Loss

Return Loss($S_{1,1}$) in telecommunication networks refers to the magnitude of the signal that returns or bounces from the antenna due to a discontinuity of the optical fiber or transmission line grid. It is expressed in decibels (dB) [10]. It is better to have a larger Return Loss ($S_{1,1}$) because the antenna absorbs less energy while the Return Loss($S_{1,1}$) is minimal. Figure-4 depicts the proposed antenna's Return Loss ($S_{1,1}$) where the obtained Return Loss($S_{1,1}$) has a value of -31.019dB and Bandwidth has a value of 0.5384GHz at the operating frequency of 2.4345GHz. At the operating frequency of 7.5176 GHz Return Loss ($S_{1,1}$) of -12.506dB and a Bandwidth of 0.1171GHz were also achieved.

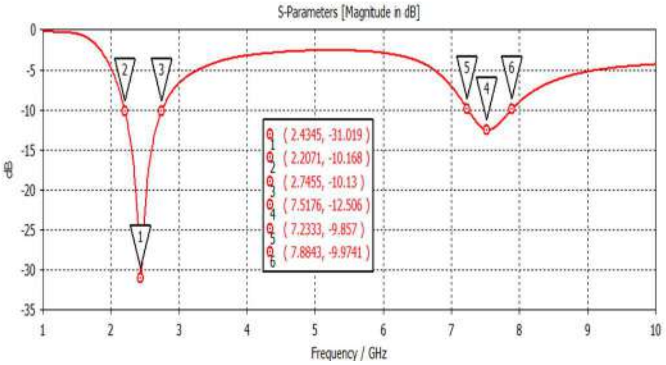

Fig.4. Return Loss ($S_{1,1}$) in Free Space

B. VSWR

The transmission line's impedance and the antenna's impedance must align to a considerable degree to transmit the necessary power to the desired antenna [11]. VSWR is crucial in this regard. The Voltage Standing Wave Ratio (VSWR), also known as SWR, is a measurement of how quickly radiofrequency power is transferred from a given power source to a load via a transmission cable. Figure 5 depicts the proposed antenna model's obtained VSWR, which is 1.0585 at the operating frequency of 2.4495GHz.

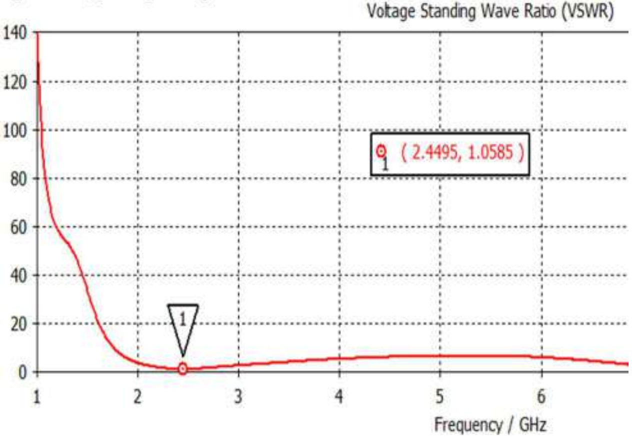

Fig. 5. VSWR in Free Space

C. Gain & Directivity

For evaluating the efficiency of an antenna, Gain and Directivity are two essential parameters. The Gain here denotes the amount of power transferred to the main beam, while the Directivity denotes the calculation of concentration radiation in a specific direction. The Gain denotes the power transferred to the main beam, and the Directivity is the calculation of the concentration radiation in a given direction [12]. Figure 6 and Figure 7 depict the 3D Gain and Directivity, with an obtained Gain of 2.026dBi and a Directivity of 2.031dBi at the operating frequency of 2.45GHz. The antenna's efficiency was measured to be 99.70% by using the formula

Efficiency = [Gain/Directivity] * 100%

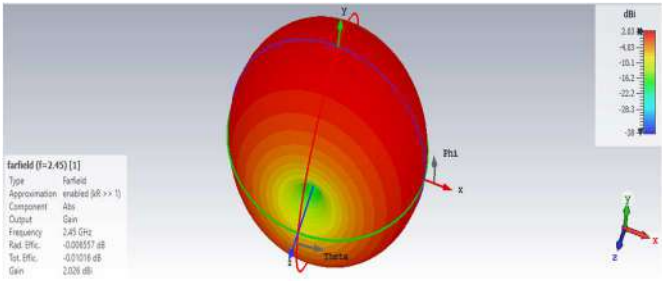

Fig.6. Gain of the Antenna in Free Space

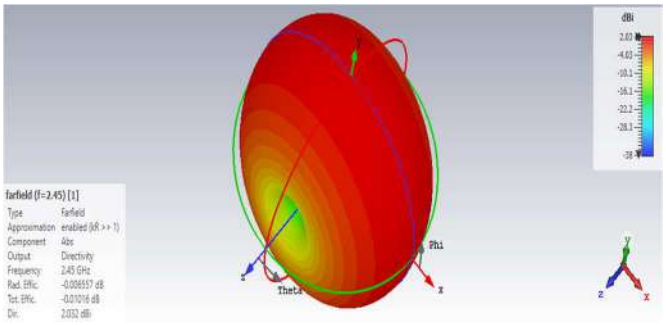

Fig.7. 3D Directivity in Free Space

D. Surface Current

Figure 8 depicts the proposed antenna model's surface current with an obtained value of 12.7A/m at the operating frequency of 2.45 GHz.

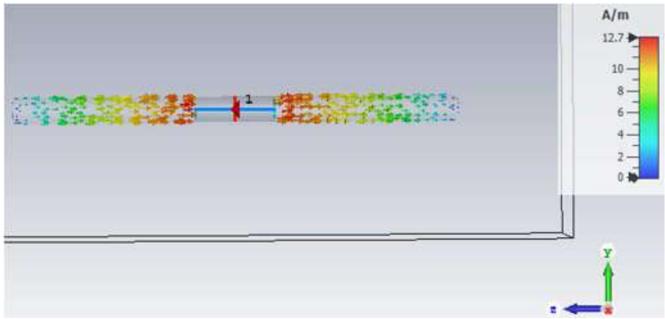

Fig.8. Surface Current in Free Space

E. Farfield Radiation (Polar Form)

Figure-9, Figure-10, and Figure-11 depict the Farfield Radiation (Polar Form for Phi 0^0, 90^0, 180^0) at the operating frequency of 2.45 GHz. In both of the cases, the Main lobe magnitude is 2.03 dBi.

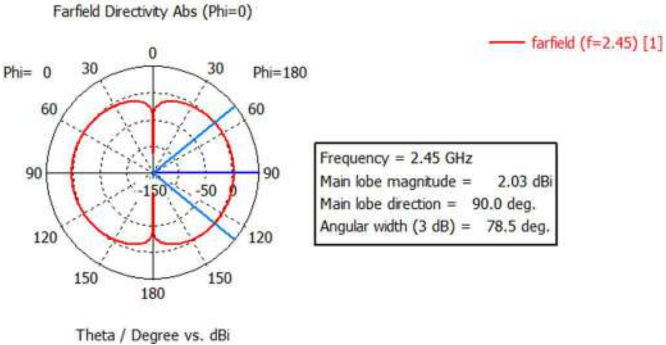

Fig.9. Farfield Radiation (Polar Form, at Phi=0^0)

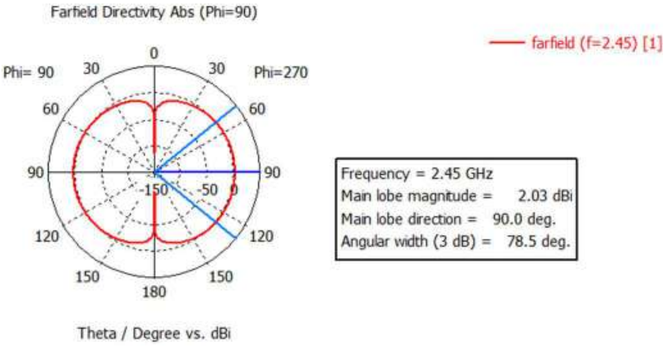

Fig.10. Farfield Radiation (Polar Form, at Phi=90^0)

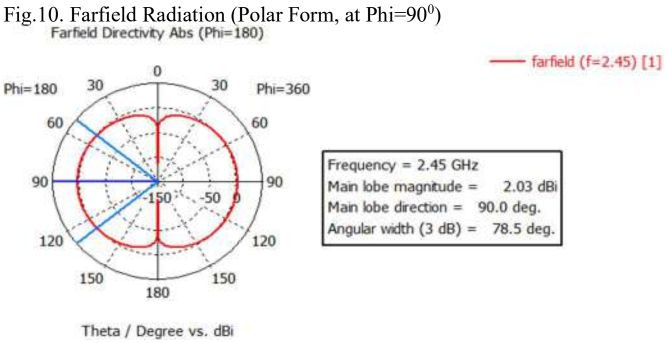

Fig.11. Farfield Radiation (Polar Form, at Phi=180^0)

Table II represents the summary of the obtained output parameters.

TABLE II. SUMMARY OF THE OBTAINED PARAMETERS

Antenna Output Parameter	*Obtained Values*
$S_{1,1}$	-31.019dB
Bandwidth	0.5384GHz
Gain	2.026
VSWR	1.0585
Efficiency	99.70%
Directivity	2.032 dBi
Surface Current	12.7 A/m

IV. COMPARATIVE STUDY

Various antenna parameters like Gain, Bandwidth, Return Loss [$S_{1,1}$], from many previous research works have been analyzed. Compared to the other reference paper mentioned in Table III, a better ($S_{1,1}$) parameter after conducting the simulation on CST at 2.45 GHz has been obtained. Since the value of the Return Loss is higher, the proposed model will accept more RF (Radiofrequency) energy compared to the other model.

TABLE III. COMPARISON OF THE ANTENNA MODEL WITH PREVIOUS RESEARCH PAPER

Return Loss ($S_{1,1}$) (dB)	*Bandwidth (Max) (GHz)*	*Gain (dBi)*	*Comment*	*Ref.*
-23	1.79	3.1	Low Gain, High Bandwidth	[13]
-19.89	0.2	2.07	Low Gain, Low Bandwidth	[14]
-	2.5	3.7	Low Gain, Low Bandwidth	[15]
-18.86	0.23	4.01	Low Gain, Low Bandwidth	[16]
-27	0.4	4.59	Low Bandwidth, Low Gain	[17]
-31.02	0.54	2.03	High Efficiency, Low Gain, Low Bandwidth	Proposed Antenna

V. CONCLUSION

For the sake of high-speed data transmission and for using the internet more conveniently, a Dipole Antenna has been designed for WLAN and Wi-Fi systems with an operating frequency of 2.45 GHz (ISM-band) ranging from 1 to 10 GHz in CST Studio Suite Software. Furthermore, the proposed model's different parameters are depicted in this article. Besides, the designed antenna model has an ($S_{1,1}$) value of -31.019 dB with a bandwidth of 0.5384 GHz. The antenna model's size has been kept compact to conserve space. The efficiency of the antenna is 99.70% which shows its effectiveness. To overcome Wi-Fi and WLAN systems' future challenges, The Return Loss ($S_{1,1}$), Gain, Bandwidth, and other obtained performance parameters of the antenna can be easily upgraded. A summary of all the performance Parameters was given in Table-ii, and a comparison of these parameters with some previous researches was mentioned in Table-iii. Taking both of these factors into consideration, it can be said that the proposed model may be an outstanding solution for Wi-Fi and WLAN communication systems, with its promising future.

***Abstract*— COVID-19 is a global pandemic that has caused an increase in remote work. Sitting in various positions at home without the proper back support is undesirable and can cause chronic back pain and other undesired side effects. Therefore, a new non-intrusive method to continuously monitor back postures in homes is proposed. A shirt is designed with integrated magnets. A magnetic sensor would be placed above the body's sternum, and magnets will be implemented on a shirt. The sensor will help ascertain the back posture position (straight or curved) and help provide feedback to mend the posture if deformed. In this paper, the initial results using the proposed system are presented using a wearable sensor system with a magnet integrated garment that can continuously monitor the varying sitting postures throughout daily lives. In addition, we discuss how the lower body posture affects the magnetic recording otherwise not detectable using the accelerometer-based systems currently available on the market.**

Keywords—activity detection, posture detection, magnetic sensor

I. Introduction

Wearable sensing through clothing minimizes the need for bulky devices, enabling a pragmatic approach to long-term monitoring of the body. Minimizing the wearable system allows for body movements to be captured easier without affecting everyday activities. In order to maximize the effectiveness, a loose shirt is implemented as the proposed platform in the wearable solution.

With the rise of remote work due to the COVID-19 crisis, the proposed system aims to detect the spinal postures of people working at home. Make-shift home offices often lack ergonomic furniture that impedes healthy posture [1]. Without proper desks or chairs, many remote workers find themselves on couches or kitchen tables hunched over their laptops, causing an increase in neck and lower back pain [2]. Additionally, the use of non-ergonomic equipment may increase Musculoskeletal (MSK) disorders [2]. MSK disorders are defined by pain and limitations in mobility, dexterity, and overall body functionality [3]. The number of people with MSK disorders and lower back pain will increase in the near future due to the COVID-19 crisis.

Many studies suggest an ideal home workstation setup where ergonomic principles are unattainable, creating a footrest when feet do not touch the floor when sitting [4]. Another study investigated adjustable desks and their relationship to healthy postures [4]. Other studies have investigated different sensing techniques to monitor back posture [5, 6, 7]. A research group investigated the use of conductive silicon to movement [8, 9]. Current advertised products to detect slouching only focus on forwarding or backward spinal postures. The proposed wearable system can detect the left and right and the forward and backward spinal postures.

Presented are the results of using a magnetic sensor to detect upper body posture while remotely working from home. First, the design of the garment-integrated system is introduced. Then, results from the posture monitoring sensor system are analyzed and presented. Finally, current progress and the next steps of the research are declared.

II. Sensors and System Overview

The objective is to detect the relative position of small magnets on a shirt using a magnetic sensor. The position will be used to determine upper body postures. Therefore, the proposed system will have a grid of magnets integrated onto a shirt and record the sensor's output [10, 11].

The magnetic sensor chosen for the proposed wearable system is Mbientlab's MetaMotionR (MMR). The wearable sensor provides real-time and constant monitoring of environmental data. The spinal position is extracted using x, y, and z-axis data collected. The x-axis data corresponds to left and right movement, and z-axis data corresponds to the front and backward movement, while the y-axis data corresponds to up and down movement of the upper body.

A grid of nickel-plated neodymium magnets (D42-N42) is placed in a 3x3 grid on a T-shirt. The magnets are placed on the shirt's front for the proposed system, as shown in Figure 1. Nine pockets placed 2 inches apart horizontally and 4 inches apart vertically are sewed onto the shirt for the magnets to be placed. Consistent magnetic polarity is ensured by fixing the magnets to cuttings of cardstock before placed in the pockets. The MMR sensor is placed on the body beneath the shirt and at 2 inches below the top row's middle magnet.

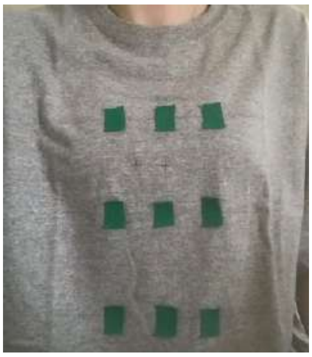

Figure 1. Subject wearing the magnet integrated shirt.

III. Data Collection and System Testing

The MMR sensor can configure sampling frequencies for all data types using the mobile phone application. For all experiments, the sensor recorded the magnetometer data at a frequency of 25 Hz. The data recorded was placed through a lowpass Butterworth filter to eliminate unwanted noise. All data captured from the MMR was processed in MATLAB.

A. Initial Test Procedure and Results

Two protocols were designed and conducted to monitor upper body postures. For both protocols, the participants began and ended with a straight posture. Furthermore, the participants held each position for 15 seconds intervals. A straight posture is established with the head and upper body aligned with the spine. In the first protocol, the participants leaned left and right at 20 degrees. In all trials, leaning left increases the magnetic flux and leaning right decreases magnetic flux in the x-direction. It is determined that the x and y fields are beneficial when analyzing changes in side-to-side postures.

In the second protocol, participants pose their own version of a slouching posture by leaning forward of approximately 20 degrees or more. In all trials, the magnetic flux increases in the x-direction when the participant leaned forward. Changes in the y- and z-directions represent the shirt hanging away from the body, which creates a distance between the MMR sensor and the magnetic grid.

B. Further Testing Procedures and Results

In the initial testing, the magnetic flux does provide a consistent value to indicate straight posture. But, as it can be seen from figures 1 through 3, there exists a slight amount of noise due to the movement of the person. The Z-field of the sensor data, which detects the magnetic field variation with respect to the distance from the chest to the shirt, is bit noisier. This is due to the folding and creasing of the shirt that occurs after the movement. The magnetic flux shows the leaning direction of the participant. Therefore, the magnetic flux is beneficial when analyzing changes in side-to-side postural behavior. To determine when a participant is in a neutral posture, accelerometer and gyroscope measurements are added to the wearable system. The MMR sensor also provides accelerometer and gyroscope measurements. The DC offset with respect to the gravity present in the accelerometer measures the acceleration forces on the body to determine the position and monitor the movement of the body while the gyroscope measures the change in rotation angle of the body. In all trials, the accelerometer, magnetometer, and gyroscope are set to a sampling frequency of 25 Hz. The same two protocols as the initial testing were performed with the participant sitting and standing. Furthermore, each posture position is held for a 15 second interval. Although the accelerometer data is less noisy on the static posture data, its limitations are that it cannot detect the postural changes of the lower body while the magnetic sensor can, as it detects the changes due to a coupling of the lower body movement with the shirt movement, which in turn changes the magnetic fields detected by the magnetometer.

In both protocols, the participants began and ended with a straight posture. In the first protocol, the participant leaned left and right at 20 degrees. Figures 2, 3, and 4 show the magnetic flux, acceleration, and angular velocity strengths detected when the participant was sitting. The change in magnetic flux shows the side-to-side postural changes. Leaning left increases the magnetic flux and leaning right decreases the magnetic flux in the x-direction. The fluctuations in the y- and x-direction of the accelerometer are used to analyze when the participant has a straight, neutral posture. Leaning left decreases the change in acceleration and leaning right increases the change in acceleration in the x- and y-directions.

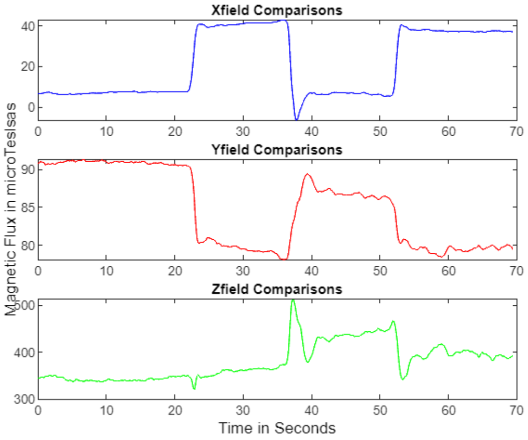

Figure 2. Magnetometer readings of the participant leaning straight, forward, and straight while sitting.

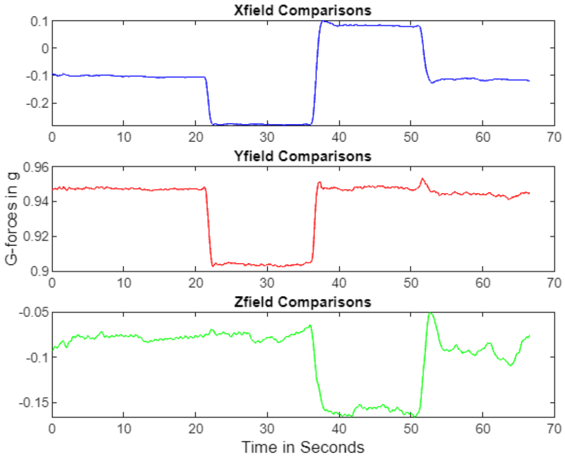

Figure 3. Accelerometer readings of the participant leaning straight, forward, and straight while sitting.

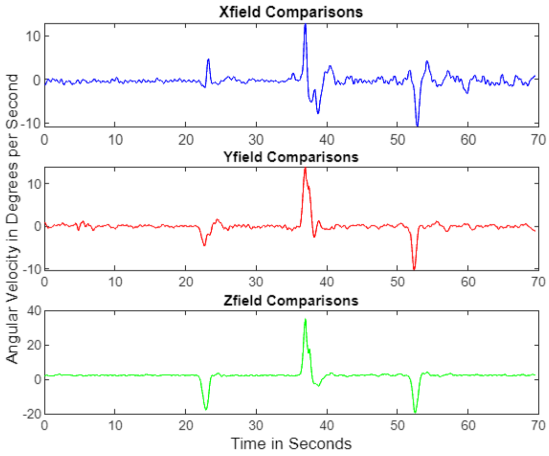

Figure 4. Gyroscope readings of the participant leaning straight, forward, and straight while sitting.

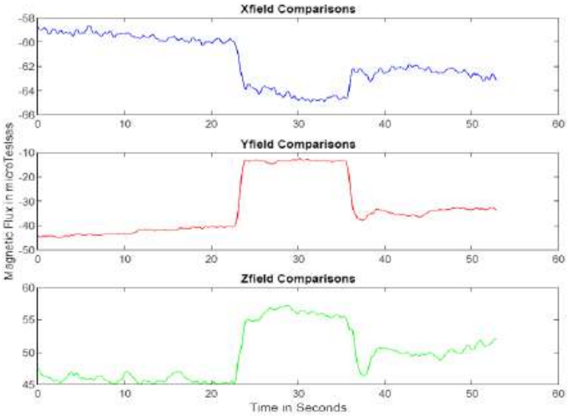

Figure 5. Magnetometer readings of the participant leaning straight, forward, and straight while standing.

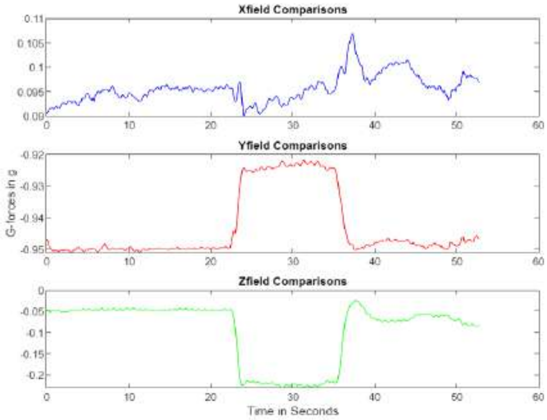

Figure 6. Accelerometer readings of the participant leaning straight, forward, and straight while standing.

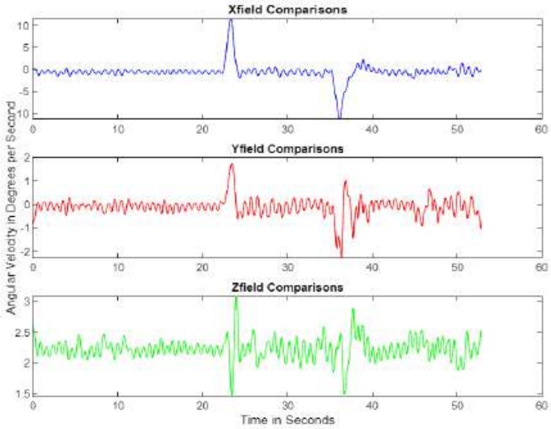

Figure 7. Gyroscope readings of the participant leaning straight, forward, and straight while standing.

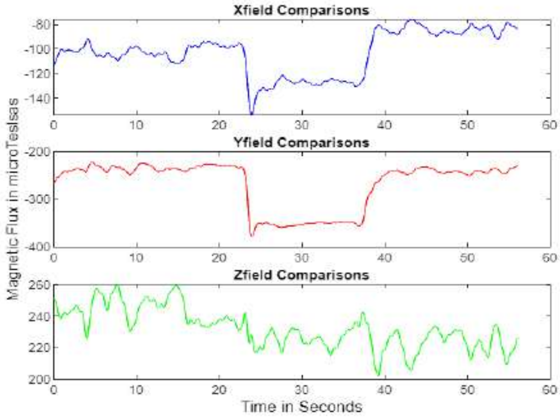

Figure 8. Magnetometer readings of the participant sitting straight, crossing right leg over left leg, and sitting straight.

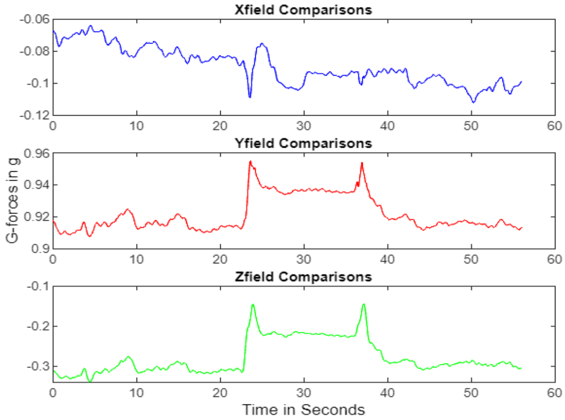

Figure 9. Accelerometer readings of the participant sitting straight, crossing right leg over left leg, and sitting straight.

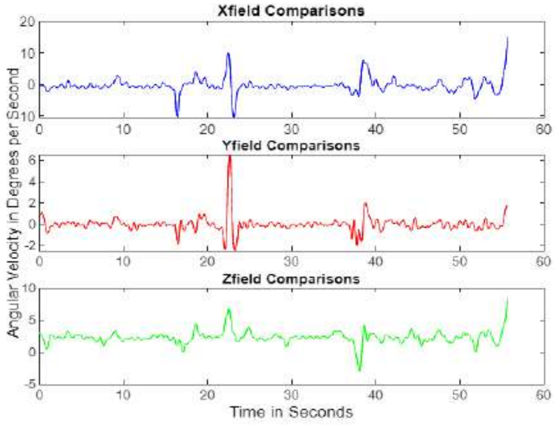

Figure 10. Gyroscope readings of the participant sitting straight, crossing right leg over left leg, and sitting straight.

In all trials, the accelerometer has an initial value approximately zero-G for x and z axis while the y-axis show near one-G for sitting straight up postures. When the participants return to the straight posture after altering postures, the values of the beginning and ending straight posture simulations align. Therefore, accelerometer shows when a participant has a straight, neutral posture. The exact value of the straight posture will change depending on the participant and where the shirt falls on the body. The fluctuations in the y- and z- directions of the gyroscope are useful when determining a change in posture position occurs. Leaning left produces a short decrease in the angular velocity and leaning right produces a sharp increase in the y- and z-directions. Changes in the angular velocity is indicative of the participants holding a constant posture.

The second protocol to simulate a slouching posture was then performed. In this protocol, the participants leaned forward at 20 degrees. Figures 5, 6 and 7 display the changes in magnetic flux, accelerometer/position, and angular velocity of when the participant was standing. When the participant is leaning forward, the magnetic flux is increased in the y- and z-directions. The accelerometer data shows an increase in the y-direction when the participants leaned forward. The x and z directions decrease in the accelerometer data when leaning forward. The accelerometer shows participants holding a straight posture due to its initial and ending value being the same. The initial value will slightly change depending on the participants; however, it is observed that the value is approximately zero. The gyroscope data has a sharp increase in the angular velocity in x- and y-directions when the participant leans forward. This is indicative of the sensor becoming closer to the ground as the participants lean forward.

Throughout all trials, changes in magnetic flux corresponds to the direction the participant has leaned. The addition of the accelerometer indicates when a participant has a straight posture. The gyroscope indicates when and how quickly a change in posture occurs. All measurements indicate how long the participant is holding the posture; however, the gyroscope provides the most promising results in identifying the instance in which a posture is held, although this information can also be extracted from the magnetometer.

C. Common Posture Testing and Results

The initial two protocols gave baseline results of straight posture compared to a slouching left, right, or forward posture. The results were then used to observe the most common types of posture while sitting at a desk. In all trails, the participants held each position for a 15 second interval. The sampling frequencies of the magnetometer, gyroscope, and accelerometer was set to 25 Hz. For all trials, the participant began and ended with a straight posture.

For the first simulation, the participants crossed the right leg over left leg. Figures 8, 9, and 10 show the change in magnetic flux, acceleration, and angular velocity when the participant crosses the right leg. It is observed that the magnetic flux decreased in the x- and y-directions. The z-direction of the magnetometer is noisy due to the movement of the shirt when adjusting position. The accelerometer data shows an increase in the y- and z-directions when crossing the right leg. The accelerometer shows the participant holding a non-straight posture due to the constant increase in the y- and z-directions. The gyroscope data has sharp increases in the angular velocity in the x-, y- and z-directions. This is indicative of the quick change in posture position, which can be tracked via sensor data analysis.

For the second simulation, the participants crossed their left leg over the right leg. It was observed that behaviors of the accelerometer, and gyroscope data values were the same as the observed data patterns of crossing the right leg over the left leg. For all trails regarding the participants crossing the right or left leg over the opposite leg, it was observed that the magnetometer can detect the change in the crossed legs. Depending on where the participants cross their leg, near the knee or further up the opposite leg, the values of the magnetometer data will change; however, the data patterns of the values remain the same. The folding or creasing of the shirt will also change depending on the position of the crossed leg. This is indicative of how noisy the data becomes in the z-direction. This noise due to the creasing and folding of the shirt allows the system to distinguish the lower body postures. For accelerometers, when the lower body position change occurs, there are instantaneous changes but the change in value is not maintained throughout the duration of the posture because the accelerometer responds to the acceleration and when the sensor does not move, it responds to gravity only. The gyroscope data is again an indicative of the instance when the adjustment in position occurs.

Other experiments to simulate common postures at a desk involve various ways of crossing one or both legs. Trials simulating the tucking of a leg under the bottom of the participants as well as placing the bottom of one foot on the chair and leaning on the same leg were conducted. Furthermore, methods involving the movement of an arm in relation to the upper torso, such as the participants leaning the head on the hand with the elbow on the desk, were examined. In all simulations, the magnetometer, accelerometer, and gyroscope data values were observed and analyzed. Again, the changes in the magnetic flux observed are indicative of the position the body. In summary, the magnetometer data corresponds to how far the participants have leaned as well as the sensor placement in relation to the grid of magnets on the shirt. Furthermore, the magnetometer is affected by the folding of the shirt. It is observed that the folding or creasing on the shirt will provide some noisy data when altering positions. The accelerometer helps determines when the participants are holding a neutral posture and when a change of posture occurs. The gyroscope is indicative of the time it takes to change posture position and when the participant holds the posture steady.

D. Current Research Progress

Currently experiments are being completed to allow the system to automatically detect the posture position and provide feedback to the participant. The experiments previously discussed were manually identified and labeled by the research team. An algorithm to determine how far the participants are leaning is being created: it will correlate the angles of leaning to specific postures. This will allow the algorithm to self-identify posture positions and provide feedback to the participants. The feedback will suggest ways in which the participants can change their posture positions. If the participants are leaning in a specific direction for a given amount of time, the system will identify the poor posture behavior, alter the participants of the behavior, and give directions to the participants to correct their posture. The system will recommend the participants to be in specific positions for a given amount of time to elevate the stress on their backs from the poor posture behaviors. The algorithm will provide the feedback recommendations from the data collected in the previous experiments. It will learn and adjust to the different postural positions and provide the most optimal feedback to the participants.

Allowing the system to have a feedback recommendation allows for participants to monitor their own postural behaviors when working from home. This will help elevate the stress on backs when sitting for long periods of time without proper posture due to lack of ergonomical furniture. For the purpose of this document, however, only the data collected and analyzed which proved constant throughout all trials from the magnetometer, accelerometer, and gyroscope changes were discussed.

IV. Conclusion

Through the initial experiments, an unique inexpensive wearable system using magnets, magnetometers, accelerometers, and gyroscope measures to monitor poor postural behaviors has been developed. The system provides a continuous monitoring of the spine in side-to-side and forward leaning positions. The wearable system is washable and can be used multiple times, allowing for an easy access to work at home. With the increase in remote work due to the COVID-19 crisis, the wearable system is an in-home health monitoring tool that can be used on participants in all ages. Furthermore, with more research and development, the wearable system may be used for long-term clinical monitoring on Spine Curvature Disorder (SCD), a medical condition that affects the shape of the spine.

***Abstract* - Heat exchangers are commonly used in industries for the transfer of heat from one fluid to another fluid or from one form to another form. In this process of heat transfer, there is a need for continuous monitoring and control of the system to achieve desired heat levels. Normally, a robust PID controller is used for this purpose. To tune these PID controllers, many conventional methods are available. Of these methods, the OLTR (Open Loop Transient Response) methods are frequently used to obtain the gain parameters of the controllers. However, these methods are limited with respect to adjustment of steady-state error. As the heat exchanger systems are so sensitive to transients, any minor error can deviate the system behavior. In such systems, EPI (Error performance Index) methods provide a better system response by effectively nullifying the steady-state errors. Hence, this paper presents the design of PID controller gain parameters using various EPI methods. MATLAB/Simulink software is used to model the entire heat exchanger system and various control methods. The results justify that a better response is achieved with the use of ITAE based EPI method.**

Keywords - Heat exchanger system, manual setting of gains, PID controller, EPI Tuning methods, Performance parameters, MATLAB/Simulink

I. Introduction

The heat exchanger is generally used in industries for the transfer of heat energy from one liquid to another liquid as shown in Fig. 1. It is equally used for the cooling process also as mentioned in [1]. Some of the applications of heat exchanger systems are extensively refrigerating systems, air conditioning systems (AC's), sewage management systems, petroleum extracting, internal combustion engines (ICE) and refineries. In heat sinks, the heat generated from the electronic components and mechanical components is absorbed and transferred to the coolant fluid with the help of a heat exchanger [2]. In all these applications, there is a need for continuous supervision and control over the system. The common way to achieve this is by using a PID controller [3]. Obtaining the gain parameters for the PID controller that suits the system is a difficult task and there are many tuning methods available to compute gain values. Of all these available methods, the OLTR method is the oldest method and most commonly used [4]. These methods use the open-loop response of the system to obtain gain parameters [5]. The gain values that are obtained using these methods may not be effective for the closed-loop system and many methods in this group give only proportional gain and integral gain values to control the system [6], [7]. The differential gain parameter which plays an important role in controlling the system is ignored by the methods of this group.

In EPI methods, there are procedures to compute all the three gain parameters [8], [9]. These methods use the error between the reference (set value) and the present value of the output to compute gain values. This method is well suited to the considered heat exchanger system as the difference in temperature is a crucial factor to generate the output. The transfer function of a heat transfer system is given by (1).

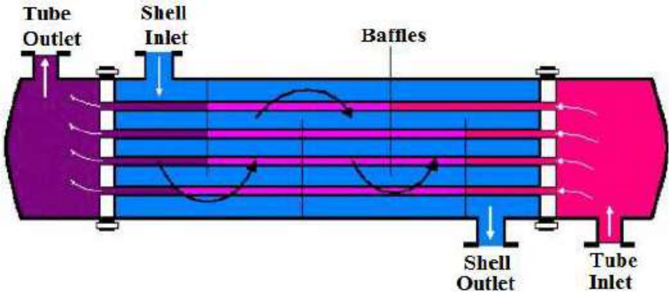

Fig. 1. Simplified representation of heat exchanger module.

$$G(s)=\frac{1}{38s+1}e^{-15s} \tag{1}$$

II. EPI Methods Based PID Tuning for the Control of Heat Exchanger System

A. Design of PID controller by manual setting up of gains:

The design of the PID controller includes proper tuning of gain parameters. These gain parameters are designed by changing the parameters manually according to system requirement or can be computed by some predefined tuning methods [10]- [12]. Many tuning methods are available to set PID gains and out of them, EPI methods are mainly chosen to control many system parameters. The PID controller block consists of proportionality gain, integral gain constant as well as derivative gain constant. All resultants of these three constants are summed up by using an adder block. The output of the PID controller will be a control signal which is a sum of all three gain constants as shown in Fig. 2. The mathematical notation of the controller is shown in (2). The values of K_P, K_I and K_D determine the dynamic performance of the system.

$$U(t)=K_p e_p(t)+K_I\int_0^t e_p(t)dt+K_D\frac{de(t)}{dt} \tag{2}$$

Where,

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$U(t)$ = Output of PID controller (control signal)

K_p = Constant of Proportionality

$K_I = \frac{K_P}{T_I}$ = Constant of Integration

$K_D = K_P \times T_D$ = Constant of Differentiation

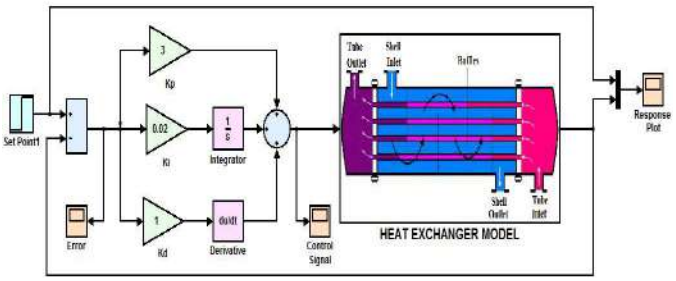

Fig. 2. MATLAB/Simulink model to represent the manual setting of PID gain.

The advantage of increasing the value of K_P is the decrease of error in steady-state and reduced rise time. It has a disadvantage of increased signal peak overshoot and change in settling time of the signal. Increasing the value of K_I creates an advantage of the decrease in rise time and error, but it affects the peak overshoot and settling time. Increasing the value of K_D reduces the peak overshoot of the signal and settling time, but results in a minor decrement in rise time and does not affect the error. Hence, in general for any systems which require a quick response, a PD controller is highly preferred, and for the systems which are more sensitive to steady-state error, a PI controller is preferred. At present, in many parts of industries, the PID controller is preferred because of having flexible control among all performance parameters. So, for a system to be stable and to acquire the desired response, an appropriate controller need to be designed [13].

B. Controller design with EPI tuning methods:

Error performance indices methods help to attain an improved performance and stability for the heat exchanger module. The steps which are to be followed to calculate the gain parameters are described as follows [14].

- **Step-1:** This step includes removal of negative feedback loop and controller of the system so that no control action is provided to the system. The feedback loop is connected between output of the system and the input of the controller.
- **Step-2:** Here, the step response of the system is probed and the response obtained is termed as process reaction curve.
- **Step-3:** In this step, a tangent is drawn to the open-loop reaction curve at the contact point of inflection. Inflection point is termed as the point at which the tangent and reaction curve have maximum contact area. At this point, the slope of the reaction curve starts decreasing. From the marked points, lag time (L_t), process reaction time (T_p) and stationary gain (K) are computed.
- **Step-4:** This step includes the calculation of PID gain parameters (K_P, K_I, K_D) by using (3)-(5). The constant values x_1, x_2, x_3, y_1, y_2, y_3 are given in Table. I for the calculation of K_p, T_I, T_D.

Where 'L_t' is the time interval between origin and the point at which the tangent line crosses the x-axis (time axis). Also, 'T_p' is defined as the time interval between point of intersection of tangent with time axis and the point on the time axis at which the tangent crosses the desired input as shown in Fig. 3. 'K' is stationary gain. Fig. 4 shows the simple flowchart representation of the process used to find gain parameters using EPI tuning.

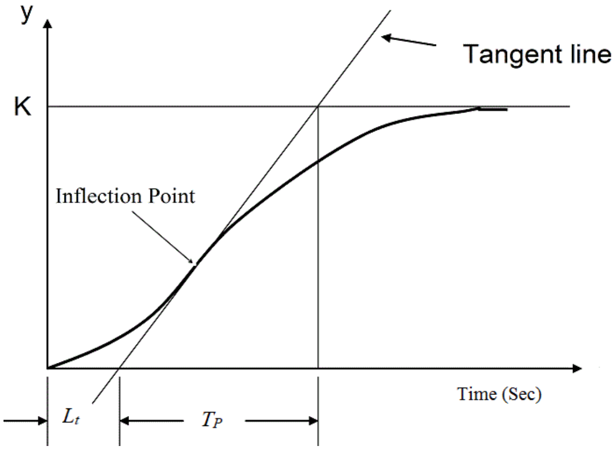

Fig. 3. Process reaction curve.

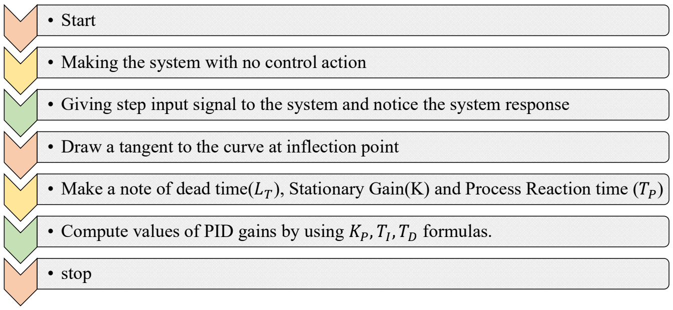
$$K_P = \frac{x_1}{K}\left(\frac{L_t}{T_p}\right)^{y1} \tag{3}$$

$$T_I = \frac{T}{x_2 + y_2\left(\frac{L_t}{T_p}\right)} \tag{4}$$

$$T_D = x_3 T\left(\frac{L_t}{T_p}\right)^{y3} \tag{5}$$



- Start
- Making the system with no control action
- Giving step input signal to the system and notice the system response
- Draw a tangent to the curve at inflection point
- Make a note of dead time(L_T), Stationary Gain(K) and Process Reaction time (T_P)
- Compute values of PID gains by using K_P, T_I, T_D formulas.
- stop

Fig. 4. Steps for computing tuning parameters using EPI methods.

TABLE I. PARAMETERS FOR CALCULATING PID GAINS USING EPI METHODS

Constants	ISTSE	ITAE	ISTE	ISE
x_1	1.042	0.965	0.968	1.048
y_1	-0.897	-0.85	-0.904	-0.897
x_2	0.987	0.796	0.977	1.195
y_2	-0.238	-0.1465	-0.253	-0.368
x_3	0.385	0.308	0.316	0.489
y_3	0.906	0.929	0.892	0.888

III. Time-Domain Performance Indices

When a closed-loop system response changes with respect to time, it is termed as the dynamic performance of the system. There are certain performance parameters as mentioned in [15], which are helpful to validate the system response. They are described as follows. Fig. 5 represents all the performance indices, which are helpful to analyze the stability of a system.

- **Delay-Time(T_d):** In transient state, the time required for the system response to outstretch from 0 – 50% of the desired value for the initial period of time is defined as Delay Time.
- **Rise-Time(T_r):** In transient state, the time required by system response to outstretch from 10 – 90% of the desired output for the initial period of time is said to be Rise-Time.
- **Settling-Time(T_s):** In transient state, the time required by the system to fix in a band of (2 – 5%) tolerance is termed as settling time.
- **Peak-Overshoot(M_p):** The deviation of the output response well above the desired output value (setpoint value) is considered as the Peak Overshoot. It is calculated by (6).

$$M_P(\%) = \frac{\textit{Peak value - Desired value}}{\textit{Desired value}} \times 100 \qquad (6)$$

- **Steady State Error(SSE):** The deviation of the system response from the desired value in steady-state is considered as steady-state error.

The simulink model for the heat exchanger system considered for the analysis is shown in Fig. 6. It contains step input signal block which is also termed as a desired response, summation block which calculates the error, PID block which is used to control the system and scope which is used to visualize the output response of the system.

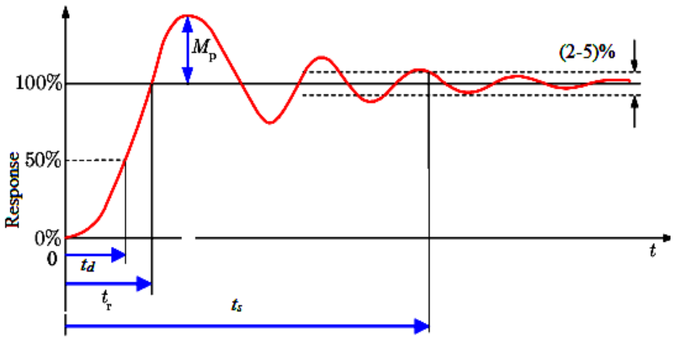


Fig. 5. Performance parameters for a first-order system response.

IV. Simulation Results

The following simulations represent the output responses of the system achieved by applying PID gains to the controller. controller gains for various tuning methods are represented in Table. II. Performance indices are used to justify the system stability in the time domain. For a system that has less performance indices values are said to be a stable system. ISE and ISTE methods give more oscillations in their transient time as shown in Fig. 7 and Fig. 8. For ISTSE and ITAE methods, the responses recorded less oscillations in transient time as shown in Fig. 9 and Fig. 10. Comparative visualization of all the system responses is shown in Fig. 11, where it is easy to compare responses in terms of performance indices.

TABLE II. Controller Gains For Various EPI Methods

S. No	Tuning Methods	K_p	K_i	K_d	T_i	T_d
1	ISE	3.1713	0.06636	26.607	47.788	8.391

TABLE III. Time Domain Performance Indices of the System Simulated with Various EPI Methods

S. No.	**EPI Tuning Method**	**Time Domain Performance Indices**				
		Delay-Time/ Lag Time (T_d)	***Rise-Time(T_r)***	***Settling-Time(T_s)***	***Peak-Overshoot(M_p)***	***Transient Nature of the System***
1.	ITAE Method	18.1	25.6	88	24.81	Oscillatory
2.	ISE Method	16.01	19.05	200	40.11	Oscillatory
3.	ISTE Method	16.02	21.23	132	34.64	Oscillatory
4.	ISTSE Method	17.2	24.95	109	27.53	Oscillatory

V. Conclusion

This paper implements and evaluates all the Error performance index based PID tuning methods for heat exchanger control system. Various time-domain performance results are obtained for the comparative analysis. These are computed for each EPI method and tabulated as shown in Table. III. By comparing all these obtained values, the following conclusions are made.

- ITAE method takes less time to settle, less percentage of peak overshoot and no steady-state error when compared with other EPI methods.
- ISE method has shown degraded performance for this system as it has a high settling time and peak overshoot. Further, it is having high oscillatory behavior in the transient state.

Thus, among all the EPI methods, ITAE is recommended as the superior method for the design of the PID controller for the heat exchanger system.

***Abstract* - The industrial heating furnace (IHF) is a system that requires continuous monitoring and control over the temperature. A small deviation in the temperature may create a huge impact on the system. So, there is a need for proper control for IHF. The conventional way is using PID (Proportion + Integral + Derivative) controller as the process controller in industries. Many standard tuning algorithms are present to compute gain values for the PID controller. The drawback of these conventional controllers is poor disturbance rejection as these are tuned offline to the system so that they cannot address the disturbances that occur while the system is working. So, there is a need for an artificial intelligent controller that can rectify the disturbance that occurs while the system is running. This can be achieved by using Fuzzy logic based controller that feeds the gain values externally to the PID controller according to the disturbance. The entire system design is simulated with the help of MATLAB/Simulink software. The outcome depicts that the proposed fuzzy-based controller has the best dynamic performance, rapidity, and good robustness.**

I. INTRODUCTION

The device that is used for heating the materials in industries is defined as a furnace. Heat will be generated in the furnace by mixing up fuels with air. Industries use these types of furnace equipment for melting up of metals, for combining two metals, forging (shaping) of metals, galvanizing, enamelling (coating of glass on the metals) etc. Some of the furnaces types are household furnaces, metallurgical furnaces, and industrial furnaces.

The use of Household furnaces is to generate heat inside the house. Generally, a household furnace is installed by providing the movement of fluid, which may be through hot water, steam or air. Metallurgical furnaces are used in factories for casting metal. In these, furnaces are used for heating and reheating of the metals which are used in: Slitting mills, including tinplate works and Rolling mills and industrial furnaces or direct fired heaters, are used for generation of heat in the industries. These furnaces are also used to serve the reactor which provides heat for the reaction. These types of furnaces have many designs. The designs vary because of fuel used and purpose of heating and the method of initiating combustion air. A simplified representation of an industrial process furnace is as shown in Fig.1.

In IHF the control aspect of temperature is the key part of the industrial process. So this control of the temperature can be achieved using a conventional PID controller [1]. For obtaining the gain values for this PID controller many traditional tuning methods are available [2]. Of these available tuning methods, some of the methods use only the open-loop response of the system which may not be appropriate when these values are used for closed-loop response of the system and another group of methods requires the sustained oscillations for calculating the gain values as it is not possible for all kinds of systems [3]-[5].

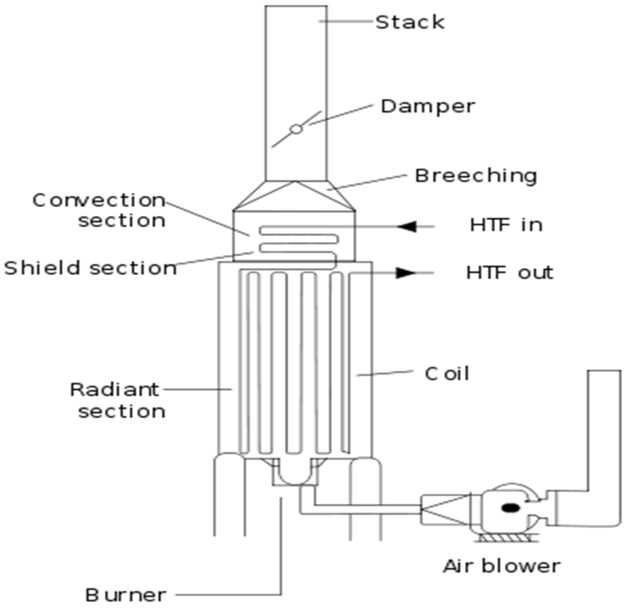

Fig. 1. Simplified representation of an industrial process furnace

In the same way, certain limitations are associated with each of the traditional tuning methods. So, picking up the correct tuning method for the targeted system becomes a difficult task and also the main imperfection of these traditional methods is that the rejection of disturbance is very poor and also these cannot address the online disturbance i.e. disturbances that occur while the system is running [6]-[8]. To overcome all the above-discussed problems there is a necessity of going to a fuzzy logic-based PID (FLP) controller which uses the fuzzy theory for obtaining the gain values according to the disturbance and feed them to the conventional PID externally [9], [10]. So, in this paper FLP controller is used to control IHF. The IHF can be qualitatively modelled using equations (1) - (2). The transfer function for this system can be obtained from [11].

$$H(s) = \frac{K}{TS+1} e^{-\tau s} \qquad (1)$$

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

$$H(S) = \frac{11}{50\,S + 1} e^{-8S} \qquad (2)$$

Where, K = 11, which represents the static gain; T = 50 sec, which represents the time constant; τ = 8 sec, which represents the lag delay time.

II. Implementation of Conventional PID Controller

Many industrial applications use PID controller for controlling different processes like temperature flow, pressure flow, liquid level etc. PID controller sets the system response to our desired response by choosing appropriate K_p, K_i, K_d gains values. Many conventional tuning rules are present to calculate the gain values but selecting a particular tuning rule for a PID controller is a tough task [5]. Moreover, all these methods are offline and need to set up manually to the controller. Proportional, Integral and Derivative gain are added up to obtain controller output as shown in (3).

$$U(t) = K_p e(t) + \frac{K_p}{T_i}\int_0^t e(t)dt + K_p T_d \frac{de(t)}{dt} \qquad (3)$$

Where,

U (t) = controller's output signal given to system
K_P = Proportional-Gain
$K_I = K_P / T_i$ = Integral-Gain
$K_D = K_P \times T_D$ = Derivative-Gain
E = Error = Desired value (DV) – Obtained Value (OV)
T = Time or instantaneous time

The following are some of the PID tuning rules for designing gain values of the PID controller.

Ziegler and Nichols introduced two methods namely Ziegler-Nichols (ZN) closed-loop method and Modified Ziegler-Nichols (MZN) method in the year 1942 [3]. While designing their controller tuning algorithms they used a phenomenon called allowable stability which mentions that the ratio of two succeeding peaks of the system response is close equals to 1/4 as shown in Fig.2. Modified Ziegler-Nichols (MZN) is another tuning method for designing gain values of closed-loop systems which are introduced by Ziegler and Nichols. The main focus is to initiate this method to provide good stability and better time-domain specifications when compared with the ordinary ZN tuning method.

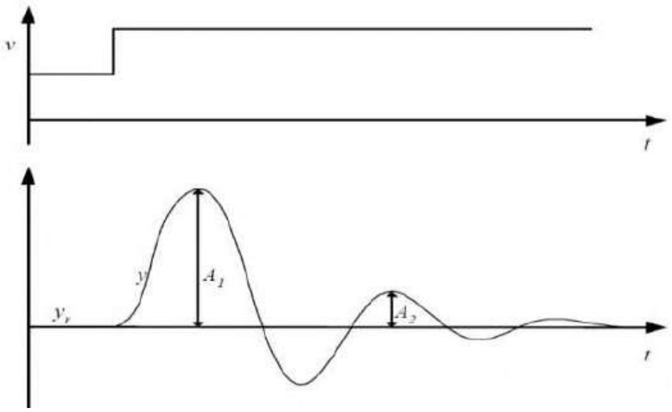

Fig. 2. Allowable stability condition for ZN method

Tyreus-Luyben's method was originated in the year 1992 which depends on oscillations in Ziegler-Nichols Method but with some minute changes in formulas for calculating PID gains. This method gives better stability in contrast to the Ziegler Nichols method [7]. The output response of the system which uses this method will have less oscillatory and less subtle uncertainty. Shinskey PID Controller is another tuning method for a closed loop control system. The main scope of this method is to yield good stability and better time-domain specifications and Zhaung-Atherton PID Controller is another tuning method for the closed loop control system. The main objective of this method is to provide good stability and better time domain specifications. So the formulas for designing the controller gains for various methods are given in Table. I.

The entire system design with the conventional controller is shown in Fig.3 where the desired value is considered as a step signal and controller gains are taken as shown in Table. II.

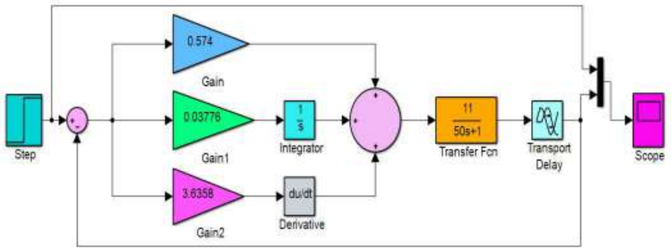

Fig. 3. System design with conventional PID controller

III. IMPLEMENTATION OF PROPOSED FUZZY LOGIC BASED PID CONTROLLER

Fuzzy logic is the most effective controller for nonlinear, time-variant systems and also it doesn't require the transfer function of the system for obtaining gain values [12]. The IHF considered in this paper is a nonlinear system as the temperature of the furnace should be regulated constantly even in the case of disturbances that occur externally. So, to achieve this, the FLP controller is used for controlling the IHF in this paper. The fuzzy logic controller converts all the input and output values given to it in the range of 0 to 1. Thus, converted inputs and outputs are mapped using the fuzzy inference structure (FIS) as shown in Fig.4. In fuzzy logic control (FLC) all the crisp values are converted into the fuzzified values (between 0 to 1) and this process is called fuzzification. In this fuzzification process, many membership functions such as trapezoidal, triangular, signum etc., membership functions (MFCN) are available. These MFCN's are to be taken according to the type of the system. Mamdani and Sugeno are the two conventional fuzzification processes that are available. The defuzzification process starts after the processing of input data is done. The defuzzification process is quite opposite of the fuzzification process. In this, the fuzzified values are converted back into the crisp values. In the case of the defuzzification process, there are many methods such as the centre of sums, first of maxima method etc. are available. The relation between the input and output MFCN is done by creating the set of rules. The efficacy and the intelligence of the FLC depend on the rules that are fed to it. By using the FLP, it takes the supremacy of both the conventional PID controller and the intelligent FLC in controlling the system [13]. The gain values according to the disturbance are fed to the conventional PID controller so that it can address the disturbances efficiently [14] - [16]. So, this paper proposes the FLP controller developed using the gaussian MFCN and Mamdani method. MATLAB/Simulink model of the system with Fuzzy PID controller is shown in Fig.6 and the ranges of each MFCN is described in Table. IV. The Table. III and Fig. 5 shows the rules for mapping input and output where P1>P2>P3.

IV. Results and Analysis

The results are segregated into time-domain response analysis and frequency-domain response analysis. These results discuss the system behaviour under the transient state and the steady state as described follows.

A. Time-Domain Response Analysis

The following results show the time domain system response with various conventional PID controller and FLP controller. The time-domain specification will help to judge whether the system response is better or not. Various time-domain performance indices like Rise time (RT), Delay Time (DT), Settling Time (ST), peak overshoot (PO) and transient behaviour for all the system responses are listed in Table.5. The responses which are having less settling time with no peak overshoot and smooth transient behaviour will be considered as a good response. The output response of the system with the ZN method, MZN method and Shinskey method has a high Peak overshoot. In transient state, all the system responses with conventional tuning methods show oscillations except Fuzzy PID and Tyreus-Luyben as shown in Fig.7 and Fig.8.

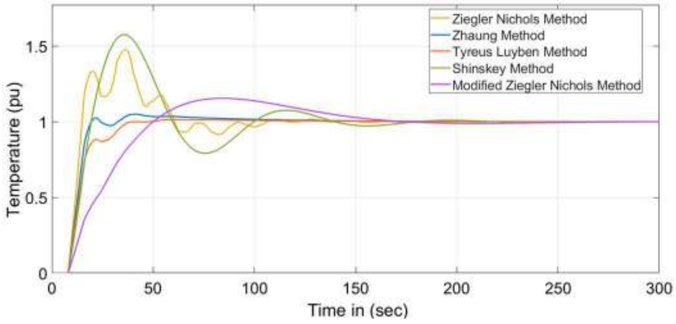

Fig. 7. Comparison of various traditional PID methods for the system

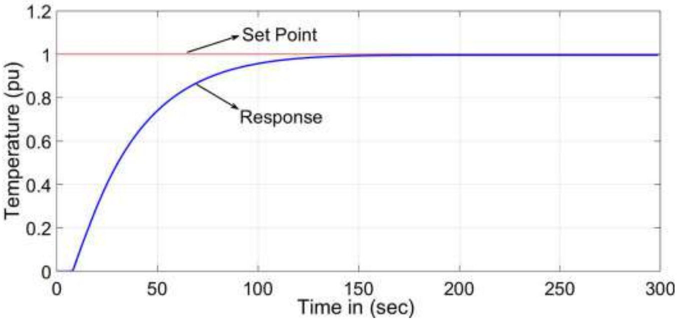

Fig. 8. System output with FLP controller.

TABLE V. Time Domain Perfoemance Indices of Conventional vs Proposed Fuzzy PID controller

S. No	Tuning methods	Delay-Time (D_T) in sec	Rise-Time (R_T) in sec	Settling-Time (S_T) in sec	Peak-Overshoot (P_O) in %	Transient Behavior
1	Ziegler-Nichols PID Controller	3.59	5.544	109.14	47.25	Oscillatory
2	Modified Ziegler-Nichols PID Controller	15.87	33.155	170.194	15.81	Oscillatory
3	Tyreus-Luyben PID Controller	5.363	20.698	39.665	1.5	No Oscillations
4	Shinskey PID Controller	11.48	12.455	175.3	57	Oscillatory
5	Zhuang-Atherton PID Controller	9.6	8.86	106.3	7	Oscillatory
6	Fuzzy-PID Controller	24.4	65.754	129.2	No Overshoot	Smooth

B. Frequency-Domain Response Analysis

The most commonly used methods for analysing the stability of the system in the frequency domain is the bode plot. Bode plot analysis is a process of analysing the transient-state and the steady-state response of the system with the help of frequency and phase. The stability of the system is given can be decided with the help of gain margin (GM) and phase margin (PM). So, to analyze these parameters, the bode plots are drawn as given through Fig. 9 to Fig. 14. The observations from these plots are given as follows.

- Fig 9 shows the bode plot for the ZN-PID method and from this, it can be observed the PM value are 138, -180 and the GM value is 0.
- Fig 10 shows the bode plot for the MZN PID method and from this, it can be observed the PM value are 152, -180 and the GM value is 0.
- Fig 11 shows the bode plot for the Zhaung-Atherton PID method and from this, it can be observed the PM value is -180 and the GM value is 0.
- Fig 12 shows the bode plot for the Shinskey-PID method and from this, it can be observed the PM value are 119, -180 and the GM value is 0.
- Fig 13 shows the bode plot for the Tyreus-Luyben PID method and from this, it can be observed the PM value are 152, -180 and the GM value is 0.
- Fig 14 shows the bode plot of the FLP method and from this, it can be observed the PM value is -180 and the GM value is 28.2.

Normally, the response with high PM and GM are considered as the more stable system. Hence, it can be concluded that the proposed FLP method is superior in terms of GM.

V. Conclusion

With the use of the traditional PID controller for controlling the IHF system, there are some drawbacks such as poor rejection of disturbance, picking of the appropriate method according to the system, etc. These are addressed by using the proposed FLP controller. With the use of the proposed FLP for the IHF system, the following achievements are obtained.

- As the IHF system has non-linear characteristics, the controller design using traditional methods is not effective. Whereas, the use of the proposed FLP controller has produced better output.
- The proposed FLP controller produces a smooth response of the system with no peak overshoot wherein case of using the traditional controller, the system produces an oscillatory response with peak overshoot.
- The proposed FLC has a higher capability to reject the disturbance.

***Abstract*—Smartphones are considered as the most pervasive electronic devices all over the world. These hand-held devices are carried with people wherever they go. Thanks to the availability of communication infrastructures anywhere, people depend on these devices to accomplish some tasks related to their work (resp. study), indispensable social media tool and a storage tool for a lot of user's private content such as photos, videos, messages, emails, etc. For that, smartphones should be protected against unauthorized access. Current access control models to services and applications of the smartphones are static (fixed) even though the user context is dynamic, and some access control model could not be appropriate in some contexts for the security and safety of both user's privacy and smartphone. Moreover, existing access control models are not dedicated to personal devices like smartphones but oriented to multi-users and network devices. In this paper I propose a context-aware access control model for smartphones which adapts dynamically to the user's context and provide appropriate access control mechanism to improve the security and safety of both user's privacy and smart phones.**

***Keywords*—smartphones, access control, context, authorization, dynamic, permission.**

I. Introduction

People nowadays rely on their smartphones to accomplish a lot of their everyday tasks, social communication and storing private contents. Smartphones are becoming a precious device for them which should be protected against unauthorized access and should be kept secure all the time. Current access control mechanisms to services and applications of the smartphone are mostly static (set once by the user) even though the user context is dynamic and access control model could not be appropriate in some contexts for the security and safety of both user's privacy and smartphone. Some safe and trusted contexts such as sitting alone at home do not require a powerful mechanism for access control to smartphone and its applications because the security risks (e.g., shoulder surfing or the use by non-trusted person) are minim. On the other hand, if the user is in a public place such as a cafe, the smart phone access system should consider the risk of using the smartphone in such a place like shoulder surfing when user access some services to keep his/her privacy away from the eyes of nosy people. Also reinforce the security of the smartphone when there is a possibility that the user's smartphone is used by a stranger which could be happen frequently when the user forgets to take his smartphone with him/her and leaves it with companions for whatever reason. In addition, mostly access control mechanisms are not oriented to personal devices like smartphones but to multi-users devices and networked equipment. In this paper I propose an approach to adapt the access control system to the changing context of the user to provide appropriate and secure access to smartphone and its applications. The context-aware access control adaptation is done using contextual information especially location and surrounding people.

The rest of this paper is organized as follows: Section 2 presents previous work on access control models. Section 3 discusses the risks of using a smartphone related to location and nearby people. Section 4 describes the proposed approach for context-aware access control and Section 5 concludes the paper.

II. Previous work

In the field of information security, Access control is a fundamental security mechanism to regulate who can access an asset and what can be done with it. Access control is a selective restriction of access to computer devices, networks, applications and data. Its main goal is to minimize the security risks of an authorized access by ensuring that users are who they claim they are and have been granted the appropriate permissions. Generally, the access control system process consist of three basic steps:1) identification is the act of uniquely identify a person (resp. a subject) which performed generally by providing a user name, smart card or anything else that uniquely identify the user. 2) authentication which consists of proving a claimed identity by providing the appropriate credentials such as password, a personal identification numbers (PINs), a security token, biometric scans or other authentication factors. 3) authorization that specifies access right/privileges to resources and what can be done according to permission granted.

Among the first models of access control is the Discretionary Access Control (DAC) [1] which is based on an access control list that describes what operations can be done on a given object by each subject. Another model is the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

mandatory access control in which a central authority regulates access rights to resources according to a multiple level of security. The role-based access control model was introduced by [2] to enforce the previous access control ones where access to resources is granted according to the job function of a user (resp. group of users) inside an organization instead of identities of individual users. Wang et al.[3] proposed the Attribute-based access control (ABAC) model in which access to resources was granted according to the attributes of users, systems and environmental conditions. Das et al [4] developed the MITHRIL framework [5] which included an access control component called the MithrilAC that used the Attribute-Based Access Control standard. The aim of the MithrilAC component was to capture the behavior of an application in a particular context and user's access control needs in order to refine the access control policy. Arfaoui et al. [6, 7] proposed a new context-aware attribute-based access control scheme which took into account the dynamic change of context. the proposed approach was oriented to IoT devices which have limited processing capabilities. They combined the user's attributes with contextual information to check if the user satisfies or not the access policy. They used the CP-ABE (ciphertext-policy attribute-based encryption) scheme and embed the contextual information into access structures using contextual tokens. Kayes et al. [8] Presented a survey of security, privacy and access control research which used contextual information and oriented to cloud and fog networks. They proposed a Fog-Based Context-Aware Access Control (FB-CAAC) framework for accessing data from distributed cloud data centres along with IoT devices and fog computational nodes. Kayes et al. [9] proposed a Context-Aware Access Control (CAAC) Policy Framework based on the role-based access control approach which used a formal policy model to specify user-role and role- permissions assignment based on relevant contextual information. The policy used a context specification language and ontology for modeling context-aware access control (CAAC) policies. Ternka et al. [10] made an interesting survey on authentication and authorization methods for internet of things in which they showed how context-awareness extends security. Some other work like [11, 12, 13] were oriented to context-aware authentication systems rather than to the whole access control process.

III. RISKS RELATED TO LOCATION AND NEARBY PEOPLE

Nowadays, the best known and used technologies for wireless communication are Bluetooth and Wi-Fi and all smartphones are equipped with both wireless technologies. Several risks related to our pervasive use of smartphones need to be addressed and wireless security is just one often-overlooked piece of the mobile security. In a public place or in a crowded untrusted place, hackers can potentially gain access to a smartphone through either Bluetooth or Wi-Fi protocols. They can eavesdrop on our conversations and even steal our personal and business' data stored on smartphones. Some well-known attacks related to Bluetooth protocol are: 1) Bluebugging or Bluejacking attacks which are somehow old and recently are easily prevented. 2) Bluesnarfing attack where it is possible to access personal content and even copy the content of the smartphone. Alike, common Wi-Fi attacks include: 1) session Hijacking where hackers use sniffer tools to look through transmitted packets and find the information needed, generally occur when using an open Wi-Fi network. 2) Evil Twin attack where a fake access point with the same name of the one used by the user is setup by the attacker to capture all the data traffic made by the user's smartphone. 3) Man in the middle attack where the hacker listen and modify transmitted data between the user's smartphone and other parties. This attack can be initiated using DHCP spoofing among others methods.

To avoid the aforementioned attacks on wireless protocol, user's should avoid using public Wi-Fi networks or use a connection encrypted by a VPN (Virtual Private Network). Keep Bluetooth settings to non-discoverable or invisible in public places and switch it off when it is not in use. Also require user approval for devices pairing with the smartphone.

Due to the user's mobility, most smartphones services and applications can be accessed even in public places resulting in a high probability of a social engineering attack called shoulder surfing which consists of observing other people's information without their consent over their shoulders. This attack is generally used to obtain information such as passwords and other confidential data. To protect against such attack, the smartphone should demand a two-factors authentication (preferably one of them biometric) to access sensitive applications in public places. It is also possible that the smartphone notify the user to be with his/her back to the wall or to angle the smartphone screen so that other people cannot see what he/she is typing or watching. These are the two common ways to protect from prying eyes.

IV. CONTEXT-AWARE ACCESS CONTROL MODEL

A smartphone provides a set of services to the user and allow him/her to access and use several applications. In order to access the smartphone services and applications, user should be granted authorization to use the smartphone which generally locked for security purpose an require an authentication method which mostly a password, a PIN (personal identification number), a pattern drawing, fingerprint etc. But some users allow a direct access to their phone which is not advised at all in some contexts. Once user has access to smartphone, he/she could access most applications which do not require new authentications since user was already authenticated previously except some applications which demand a new authentication at each access. This situation exposes the smartphone to many risks related to access to personal data (resp. credentials) and the possibility of it being stolen if another person accesses the user's smartphone or sees the content of the smartphone by another person during normal use by the owner of the smartphone.

A. Applications classification

In order to provide a personal authorization system, smartphone user should provide his/her preferences in term of which permission should be granted to which applications. For this reason, applications (including access to smartphone) are classified in two categories: sensitive and normal.

It is up to the user to classify each application to either sensitive or normal application. The classification is done according to whether the application contains private data or user's credentials. For example, the clock application could be classified as a normal one because it does not contain any user's private data or credentials and access such application does not present any risk. However, a banking application should be classified as a sensitive one because it contains both private data and user's credentials. One example of possible applications classification is given by Table 1.

TABLE I. APPLICATIONS CLASSIFICATION

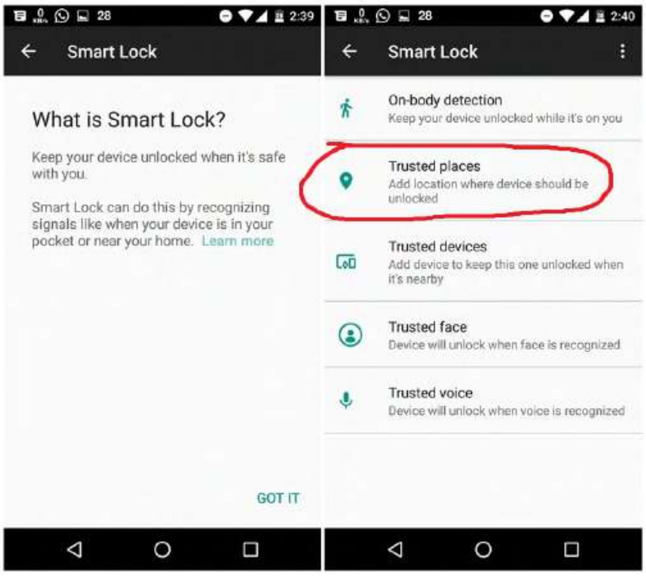
Application	**Type**	
	Sensitive	***Normal***
Access to smartphone (unclock)	■	
Clock		■
Social media (facebook, what's up, …)	■	
Calender		■
Banking	■	
Photo/video galery	■	
Phone book	■	
Games		■
Health	■	
e-mail	■	
Weather		■
SMS	■	
…	…	…

B. *Locations classification*

User and his/her smartphone can be in multiple locations which can be classified mainly in two types of location:

- Private location: set of places where risks of accessing smartphone and its applications are minim. It is somehow a trusted location. The best example of such location is home where user is not afraid that his/her smartphone can be used by a stranger and steal or view his/her personal data (resp. credentials). Such locations do not require high level permissions.
- Public location: the set of places where there are a lot of strange and non-trusted people and present a high security risk for smartphone accessing. These types of locations generally refer to public places and can be subdivided into two types:
    - ➢ Trusted public place: security risks on smartphone are not raised in such place. it is a trusted place. The ideal example of a trusted public place is the user's office at work.
    - ➢ Non-trusted public place: user does not has a private corner in such places and surrounded with a lot of strange people. These places present a high risks on smartphones.

A somewhat similar classification that allows the user to choose his trusted places to automatically unlock his/her smartphone without going through the authentication step is provided by the Google Smart Lock for android devices [14] (see Figure 1). However such application does classification into either trusted places or non-trusted places. In addition, this application is specific for only automatic unlock of smartphones and not for unlocking or accessing other applications.



What is Smart Lock?

Keep your device unlocked when it's safe with you.

Smart Lock can do this by recognizing signals like when your device is in your pocket or near your home.

On-body detection
Keep your device unlocked while it's on you

Trusted places
Add location where device should be unlocked

Trusted devices
Add device to keep this one unlocked when it's nearby

Trusted face
Device will unlock when face is recognized

Trusted voice
Device will unlock when voice is recognized

Fig. 1. Google Smart Lock [13]

C. *User's situations classification*

Due to the permanent user mobility, context of use of smartphone is ever changing. One important information which affect the context of use of smartphone is the user's nearby people. The main risk generated by this context element is the shoulder surfing attack especially when the user is surrounded by some people and trying to access sensitive (resp. private) data through his/her smartphone. This context element is not independent but influenced by the user's location. Even though in a same situation where the user is alone, it differs either his alone in a private place or alone in a public place. So granting permission to user should consider both his/her situation and location. There are two main situations:

- Alone: In this situation, the risk of shoulder surfing attack is practically absent.
- Not alone (surrounded): in this situation the occurrence of a shoulder surfing attack is strongly possible.

D. *Smartphone's use context*

In all, there are six smartphone's use contexts related to locations and user's nearby people which are the result of the cartesian product of the set of possible user's locations and user's situations (Fig.2 shows all possible smartphone’s use context).:

- **C1**: The user is alone in a private place.
- **C2**: The user is not alone in a private place.
- **C3**: The user is a lone in a trusted public place.
- **C4**: the user is not alone in a trusted public place.
- **C5**: The user is alone in a non-trusted public place.
- **C6**: The user is not alone in a non-trusted public place.

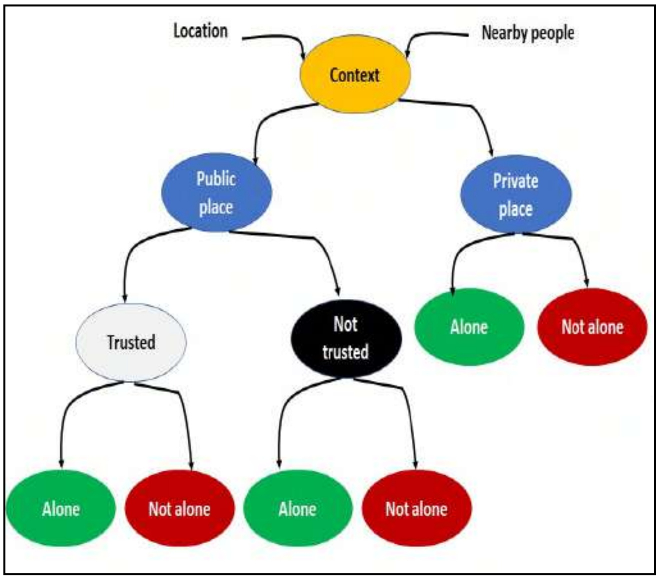


Fig. 2. Set of smartphone use context

E. Context-aware authorization model

In each of the aforementioned contexts, the user is vulnerable to some threats. Generally we can classify these threats into four classes (T1, T2, T3, T4) as follows:

- Use of public Wi-Fi network **(T1)**: the use of a public WiFi network can make the smartphone vulnerable to some attecks as mentioned in section III.
- Open Bluetooth **(T2)**: if the user's smartphone is open it could be vulnerable to some kind of attacks related to Bluetooth
- Visible content **(T3)**: when the smartphone content is visible, shoulder surfing attack may occur by nosy people and prying eyes
- Available smartphone **(T4)**: if user forget to carry his smartphone with him where ever he goes, it could be then accessed by someone else.

To every context of use is assigned a risk degree from the following list: {Zero, Low, Average, High, Very high} depending on how many type of the above risks present in that context.

In context C1, when the user is alone in a private place and using his private Wi-Fi network with trusted people, normally there is no threats and the risk degree will be zero in such context. Context C2 is alike to context C1 except the user is not alone, so the threat of accessing his/her smartphone by someone else or watching his/her personal content over his/her shoulder is present. So the risk degree will be Average. When the user in alone in a trusted public place, the smartphone will be connected to a trusted Wi-Fi network and controlled environment (case of office). The smartphone is vulnerable to one possible threat related to open Bluetooth connection where people generally omit to close their Bluetooth in a trusted place. In this case the risk degree is low because the possibility of making Bluetooth attacks in a trusted place is minim. In context C4, when the user is not alone in a trusted public place, the smartphone can be vulnerable to both shoulder surfing attack and access by other people in addition to possible Bluetooth related attack. In this case the risk degree is high. When the user is alone in a non-trusted public place (context C5), the smartphone is vulnerable to both Wi-Fi related attacks and Bluetooth related attacks. The risk degree will be then average. Finally, in context C6 when the user is not alone in a non-trusted public place, the smartphone is vulnerable to the four possible threats. and the risk degree of such context is very high. Table II shows the risk degree of each possible context of use.

TABLE II. RISK DEGREE OF EACH CONTEXT

	T1	**T2**	**T3**	**T4**	**Risk degree**
C1					Zero
C2			■	■	Average
C3		■			Low
C4		■	■	■	High
C5	■	■			Average
C6	■	■	■	■	Very high

Authorization to access smartphone or its applications will basically depend on two factors: context of use and sensitivity of the applications. The authorization system will consist of a simple if-then statements where the antecedent (the if-clause) is composed of the context of use and (logic and) the type of demanded application whereas the consequent (the then-clause) is the appropriate authorization. This rule-based authorization adaptation system will provide an acceptable decision speed which is required for the usability of the smartphone and it does not consume much resources of the smartphone which are limited in most cases.

Normal applications of the smartphone are granted a direct full access without any authentication after an authenticated access to the smartphone. For sensitive applications, access will be granted according to the current context of use and its degree of risk. The latter will determine the access method using a one-factor, two-factor or three-factor authentication to enforce the security of the smartphone.

In case of the usage of sensitive applications within the six aforementioned contexts, the access method will be chosen according to the risk degree of each context of use which composed of five degrees namely: zero, low, average, high and very high. The authorization method will adapted to current context of use as follows:

- In context C1with zero risk degree, the access to the smartphone and its application is direct with full permissions.
- In contexts C2 and C5 with an average risk degree, the access to the smartphone will be granted by unlocking the smartphone using any method (passcode, PIN, graphic pattern, fingerprint, ...) and sensitive applications will be accessed using a one factor authentication method. Normal applications will be accessed directly without authentication.
- In context C3 with a low access degree, the access to the smartphone is granted after unlocking the smartphone using any method and access to all applications is direct without additional authentication.
- In context C4 with a high risk degree, Access to smartphone is granted after unlocking it and access to sensitive applications will be granted after a two-factor authentication (e.g. password + fingerprint).
- In context C6 with a very high risk degree, access to smartphone is granted after unlocking it and access to sensitive applications will be granted after a three-factor authentication.

The set of rules that allow to use the appropriate access method is given by TABLE III.

TABLE III. ACCESS METHODS RULES OF ADAPTATION

Context	*Unlock*	*Sensitive App.*	*Normal App.*
C1	Automatic	Direct access	Direct Access
C2 & C5	Explicit unlock	One-factor authentication	Direct Access
C3	Explicit unlock	Direct Access	Direct Access
C4	Explicit unlock	Two-factor authentication	Direct Access
C6	Explicit unlock	Three-factor authentication	Direct Access

The explicit unlock means that the user should authenticate before using the smartphone. Two-factors and three-factor authentication are obviously considered heavy solution for the smartphone usability, but security has a price and users should invest in their privacy and security.

V. CONCLUSION AND FUTURE WORKK

Smartphones are carried with users where ever their go and we rely on them to perform several tasks in our everyday lives. Moreover we store in them a variety of private contents. The security of smartphones is becoming a must and a permanent concern for users. smartphone should be protected against unauthorized access. Unfortunately existing methods of access control do not consider the ever changing context of user and do not adapt dynamically to this context in order to provide an appropriate access method. In this proposed I proposed a context-aware access control method based on two main elements of context namely location and nearby people. The proposed approach change the access method according to the current context and the type of application to be accessed. The future work will consist on detailing sensitive applications and provide a more appropriate access method.

***Abstract*—Connected and Autonomous Vehicles (CAVs) combine both the characteristics present in autonomous vehicles and those already implemented in large parts in connected vehicles. Therefore, CAVs expose a larger attack surface. In this work, we propose a threat model concerning the attacks that can take place in the community of CAVs by exploiting the Vehicle to Vehicle (V2V) communication channels. Then, we simulate the proposed model using NetLogo (1000 simulation for each scenario). The adoption of multi-agent-based simulation allows us to abstract the nature of the attack, which leaves us to focus on the macroscopic effect of this on different traffic densities. The got results show that the more a CAV is engaged in dense road traffic, the more it is likely to be compromised. Finally, in order to reduce the effect of this category of cyberattacks, we are introducing countermeasures to be adopted in the development of security policy within the context of Intelligent Transportation System (ITS).**

***Index Terms*—connected and autonomous aehicles (CAVs), cyberattack, cybersecurity, intelligent transportation system (ITS), multi-agent-based simulation (MABS), Threat Model, V2X, V2V.**

I. Introduction

The capacity of a vehicle to exchange information with its environment according to the V2X paradigm is at the heart of the development of intelligent transport systems. This being effective thanks to the sensors available to the CAV allowing it to extract useful information concerning its ambient environment. Such information can be road signs, start lines or obstacles to avoid. A CAV can use the cellular or ad-hoc networks at its disposal to share relevant information with other components of the intelligent transport system.

802.11p gave emergence to two more or less similar protocols: DSRC adopted by North America and C-ITS used in Europe. Adoption of one of these standards allows moving vehicles to establish communications with other vehicles nearby and with road infrastructure. In this approach, a CAV can transmit messages step by step without having to resort to the cellular network. Such interactions are characterized by very low latencies and ranges of the order of a kilometer. The main applications using this type of communication are those related to CAV safety, such as collision avoidance and overtaking assistance systems.

The decentralized nature of V2V communications results in a significant attack surface [1], [2]. Sybil is an example of an attack that the intelligent transport system may be the target [3]. This attack consists of forging false identities of CAVs in order to make the rest of the system believe the presence, in a zone, of a certain number of these. The aim is to manipulate the behavior of the intelligent transport system according to a logic previously set by the attacker. Forced routing of packets to a destination other than that intended by the source is another type of attack that CAV systems can suffer from. We know this type of attack as black holes.

The safety of the CAV relies on the reliability and security of communications carried out according to the V2V paradigm [4], [5]. This requires a minimum of reciprocal trust between the various stakeholders. The authors of [6], [7] have already pointed out the threat of computer attacks targeting CAVs because of their interaction with their environment. For example, an attacker can block a CAV just by sending it malicious packets [6]. Many works have noted that the systems embedded in CAVs are vulnerable to remote attacks or those targeting its sensors [8], [9]. Therefore, it is crucial to consider these attacks and the spread of their underlying malwares as an emerging phenomenon in the CAVs community when they will hold a considerable part of road traffic.

Malware spreading in V2V ad-hoc networks is not the same as the one in the computer networks. Thus, applying the classical approaches as they exist to protect a CAV from other CAVs, may not be a good countermeasure. We can summarize the major differences in: (i) time and traffic conditions involve a dynamic topology of the network; (ii) Driving way or mobility is another factor that can affect the V2V links configuration which can bring more or less cybersecurity risks to the targeted vehicle; (iii) Target pointing is another reason that can distinguish CAVs networks from computers ones.

Two models can help to characterize a V2V network

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

topology: the CAV mobility and the V2V communication models. The CAV mobility model deals with the movement of CAVs and defines the neighborhood of each CAV. This model depends on traffic density and road topology. The V2V communication model deals with data transmission and its underlying constraints such as interferance and transmission power. To study Malware propagation behavior in a such Networks, one needs to know all their topological details.

In what follows, our contribution is threefold: (i) we set up a threat model for traffic of CAVs, in a four-lane highway, in which one of the CAVs is malicious. (ii) We simulate our model by adopting the multi-agent-based approach to consider emerging phenomena and this using the NetLogo software. After carrying out 1000 simulation runs for each scenario, we visualize the results as tables and plots using Matlab. (iii) Finally, we introduce draft solutions aimed at clarifying the logic of the distribution of roles on the different stakeholders in order to reduce the intensity of cyber attacks having traffic density as a catalyst.

We can summarize the structure of this paper, as follows: We find just after the introductory section (sec. I), A section dedicated to the review of the literature related to the subject, here discussed (sec. II). At, the end of this section we give the research gap treated. The next section (sec. III) presents the adopted threat model. It determines the threat agent, the attack surface and the attack methods. Section IV concerns the simulation scenarios adopted and the different parameters considered. Quite after, section V discusses the main results. The last section (sec. VI) is dedicated to the conclusion of this work.

II. Literature review

A. Automotive cyber-security incidents

According to [10], the profitability of cybercrime, including the (ITS) sector, exceeds that of global illicit drug trafficking by 200 billion dollars (600 billion dollars against 400 billion dollars).

Thieves in India could steal 41,118 vehicles in 2019, according to a statement from Gurugram police. This has been possible using only inexpensive electronic devices [11]. Once the vehicle is stolen, its GPS service is deactivated, its license plates changed and a new registration certificate is issued.

Researchers stopped a Tesla Model X by attacking its Advanced Driver Assistance System (ADAS) by inserting an image of the stop sign in a roadside advertisement. The autopilot saw the image as a real sign. Likewise for Mobileye 630 Pro. Also, this type of attack can be applied remotely using a portable projector thus triggering a braking or a deviation, of the vehicle, towards oncoming traffic which can be fatal [12].

Security researchers from the Sky-Go team could open the doors and remotely start the engine of a Mercedes-Benz E-Class by exploiting 19 vulnerabilities [13].

B. Related works

We can find in the research literature various works that model the dynamics of malware spreading in computer networks. The most significant ones are based on [14], which addresses the epidemic spreading in a homogeneous population of individuals applying mathematical theories. The authors in [15] explain that medium access control mechanism reduces the virus spreading in WSN and they demonstrate that the higher is the node density or the node communication radius the higher is the number of infected nodes. Authors in [16] provide a controlled epidemic model with alert and develop an optimal control problem based on the elaborated model. That is a solution for dynamic containment of malware, at a lower cost. Khayam and Radha in [17] establish a model describing dynamics of worms spreading in WSN that has two categories of nodes: Suscptible or Infected. They defined Suscptible and infected as to be, respectively, a node that can be infected when coming in contact with infectious node and a node which has received a worm payload.

In [18], the authors provide a two-layer model to describe network to network propagation of malware. They establish that the exponential distribution is the most likely distribution in the early stages while power law with a short exponential tail and the power law are, respectively, the more adequate distributions for the late and final stages. They have performed real-world experiments on malware data sets to validate their theoretical findings.

The authors in [19] have studied worms spreading over VANETs. They have considered low-density traffic and the congested situations to build a model based on stochastic infectious disease modeling. The established model allows to investigate worms spreading parameters in the considered context. The same work analyzes scenarios for preemptive and interactive patching.

The work [20] provides an alternative way to deal with contagions in vehicular environments by considering epidemic's blocking as a separate process from the curing one. The adopted approach consists on using distributed infrastructure rather than the fixed one to block the spreading of malicious software. To validate their work, the authors setup a simulation to emphasis the performance of the followed method.

After modeling the mobility, the communication channel, the MAC and the worm propagation, the authors in [21] analyzed the spreading of worms in the case of urban traffic under some assumptions. They utilized Monte Carlo simulation to reveal the impact of transmission range, velocity, vehicles density and MAC on worm spreading in VANETs. The authors, finally, determine the relation of the infection rate with network parameters.

Most of the works mentioned above focus on the microscopic aspects of the security of CAVs or their underlying ad hoc networks facilitating cooperative driving. However, when one considers several CAVs new case studies emerge thus revealing new challenges manifesting themselves just at the macroscopic scale. The impact of road traffic density on the number of CAVs compromised by a malicious CAV forming part of the same traffic is an example which, to the state of our knowledge, has not yet been dealt with in the research literature.

III. Threat Model

A. Threat Agent

The first component to consider in our threat model is the threat agent. In this work, a threat agent is any CAV whose controller has sufficient motivation to attack any other CAVs by exploiting the attack surface offered to him. These motivations can be financial, such as organized crime, industrial competition, or the theft of resources, or ideological, as with terrorism and hacktivism. Also, a threat agent must have all the knowledge and resources necessary to complete successfully his attack. In the simulation section (sec. IV), a black hat CAV (black CAV) represents a threat agent.

B. Attack Surface

Because of its aspects of autonomy and cooperation, a CAV exhibits a fairly large attack surface. We can distinguish the classes of vulnerabilities that can be exploited locally from those that can be exploited remotely. In the latter's context, we can cite, among others, the updating of maps, the communication of the CAV with the road infrastructure (V2I) and the communications taking place between CAVs according to the V2V paradigm. It is the latter that we will consider further. We will be interested in attacks originating from communications according to the V2V paradigm.

C. Attack methods and Attack Potential

Based on the STRIDE framework [22], the attack methods that can be implemented within the framework of the considered attack surface fall under the following four categories: (i) Spoofing, (ii) Tampering, (iii) Denial of service, and (iv) Information disclosure.

Regardless of the attack as specified by STRIDE, an attack always needs a window of opportunity i.e. the time needed to be completed, the financial means, the knowledge regarding the target CAV, the required expertise and the means in terms of equipment. We propose to capture most of these factors by the simulation parameters proposed in TABLE I.

IV. Agent based simulation of V2V penetration rate

The interest of multi-agent modeling lies in its ability to provide models considering different levels of abstraction. The agents taken apart are of a lower level of abstraction compared to that of a system formed by these agents. It describes the causes and rules of behavior at a local level. So instead of describing the dynamics of a system by mathematical equations, the multi-agent paradigm dissects the global system into several agents and makes it possible to deduce the dynamics of the system from the interactions taking place between the different agents and with their environment. We recognize at this level the notion of emergence [23].

In this part of our work, we use NetLogo as a simulator which is a well-known, in the scientific researchers community, as a cross-platform software that allows modeling conforming to the multi-agent paradigm [24]. Turtles are the agents in NetLogo. A script written in a language specific to NetLogo describes the dynamics of the system and the behavior of each turtle. A user can interact with NetLogo using a graphical user interface to configure the simulation parameters of a system with buttons linked to the script and to visualize its evolution using outputs gadgets such as monitors. Two procedures that a NetLogo-based simulation cannot get rid of: the setup and the go procedures. The first procedure concerns the initial parameters of the simulation and the second the evolution of the system by one step.

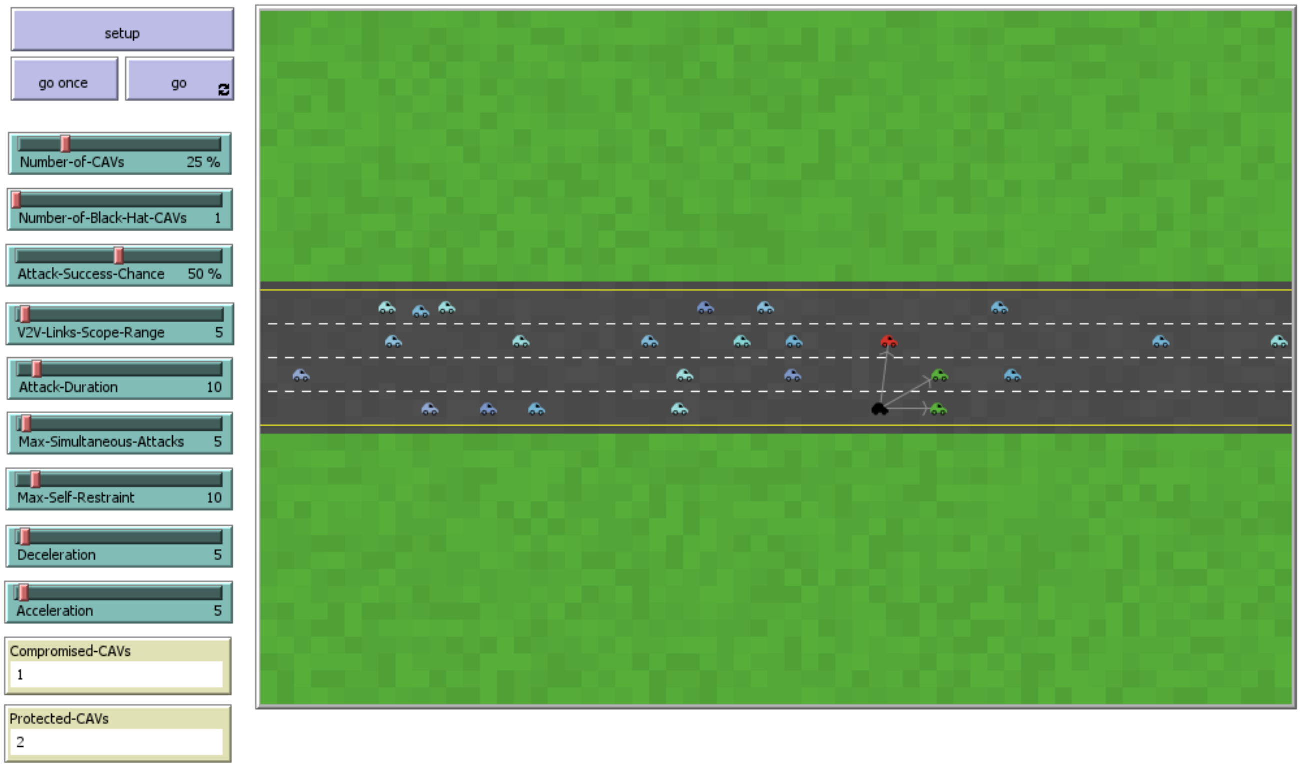
A. Simulation Parameters

In this section, we propose to simulate the impact that a black hat CAV would have on CAV traffic as a function of its density. For this, we consider the following simulation parameters: (i) The duration of the attack which presents the time slots during which the black hat CAV tries to compromise one or more target CAVs. (ii) The maximum number of attacks that a CAV can attempt to carry out simultaneously. This parameter is variable during a simulation run and varies between one attack and the maximum number of this one fixed by the user. (iii) The chance of an attack to succeed. (iv) The maximum self-restraint which reflects the tendency of a CAV to change the lane, this parameter is deduced from the number of brakes that a CAV has performed. (v) The deceleration takes place if one CAV is hampered by another one. (vi) acceleration is a parameter which reflects the increase in speed when the context permits. (vii) The number of CAVs is the number of this one without counting the CAV of the attacker. We assume for this parameter that the section of highway considered is saturated if one hundred CAVs occupies it. (viii) The purpose of the V2V link scope range parameter is to consider the physical limits of the communication channels between two CAVs and the number of these that a CAV wishes to put in place for cooperative driving. (ix) The last parameter specifies the number of CAVs used to perform the attack. We fixed it at one throughout the simulation.

TABLE I
Simulation parameters values

Simulation Parameter	Value
Attack-Duration	10
Max-Simultaneous-Attacks	$up - to$ 5
Attack-Success-Chance	50%
Max-Self-Restraint	50
Deceleration	5
Acceleration	5
Number-of-CAVs	25 $(resp.$ $50; 100)$
V2V-Links-Scope-Range	5
Number-of-Black-Hat-CAVs	1

TABLE I summarizes the values adopted for each parameter during the simulation. Note that the Max-Simultaneous-



Number-of-CAVs 25 %
Number-of-Black-Hat-CAVs 1
Attack-Success-Chance 50 %
V2V-Links-Scope-Range 5
Attack-Duration 10
Max-Simultaneous-Attacks 5
Max-Self-Restraint 10
Deceleration 5
Acceleration 5
Compromised-CAVs 1
Protected-CAVs 2

Fig. 1. The Graphical Interface screenshot of the performed Simulation

Attacks parameter is free to take any value between one and five. In addition, the Number-of-CAVs parameter takes the values 25%, 50% and 100% respectively, which corresponds to the simulation scenarios carried out.

Fig. 1 is a screenshot of the graphical interface provided by NetLogo to allow the user to control the simulation parameters. In the world part of this interface, there is a highway occupied by twenty-five CAVs. CAVs whose colors tend towards blue are CAVs susceptible to be attacked by black CAV. While the red and green CAVs are CAVs already attacked by the latter and which were, respectively, compromised and resistant.

B. Simulation Logic

When the simulation is launched, the black hat CAV tries to attack other CAVs and this according to a logic dictated by the values assigned to the different parameters. Apart from the number of CAVs we do varied here. All other parameters are fixed. For example, the CAV cannot exceed a well-defined range through the parameter *V2V-Links-Scope-Range*. Also, the number of attacks in parallel cannot be higher than that fixed by the parameter *Max-Simultaneous-Attacks*. After interaction with the black CAV, a target CAV is compromised (red CAVs) or protected (Green CAVs). The choice between these two states (red or green) is made randomly with the contribution of a weighting by the value of the *Attack-Success-Chance* parameter.

One CAV is black and the other CAVs are blue is the first step in every simulation run. When we execute the *go* procedure the black CAV tries to compromise the blue CAVs according to the logic mentioned in the previous paragraph. The consumption of a *tick* characterizes each step. In our case an attack attempt can last up to ten ticks after which a target CAV is either compromised or protected. However, it should be noted that once a CAV is subjected to an attack, it is not in the next *ticks* of a simulation run. Finally, a simulation run ends if all the CAVs are visited by the black one or if a certain maximum number of *ticks* is set by the user.

V. Discussion

A. Simulation Results

TABLE II
SIMULATION RESULTS SUMMARY

T. Den. (%)	Rate Mean	Std. Dev.	95% C. I.
25	0.3002	0.1068	[0.2935, 0.3068]
50	0.3516	0.0802	[0.3467, 0.3566]
100	0.3907	0.0498	[0.3876, 0.3938]

To get the results in TABLE II, we ran the simulation a thousand times (1000 runs) for each traffic density. At the end of each simulation run, we measure the rate of CAVs having been compromised. As shown by the figures in TABLE II, the more the traffic density increases, the more

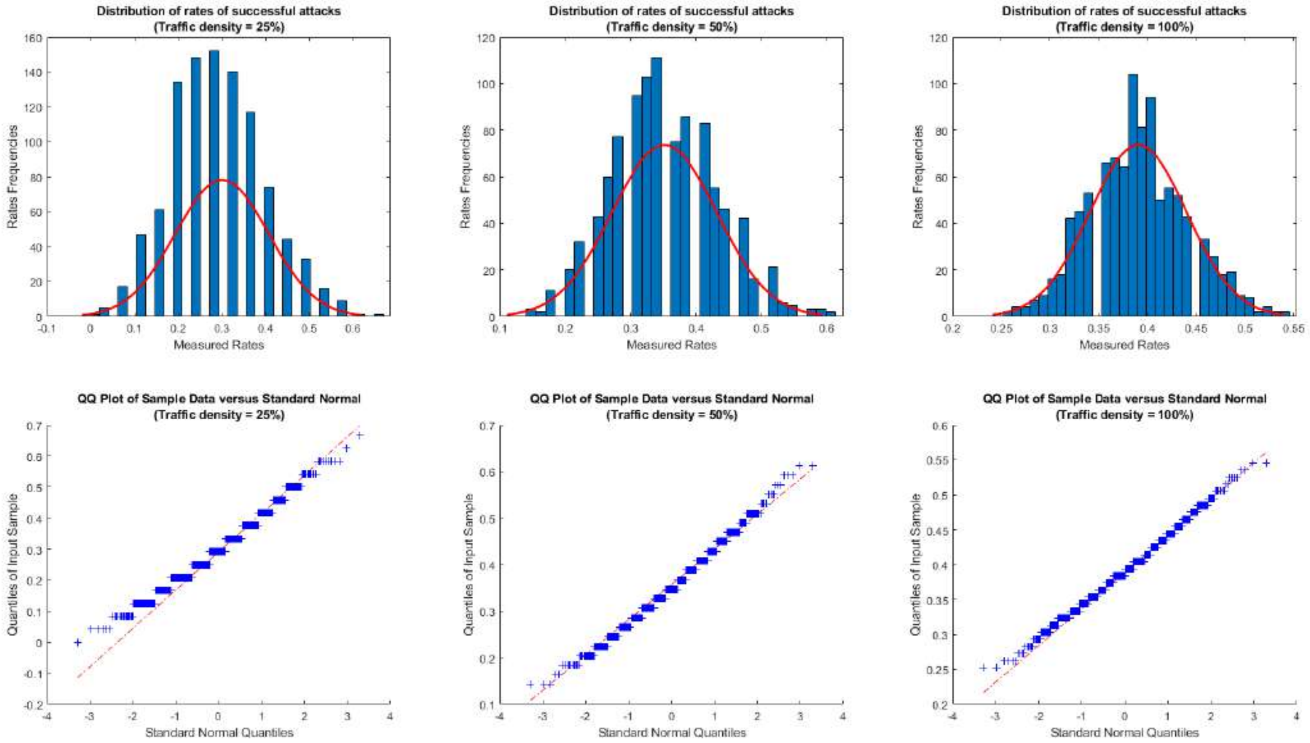


Fig. 2. The graphics showing the obtained results for the three densities

the rate of compromised CAVs increases. Also, we notice that the difference between the different mean of the rate of compromised CAVs tends to shrink despite the increase in traffic density. For example, the deviation of 25% in the range of traffic density less than 50% induces a deviation of the order of 0.05 regarding the sample mean rate, while a deviation of 50% in that greater than 50% only introduces a difference of 0.04 in terms of the sample mean rate. For each calculated sample mean, using the Matlab software, we associate it with a 95% confidence interval specifying the possible values that the true mean can take.

In Fig. 2, we represent the histograms associated with each simulation scenario and their respective Quantile-Quantile plots. We note, from the histograms that the distributions of the rates corresponding to the different scenarios take the form of a Normal centralized on the means specified in TABLE II and having a width dictated by the standard deviations mentioned in the same table (TABLE II).

QQ plots inform us of the degree to which the quantiles of the sample data fit well with that of a Standard Normal. We can see that for a traffic density equal to or greater than 50%, the fitting of the quantiles resulting from the data generated by the simulation with those of a Standard Normal, is more consequent than that for low densities.

If we inspect the Q-Q plots, we can see that for the traffic density of 25%, the small values of the sample data deviate a lot from those corresponding to the theoretical distribution. We can attribute this to the fact that during a simulation, the black hat CAV can always find several CAVs to compromise, greater than the number theoretically predicted by the normal distribution. This is mainly because of the non-uniform nature of the movements of the CAVs. While, sample data values greater than 0.6 are lower than those that enter the normal distribution because of their scarcity in the low-density case.

For the Q-Q plots corresponding to the traffic densities of 50% and 100%, we notice the reduction in the deviations of the sample data from the normal. In fact, more values of the compromised CAV rate are occupied as the traffic density becomes greater and the simulation time has virtually no impact on these values.

B. Lessons to learn

The results got during the simulation highlight the close relationship that exists between the density of CAVs in a road and the rate of successful attacks considering a single attacking CAV. To develop countermeasures, this may require the intervention of several stakeholders who share responsibilities according to the following logic: (i) Road traffic management can play a major role in reducing attacks between CAVs, and therefore limit the spread of malware within the CAV community. In fact, the more the road traffic management system keeps low and regular traffic densities, the lower the rate of attacks or malware propagation. (ii) The incentive to promote public transport and transport sharing are other solutions allowing the reduction of the attack rate because they have a direct impact on the reduction of the traffic density.

(iii) Designers and developers of CAV control software and protocols should know the more communication links a CAV establishes with its counterparts, the greater the risk of the latter being compromised. So establishing the bare minimum of V2V links would compensate for the effect of traffic density.
(iv) The responsibility of CAV manufacturers to make their product difficult to compromise will have a direct impact on the reduction of attacking CAVs and make the target CAVs more resistant.

VI. Conclusion and Further Works

During this work we produced a threat model to specify the study considered here. Then we used NetLogo which is a simulator dedicated to performing agent-based simulations. We have fixed all the simulation parameters except for the density of CAVs in order to study the impact of this on the evolution of the rate of compromised CAVs when the latter are targets of cyberattack originated from other CAV.

The results show that the more dense the traffic in which a CAV is engaged, the more it is susceptible to being attacked by another CAV. However, the results show that the evolution of the rate in question is not necessarily monotonous. In fact, the velocity of change in the rate of successful attacks decreases while approaching 100% density.

In order to reduce the impact of traffic density on the security of target CAVs, we have proposed draft solutions to which several stakeholders such as CAV manufacturers, Governments, standardization Bodies, and researchers can contribute, each according to their perspective. Basically, these draft solutions proposed revolve around regulating the density of traffic and compensating for the effect that the density of CAVs has on the rate of successful attacks by optimizing the number of V2V links required that a CAV must establish with its counterparts.

As future work, we intend to examine other situations by varying other parameters such as those related to the way of driving, with the structure of roads, and those of intelligent traffic management.

Efficient CPW Fed UWB Antenna with Triple Notch Band Characteristics

Srijita Chakraborty[a], Dr. N.N.Pathak[b] ,Dr.Mrinmoy Chakraborty[b]

[a]*Institute of Engineering & Management,Kolkata, W.B., India,* [b]*Dr. B.C. Roy Engineering College, Durgapur*

Abstract: A novel CPW fed UWB antenna with 4GHz/5.48GHz/7.5Ghz triple notch band features has been proposed. The antenna which has a dimension of 35.4mm×28.8mm, is composed of pentagonal radiating stub with CPW framework. The ultra wide band from 3.03GHz to 11.1GHz frequency range has been obtained and by inserting three simple L shaped regular slots at the ground plane and the stub and optimized in order to achieve desired stop band characteristics . The triple frequency band notched characteristics has been achieved at IMT (International Mobile Telecommunications) advanced system 4th generation mobile communication system (3.4-4.2GHz), WLAN (5.15-5.3GHz) and X Band satellite communication(downlink) (7.25-7.75GHz). The antenna shows broad bandwidth, good impedance match and omnidirectional radiation patterns in the entire frequency range.

Keywords: UWB antenna, Notch characteristics, L slot, CPW Fed

I. INTRODUCTION

Ultra-wideband (UWB) technology has received much attention due to some important features such as low cost, low complexity, low spectral power density, high precision ranging and have become the most potential candidate for short-range high speed wireless communication systems. As a key component of the UWB systems, the antennas with ultra-wide bandwidth have been widely investigated by both industry and academia since the Federal Communications Commission (FCC) released 3.1 to 10.6 GHz unlicensed band for radio communication. To meet UWB requirements several coplanar waveguide-fed and microstrip-fed planar antennas have been proposed till date.

Using frequency band rejected characteristics structure, several UWB antennas have been attempted to solve interference problems. Many techniques, such as an isolated slit inside a patch, two open-end slits at the top edge of a T-stub, two parasitic strips, embedded semi-circular annular parasitic strip; and a pair of T-shaped stubs inside an elliptical slot, inclusion of an additional small radiating patch, L-shaped quarter wavelength resonators coupled to the patch have been used to design band notched antennas [1,2,3].

It is difficult to monitor the bandwidth of the notch-bands in a limited space when designing a dual or triple notch band antenna. The key challenges in achieving an effective triple band-notch UWB antenna with balanced VSWR characteristics is strong coupling between the band-notch characteristic designs for adjacent frequencies. [4,5,6,7].

To realize ultra wide band, complementary antenna design technique can be implemented where the patch and ground are complementary to one another with respect to their positions.. It can be observed that ground plane effect is reduced in case of complementary structures and thus ultra wide band is realizable.

In this paper, a novel pentagonal CPW fed antenna has been proposed which consist of a pentagonal patch with microstrip feed and rectangular ground plane. After realization of the ultra wide band , three simple L shaped slots are inserted at the ground plane and patch to notch the application frequency bands viz. IMT (International Mobile Telecommunications) advanced system 4th generation mobile communication system (3.4-4.2GHz), WLAN (5.15-5.3GHz) and X Band satellite communication(downlink) (7.25-7.75GHz).

II.ANTENNA DESIGN AND ANALYSIS

The final optimized design of the proposed antenna was simulated using the electromagnetics simulator tool as shown in Fig. 1. The simulated antenna was printed on the FR4 substrate with thickness of 1.6 mm, relative dielectric constant of 4.4, and loss tangent of 0.002. The radiating patch is fed by microstrip fed line. The simulated antenna is found to exhibit omnidirectional radiation pattern, stable gain and good impedance match throughout the entire bandwidth. Detailed dimensions of the CPW fed UWB antenna are shown in Fig.1.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

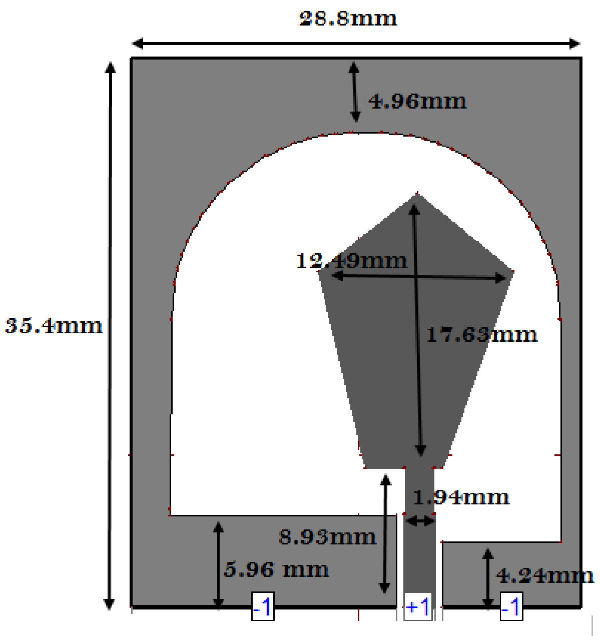

Fig 1. Pentagonal UWB antenna

The antenna is found to give perfect UWB characteristics throughout the entire frequency range.

Capacitive loaded transmission line resonator can be realized using microwave loop resonators. Microwave loop resonators can essentially behave as slow wave structures confining the current density within. Thus slow wave loop resonators can be effectively implemented to notch any desired application frequency bands. It is a general observation that with the increase of the resonator width the frequency notch bandwidth increases and vice versa. The notch characteristics can be implemented by shifting the resonator to the optimum position and modifying the structures.

In this proposed paper we have introduced L shaped slot resonators to notch the frequency bands viz. IMT (International Mobile Telecommunications) advanced system 4th generation mobile communication system (3.4-4.2GHz), WLAN (5.15-5.3GHz) and X Band satellite communication(downlink) (7.25-7.75GHz). Here initially the length of the resonator has been varied to get the notched frequency band and by varying the resonator width the bandwidth is further adjusted. The width of all the slots are 0.2mm. Detailed dimensions of the slots are shown in Fig.2.One of the main problems that is generally encountered in UWB antenna with triple notch characteristics is mutual electromagnetic coupling between the resonators. Electromagnetic coupling is a phenomenon where an electromagnetic field in one resonator results in electrical charge in another. A transferring of electromagnetic properties from one location to another takes place without any physical contact which tend to modify the notch bands. To minimize coupling the resonators must be placed in an optimum position.

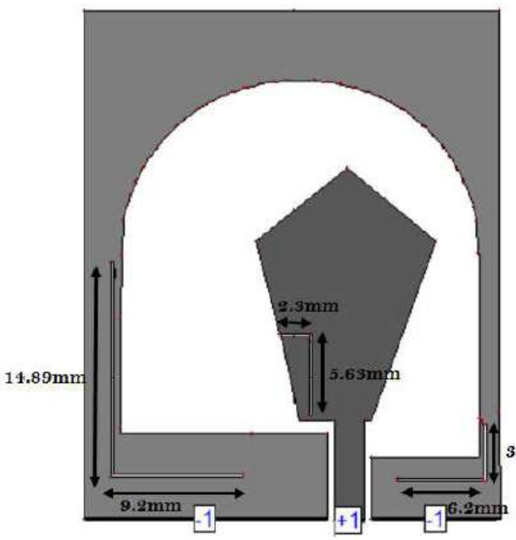

Fig 2: UWB antenna with L shaped slot resonators

III. RESULTS AND DISCUSSION

S11 Versus Frequency Graph

The S11 versus frequency graph of the UWB antenna is given in Fig. 3, where it can be seen that the antenna resonated from 3GHz to 11.2 GHz, covering the entire UWB frequency range. Fig. 4 demonstrates the impedance versus frequency variation of the CPW fed UWB antenna. It is observed that at resonance, the resistive part of impedance of the antenna varies between 40-60 ohms; while the reactive part varies from -10 to +10ohms for optimal performance.

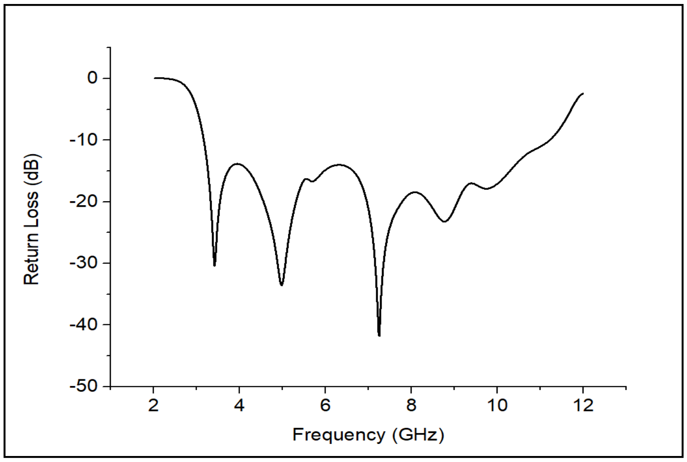

Fig 3: Return loss versus frequency of UWB antenna

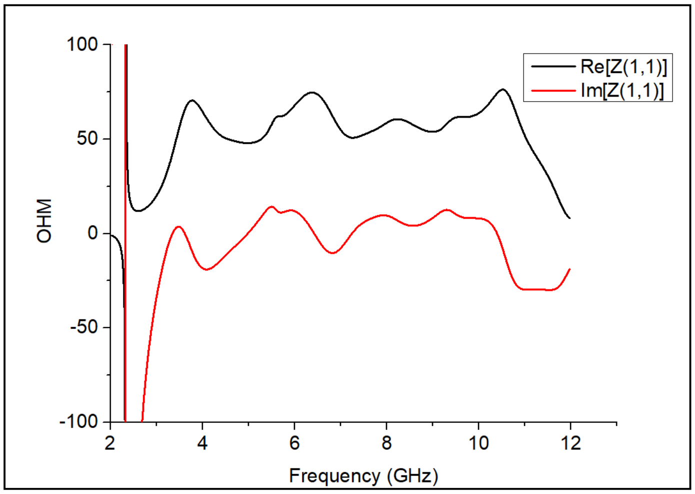

Fig 4: Impedance loss versus frequency of UWB antenna

Therefore at the resonating frequency the UWB microstrip antenna is perfectly matched for optimum performance. Fig. 5 displays the gain versus frequency variation of the CPW fed UWB antenna and it has been seen that throughout the UWB band, the overall gain is more than 3dBi.

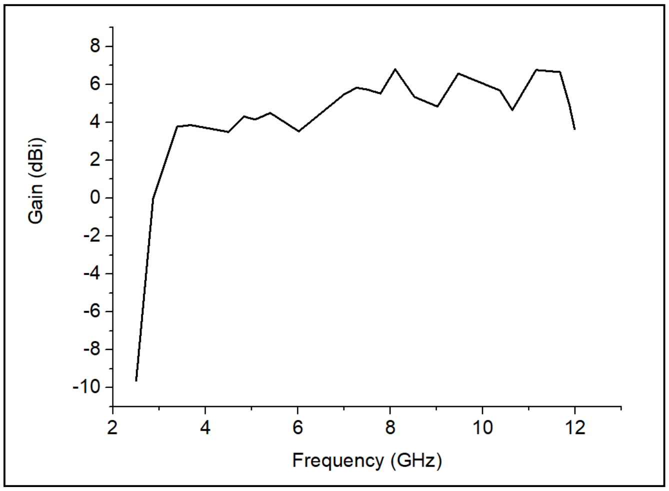

Fig. 5. Gain versus frequency variation of UWB antenna

In the proposed UWB antenna, the first slot is introduced in the ground plane to obtain the first notch (IMT frequency band) with notch bandwidth 3.4GHz to 4.2Ghz and VSWR 5.1 dB. Second slot is introduced at the patch to obtain the second notch (WLAN band) with notch bandwidth 5.15GHz to 5.3Ghz and VSWR 5dB. Third slot is introduced in the ground plane to obtain the third notch (X band communication downlink) with notch bandwidth 7.23GHz to 7.80Ghz and VSWR 5dB.

Extensive study has been conducted on individual L shaped slots by varying the resonator width. It has observed that as the resonator width is increased the notch bandwidth gradually increases confirming the theory of resonators. The variation of resonator width has been plotted in figure. Moreover it has been seen that the slots are placed at an optimum position so as to minimize the coupling effect. Figure 6 and figure 7 demonstrates the return loss and VSWR characteristics of the UWB antenna with triple notch band characteristics. Figure 8 demonstrates the impedance versus frequency curve for pentagonal UWB antenna with three notches.

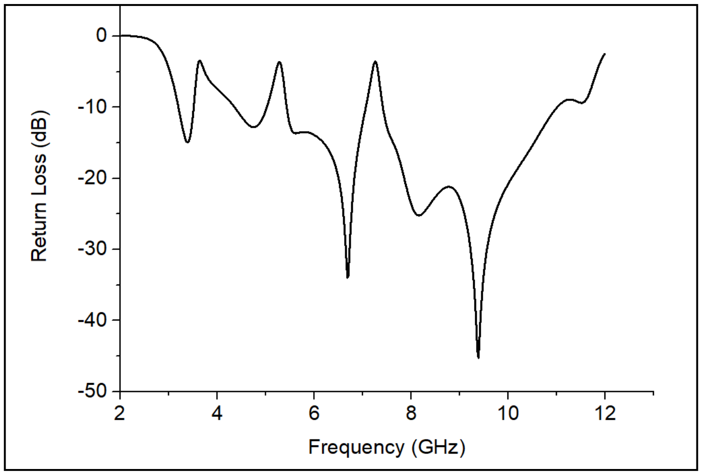

Fig : 6 Return loss versus frequency curve for pentagonal UWB antenna with three notches

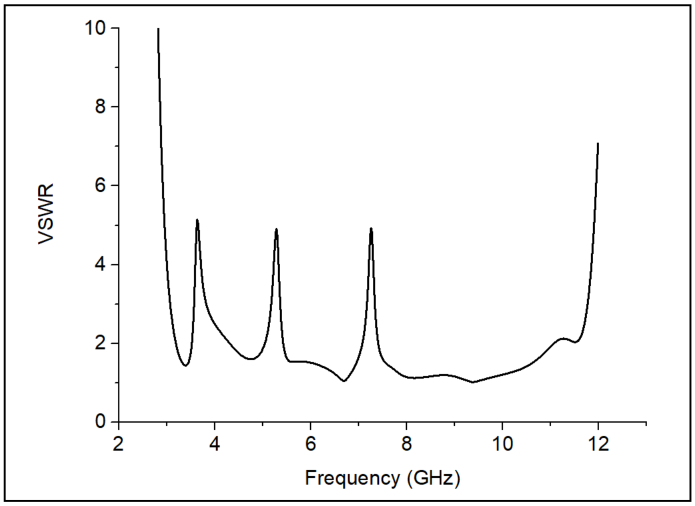

Fig : 7 VSWR versus frequency curve for pentagonal UWB antenna with three notches

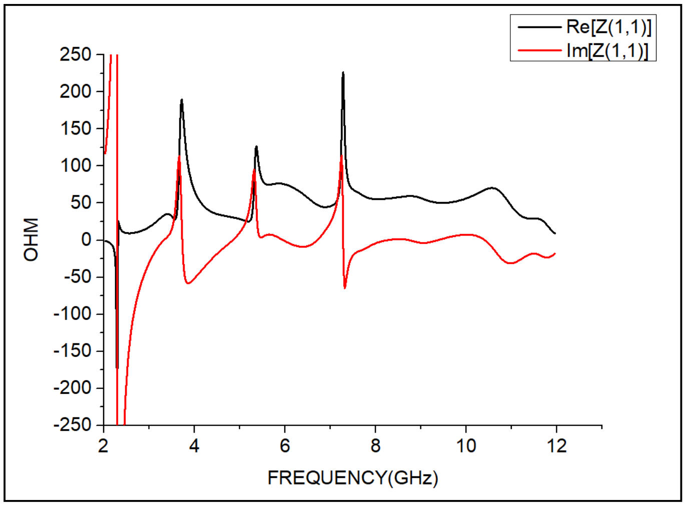

Fig : 8 Impedance versus frequency curve for pentagonal UWB antenna with three notches

IV. CONCLUSION

In this work, a CPW fed pentagonal planar ultra-wideband (UWB) antenna with 4GHz/5.2GHz/7.5GHz triple band notch characteristics has been proposed. Three L shaped slots are placed in to achieve triple notched bands of 3.4-4.2 GHz, 5.15-5.3 GHz, and 7.24-7.80 GHz. It has been seen that changing of parameters of the band notch structure influences only the notched bands, the rest of the UWB frequency band remains unaffected. Thus the UWB antenna with triple notch band characteristic can find immense application in practical UWB systems.

ACKNOWLEDGMENT

The proposed research work is done in Dr. B. C. Roy Engineering College, Durgapur, India and the authors would like to acknowledge the contribution of all concerned.

***Abstract*—This work focusses on predictive PI (PPI) control law employing on a class of stable, nonlinear benchmark process. To facilitate controller parameter(s) updation, two different types of derivative based Kalman filter (KF) strategies like Extended Kalman filter (EKF) and Ensemble Kalman filter (EnKF) techniques were taken into consideration. The servo-regulatory performance of the PPI controller was found satisfactory even in presence of white Gaussian noise. From the extended simulation studies, it can be inferred that EnKF-PPI control logic implemented on the nonlinear dynamical systems are having slightly better performance over EKF-PPI control law. Demonstration and practical utility of the PPI control method in the presence of process uncertainty or process-model mismatch scenario have also been investigated in this work.**

***Keywords*— Van de Vusse Reactor, parameter estimation, PPI, EKF, EnKF.**

I. Introduction

Unitary controls schemes like *P/PI/PID* control laws have drawn significant attention over wide range of control theory and applications due to its simplicity and cost effective nature [1-3]. To facilitate better closed loop performances using *PID* control law, many researchers have put their efforts [9, 11]. For the time-varying processes, offline *PID* controller tuning rule is not sufficient enough to provide adequate performances. To enhance the transient performances online tuning methodologies would be more appropriate for the process whose parameters are uncertain or the case where plant dynamics exhibits under multi-operating regions [13]. Self-tuning control (*STC*), Gain schedule (*GS*) scheme, model reference adaptive controller (*MRAC*) are the commonly used adaptive control schemes used for a class time-varying stable/unstable systems [2, 16]. However, the tuning methodologies for the classical adaptive *PI* (*CA-PI*) control methods are broadly be classified in some major categories like *PID0*, *PID1*, *PID2* and *PID3* [8]. While synthesizing *PI* control rule, it comes under *PID1* or *PID2* category.

As a well-established and widely-used example of online tuning methodologies, predictive *PID* control theories took attention on several realistic applications over last two decades [5]. The *PPI* control strategies were studied in several engineering applications like predictive set point algorithm[4], nonlinear state-feedback based approach [5], robust type of *PPI* control scheme [10], state-space method using pole placement technique [11], event based *PPI* controller [12], *PPI* control rule without using any addition filter [13], fractional order *PPI* [14], using *EKF* [15, 18] and Unscented Kalman filter (*UKF*) [17] methods, Grey-Wolf optimization logic [19] and so on.

This work deals with extension of Pandey et al. (2021) with imposing state and input constraints in order to address desire trajectory tracking and disturbances attenuation problems in the presence of white Gaussian noise for a class of finite dimensional, nonlinear processes. Thus, the aim of this paper exploits designing of derivative based Kalman filter approaches, where the controller parameters were updated by the predictive mechanism. A Typical structural characteristic based benchmark industrial process were presented and analyzed in this theoretical foundation. Hence, the motivation of the developed work extends with employing an efficient, computationally less complex type of control methodologies, which preserves satisfactory set-point tracking performances and would be sufficient enough to attenuate noises and able to cope up with parametric uncertainties. Performance analysis of different *PI* control efforts using derivative based estimators were discussed well. Since, the salient features of the proposed *PPI* control logics are summarized below:

1) Able to preserve desired closed loop performances with complex nonlinear processes by adjusting controller parameters while process moves to the new operating regions.

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

2) The methodologies can be implemented on a wide range of linear/nonlinear, stable/unstable processes.
3) Alike other types of *PI* control laws, *PPI* method practices explicit considerations of input/state constraints.
4) The developed techniques promises desired set-point tracking performance or regulatory compliance even in the presence of observational noise.
5) They also facilitate satisfactory robust performances even with model-plant mismatch scenario.

The organization of the research work is mentioned as: Section *I* emphasizes academic literatures and more significantly the motivation of the proposed scheme. Section *II* addresses derivative based Kalman filter strategies used to formulate control framework. Details of the case based example specifying with servo-regulatory compliance, elimination of observational noise, performance comparison and assessing robustness with different control strategies were discussed in section *III*. Section *IV* offers conclusion of this control method.

Basic Preliminaries and Assumptions: Here, $u \in \mathrm{U} \subseteq R^{m}$ represents the manipulated variable(s), $x \in \mathrm{X} \subseteq R^{n}$ denotes the state(s), $pv \in \mathrm{PV} \subseteq R^{r}$ signifies the process output(s), d is the added nonlinear component or external perturbation(s) $(d \in R^{n_d})$. It should be noted that u, x, pv and d are time-varying signals. However, under some necessary conditions and convexity assumptions, the proposed control schemes are established well.

Assumption1: Consider the vector $f : R^{n} \times R^{m} \times R^{n_d}$ is continuous in $u$and d and is locally Lipschitz in x and it follows the condition $f(0,0,0) = 0$.

Assumption2: The vector field $g : R^{r}$ is also continuous in$x$. Predetermined set point $(pv_{sp} \in R^{r})$ and the process output (pv) are assumed either as constant or slow time-varying, bounded and piecewise signal $(pv_{\min} \le pv_{sp}(t) \le pv_{\max}, pv_{\min} \le pv(t) \le pv_{\max})$ for all $t \ge 0$ with having finite number of discontinuities.

Assumption3: Both $u(t)$ and $d(t)$ are bounded and piecewise continuous signals for all $t \ge 0$ with having finite number of discontinuities.

II. Control Schemes

A. Classical adaptive PI control scheme:

The classical adaptive *PI* control rule is expressed by the common equation as mentioned below [3]:

$$u(t) = u(t-1) + (k_c * \text{ƛ}e(t)) + (T_s * (k_c / \tau_i) * e(t)) \quad (1)$$

Here, k_c and τ_i denote the proportional-gain and integral-time-constant of the *CA-PI* control rule respectively. T_s specifies sampling instance. e represents measurement error and can be expressed by:

$$e(t) = y_{sp}(t) - y(t) \quad (2)$$

$$\text{ƛ}e(t) = e(t) - e(t-1) \quad (3)$$

B. Proposed adaptive PI control law using EKF tuning logic:

Firstly, the *PI* controller tuning parameter(s) $(k_c ; \tau_i)$ were updated/estimated by *EKF* technique and we have named this scheme as *EKF-PI* shortly. The basic steps involve with updation/estimation of the controller parameters are given as follows [6,15]:

Initialization of the controller parameters:

$$\hat{\mathbf{\Theta}}_0^a = E[\mathbf{\Theta}_0^a] \quad (4)$$

$$\mathbf{P}_{\Theta_0} = E[(\mathbf{\Theta}_0^a - \hat{\mathbf{\Theta}}_0^a)(\mathbf{\Theta}_0^a - \hat{\mathbf{\Theta}}_0^a)^T] \quad (5)$$

Time update equations:

$$\hat{\mathbf{\Theta}}^f(t) = \hat{\mathbf{\Theta}}^a(t-1) \quad (6)$$

$$\mathbf{P}_{\Theta}^f(t) = \mathbf{P}_{\Theta}(t-1) + \mathbf{Q} \quad (7)$$

Computation of Kalman gain:

$$\mathbf{K}_{EKF,\Theta} = \mathbf{P}_{\Theta}^f(t)\mathbf{J}_{\Theta}^T(\mathbf{J}_{\Theta}\mathbf{P}_{\Theta}^f(t)\mathbf{J}_{\Theta}^T + \mathbf{R})^{-1} \quad (8)$$

$\mathbf{J}_{\Theta}$ denotes Jacobian of the measurement matrix and is described by:

$$\mathbf{J}_{\Theta} = \left.\frac{\partial h(\mathbf{x}(t-1), \mathbf{\Theta})^T}{\partial \Theta}\right|_{\left(\Theta = \hat{\Theta}^f(t)\right)} \quad (9)$$

Hence, the measurement update equations are as follows:

$$\hat{\mathbf{\Theta}}^a(t) = \hat{\mathbf{\Theta}}^f(t) + \mathbf{K}_{EKF,\Theta}(\mathbf{pv} - h(\mathbf{x}(t-1), \hat{\mathbf{\Theta}}^f(t))) \quad (10)$$

$$\mathbf{P}_{\Theta}^a(t) = (\mathbf{I} - \mathbf{K}_{EKF,\Theta}\mathbf{J}_{\Theta})\mathbf{P}_{\Theta}^f(t) \quad (11)$$

C. Proposed adaptive PI control law using EnKF tuning logic

In another approach, $(k_c ; \tau_i)$ were estimated/updated by *EnKF* technique (we have named this algorithm as *EnKF-PI* shortly). Let's assume, $\overline{\mathbf{\Theta}}^f$ and $\overline{\mathbf{\Theta}}^a$ represent forecast and posterior ensemble mean of the estimated parameter(s) $\hat{\mathbf{\Theta}}^f$ and $\hat{\mathbf{\Theta}}^a$ respectively whereas $\mathbf{P}^f$ and $\mathbf{P}^a$ corresponds to the covariance's of the forecast and analysis respectively. Skipping the filter initialization (mentioned in equation: 4-5), time update equations can be written as [21]:

$$\hat{\mathbf{\Theta}}^f(t) = f(\hat{\mathbf{\Theta}}^a(t-1)) + \mathrm{w} \quad (12)$$

$$\mathbf{P}^f H^T \equiv \frac{1}{N-1}\sum_{k=1}^{N}(\hat{\mathbf{\Theta}}^f - \overline{\mathbf{\Theta}^f})(H\hat{\mathbf{\Theta}}^f - \overline{H\mathbf{\Theta}^f})^T \quad (13)$$

$$H\mathbf{P}^f H^T \equiv \frac{1}{N-1}\sum_{t=1}^{N}(H\hat{\mathbf{\Theta}}^f - \overline{H\mathbf{\Theta}^f})(H\hat{\mathbf{\Theta}}^f - \overline{H\mathbf{\Theta}^f})^T \quad (14)$$

$$\mathbf{K}_{EnKF,\Theta} = \mathbf{P}^f H^T (H\mathbf{P}^f H^T + \mathbf{R})^{-1} \quad (15)$$

$$\mathbf{pv}_i(t) = \mathbf{pv}(t) + v \quad (16)$$

$$\hat{\mathbf{\Theta}}^a(t) = \hat{\mathbf{\Theta}}^f(t) + \mathbf{K}_{EnKF,\Theta}(\mathbf{pv}_i(t) - H\hat{\mathbf{\Theta}}^a(t)) \quad (17)$$

We have prepared mean square error (MSE) and control effort (CE) chart for identifying close loop performances of the said controllers [17, 20].

$$MSE = \frac{1}{t}\sum_{i=1}^{t}\left\| pv_{sp,i} - pv_i \right\|^2 ; \text{ for } i = 1 \ldots N \quad (18)$$

$$CE = \frac{1}{t}\sum_{i=1}^{t}\left\| u_i(t) - u_i(t-1) \right\| ; \text{ for } i = 1 \ldots N \quad (19)$$

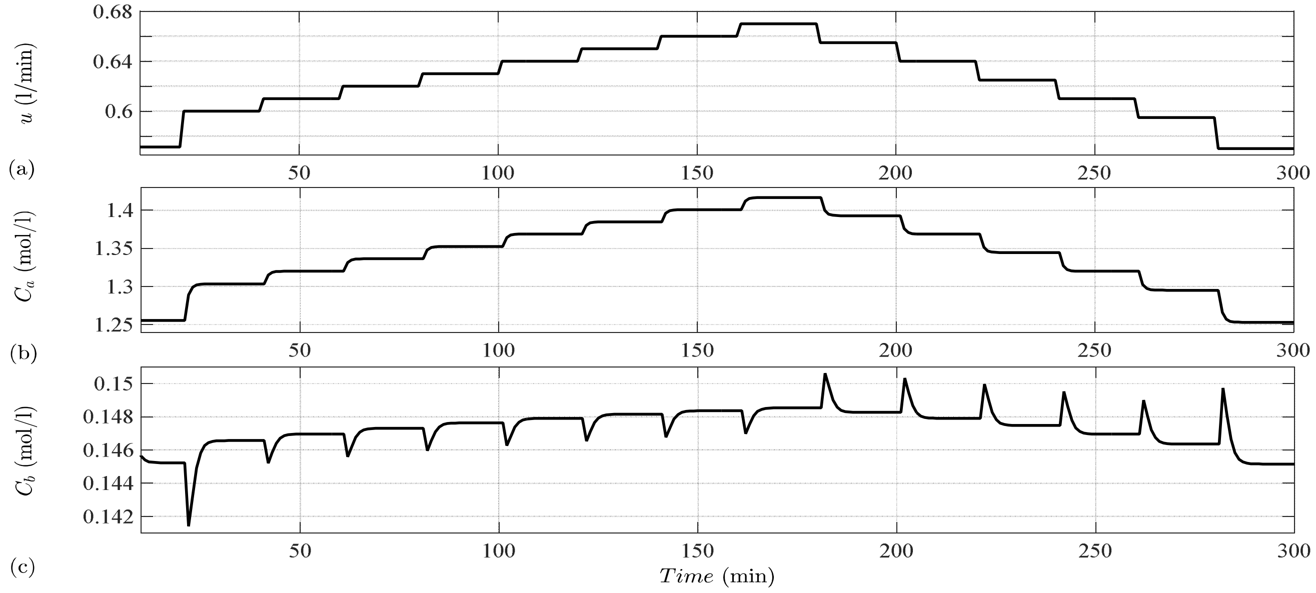

Fig. 1. Open loop response of the Van de Reactor; (a) variation in manipulated variable, *u*; (b) process output, C_b; (c) variation in C_b

III. Process Description and Simulation Studies

The processes taken for the simulation study is Van de Vasse Reactor.

A. Process description:

Let us consider, constituent ‘a’ decomposes into product ‘b’ in an isothermal *CSTR*. Product ‘b’ further converted into product ‘c’ and finally transformed into product ‘d’. The reaction chain can be expressed as [7, 18]:

$$a \longrightarrow b \longrightarrow c$$
$$2a \longrightarrow d$$

The material balance equation of the Van de Vusse Reactor mentioned in [7] has been considered in this work. Concentration of product ‘b’ is the process output. Disturbance was introduces through changes in the concentration of ‘a’ in the inlet flow (C_{af}). Table I mentions the system parameter values for the benchmark

Van de Vusse Reactor. Using 1st principle equation, the process is described by [7]:

$$\frac{dC_a}{dt} = \frac{q}{V}(C_{af} - C_a) - k_1 C_a - k_3 C_a^2 \tag{20}$$

$$\frac{dC_b}{dt} = k_1 C_a - k_2 C_b - \frac{q}{V} C_b \tag{21}$$

All the simulation executes by considering equations [20-21]. Sampling time was taken as 0.1 min. A constrained on the controller output $(10^{-h} < u < 400^{-h})$ were imposed. An equilibrium point of interest $(\bar{C}_a = 3, \bar{C}_b = 2.84, \bar{u} = 55.7)$ [7] was considered for the entire simulation studies.

TABLE I. Standard Values of the System Parameters: Van de Vusse Reactor

Process variable	Normal operating condition
Concentration of A (C_{af})	10 mol/l
Reactor volume (V)	1 l
Reaction rate constant (k_1)	100/h
Reaction rate constant (k_2)	50/h
Reaction rate constant (k_3)	10 l/mol/h
Inlet flow rate (F)	55.7 l/h

B. Open loop study:

In order to assess open loop study with Van de Vusse Reactor, a stepwise changes (combination of positive and negative steps) in the manipulated variable (u) have been introduced (see Fig. 1(a)). It should be noted that manipulated variable (u) can be obtained based on the ratio of inlet flow rate and volume of the Reactor. The evolution of process output (C_b) and another state variable (C_a) are shown in Fig. 1(b-c) respectively.

C. Servo-regulatory Response

In order to identify the tracking capability of all the above mentioned control schemes, below pattern of set-point (variation (as shown in Fig. 2(d)) has been introduced.

$$pv_{sp} = \begin{cases} 3 & \text{for } \ 0 \le t < 25 \\ 3.2 & \text{for } \ 0 \le t < 100 \\ 3.15 & \text{for } t \ge 100 \end{cases} ;\ C_{af} = \begin{cases} 10 & \text{for } \ 0 \le t < 65 \\ 9 & \text{for } \ 65 \le t < 160 \\ 9.8 & \text{for } \ t \ge 160 \end{cases} \tag{22}$$

To measure load rejection capability of the PPI control techniques, sequence of negative and positive stepwise changes in concentration of A with the above magnitude were introduced (see Fig. 2(a)). Table II represents the parameters associated with EKF/EnKF estimation strategies. Fig. 2(d) infers that the PPI controllers are sufficient enough to bring back the process variable at desired value. It was also concluded that the said control schemes performs satisfactory to eliminate load disturbances. The variation in the manipulated variables were portrayed in Fig. 2(e). The evolution of the $(k_c; \tau_i)$ were presented in Fig. 2(b-c).

D. Performance assessment with PPI control approaches

In order to analyse performances of PPI control methods for the servo-regulatory phase (both with and without presence of co-related noise), MSE (see Table III) and CE

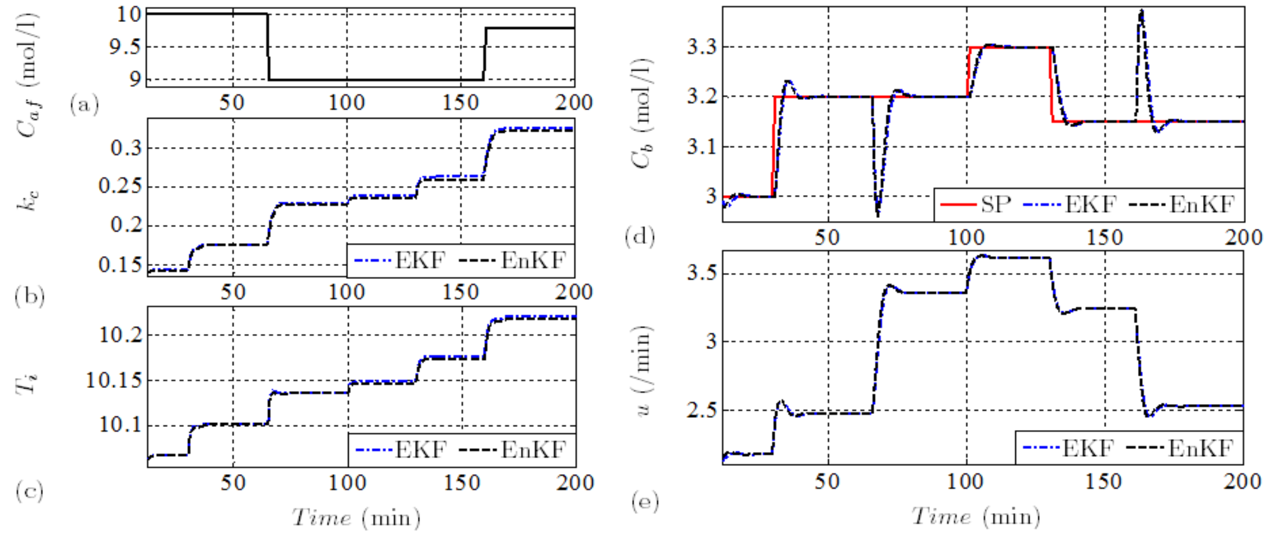

Fig. 2. Servo-regulatory response of Van de Vusse Reactor: (a) variation of C_{af} ; (b) evolution of k_c ;(c) evolution of τ_i (d) process output, C_b ; (e) variation of controller output, u

(see Table IV) chart has been prepared. It should be noted that, servo-regulatory performance chart for the Van de Vusse Reactor was prepared based on Fig. 2(d). However it was observed that EnKF-PI scheme is having slightly better performance (MSE, CE) over EKF-PI control method. It can also be inferred that, the closed loop performances deteriorates in the presence of Gaussian noise (noise to signal ratio (NSR) = 0.01). Toward the end, it was concluded that, both EKF-PI and EnKF-PI control strategies preserves satisfactory set-point tracking performances and able to attenuate load disturbances.

E. Impact of process-model mismatch

In order to identify goodness of PPI control strategies in the presence of observational noise (NSR=0.01), step like changes on different process parameters (C_{af} and k_1) of the following pattern have been considered (reported in Fig. 3(a), 3(c)). From Fig. 3(b), it can be inferred that

$$C_{af} = \begin{cases} 10 & \text{for } 0 \le t < 75 \\ 10.3 & \text{for } t \ge 75 \end{cases}; \; k_1 = \begin{cases} 0.8333 & \text{for } 0 \le t < 125 \\ 0.75 & \text{for } t \ge 125 \end{cases} \tag{23}$$

PPI controller brings the process variable back to the desired value even in case of parametric uncertainty. The evolution of the manipulated variable has been shown in Fig. 3(d). From the result and discussion, it was observed that the PPI control method provides acceptable performances even in the presence of model-process mismatch scenario.

TABLE II. PARAMETERS ASSOCIATED WITH EKF/ENKF ESTIMATION TECHNIQUE

Parameter	Value
Observational noise covariance (R)	$\begin{pmatrix} 0.0015 & 0 \\ 0 & 0.005 \end{pmatrix}$
System noise covariance (Q)	$\begin{pmatrix} (0.035)^2 & 0 \\ 0 & (0.05)^2 \end{pmatrix}$
Initial value of parameter vector $\hat{\boldsymbol{\Theta}}_0^{\mathrm{a}}(0\,\|\,0)$	$\hat{\Theta}_0^{\mathrm{a}}(0\,\|\,0) = [0.1 \quad 10]^{\mathrm{T}}$
Initial value of error covariance $\mathrm{P}(0\,\|\,0)$	$\begin{pmatrix} (0.005)^2 & 0 \\ 0 & (0.05)^2 \end{pmatrix}$

TABLE III. MSE COMPUTATION FOR SERVO-REGULATORY (S-R) COMPLIANCE WITH (NSR = 0.01) AND WITHOUT PRESENCE OF OBSERVATIONAL NOISE FOR PPI CONTROLLER

Control schemes	(S-R) level	(S-R) level (with measurement noise)

EnKF-PI	6.0749*e-08	1.7942*e-06

TABLE IV. CE COMPUTATION FOR SERVO-REGULATORY (S-R) COMPLIANCE WITH (NSR = 0.01) AND WITHOUT PRESENCE OF OBSERVATIONAL NOISE FOR PPI CONTROLLER

Control schemes	(S-R) level	(S-R) level (with measurement noise)
EKF-PI	9.5107*e-02	7.3842*e-01
EnKF-PI	9.3924*e-02	7.3615*e-01

IV. CONCLUSION

In this work, a successful deployment of EKF and EnKF logic based time-varying PI control approaches were reported. From the realistic simulation, it was observed that servo-regulatory response (both with and without presence of measurement noise) of the PPI control laws with Van de Vusse Reactor promises satisfactory results. In a detail analysis, it was investigated that the PPI control strategy takes less time reach steady-state condition. From the settling time point of view, EnKF-PI shows slightly better over EKF-PI control approach. With introducing parametric uncertainty, it was investigated that the PPI controller facilitate desired closed loop performances even in presence of white Gaussian noise. From the performance comparative charts (MSE and CE), it was inferred that EnKF-PI controller results slightly better over EKF-PI scheme. From the overall analysis, it was concluded that the PI control scheme poised with derivative based predictor approaches preserve acceptable performances. In the future scope, the proposed EKF-PI and EnKF-PI schemes can be utilised to design a set-point tracking controller for nonlinear Negative Imaginary (NI) systems [22, 23, 24, 25, 26, 27 and 28] with actuator saturation. Moreover, this type of stochastic nonlinear model-based control scheme can be extended for Micro/Smart-grid systems [29].

***Abstract*—This brief proposes an optimal type-1 servo scheme for autopilot design for a class of rear-controlled, flight-path-rate-demand, guided, lateral missiles. The rear-controlled missiles pose significant challenges in the autopilot design due to their non-minimum phase (NMP) characteristic and open-loop instability. The control objective is to design a flight-path rate demand, two-loop, lateral missile autopilot minimising the initial undershoot in the time response (due to the presence of NMP zero). An existing linearised model of a rear-controlled missile has been considered in this paper. The proposed scheme employs a reduced-order observer for generating some of the states of a missile that are difficult to measure in practice. The LQR principle has been used to find the optimal feedback gains based on the given time-domain performance criteria. An exhaustive Matlab simulation study has been carried out to demonstrate the effectiveness of the proposed autopilot scheme in achieving the desired control objectives. The simulation results suggest that the optimal type-1 servo scheme performs better than the conventional frequency-domain design methodologies.**

***Index Terms*—Missile autopilot, non-minimum phase system, reduced-order observer, generalized matrix inverse, type-1 servo control, LQR.**

I. Introduction

Missile autopilot design has always been a critical task since most missiles exhibit non-minimum phase (NMP) behaviour, and they have open-loop unstable dynamics. Moreover, the missiles are highly nonlinear. For these reasons, autopilot design has drawn serious attention from the control and aerospace community. The effectiveness of an autopilot relies heavily upon the modelling of a missile configuration and the accuracy of the sensors. The control scheme for an autopilot needs not only to be effective and reliable but also fast enough. In that respect, a highly advanced and complex controller may offer outstanding performance but at the cost of increased processing time. Hence, a control engineer often seeks to choose a trade-off between the complexity of a control algorithm and its executing time. It has been investigated that for a class of rear-controlled, guided missiles (see Fig. 1[1]), linear gain-scheduled autopilots ensure a fair stability margin and good dynamic performance [1]–[3].

Fig. 1. Coordinate system of a rear-controlled guided missile.

The articles [1]–[3] did pioneering research on developing frequency-domain autopilot design methodologies relying on the linearised missile dynamics. [1] first proposed a two-loop flight-path-rate-demand autopilot (see Fig. 2) for a class of rear-controlled, guided missile. The terminology ‘two-loop’ [1] was given after the fact that the proposed autopilot scheme was comprised of two loops – the outer-loop provides the flight-path-rate feedback and the inner-loop gives the body-rate (pitch rate in this paper) feedback. [1] and [2] adopted a linearised model of a rear-controlled, tactical, homing missile from [12] and developed three different autopilot tuning methodologies utilising the classical frequency-domain techniques. However, the authors later realised that a two-loop autopilot configuration had no direct control over the missile’s body-rate. In the cases of tactical missiles, the body-rate must be controlled in addition to the flight-path-rate to keep the

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

body-rate demand within the prescribed limit and reduce the body acceleration.

To overcome this limitation, the same group of authors introduced a ‘three-loop’ autopilot configuration in [3] by inserting an additional loop (called the middle-loop) that provides rate gyro feedback (refer to Fig. 3). This middle-loop integrates the body-rate error signal and thereby facilitates meeting the body-rate demanded by the outer-loop. It has been observed that the ‘three loop’ autopilot offers a larger DC-gain and a lower high-frequency gain in contrast to the two-loop configuration. These two factors significantly improve the steady-state performance and reduce the initial undershoot in the step response without sacrificing the speed of response [3]. In recent times, [5] has developed an improved version of the classical three-loop lateral missile autopilot scheme proposed in [3] using a frequency-domain approach. [5] has also done a valuable survey on a variety of three-loop autopilot configurations available in the existing literature. Subsequently, in [6], the authors have exploited a PI compensator to eliminate the small steady-state error in the flight-path-rate that appears in the classical two-loop and three-loop autopilots.

Drawn by the advancements and the limitations mentioned above, this paper aims to design a reduced-order observer-based, optimal, type-1 servo scheme for tuning a flight-path-rate-demand lateral autopilot for a class of rear-controlled, tactical missiles. The proposed scheme involves a forward-path PI controller in addition to the state feedback to enforce more substantial control over the flight-path-rate ($\dot{\gamma}$) and the body-rate (q). The LQR technique has been exploited to find the optimal feedback gains, including the integral gain. An iterative algorithm is also provided to choose the weightage matrices $Q > 0$ and $R > 0$ required to run the LQR command. Finally, an exhaustive Matlab simulation study has been done, which underpins the usefulness and effectiveness of the proposed type-1 servo scheme for tuning the flight-path-rate-demand autopilot over the classical two-loop and three-loop autopilots given in [1]–[3].

Notation and symbols

We will now introduce the mathematical symbols used in this paper to denote the missile parameters. $\dot{\gamma}$ and q denote respectively the flight-path rate and the pitch rate of the missile. ω_a is the natural frequency of the actuator and ζ_a denotes its damping ratio. ω_a indicates the weather cock frequency. τ_a is the incidence lag of the airframe. η represents the elevator deflection. σ is a quantity whose inverse determines the frequencies of the NMP zeros associated with the linearised model of the autopilot configuration considered in Fig. 2 and Fig. 3. k_p, k_q and k_b stand for the control gains used in the autopilot schemes shown in Fig. 2 and Fig. 3.

II. Technical Background and Problem Formation

This section provides the backbone for developing the main results of the paper. We will first present the two-loop and three-loop configurations of the classical flight-path-rate-demand autopilot for a class of rear-controlled, tactical, guided missile. After that, we will formulate the research problem addressed in this paper.

Fig. 2. The classical two-loop autopilot configuration [1], [2].

Fig. 2 shows the classical two-loop flight-path-rate-demand autopilot, as developed in [1] and [2]. The linearised missile dynamics consists of three transfer function blocks: $G_1(s) = \dfrac{k_b\omega_b^2(s\tau_a+1)}{s^2+\omega_b^2}$, $G_2(s) = \dfrac{1-\sigma^2 s^2}{\tau_a s+1}$ and $G_3(s) = \dfrac{k_q\omega_a^2}{s^2+2\zeta_a\omega_a s+\omega_a^2}$. The two-loop configuration was later upgraded to a three-loop configuration in [3], known as the three-loop flight-path-rate-demand autopilot, as depicted in Fig. 3. The three-loop scheme significantly strengthens the two-loop scheme since the former provides a direct control over the body-rate (q) via the middle loop.

We now derive a state-space description $\Sigma : \begin{cases} \dot{x} = Ax + Bu, & x_0 = x(0); \\ y = Cx; \end{cases}$ of the open-loop model of the linearised missile dynamics based on the component transfer functions $G_1(s)$, $G_2(s)$ and $G_3(s)$ included in Fig. 2. The A, B and C matrices are given below in (1).

State-space description of the linearised missile dynamics

$$A = \begin{bmatrix} -\dfrac{1}{\tau_a} & \dfrac{(1+\sigma^2\omega_b^2)}{\tau_a} & \dfrac{-k_b\sigma^2\omega_b^2}{\tau_a} & -k_b\sigma^2\omega_b^2 \\ \dfrac{-(1+\omega_b^2\tau_a^2)}{\tau_a(1+\sigma^2\omega_b^2)} & \dfrac{1}{\tau_a} & \dfrac{k_b\omega_b^2\tau_a(1-\frac{\sigma^2}{\tau_a^2})}{(1+\sigma^2\omega_b^2)} & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -\omega_a^2 & -2\zeta_a\omega_a \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 0 \\ 0 \\ k_q\omega_a^2 \end{bmatrix}, \quad \text{and} \quad C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}. \tag{1}$$

Fig. 3. The classical three-loop autopilot configuration [3].

The state vector $x \in \mathbb{R}^{4\times 1}$ is comprised of four states *viz.* $x_1 = \dot{\gamma}(t)$ denotes the flight-path-rate, $x_2 = q(t)$ represents the pitch-rate, $x_3 = \eta(t)$ indicates the angle of elevator deflection and $x_4 = \dot{\eta}(t)$ signifies the rate of the change of elevator deflection. For simplicity of the presentation, from now onwards, we will omit the explicit dependence of the time t. The states-space model Σ has two outputs $y = \begin{bmatrix} \dot{\gamma} \\ q \end{bmatrix}$ and one input u.

A. Problem statement

Given the linearised dynamics (1) of a rear-controlled, tactical missile, design a reduced-order observer-based, optimal, type-1 servo control scheme such that the autopilot configuration shown in Fig. 4 can i) perfectly track the commanded flight-path-rate $\dot{\gamma}_d$, ii) keep the pitch-rate (q) demand within the prescribed limit, iii) keep the peak undershoot below 5% and iv) reduce the peak overshoot and undershoot of the elevator deflection (η) and the rate of elevator deflection ($\dot{\eta}$).

III. Main Results

This section caters the main contribution of the paper. A reduced-order observer-based, optimal, type-1 servo control scheme (shown in Fig. 4) is proposed for tuning the flight-path-rate-demand lateral missile autopilot taking the inspiration from [8]. The terminology 'type-1' has been chosen to recall its connection with the classical servo control mechanism used for constant input reference tracking for type-0 plants.

The scheme shown in Fig. 4 utilises an output feedback on the basis of $\dot{\gamma}$ in addition to the state feedback and a PI controller in the forward path to enable perfect flight-path-rate tracking. We assume that the flight-path-rate ($\dot{\gamma}$) and the pitch-rate (q) are measures by onboard accelerometer and rate gyro sensors. A reduced-order observer is therefore employed to generate the remaining states $x_3 = \eta$ and $x_4 = \dot{\eta}$. Note that according to the practical guidelines on aerospace system design, we try to reduce the number of sensors as i) it is often difficult to find appropriate and accurate sensors, ii) sensor-measurement is the primary source of high-frequency noise, and iii) the onboard sensors and the associated signal-conditioning units require sufficient space and they increase the overall weight of the missile resulting in a reduced capacity of the payload.

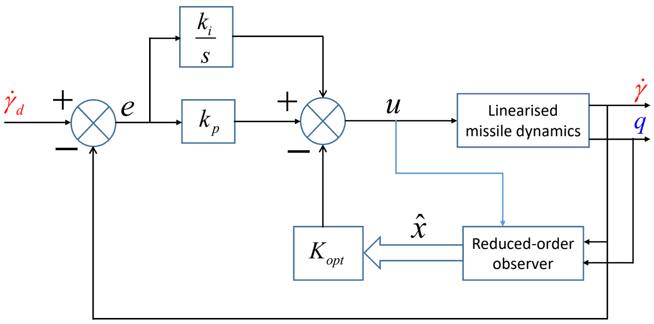

Fig. 4. A reduced-order observer-based, optimal, type-1 servo scheme for a class of flight-path-rate-demand lateral missile autopilot.

In this paper, we have used a Generalised Matrix Inverse (GMI)-based reduced-order observer introduced in [4] instead of the commonly used reduced-order Luenberger observer [10], [11]. Note that although this GMI-based reduced-order observer design methodology [4] is unconventional, it is equivalent to the Luenberger observer and in some cases, the former offers certain advantages over the latter. It was shown in [9] that Luenberger observer works only when the C matrix has the particular form $\begin{bmatrix} I & \vdots & 0 \end{bmatrix}$, otherwise, a coordinate transformation is required to transform the C matrix into the said form. However, the GMI-based reduced-order observer does not have this limitation.

The GMI-based reduced-order observer is governed by the following state-space equations:

$$\begin{cases} \dot{\hat{q}} = \hat{A}\hat{q} + \hat{J}y + \hat{B}u, & \hat{q}_0 = \hat{q}(0) \\ \hat{x} = \hat{C}\hat{q} + \hat{D}y \end{cases} \tag{2}$$

where $\left[\begin{array}{c|c} A & B \\ \hline C & 0 \end{array}\right]$ is the given minimal state-space realisation of a plant with $\operatorname{rank}[C] = r \leq m$, $\hat{x} \in \mathbb{R}^{\hat{n}}$, $\hat{n} \leq n$, is the desired the observed state vector and

$$\begin{cases} \hat{A} = \left(L^g AL - MCAL\right), \\ \hat{J} = \left(L^g AC^g - MCAC^g\right) + \left(L^g AL - MCAL\right)M, \\ \hat{B} = L^g B - MCB, \\ \hat{C} = L, \\ \hat{D} = C^g + LM, \end{cases}$$

where the matrix $L \in \mathbb{R}^{n\times k}$ is chosen such that L has full column-rank and satisfies the relationship $LL^g = I_n - C^g C$ via [4] and $M \in \mathbb{R}^{(n-r)\times m}$ plays the role of the observer-gain matrix. The symbols L^g and C^g denote the generalised matrix inverse [13] of the matrices L and C respectively.

Let x_i denote the state of the integrator placed in the forward path of the proposed scheme in Fig. 4. We have from Fig. 4

$$\dot{x}_i = r - \dot{\gamma} = r - x_1 = r - C_1 x \tag{3}$$

where $r = \dot{\gamma}_d$ is the flight-path-rate command and $C_1 =$

$\begin{bmatrix} 1 & 0 & 0 & 0 \end{bmatrix}$. The error signal $e(t) = \dot{x}_i$. Now, we obtain the combined state-space model of the augmented system (i.e. the combination of the reduced-order observer-based state feedback, output feedback and the PI controller) as

$$\begin{bmatrix} \dot{x} \\ \dot{x}_i \\ \dot{\hat{q}} \end{bmatrix} = \begin{bmatrix} \begin{pmatrix} A - Bk_pC_1 \\ -BK_{opt}\hat{D}C \end{pmatrix} & Bk_i & -BK_{opt}\hat{C} \\ -C_1 & 0_{1\times 1} & 0_{1\times 2} \\ \begin{pmatrix} \hat{J}C - \hat{B}K_{opt}\hat{D}C \\ -\hat{B}k_pC_1 \end{pmatrix} & \hat{B}k_i & (\hat{A} - \hat{B}K_{opt}\hat{C}) \end{bmatrix} \times \begin{bmatrix} x \\ x_i \\ \hat{q} \end{bmatrix} + \begin{bmatrix} Bk_p \\ 1 \\ \hat{B}k_p \end{bmatrix} r, \tag{4}$$

$$Y = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ x_i \\ \hat{q} \end{bmatrix} \quad \text{and} \tag{5}$$

$$\hat{x} = \hat{C}\hat{q} + \hat{D}y = \hat{C}\hat{q} + \hat{D}Cx. \tag{6}$$

The designed control input is given by

$$u = k_i x_i + k_p e - K_{opt}\hat{x} \tag{7}$$

according to the proposed type-1 servo scheme, shown in Fig. 4, where $K_{opt} \in \mathbb{R}^{1\times 4}$ is the optimal feedback gain to be determined by the LQR algorithm. The type-1 servo scheme also facilitates to find k_i and K_{opt} together $[K_{opt} \ \vdots \ -k_i]$ by applying the LQR algorithm on the augmented system model $\left(\begin{bmatrix} A & 0_{4\times 1} \\ -C_1 & 0_{1\times 1} \end{bmatrix}, \begin{bmatrix} B \\ 0_{1\times 1} \end{bmatrix} \right)$ subject to a given choice of $Q = Q^\top > 0$, $Q \in \mathbb{R}^{5\times 5}$, and $R = R^\top > 0$, $R \in \mathbb{R}^{1\times 1}$ (refer to [14]). We have also given an iterative process (Algorithm 1) for finding the LQR weightage matrices Q and R based on the given time-domain performance specifications.

IV. Matlab simulation results: A comparative study among the classical two-loop, three-loop and the proposed type-1 servo scheme

This section presents a comparative study on the simulation responses achieved by the classical two-loop and three-loop autopilot and the proposed type-1 servo scheme. The missile parameter values (tabulated in Table I) have been taken from [3]. Based on this data set, we compute the state-space matrices (A, B, C) of the open-loop model of the linearised missile dynamics (1), as given below:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} -2.77 & 2.8894 & 1.1860 & 0.4269 \\ -50.6161 & 2.77 & -508.388 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -32400 & -216 \end{bmatrix} \times \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ -3888 \end{bmatrix} u.$$

σ^2	0.00029 sec^2
ω_b	11.77 rad/sec
ω_a	180 rad/sec
ζ_a	0.6
ν	470
k_p	5.51
k_b	-10.6272 /sec
k_q	-0.07
k_i	22.2

We then find the state-space matrices of the overall closed-loop scheme (Fig. 4) described via (4)–(6). As mentioned earlier, the proposed scheme has one control input u and two outputs $\dot{\gamma}$ and q. The augmented state vector $X = \begin{bmatrix} x^\top & x_i & \hat{q}^\top \end{bmatrix}^\top \in \mathbb{R}^{7\times 1}$.

Following Algorithm 1, we obtain the LQR weightage matrices Q and R. Based on these Q and R, we find the required set of optimal gain values K_{opt}, k_i and k_p. After feeding all the computed numeric values into the Matlab-Simulink model of the type-1 servo autopilot scheme, we perform a unit-step simulation by choosing the reference command $\dot{\gamma}_d = 1$. The same unit-step simulation is performed for the two-loop and three-loop configurations shown in Fig. 2 and Fig. 3, respectively. Finally, three sets of simulation responses are plotted on the same graph (Fig. 5–Fig. 8), corresponding to each of the four states $\dot{\gamma}(t)$, $q(t)$, $\eta(t)$ and $\dot{\eta}(t)$.

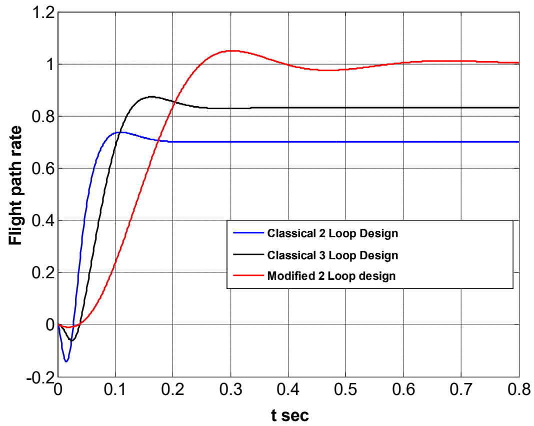

Fig. 5. Comparison among the flight-path-rate responses ($\dot{\gamma}$) achieved by the two-loop, three-loop and type-1 servo schemes.

Fig. 5 shows the comparative plot obtained by the two-loop, three-loop and type-1 servo autopilot schemes, subject to unit-step command (i.e. $\dot{\gamma}_d = 1$). Note that the Red-coloured plots in each of these four figures (designated by 'Modified 2 loop design') indicate the responses achieved by the type-1 servo autopilot. Fig. 5 reveals that the flight-path-rate $\dot{\gamma}$ has entered into the 2% tolerance band with respect to the commanded signal $\dot{\gamma}_d$ within only 0.22 sec and the percentage peak overshoot is less than 5%. Most importantly, the peak undershoot of the $\dot{\gamma}$-response (subject to $\dot{\gamma}_d = 1$) is now only -0.00984 in contrast to -0.1428 and -0.0544 in the cases of the classical two-loop and three-loop schemes, respectively. Although the settling time 0.22 sec is slightly more than 0.17 sec and 0.20 sec achieved by the two-loop and three-loop schemes, respectively, the reduction of the peak undershoot in the case of type-1 servo scheme is much stronger than the classical ones. A similar performance improvement is observed in the remaining three figures: Fig. 6, Fig. 7 and Fig. 8 show the comparative plots of the pitch-rate (q), angle of elevator deflection (η) and the rate of the change of elevator deflection ($\dot{\eta}$), respectively. The performance improvement in terms of the reduction in the peak overshoot and undershoot, increase in the speed of response (decrease in the rise time and peak time), reduction in the settling time, nullification of the steady-state error, etc., are now quantified based on the comparative plots given in Fig. 5, Fig. 6, Fig. 7 and Fig. 8 and tabulated in Table II. The comparative study in Table II recommends a remarkable improvement in both the steady-state and transient performance (in all four states, including the outputs $\dot{\gamma}$ and q) achieved by the proposed type-1 servo scheme over the classical two-loop and three-loop techniques.

V. Conclusions

This paper proposes a reduced-order observer-based, optimal, type-1 servo configuration for tuning a flight-path-rate-demand autopilot for a class of rear-controlled, tactical, guided missiles. The linearised missile configuration exhibits NMP behaviour and has open-loop unstable dynamics, which

offer non-trivial challenges in the autopilot design. An in-depth Matlab simulation study has been performed, which shows significant improvement in the transient and steady-state performance of the proposed type-1 autopilot scheme over the classical two-loop and three-loop design methodologies [1]–[3]. In the future scope, Negative Imaginary (NI) theory can be applied to develop a robust autopilot design methodology following the ideas given in [15]–[20]. Moreover, cooperative control of multiple missiles can be developed using the scheme proposed in [21].

ACKNOWLEDGEMENT

Abstract— **Being a promising alternative to traditional antennas, liquid antennas have gained high attention in the recent years due to their reconfigurability. As the probe feed position alters the impedance matching and electrical length, the performance like S11, gain and BW will change. This paper tries to illustrates the outcome of different probe positions for different probe types used in the cylindrical liquid antenna which is further optimized using Particle Swarm Optimization. CST Studio suite have been used to simulate the results. 4GHz frequency was maintained throughout the experiment by changing the feed lines and keeping the inner radius of the cylinder, height of the liquid and dielectric constant to excite the different modes of the antenna for multiple applications.**

Keywords— *liquid antenna, probe, particle swarm optimization*

I. INTRODUCTION

This Modern era of wireless communication require an antenna to have multiple functions within a limited space. Multiple attempts have been tried to upgrade the reconfigurability of the metallic antennas in the areas of the radiation pattern, operating frequency and bandwidth .The performance of the low cost radio frequency switches was not good due to presence of metal strip biasing circuits which would be difficult to embed with antennas.[1,3] Again , the high performance RF switches are highly priced. Thus, dielectric resonators were used as radiating elements. The popularity of these antennas increased as they can switch between functions within a single structure without resorting multiple antennas.[2] Since, liquids have high conformability, reconfigurability, improved electromagnetic coupling, thus water having high permittivity is used in the antenna construction. Here, for different Probe types different Probe positions were taken then optimized using Particle Swarm Optimization available in CST.[4] We have stated the effect of changing the probe positions on the working of the dielectric liquid antenna.

II. DIFFERENT PROBE POSITIONS

Here, in this paper we have used three different probe positions for three different feed types in the liquid antenna , namely Probe feed, Conical feed and Disc feed .

A. Probe Feed

The most common feeding method is the co- axial feeding method.[5] The inner cylindrical conductor of the co-axial connector is adhered to the cylindrical tube of the antenna and the outer part is connected to ground.[6] The radius of the dielectric fluid used here is 6.94084 mm.

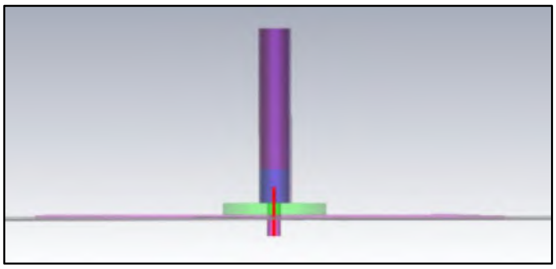

Figure 1: Probe feed

B. Conical Feed

The conical feed is mostly used in reconfigurable water based antenna[7]. The conical feed is projected from the liquid into to cylindrical tube containing the water.[8] The radius of the water used here is 8.45 mm which is the highest among the three[9]. This antenna has a wider aperture which provides greater directivity.

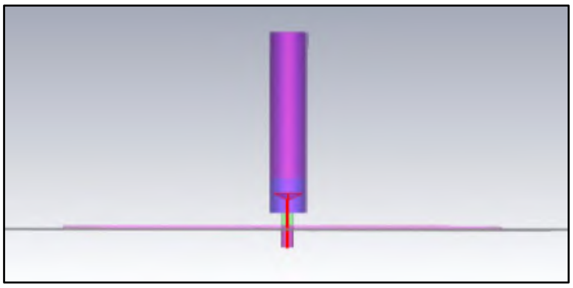

Figure 2: Conical feed

C. Disc Feed

The disc feed is attached to cylindrical tube that contains the water in it.[10] This type of antenna is widely used in satellite communications and also helps to improve the transmittance and signal reception on all the planes. The radius of the water used here is 6.78 mm The circular shape provides higher directivity and a wider aperture[11].

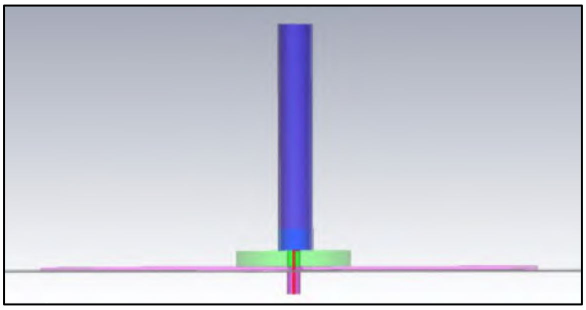

Figure 3: Disc feed

TABLE 1: DIFFERENT PROBE POSITIONS FOR DIFFERENT PROBE TYPES

Type of Feed	Radius of liquid(mm)	X-Position	Y-Position
Probe	6.94084	-0.35	-0.68
Disc	6.78	-0.44	-0.97
Conical	8.45	-0.32	-0.9

III. RESULTS

A. Probe Feed

A bandwidth of approximately 0.9967 GHz is achieved and the value of the S-parameter is approximately -24.04 dB at the operating frequency of 4 GHz. Here, the directivity which is the main lobe magnitude is 15.4 dB (V/m). In the far-field radiation pattern the angular width of 38.8 degrees is observed. The main lobe direction is directed towards 63.0 degrees and the sidelobe level is observed to be -1.1 dB. At 4 GHz the maximum gain over frequency is optimized which is 1.45 as shown in Fig 6.

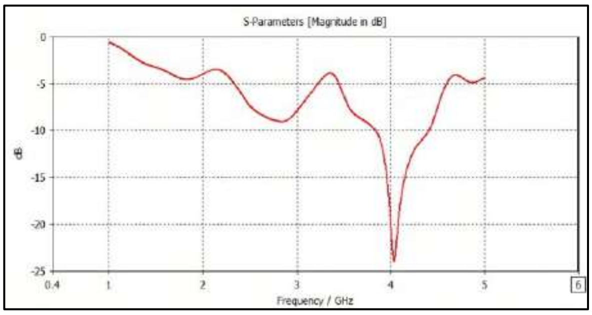

Figure 4: S- Parameter

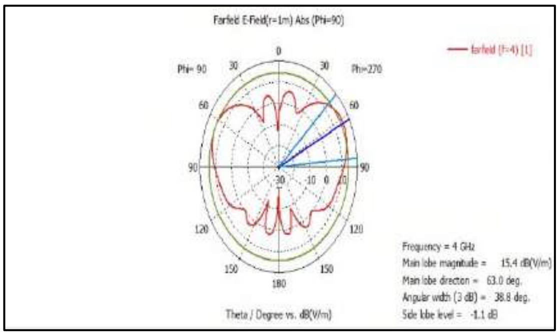

Figure 5: E- Field(4GHz)

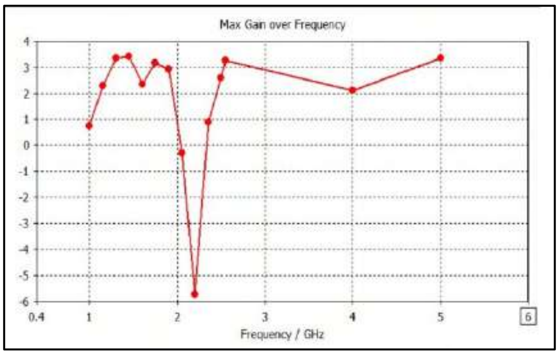

Figure 6: Maximum Gain Over Frequency

B. Conical Feed

A bandwidth of approximately 0.994 GHz, which is the lowest among all the feeds, is achieved and the value of the S-parameter is approximately -14.512 dB at the operating frequency of 4 GHz. Here, the directivity of the radiation pattern is 15.6 dB (V/m). In the far-field radiation pattern the angular width of 39.1 degrees is observed. The main lobe direction is directed towards 58.0 degrees and the sidelobe level is observed to be -6.5 dB. At 4 GHz the maximum gain over frequency is optimized as shown in Fig 9.

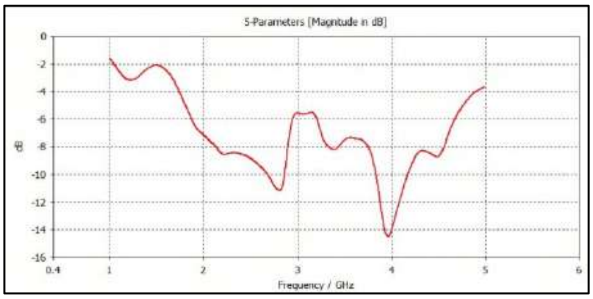

Figure 7: S- Parameter

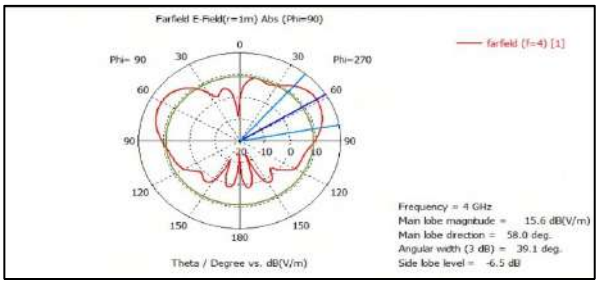

Figure 8: E- Field(4GHz)

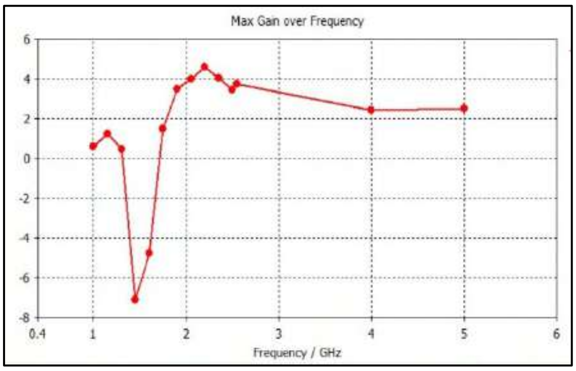

Figure 9: Maximum Gain Over Frequency

C. Disc Feed

A bandwidth of approximately 1.0049 GHz is achieved and the value of the S-parameter is approximately -33.26 dB at the operating frequency of 4 GHz. Here, the directivity which is the main lobe magnitude is 13.7 dB (V/m). In the far-field radiation pattern the angular width of 42.7 degrees is observed. The main lobe direction is directed towards 57.0 degrees and the sidelobe level is observed to be -1.0 dB. At 4 GHz the maximum gain over frequency is optimized as 2.03 shown in Fig 12.

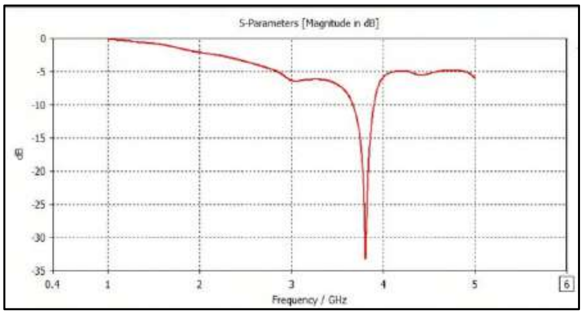

Figure 10: S- Parameter

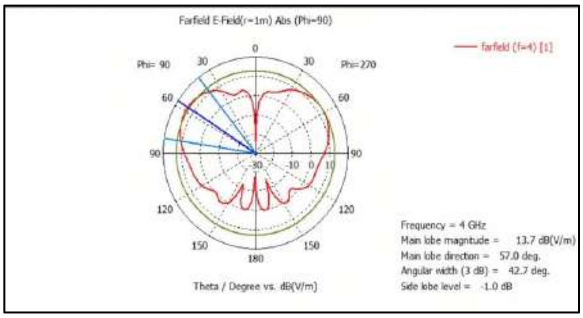

Figure 11: E- Field(4GHz)

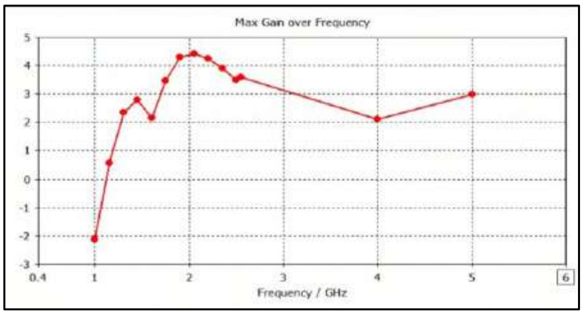

Figure 12: Maximum Gain Over Frequency

IV. COMPARISON OF RESULTS

The simulation results are assembled and compared in the table below: (all the results in comparison table are approximate value)

TABLE I COMPARISON TABLE

	Disc Feed	**Probe Feed**	**Conical Feed**
Bandwidth(GHz)	1.0049	0.9967	0.994
S-parameter(dB)	-33.26	-24.04	-14.512
Directivity(dBi)	13.7	15.4	15.6
Angular Width(deg.)	42.7	38.8	39.1
Side Lobe Level(dB)	-1.0	-1.1	-6.5
Main Lobe Direction(deg.)	57.0	63.0	58
Maximum Gain Over Frequency	2.03	1.45	2.19

V. CONCLUSION

In this paper we have reached the following conclusions from the three different probe positions for three different probe types and compared their bandwidth, S-parameter, directivity, angular width, maximum gain frequency, and sidelobe level. These are mentioned below:

1.The disk feed type has the highest angular width and the probe feed type has the least. Thus , this type of disc feed type antenna can be used for beam forming technique.

2. The conical feed has the highest directivity that is the magnitude of the main lobe is maximum while disc feed has the lowest directivity.

3. The conical feed has the highest gain over frequency and the probe feed has the least.

4. The disc feed has the highest bandwidth among the three. Thus, it can be used in the narrow band applications.

ACKNOWLEDGEMENT

We would like to express our special thanks of gratitude to Prof. Bhaskar Gupta, Jadavpur University, Kolkata for his continuous support.

***Abstract*—*Cercospora zeae-maydis* (CERCZM) is a destructive fungus that is strengthened by hot tropical weather and high humidity such as in the Philippines, resulting to recurrent adverse impacts of having maize *Cercospora* leas spot disease, and quantification of leaf damage is essential for plant phenotyping in understanding pathogen interaction. Visual detection of this disease often results in subjective classification. To address this challenge, the integration of computer vision and computational intelligence is employed in detecting healthy and damaged corn leaves and predicting the surface damage percentage due to maize *Cercospora* leaf spot. Dataset with 583 images contains matured healthy and diseased corn leaves that were grown outdoor and individually captured by a digital camera. Graph-cut segmentation through lazysnapping segmented the vegetation pixels and CIELab thresholding segmented healthy and diseased regions. Spectro-textural-morphological leaf signatures were extracted and selected using combined neighborhood component analysis and ReliefF resulting in R, H, *a, Cb, Cr, entropy, and whole leaf area. MobileNetV2 exhibited the best performance in classifying maize leaf health status. Gaussian quantum-behaved particle swarm optimized recurrent neural network (GQPSO-RNN) bested other feature-based machine learning and deep transfer image networks in predicting maize *Cercospora* leaf spot surface damage percentage with R^2 of 0.949, RMSE of 6.290, and inference time of 3 seconds. This developed seamless MobileNetV2-GQPSO-RNN model provides reliable disease detection and quantitative assessment on the maize leaf surface in on-field phenotyping.**

Keywords*—*computational intelligence, computer vision, corn leaf disease, model optimization, particle swarm optimization

I. Introduction

Crops are susceptible to pathogens that may cause outbreaks if left unchecked. To ensure that plant life is preserved, inspecting common parts of plants, such as leaves, for the manifestation of diseases should be considered. Maize or corn, otherwise known as *Zea mays L.*, is one of the most utilized crops in the animal and food industries in the Philippines [1]. It has become an essential food in several countries, surpassing the demand for wheat and rice. Leaf ailments are a hindrance to corn production. Determining leaf ailments using human judgment is not an efficient method in monitoring crops [2-3].

Similarities such as manifestations of spots that mature into yellowish lesions and can spread through the leaves of corn crops may branch out to surrounding plants, increasing its infectivity. These symptoms are caused by the *Cercospora* leaf disease (CLD). There are different variants of CLD such as bacterial leaf growth, northern corn leaf blight (NCLB), southern corn leaf blight (SCLB), and gray leaf spot (GLS) [4]. In general, *Cercospora zeae-maydis* (CERCZM) is characterized by gray leaf spot, reduced fruit size, necrotic areas in leaves, and early senescence of the whole plant. All of these variants are commonly caused by *Cercospora beticola* and can reduce a plant's vigor, making it defoliated [5].

Convolutional neural network (CNN) is capable of diagnosing early symptoms of corn crop diseases in a real-time and non-destructive manner [6-8]. Employing genetic algorithm support vector machine (GA-SVM) distinguishes the difference of each disease from one another [2]. Multifractal detrended fluctuation analysis (MF-DFA) utilized the gray variance values of blemishes seen on crop leaves with CLD [9]. Stripping the layers of crop leaves [10] and applying trifloxystrobin and epoxiconazole mixtures reduced the damage done by CLD and provided high crop yield [11]. Crop rotation, tillage residue of CLD on equipment, stressful environments, and use of chemicals are factors that should be considered to manage CLD properly [12]. Mapping genetic traces of CLD can aid in identifying early signs of the disease, preventing an outbreak from occurring [13]. Screening of plant phenotype is important to avoid abnormalities in growing crops, and thus, increasing total harvest yield [14]. Quantitative trait locus (QTL) mapping can be done to identify genetic characteristics of *Cercospora* in a different population of corn crops [4]. Monitoring plant life using ultrasonic sensing sprayers provide the optimum height and placement of sprayers to protect corn crops and increase total harvest yield [15]. Complex leaf shapes and varying colors by using integrating local threshold and seeded region growing (LTSRG) [16]. Information about leaf color can be mapped by converting

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

RGB to Cb-Cr space [17]. Computer vision (CV) technology has been widely used in classifying and identifying crop diseases through histogram-oriented gradient (HOG), segmented fractal texture analysis (SFTA), and local ternary patterns (LTP) [18-19]. Discolorations and spots are then identified to determine the presence of *Cercospora* infection [20].

Despite the abovementioned studies with technological advancements, the severity of damage due to corn leaf disease has not been explored and modeled yet. Subjective assessment of damage percentage is also evidently using human bare eyes which is not ideal for scientific phenotyping. Likewise, most plant imaging devices are bulky and placed inside a laboratory which requires transporting of leaf samples from the field that adds up to the delay in real-time phenotyping.

In this study, corn leaf quality was classified into healthy and defective in terms of the presence of *Cercospora* leaf spots, and the defective leaves have undergone surface damage computational assessment using computational intelligence (CI) models by calculating the damaged percentage in terms of the leaf area. Quantum particle swarm optimization (GQPSO) was used to improve the model performance of the recurrent neural network (RNN). GQPSO was chosen and explored because it enables both linear and nonlinear and bounded and unbounded problems to generate the best solution possible. Likewise, artificial bee colony (ABC) and genetic algorithm (GA) were also explored but resulted into convergence issue. The developed model is a novel approach to assessing corn *Cercospora* leaf spot.

II. Materials and Methods

Corn *cercospora* leaf spot is quantitatively evaluated based on its damage on the visible surface of the leaf structure. The developmental architecture of detecting corn leaf quality and assessing the percentage of the diseased surface using deep transfer image network and feature-based machine learning models is shown in Fig. 1. The model employed in this study emphasizes the degree of impact of corn leaf disease by predicting the leaf spot surface defect percentage. Images that are classified with healthy maize leaf results in 0% diseased surface percentage. MATLAB R2020a is the only computational intelligence programming platform used in computer vision, image feature extraction, leaf signatures selection, model optimization, and development of prediction models.

A. Cultivar Data Description and Environmental Condition

Zea mays convar. Saccharate var. rugosa, also known as sweet corn, was cultivated in open field agriculture in Bukidnon, Philippines from September to November 2019 through a monoculture approach. Environment temperature during cultivation ranges from 23 – 33°C. Matured 90-day old health and diseased corn leaves that are infected by *Cercospora zeae-maydis* characterized by rough gray spots were captured using a consumer-grade digital camera with an aspect ratio of 1:1 having an image spatial resolution of 256 x 256 pixels. A total of 583 leaf images was analyzed coming from 283 diseased and 300 healthy leaves. The used dataset is based on [21].

B. Leaf Segmentation, Spectro-Textural-Morphological Feature Extraction and Selection

Classified diseased maize leaf images were furtherly assessed by undergoing graph-cut segmentation of the whole leaf and diseased region to compute the damaged percentage concerning the captured leaf area (Fig. 2). Graph-cut segmentation is based on lazysnapping algorithm (Fig. 2b) that transforms RGB image to CIELab color space where L ranges from 0 to 100, a* is from -86.1827 to 98.2343, and b* is from -107.8602 to 94.4780. It employs marking of foreground and background pixels which is, in this case, are vegetative and non-vegetative elements, respectively. It categorizes a pixel based on K-means clustering characterization on edge signatures of the neighboring pixels with a superpixels value of 421.

Both whole leaf and diseased region segmented images require feature extraction for the development of a computational assessment model. Morphological area is extracted from whole leaf image ($A_{wholeleaf}$) which is then used in (1) in yielding the diseased or damaged surface percentage (DSP). For the diseased regions, spectral (R, G, B, H, S, V, L, a*, b*, Y, Cb, Cr), textural (contrast, correlation, energy, entropy, homogeneity) [22], and morphological area parameters were extracted. The morphological area of the diseased region ($A_{diseasedregion}$) is then divided by $A_{wholeleaf}$ to get the ratio of diseased and whole leaf region (1). This 18-feature vector is purposively reduced to several highly significant feature vectors based on neighborhood component analysis (NCA) and ReliefF. NCA is a multidimensional reduction based on Mahalanobis distance while ReliefF ranks the 18 features using an intelligent Relief algorithm. Combined characterization of NCA and ReliefF resulted in a 7-feature vector, [R, H, a*, Cb, Cr, entropy, whole-leaf area], which results in significant relation in predicting damaged surface percentage (Fig. 3).

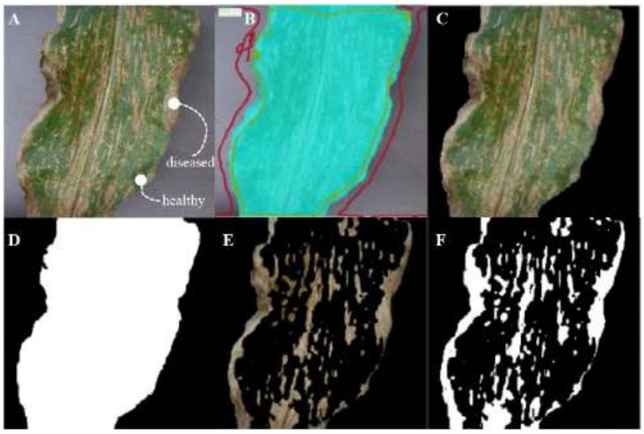

Fig. 2. Process of graph-cut segmentation of whole and diseased leaf regions: (a) raw leaf image indicatng healthy and diseased regions, (b) lazysnapping masking, (c) annotated whole leaf image, (d) whole leaf binary image, (e) diseased regions, and (f) binary diseased regions

$$DSP = (A_{diseasedregion} / A_{wholeleaf}) \text{ x } 100 \qquad (1)$$

C. Feature-Based Machine Learning Regression for Diseased Surface Percentage Prediction Modeling

Diseased leaf region percentage affected by *Cercospora zeae-maydis* is predicted using generalized processing regression (GPR), recurrent neural network (RNN), regression tree (RTree), and regression support vector machine (RSVM). GPR is optimized using constant basis function with a beta of 854.1724 and sigma value of 5.3574, squared exponential kernel function, exact predict method, exact fit method, and rando active set method. Elman RNN is optimized using QGPSO and is discussed in the next section. RTree is optimized using a minimum leaf size of 6. RSVM is optimized using box constraint of 0.21536, 0.035471 kernel scale, 0.31729 epsilon value, -3.0948x10^3 bias, and sequential minimal optimization (SMO) as solver. Hyperparameters of GPR, RTRee, and RSVM were enhanced using Bayesian optimization. Stratified sampling was employed in distributing images with 56%-24%-20% partitions for training, validation, and testing image set.

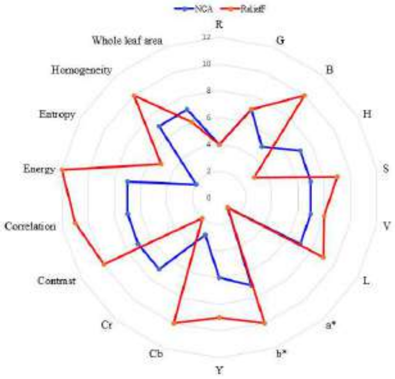

Fig. 3. Weight spectrum of spectro-textural-morphological leaf signatures as characterized by neighborhood component analysis and ReliefF

D. Parameter Optimization Using Gaussian Quantum-Behaved Particle Swarm

Gaussian quantum-behaved particle swarm optimization (GQPSO) is a quantum-based PSO with Gaussian probability distribution acting on its mutation process [23-25]. This Gaussian distribution improves the divergence of this bioinspired algorithm and is an advanced approach in mitigating local optima premature convergence. Instead of position and velocity in classical PSO, in the quantum model of GQPSO, each involved particle state is depicted by wave function *ψ(x, t)*, where *x* is the particle position at time *t*, of the standard Schrödinger equation [23]. In this study, GQPSO is performed using these chronological steps: initialization of swarm positions using Gaussian probability distribution, particle fitness evaluation, updating of the global best particle, comparing particle fitness to current best value, comparing current best particle to global best, updating particle positions using Gaussian distribution, and repeating the cyclic evolution. The algorithm stops only if the maximum number of generations is exhausted. Other optimization algorithms such as artificial bee colony (ABC) and genetic algorithm (GA) were also explored and resulted in divergence issue, making GQPSO the algorithm fit for this application.

The topology of the RNN fitness function based on the linear regression of its corresponding hidden artificial neurons and mean square error (MSE) network performance is shown in (2). The three hidden layers of RNN, N_1, N_2, and N_3, are the variables that will be generated using GQPSO. Regression coefficients α, β, γ, and δ have values of 1.432x10^{-3}, 1x10^{-7}, 1.3x$10^{-6,}$ and 1x10^{-6}, respectively.

$$MSE = f\,(N_1, N_2, N_3) = \alpha - \beta N_1 - \gamma N_2 + \delta N_3 \qquad (2)$$

In this study, the potential function configured to Delta Potential Well with 3-dimensional space, 250 swarm particles, 0 to 500 boundaries, and a non-negative constant of 0.9. GQPSO finds the global optimum of (2) at N_1, N_2, and N_3 values of 140, 100, and 30 with a smoothing fitness curve up to 100 iterations (Fig. 4).

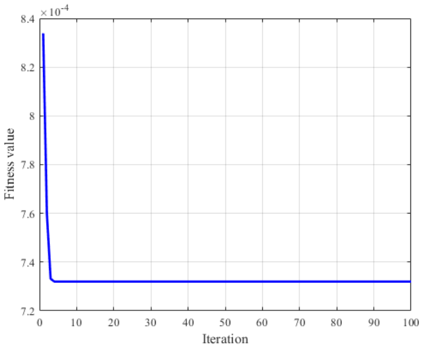

Fig. 4. Optimization curve using Gaussian quantum-behaved particle swarm optimization characterized by fitness value and iteration performance

E. Deep Transfer Image Regression for Diseased Surface Percentage Prediction Modeling

Deep transfer regression networks of MobileNetV2, ResNet101, and InceptionV3 were configured using SGDM with a minimum batch size of 20, maximum epochs of 7, 0.0001 initial learn rate, piecewise learn rate schedule, 0.1 learn rate drop factor, 20 learn rate drop period, 'every-epoch' shuffling method, and validation frequency of 3. Raw leaf images were utilized as no further image processing is required except for data augmentation to make sure that the network will not overshoot. The optimized feature-based machine learning models and image-based deep learning networks were evaluated based on root mean square (RMSE), R^2, mean absolute error (MAE), and inference time throughout training to testing stages.

III. Results and Discussions

A. *Leaf Phenotype Analysis*

Correlation analysis confirmed that the extracted a* and Cr of diseased maize leaf image has a strong positive influence on diseased surface percentage. R, S, V, and b* has very weak positive significance to DSP (Table 1). All numerical Haralick textural features have a very strong negative or positive correlation with DSP. Additionally, all spectro-textural-morphological features of healthy maize leaf images exhibit no significance with the diseased surface percentage at $\alpha \leq 0.05$.

TABLE I. Correlation Analysis of NCA-ReliefF Extracted from Pearson Correlation Analysis of Diseased and Healthy Maize Leaves

Leaf Health Status	R	H	a*	Cb	Cr	Entropy	Whole Leaf Area
Diseased	0.196	-0.655	0.784	-0.185	0.880	0.038	-0.086
Healthy	*ns*	*ns*	*ns*	*ns*	*ns*	*ns*	*ns*

[a] *ns* means not significant

B. *Maize Crop Leaf Quality Classification Using Deep Transfer Network*

Matured maize leaves were classified healthy and defective using deep transfer image classification networks of MobileNetV2, ResNet101, and InceptionV3 (Fig. 5). For 117 test samples, diseased maize leaf samples were arranged from 1 to 57 and the remaining samples are the healthy leaf images without a hint of *Cercospora zeae-maydis*. MobileNetV2 misclassified 1 healthy maize leaf as defective or diseased (Fig. 5c). On the other hand, both ResNet101 and InceptionV3 misclassified 1 diseased leaf as a healthy leaf as depicted by green and blue lines respectively (Fig. 5d). These very intelligent classification performances resulted in the same accuracy, fall-out, precision, specificity, recall, f1-score, MCC, and Hamming loss (Table 2). However, MobileNetV2 bested ResNet101 and InceptionV3 in discriminating maize leaf quality in terms of inference time with 76.25% faster than ResNet101 and 57.23% faster than InceptionV3.

C. *Feature-Based Maize Leaf Diseased Surface Percentage Prediction*

MobileNetV2-classified diseased matured maize leaves exhibiting the existence of *Cercospora zeae-maydis* were computationally assessed using GPR, RNN, RTree, and RSVM. A numerical subscript was suffixed to each machine learning model to denote the number of spectro-textural-morphological features used as descriptors such as $RSVM_{18}$ for RSVM using 18 predictors (Fig. 6a). 18-feature predictors are the original unreduced vector while the 7-feature vector is the utilized the NCA-ReliefF selected leaf elements which are R, H, *a, Cb Cr, entropy, and whole leaf area (Figures 3 and 6a). GQPSO-optimized RNN_7 performed the most accurate and sensitive predictive feature-based machine learning model used in this study in determining diseased surface percentage as reflected by lowest RMSE and MAE, highest R^2 value of 0.949, and shortest inference time of 3 seconds (Table 3). The accuracy of GQPSO-RNN_7 rose by 350.544% from its RNN_{18} performance. On the other hand, GPR_7 is also comparable with GQPSO-RNN_7 as it exhibited an R^2 of 0.945 and RMSE and MAE values close to GQPSO-RNN_7 in the testing phase. Despite the 115.545% improvement in R^2 factor of GPR_7 from GPR_{18}, its resulting value missed 0.004 to be coequal with GQPSO-RNN_7. Correspondingly, RTree variants performed the worst predictions, and RSVM exhibited the longest inference time that is 54 multiples that of the GQPSO-RNN_7. Evidently, the use of intelligently selected combinations of color, texture, and morphological features significantly resulted in improved prediction performance, thus, making MobileNetV2 the most reliable model in this application.

D. *Image-Based Maize Leaf Diseased Surface Percentage Prediction*

In contrast with GPR, RNN, RTree, and RSVM, MobileNetV2, ResNet101 and InceptionV3 utilized the raw maize leaf images as network input for prediction of diseased surface percentage (Fig. 6). ResNet101 bested out MobileNetV2 and InceptionV3 in predicting DSP in terms of lower RMSE and MAE and strong positive R^2 of 0.9333. However, the inference time of ResNet101 is more than twice of MobileNetV2 and 1.5x of the InceptionV3 model (Table 3). This makes ResNet101 the slowest deep transfer image network to predict DSP and MobilenetV2 is the fastest one. It should be taken into consideration that in this study, accuracy and sensitivity is what weighs more than that of inference time.

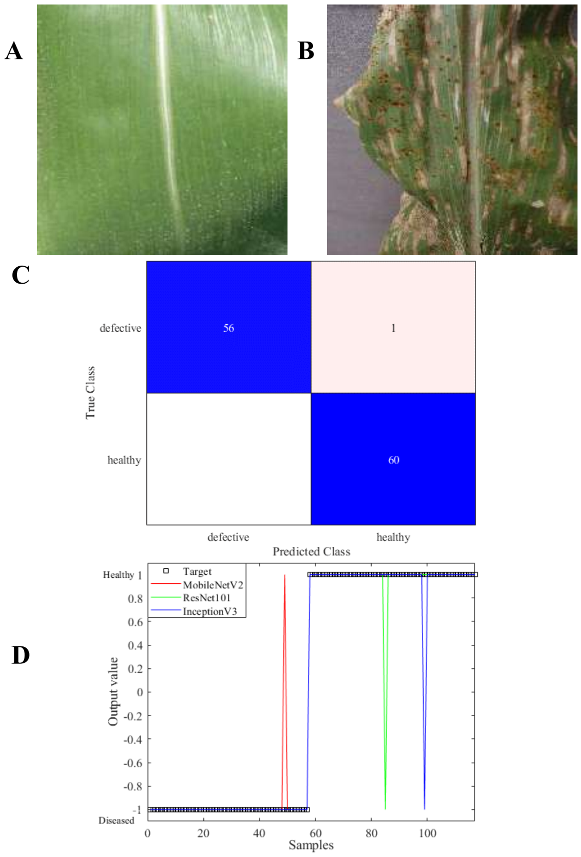

Fig. 5. Samples of (a) healthy and (b) diseased maize leaves, (c) confusion matrix, and (d) comparison of classification output of each deep transfer image network

After series of successful explorations in predicting the diseased surface percentage of maize *Cercospora* leaf spot using both feature-based and image-based computational intelligence models, it can be determined that GQPSO-RNN7 exhibited the most accurate, sensitive, and quickest model amongst GPR, RTree, and RSVM with and without using NCA-RelieF selected features, and MobileNetV2, ResNet101, and InceptionV3. In this study computer vision, through a low consumer-grade RGB camera, was employed to extract maize leaf signatures to mitigate subjective detection of the presence of fungi in crop leaf which is the challenge encountered by [2-3]. It is interesting that among 18 unreduced feature vector, S, Cb, Cr, correlation, entropy, and homogeneity of the healthy maize leaf corresponds to smaller numerical value compare to diseased leaves. With this, there is a common implication that 60% of the texture properties can independently distinguish healthy maize leaf. The a* value for a healthy leaf is 227.712% smaller than that of the disease, thus, making it profound that a healthy leaf exhibits greener vegetation pixels. The green color component from the RGB color space dictates that healthy maize leaves have an average of 131.167 G value and is 142.825% higher than the diseased leaf. It does make sense as maize *cercospora* leaf can be detected with gray, red, and darker brown spots that later on promotes necrosis.

The developed seamless MobileNetV2-GQPSO-RNN model exhibits a non-destructive approach in crop leaf phenotyping which only requires an RGB image as input for it evaluate the rendered maize leaf disease unlike [7], [9]. It is also comparable that other studies focused on using one leaf trait only as input to their phenotype model [16]-[17] but this developed framework also qualified to use combinations of leaf signatures from color, texture, and morphological components to increase the performance accuracy and sensitivity of the combined computer vision and computational intelligence.

IV. Conclusion

Maize leaf health status was classified into healthy or diseased using MobileNetV2. ResNet101 and InceptionV3 exhibited the same network performances with MobileNetV2 except that MobileNetV2 classifies leaf health status with the shortest time. The degree of evidence of *Cercospora zeae-maydis* in maize leaf was characterized by combined neighborhood component analysis and ReliefF, resulting in R, H, *a, Cb Cr, entropy, and whole leaf area as the most significant features in predicting diseased surface percentage. Lazysnapping provided exquisite segmentation of *Cercospora* leaf spot regions from other healthy vegetive and non-vegetative leaf regions. Gaussian quantum-behaved particle swam optimization significantly increased the sensitivity and accuracy of RNN by determining the optimal number of hidden artificial neurons. GQPSO-RNN with reduced predictors bested out other feature-based and deep transfer machine learning networks in predicting DSP. This low-cost plant imaging approach can be employed by low-income agriculturists who want to assess their crops effectively and quantitatively by just acquiring inexpensive camera and following the computational intelligence model development stated above. The developed seamless model of MobileNetV2-GQPSO-RNN is highly essential for computational phenotyping of maize leaf *Cercospora* leaf spot and other leaf diseases. For future studies, it is recommended to cultivate different species of corn suitable in Philippine environmental conditions and employ the developed computer vision approach for on-site leaf *Cercospora* disease phenotyping.

***Abstract*–A well functioned battery charger for electric vehicles can improve the life cycle of the battery. To control the overshoot, rise time and settling time with respect to the changing input voltage and load is the noticeable challenge in the field of battery charging. Usually, a PID controller has been used to overcome these challenges. However, PID controller is suitable for a specific configuration, and overshoot, oscillation happens when input voltage and load vary. In this paper, a buck converter-based battery charging controller is presented in which a modified proportional-integral (PI) controller is used. The modified PI controller is tuned for charging the battery with minimum overshoot and settling time. To verify the viability, the proposed system has been simulated in MATLAB. The simulation results show that the overshoot is reduced to 1.23% with the settling time of 0.01s for the 48V battery bank.**

***Keywords*–Battery charging controller, Asynchronous Buck Converter, Electric vehicle, Pulse Width Modulation, Proportional Integral**.

I. Introduction

In order to make the transportation system more efficient, environment friendly and robust the current noticeable interest has been increased to use the electric vehicle [1]. The electric vehicle (EV) can produce high speed and torque within a minimum time. Unlike conventional fuel-based vehicles the EV takes power from rechargeable battery [2]. To charge the battery with optimum efficiency ensuring the good battery life a power electronics controller is required which can convert the grid power to suitable DC for charging the battery [3].

For effective operation, it is necessary to charge the battery with lower overshoot and less settling time with respect to the variation of input voltage and load. To meet these demand, PID and other controller topologies have been proposed [4-7]. But they struggle to withstand the variation of input voltage and load. The PI or PID transient response is mostly S shaped and the delay in the initial point is noticeable as explained by Ziegler-Nichols First rule and it is very challenging to reduce the delay time, overshoot and settling time.

Many scholars avoid PI and proposed PID, forward PID, FOPID and other topologies which are complex, hard to implement, need high processing microcontroller and hence costly. While using PID the overshoot issue is still present.

Theerayod Wiangtong [8] avoided using PI and proposed PID with Flower Pollination Algorithm which makes the controller complex and still overshoot present at the output voltage although it was applied for small system. Adhul S V [9] proposed FOPID and avoid conventional PI and PID controller due to high overshoot. D. Ounnas, D. Guiza, Y. Soufi [10] also avoided PI controller due to overshoot and proposed digital PID controller for the Buck converter.

This paper presents a buck converter-based battery charging controller using modified proportional integral (MPI) control system to reduce the initial delay time, settling time and overshoot with changing input voltage and load.

II. Design of Proposed System

The block diagram of proposed buck converter controller using Modified Proportional Integral controller is depicted in Fig.1 The output voltage is sensed and compared with the processed reference value and the error goes to MPI controller and the PWM is generated based on that and thus the buck converter operates.

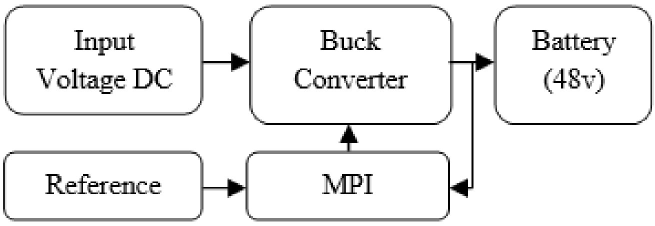

Fig. 1: Block diagram of proposed system

A. Modified PI Controller

The modified proportional integral (MPI) controller is shown in Fig.2. To find the difference between desired voltage $r'(t)$ and actual output voltage $y'(t)$, the MPI is required. The desired output voltage is sampled and further processed according to predefined tuned value. The desired output voltage which is instantaneous defined as

$$r'(t) = nu(t) \qquad (1)$$

In sample and process block the instantaneous desired voltage modified in the basis of equation (2).

$$r(t) = nr(t+0) - nr(t-m) \qquad (2)$$

where *n* is the given desired output voltage value and *m* is the desired settling time. The desired output voltage is then compared with actual output voltage and the difference between them is fed to the PI block defined as

$$y(t) = k_P e(t) + k_i \int e(t)\, dt \qquad (3)$$

where $e(t)$ is the difference between desired and actual output voltage.

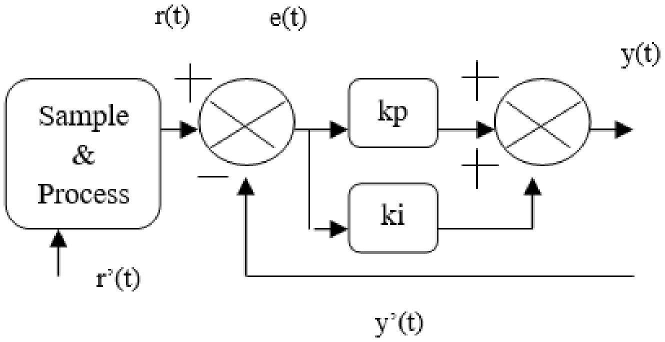

Fig. 2: Block diagram of proposed MPI system

B. PI Tuning Parameters using Zeigler-Nichols Method

The tuning parameters of PI controller have been derived using Ziegler-Nichol's frequency domain method as shown in Table I. The critical value of proportional constant k_{cr} has found from simulated results and hence the proportional constant k_p can be calculated as

$$k_p = 0.45k_{cr} = 0.45 \times \ 0.223 = 0.1$$

The period of oscillation p_{cr} has been found form simulated result and the T_i can be calculated as

$$T_i = \frac{p_{cr}}{1.2} = \frac{0.14}{1.2} = 0.117$$

Hance, the integral constant k_i can be found as

$$k_i = \frac{k_p}{T_i} = \frac{0.1}{0.117} = 0.854$$

These values of tuning parameters of PI controller have been used in the proposed system.

Table I. Ziegler-Nichols tuning parameters for PI controller

Tuning parameter	Value
k_p	$0.45k_{cr}$
T_i	$\frac{p_{cr}}{1.2}$

C. Buck Converter

To simplify the circuit design of the buck converter the following assumptions are considered:

1) all components are ideal, and
2) the inductor is operated in continuous conduction mode (CCM).

Maximum inductor current ripple can be calculated as

$$\Delta I_L = I_L \times \Delta I_{Lmax} = 10 \times 10\% = 1\text{A}$$

where the $I_L$is inductor current.

The maximum output voltage ripple can be calculated as

$$\Delta v_{out} = v_{out} \times 1\% = 48 \times 1\% = 0.48\text{v}$$

Inductor value is calculated as

$$L = \frac{v_{out}(v_{in} - v_{out})}{\Delta I_L \times f_s \times v_{in}} = 1.31017\text{mH}$$

Output capacitor value is found as

$$C = \frac{\Delta I_L}{8 \times f_s \times \Delta v_{out}} = 0.51243\text{uF}$$

The design parameters of DC-DC buck converter used in proposed charging system are listed in TABLE II.

TABLE II. Design Parameters of Proposed Charging System

Parameter	Values
Input DC Voltage	312v
Output DC Voltage	48v
Maximum Output Current	10A
Applied Switching Frequency	31kHz
Filter Inductance	1.31017mH
Filter Output Capacitance	0.51243uF
Max Inductor Ripple Current	1%
Output Voltage Ripple	1%

III. Simulation and Results Analysis

A complete circuit was developed in the MATLAB Simulink using the calculated and designed parameters to analyze the performance of the proposed system as shown in Fig.3. The MATLAB functional block consists of MPI equations as explained in section IIA. The desired voltage and actual voltage are then compared and based on that the PWM is generated at a frequency of 31kHz with the help of PI controller.

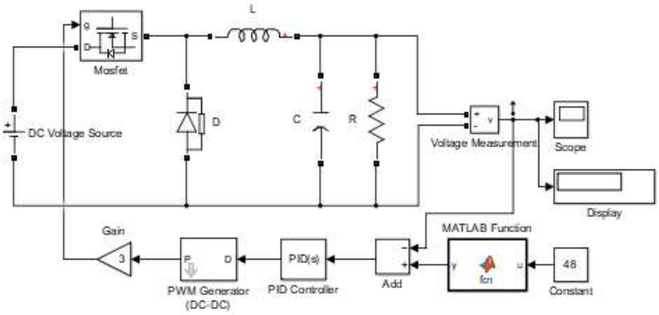

Fig. 3: Proposed MPI system

Figs. 4-8 show the direct comparison for different input voltages and loads for 48V output voltage. Both conventional PI and propose MPI used the same k_p and k_i values. The result shows that the conventional PI controller has high overshoot than that of the proposed modified PI where a settling time of 0.01s has been achieved. The conventional PI struggles for stabilizing the overshoot voltage when the input voltage and load changes whereas the proposed modified PI can handle this scenario easily and no overshoot happen during that case.

From Figs. 5-6 it is observed that the maximum overshoot of the output voltages of the buck converter increases 192.7% to a maximum of 206.25% for conventional PI controlled buck converter when the input voltage changes 290V-335V from its base voltage 312V for a fixed load of 30 ohm. On the other hand, the maximum overshoot of the output voltages of the buck converter increases 130.2% to a maximum of 209.3% for conventional PI controlled buck converter when the load changes from 10 ohms to 50 ohms for a fixed input voltage of 312V as shown in Figs. 7-8. When input voltage 312V and load 50 ohm the overshoot was maximum which is 209.3%. The results conclude when the load increases from base 30 ohm value the overshoot increases greatly as depicted in Fig. 9. This large percentage of overshoot is not suitable for EV's battery charging applications. Interestingly, a negligible overshoot of the output voltage of the buck converter exists while using the modified PI controller.

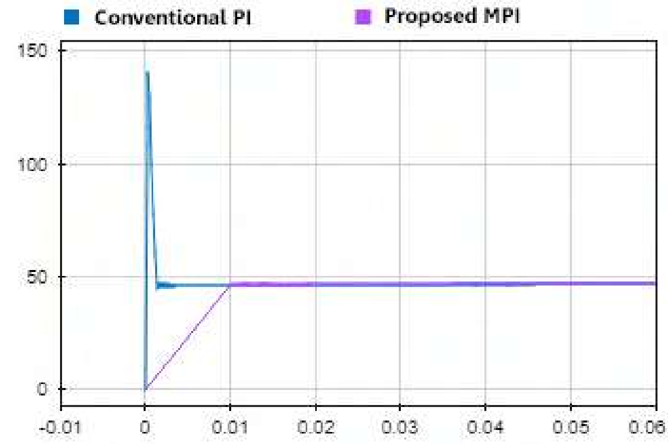

Fig. 4: Simulated Result for Vin 312 Vo 48 and load 30 ohm

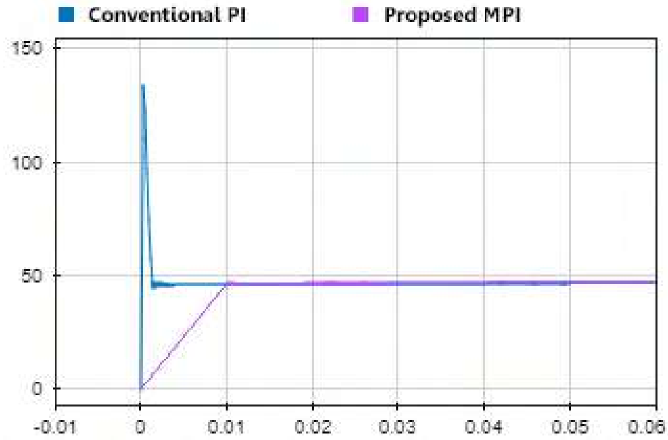

Fig. 5: Simulated Result for Vin 290 Vo 48 and load 30 ohm

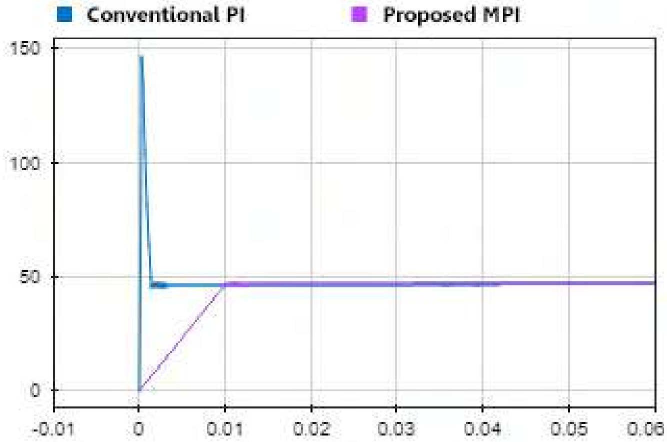

Fig. 6: Simulated Result for Vin 335 Vo 48 and load 30 ohm

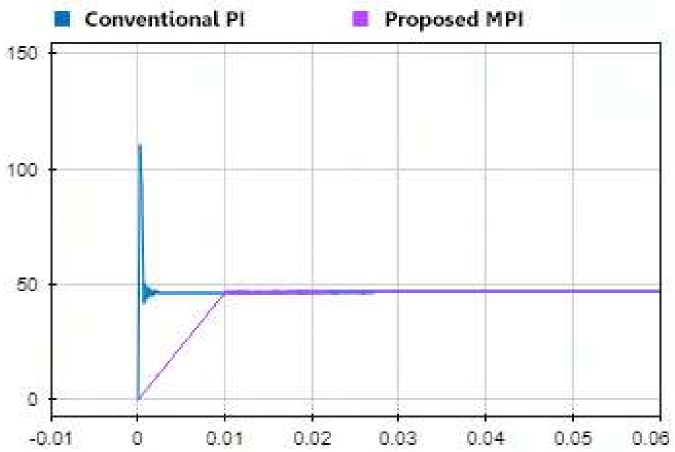

Fig. 7: Simulated Result for Vin 312 Vo 48 and load 10 ohm

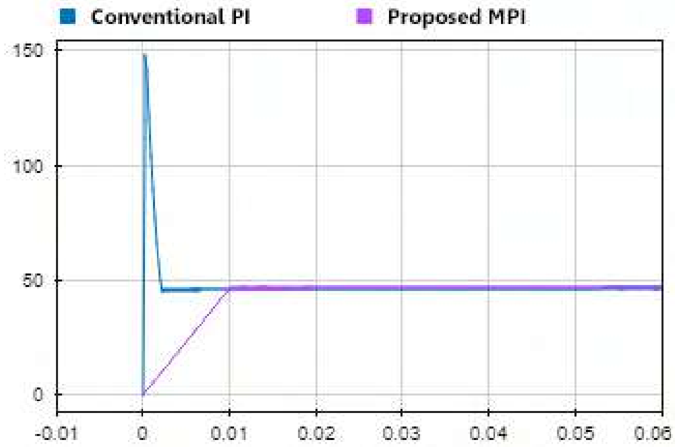

Fig. 8: Simulated Result for Vin 312 Vo 48 and load 50 ohm

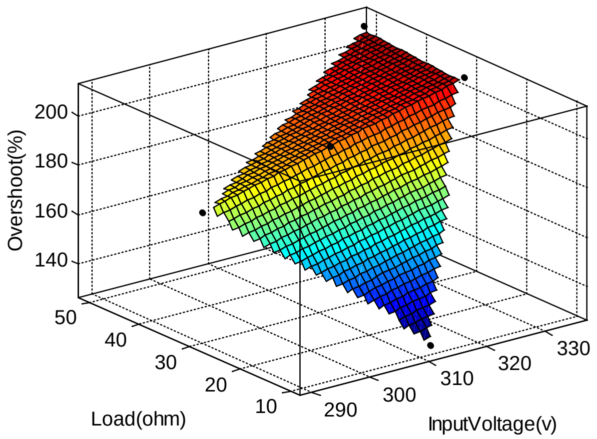

Fig. 9: Parameters for conventional PI

The voltage-gain transfer function for the proposed modified PI controlled buck converter calculated by MATLAB was found to be.

$$\frac{2.542e07}{S^2+6.933e07s+7.705e10} \tag{4}$$

The Bode diagram and pole-zero map for the proposed modified PI controlled buck converter as illustrated in Figs. 10 and 11, respectively, which confirms the stability of the system since all the poles of the voltage gain transfer function lies on the unit circle in the ***z***-plane.

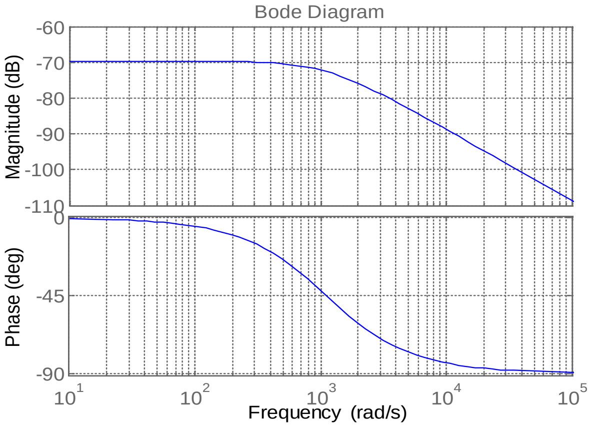

Fig. 10: Simulated Bode Diagram

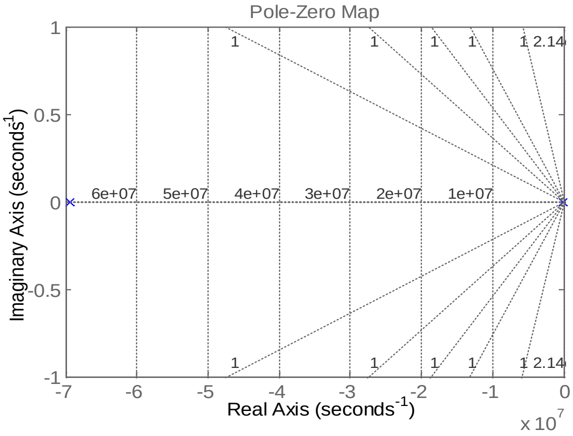

Fig. 11: Simulated Pole-Zero Map

IV. Conclusion

This paper emphasized on controlling the buck converters output voltage overshoot and settling time using a modified PI controller. A comparison of complete analysis of conventional PI and with the proposed modified PI has been investigated. The result shows that the maximum overshoot of the output voltage of the buck converter varies in the range 130.2% - 209.3% for the conventional PI controller-based buck converter when the input voltage and load changes, whereas the performance increases significantly with almost no overshoot while using the proposed modified PI controller based buck converter for a desired settling time of 0.01s. This modified PI controller-based buck converter, which has less settling time with negligible overshoot, will be very useful for EV's battery charging systems.

V. Future Work

A hardware prototype of the proposed system and its performance analysis will be presented in near future to confirm the viability of this simulation work.

***Abstract*—The challenge of keeping pace with the growth of population is synchronizing with the advancement of the technology. As a developing country it is difficult to sustain the balance between the increased inhabitants of Bangladesh and the total energy consumption. Machine learning (ML) can used to forecast the demand of energy consumption including production, organization and conservation of energy for the new buildings with respect to the citizens. This paper introduces a prediction analysis of energy consumption of a residential apartment using different machine learning models including multiple linear regression (MLR), random forest (RF), support vector machine (SVM), and k-nearest neighbors (KNN). While analyzing the models, the energy consumption data of twelve months from an apartment in Chittagong-district situated in Bangladesh was used. The analyses confirm the most effective model used for such energy demand criteria of residential buildings of that location. The outcome of the prediction method reveals that random forest (RF) model can reach to the best accuracy with the highest performance parameters.**

Keywords—energy consumption, machine learning, prediction, performance, learning models.

I. Introduction

Energy demand of a country renders crucial role to the ecosystem along with the development. Imbalance of energy consumption and demand can lead to the agony of the citizens in large scale. Around a decade, the emerge of machine learning models has taken part in almost every sector of global progress especially in energy consumption analysis. Moreover, forecasting of energy consumption building nowadays has highly subjected some prominent algorithms in machine learning to improve the conservation and modeling [1] [2]. In different area of application, the structure seems to represent different accuracy [2] [3]. In addition, support vector machine, gaussian mixture model, different neural networks and even new hybrid methods can be used in multiple platforms while acknowledging prediction analysis of energy demand or consumption [4] [5] [6]. Deep neural networking in high computational extent can sustain greater accuracy in different demanding proposals [7] [8]. In contrast, artificial neural network enables estimation to a certain level of interest where the goal focuses to the high precision in energy use [9] [10]. Besides depending on the feature extraction and the load pattern other machine learning models can signify the intention of conspicuous energy consumption. Reference [11] provides the most absolute outcome of the energy consumption forecast using support vector regression (SVR) machine based on cooling loads. Furthermore, improved results have been achieved while introducing k-shaped clustering before applying the SVR model [12]. On the other hand, hybrid models can attain the standard of accuracy while concerning the demand of short-term energy use [13]. Such classification approach highly enlarges the performance of the system while implementing on other algorithms in numerous feature analysis [14]. However, acknowledging temperature, humidity, solar parameters along with more factors, the gaussian mixture regression (GMR) even in heating, ventilation & air conditioning (HVAC) has conducted solid assessment of estimation [15] [16].

The major influences that can diversify the rate of demand in energy based on complex figures and uncertain features. In Bangladesh, around 50% of total households have domestic connections from 21.8 million grid connected consumers. Others are mostly commercial or industrial, where the total power generation is approximately 13,000MW. In favour of the growth, the intricate nature of preserving the energy demand is a challenge for the country. Among few of the implementation of machine learning in prediction models, this country has already accepted the peripherals [17] [18]. Besides, some machine learning algorithms have interestingly improved the building of energy consumption in non-residential sectors outside Bangladesh [19] [20]. Reference [21] and [22], applies such instances of promising accuracy in residential area holding the features with complication.

This paper emphasizes on different energy consumption prediction models of machine learning based on certain feature points like temperature, humidity, electric bill etc. The methods are evaluated by coefficient of determination (R^2), mean absolute error (MAE), mean square error (MSE), root mean squared error (RMSE), and coefficient of variance (CV). The energy demand assessment has been analyzed with different machine learning models including multiple linear regression (MLR), random forest (RF), support vector regression machine (SVR), and k-nearest neighbors (KNN).

The content of the paper is coordinated as follows: Section II upholds the dataset formal with detain; Section III presents the mathematical and understanding of different models; Section IV illustrates various performance parameters; Section V analyses the results of the predictive outcomes and finally draws conclusion according to the final remarks.

II. Dataset Formation

The dataset represents energy related factors of a six-story residential building including the ground floor having six types of flooring size in Chittagong district located in Bangladesh having the parameters of table 1. Various related features like area (square feet), occupancy, daytime

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

temperature (°C), nightly temperature (°C), average temperature (°C), daily sunshine (hours), average rainfall (mm), rainy days (days), sea temperature (°C), humidity (%), windspeed (kph), number of rooms, and price (BDT-excluding demand, vat, and other charges) are considered along with the 12 month of daily energy consumption from 1st January 2020 to 31st December 2020. Having six different types of flats each consisting of eight floors, the whole apartment contains 48 flats and 392 rooms in total which have been demonstrated in the table I. Likewise, the information of the consumption is being collected manually from the digital electric meter. The data-formation has 576 samples while observing all the obstacles that have limited the possible outcome. The entire dataset has been recorded as *.csv (comma separated values) file for simulation purpose.

TABLE I. BUILDING FORMAT

Type of flats	No. of floors	Size (square feet)	No of rooms
A	8	1415	9
B		1214	8
C		1206	8
D		1385	9
E		935	7
F		1047	8

III. MACHINE LEARNING MODELS

The machine learning methods include multiple linear regression (MLR), random forest (RF), support vector regression (SVR), and k-nearest neighbors (KNN) which are constituted below.

A. *Multiple Linear Regression (MLR)*

More than one input features can be related to the dependent feature that is the energy consumption while utilizing multiple linear regression model. Denoting x_0 as the constant or the intercept, p and n as the observations, β_p as the coefficient for each independent feature of p^{th} sample, $x_{e(p)}$ as the variable of p^{th} sample, and $\in$ as the error term of the fitted model; the energy consumption (y_e) of our dataset can be presented as,

$$y_e = x_0 + \sum_{p=1}^{n} \beta_p x_{e(p)} + \in \qquad (1)$$

B. *Random Forest (RF)*

Comprising of many adaptable decision trees with the ability of executing both regression and classification problems, the RF can compute with most effectiveness. Each tree contributes highly which predicting the best solution by voting. The ideology of acquiring highest accuracy in the sense of merging the training sets called by 'bagging' process, is used to ensemble the trees in this supervised algorithm. Hence, at the time of processing the model itself introduces certain randomness while equally spitting the subsets among the decision trees. The goal of such method is to recognize the best among all the features in each set. Consequently, this leads to better estimation process for any application.

C. *Support Vector Regression (SVR)*

The SVR can effectively handle outliers in any model by separating the target values and the provided data into high-dimensional hyperplanes. Different kernel functions are used to determine support vector classifier or regressors such as polynomial, linear, sigmoid, radial (radial basis function-RBF) etc. Moreover, without the transformation these functions can easily evaluate the correlation between each pair of points assuming them in greater dimensions. This phenomenon is known as the 'kernel trick' which eases the assessment of computation. The polynomial kernel uses the equation 2 for calculating the relations, where *x* and *y* are the observations of independent and dependent feature respectively, *r* is the polynomial-coefficient, and *d* is the polynomial-degree.

$$\{(x \times y) + r\}^d \qquad (2)$$

The equation 3 validates the radial function where γ weights the squared-distance and the impact. Unlike polynomial, RBF deals with infinite number of dimensions encouraging both taylor series expansion method and dot-multiplication. On the other hand, the linear kernel is associated with the equation 4, where n is the number of observations.

$$e^{-\gamma\,(x-y)^2} \qquad (3)$$

$$k(x, y) = \sum_{t=1}^{n} x_t y_t \qquad (4)$$

Most functions allow dot-multiplication for assessing the relationship while *r*, *d*, and *γ* are determined by cross-validation.

D. *k-Nearest Neighbors (KNN)*

Being able to use in both classification and regression model, KNN operates with '*k*' as the number of points closest to the required observation to find the distance using distance-measurement techniques. These techniques popularly include Manhattan, and Euclidian. A regressor would find the mean of the distance of total '*k*' points and assign that to the new one. The process stabilizes until the predictive point is in optimal state. In contrast, a classifier assigns the majority voted group-points as the predictive point where the '*k*' has to be an odd value. The corresponding equation 5 and 6 are allied with Euclidean and Manhattan distance measuring methods respectively, where x and y are the observations and the m is the total number of samples.

$$d\,(x, y) = \sqrt{\sum_{i=1}^{m} (x_i - y_i)^2} \qquad (5)$$

$$d\,(x, y) = \sum_{i=1}^{m} |x_i - y_i| \qquad (6)$$

IV. PERFORMANCE PARAMETERS

For evaluating outcomes from all the models, the specifications as coefficient of variance (CV) for both test and train dataset, coefficient of determination (*R*^2), mean absolute error (MAE), mean square error (MSE), and root mean square error (RMSE) are being figured out and compared. The simulation environment used in the purpose of modelling is the Spyder IDE (integrated development environment). As the objective is to apply regressors, the *R*^2 holds the variance of targeted outcome figure which possess the equation 7. The more the value of *R*^2, the better the model performs. Additionally, the CV retains the total amount of distributed figures concerning with the computed mean that can be calculated through equation 8. The lesser the value of CV, the performance of the model gets better. Finally, the RMSE presents the overall term of error in a model regarding in the form of root-mean-squared which can be represented by the equation 9. Furthermore, the predictive inaccuracies of the model have to go through standard deviation in order to acquire the RMSE of the model.

$$R^2 = [\frac{\sum_{i=1}^{N}\left(y_{predict,i} - \bar{y}_{data}\right)^2}{\sum_{i=1}^{N}\left(y_{data,i} - \bar{y}_{data}\right)^2} \times 100]\ \% \qquad (7)$$

$$CV = [\frac{\sqrt{\frac{\sum_{i=1}^{N}\left(y_{predict,i} - y_{data,i}\right)^2}{N-1}}}{\bar{y}_{data}} \times 100]\ \% \qquad (8)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}\left(y_{predict,i} - y_{data,i}\right)^2}{N}} \qquad (9)$$

where the y_(predict,i) is the predicted energy consumption, y_(data,i) is the actual energy consumption or the test data, N is the sample size, and y ̅_data is the average of the energy consumption.

After evaluation, the performance parameters from the models in predictive energy consumption is listed in Table I. The main dataset has been split into 50:50 ratio (test:train) while computing the analysis.

TABLE II. PERFORMANCE PARAMETERS

Model Name	R^2 **(%)**	MAE	MSE	$RMSE$	CV_{test} **(%)**	$CV_{predict}$ **(%)**
MLR	38.06	67.87	6894	83.03	17.8	11.25
KNN [k=5]	36.22	67.44	7099	84.25	17.8	13.26
RF	56.88	52.72	4799	69.27	17.8	14.61
SVR (RBF)	32.32	0.65	0.68	0.82	2469	-874.92
SVR (Linear)	33.27	0.64	0.67	0.82	2469	-506.84
SVR (Polynomial : degree=5)	36.47	0.63	0.64	0.80	2469	-1771.90

The RF model responds well corresponding to the consumption rather than other models of the building. Securing 56.88% of coefficient of determination, RF has less coefficient of variance comparing with others. Fig. 1 exhibits the comparison among models where the scatter plotting represents the real and estimated points. Likewise, the black line is just the centre line where the test value is equal to estimated value. The RF can easily disperse along the line apart from other machine learning methods that have been used. The total energy consumption from the apartment is around 340MW per year. Such analysis can definitely amplify the process of managing energy demand throughout the country effectively. Besides, it will escalate the progress rate of the entire energy system along with scope of future analogical experiments.

(e) SVR (polynomial kernel) model: without standardization

Fig. 1. Accuracy comparison among the models (a-e).

The RF method has been used to illustrate the correlation of individual variable responding with energy consumption as shown in Fig.2. Observing the change in each diagram appeared in Fig.2, dependent variables which have been considered in the dataframe according to our building parameter have steady transformation according to the energy consumption except the electricity bill (Price-BDT). Depending on the geographical features the outside weather is not so variant in nature, which leads to lower range of changing parameters. However, such patterns will cause prediction of energy consumption differently.

V. Conclusion

The paper emphasizes on energy prediction analysis on demand purpose using different machine learning models: multiple linear regression (MLR), random forest (RF), support vector regression machine (SVR), and k-nearest neighbors (KNN). Table 2 identifies the correlations among the features that have been assembled systematically for presenting the features associated with each method. Among four models, RF can deal with the relationship among the provided feature categories. Yet other models like MLR, SVR_poly, and KNN has performed similarly for the peripherals of such energy data of building in Chittagong. Nevertheless, the performance in R^2 is not so good. All the models show poor figures which can be the reason of multi-variant nature among the independent variables corresponding to the dependent one. However, the models can be effectively applied for the prediction of demand analysis for the energy consumption.

VI. Future Work

Future study on this paper is required where more samples will be considered along with more in-depth survey of hourly data configuration for energy consumption. Other machine learning models like deep neural network, gaussian process regression, gaussian mixture regression model etc. will be taken into consideration for much extensive analysis. This paper will also acknowledge some profound features for further analyzation. Besides, the work method can also be adapted in other figures with different structures.

Abstract- In this work we have reported Pd/GO FET nanocomposite field effect transistor (FET) based acetone sensor. Pd nanoparticle loaded graphene oxide (GO) was prepared by one step spray coating technique at room temperature. The morphological and structural characterizations of developed pure GO and Pd/GO samples were performed with field emission scanning electron microscopy (FESEM), Raman spectroscopy and UV-Vis spectroscopy techniques. The effect of gate voltage on sensors at different temperature range (25- 75˚C) was investigated by I_{DS}-V_{GS} characteristic. GO and Pd/GO FET sensors showed optimum response at 50 ˚C temperature with and without applied gate voltage. The response of Pd/GO FET sensor was around 8 % under zero gate voltage (V_{GS}= 0 V) at operating temperature of 50 ˚C. Due to the application of gate voltage near Dirac point voltage ($V_{GS} \approx V_{dirac}$), both the sensors showed a significant increment in the response magnitude where pure GO exhibited 22 % and Pd/GO exhibited 45 % response in the exposure of 80 ppm acetone at 50 ˚C. The Pd/GO FET sensor showed ~6 times amplification in sensitivity as the consequence of applied gate voltage.

Keywords- Pd/GO hybrid, FET, acetone sensing, Amplified sensitivity

I. INTRODUCTION

Volatile organic compound (VOC) detection attracted a significant attention in sensing field due to their extensive application in detection of toxic, hazardous and flammable VOCs in pharmaceutical, water treatment, automotive industry, beverage industry, power plants, medical diagnosis, air quality treatment and food processing [1,2]. In a more specific and influential way, acetone is a breath marker for diabetes and halitosis disease and offer a valuable research perspective in detection of acetone in exhaled breath for disease monitoring and diagnosis [3]. In general, VOC sensor operates on a principle where surface interaction of sensing layer with target VOC results in modulation of electrical properties [4]. A variety of materials are involving as sensing layer like nanoscale semiconducting metal oxides [5,6], 2D materials, stable polymers [7] and thin metal films [8] etc. but among all of them 2D nanomaterials such as graphene, chalcogenides etc. and their composites attracted much attention due to their outstanding inherent properties such as good compatibility with environment, high specific surface area, high activation energy, room temperature stability, ballistic transport, fast response and low cost detection of VOC's[3,6, 9,10].

Since last two decades, graphene and their derivatives like graphene oxide (GO) and reduced graphene oxide (RGO) based gas/vapor sensors have been explored significantly due to their exciting properties like extremely high effective surface area, high mobility, electrical conductivity and easy functionalization properties [11]. However, research data also envisage that surface modified graphene has a greater number of defects and impurities which drastically improved the sensitivity and other sensing performances [3,6,9]. Incorporation of other sensing materials in GO improves its gas sensing properties and offers high sensitivity, fast response and recovery, long term stability etc. More significantly, GO based nanocomposites showed highly selective behaviour toward a target VOC. Bo Zhang et al reported RGO/α-Fe_2O_3 based acetone sensor and showed that mixing of RGO with metal oxide results in fast response and recovery with moderate sensitivity at 100 ppm but at high operating temperature (225˚C) [5]. Similarly, Pengpeng Wang et al reported ZnO/GO sensor for breath acetone detection with 35.8 % response for 100 ppm of concentration at relatively high operating temperature (240˚C) [9]. Noble metals (Ag, Au, Pd, Pt) nanoparticles functionalization on

978-1-6654-4067-7/21/$31.00 ©2021 IEEE

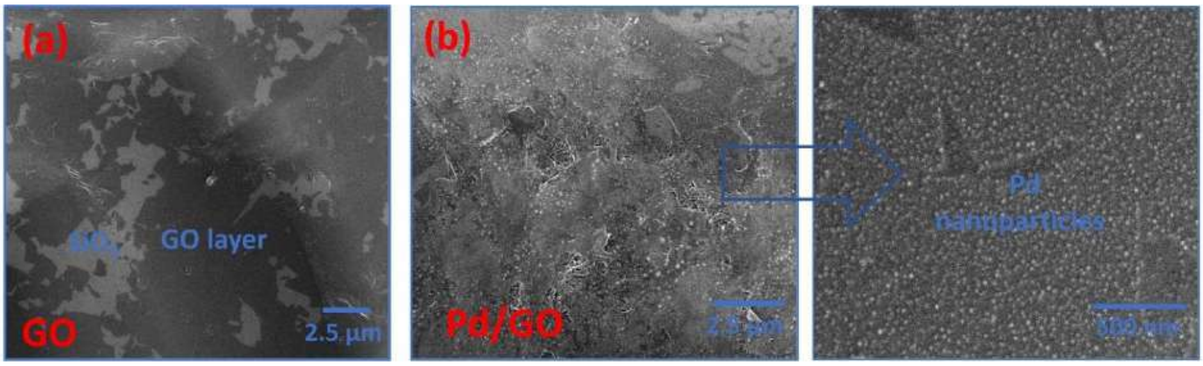

Fig. 1 FESEM images of pure GO (a), Pd/GO (b) and high-resolution image of Pd/GO samples on Si/SiO_2 substrate.

GO sensing layer influence sensing performance by their electrical and chemical sensitization mechanism [10, 12-15]. Ali Esfandiar and coworkers have shown the influence of Pd nanoparticles on WO_3/GO composite in hydrogen sensing performance. The sensor response was good enough with moderate operating temperature (100 ˚C) with outstanding response and recovery (less than 1 min) [14].

Besides the above mentioned advantages of GO composite, graphene and its derivatives also proved its potential in field effect transistors (FET) structure for efficient gas/VOC sensing.

Owing to the tuneable bandgap, limited majority carrier concentration, pure 2D structure, graphene and its derivatives exhibit field controlled current conduction in it [16-18]. Current in the graphene oxide channel can modulate significantly by applying suitable gate voltage in FET configuration that significantly improves the gas/vapor sensing performance of GO FET. A limited number of reports have been found on GO based FET system for gas sensing purpose [19,20].

In this work, we are reporting Pd/GO FET sensor system for the detection of acetone vapor at temperature range 25-75 ˚C. Here our main focus to study the effect of Pd nanoparticles loading on GO channel and the application of back gate bias voltage on acetone sensing performance of Pd/GO FET. The GO and Pd/GO FET sensors were fabricated on SiO_2/Si substrate by one step spray coating method. The attachment of Pd nanoparticles on GO surface was investigated by using scanning electron micrograph which demonstrated uniform distribution of GO sheets and as well as Pd nanoparticles with no aggregation. The effect of gate voltage on sensors at different temperature was investigated with I_{DS}-V_{GS} characteristics study and the effect of gate voltage on sensing performance of sensors was examined by exposing them to 80 ppm acetone at applied V_{GS} and different temperatures. In last, a possible sensing mechanism of proposed sensors was discussed.

II. EXPERIMENTAL

(a) Synthesis of nanocomposites

0.2 wt% (>80%, flake size: 0.5-5 µm; purchased from graphene supermarket) graphene oxide (GO) aqueous solution was prepared and further solution was ultrasonicated for 1 h for better dispersion. 1 M noble Pd nanoparticles solution was prepared by adding 0.17 gm palladium chloride ($PdCl_2$) into 1 L deionized water with continuous stirring at room temperature. Later, Pd nanoparticles solution was stabilized by adding diluted HCL dropwise with continuous sonication.

Boron-doped, ~500 µm thick <100> SiO_2/Si substrate having SiO_2 thickness of 90 nm was used as a substrate for the nanocomposite formation with resistivity of Si in the range of 0.001-0.005 Ω-cm. 10-20 µl GO solution was deposited on substrate by spray coating technique in air at the room temperature and sample is marked as S1. On the other hand, Pd/GO nanocomposite was synthesized by depositing 10-20 µl GO dispersion and then Pd nanoparticle solution in the same amount on substrate at room temperature and marked as S2.

After drying the samples, a thermal annealing was carried out on both the samples for 4 h at 250 ˚C temperature to achieve the thermal stability.

(b) Device fabrication

To fabricate the back gated field effect transistors, both top and bottom electrodes was deposited. Back gate contact was taken by selective removal of backside (1 mm×1 mm) SiO_2 layer of the substrate by HF etching with the help of negative photoresist. Top Au source and drain electrodes of thickness 150 nm was deposited by electron beam evaporation unit by using Cu physical mask.

(c) *Material characterizations*

Morphology of both the samples was characterized by field emission scanning electron microscopy (FESEM) technique. Structural properties and bandgap of samples was identified by Raman spectroscopy and UV-Vis spectroscopy techniques, respectively.

(d) Sensing characterization

GO and Pd/GO FET sensors were characterized by placing them inside a closed glass chamber with volume 450 ml. The glass chamber was then placed on a heating coil to vary the temperature from 25 to 75 ˚C. The sensors were characterized on a static mode gas sensing technique, where acetone was injected by micro syringe (Hamilton 705RN 50UL SYR) and sensors were recovered by continuous flowing of 450 SCCM air by mass flow controller (MFC). The reading of FET sensors was taken by the help of two source meters (keithley 6487). To measure the injected acetone Concentration (volume: V_1); C (ppm)=2.46 × (V_1D/VM) × 10^3 relation was used, where D (gm/mL), M (gm/mol) and V (Lit) represent density of liquid, molecular weight of liquid and volume of vaporization chamber respectively [21,22]. Response magnitude (RM) of the sensors was calculated by using the formula RM= $[(I_v- I_a)/I_v]\times100$ where I_a and I_v were the currents of the sensor in the air and acetone at operating temperature. The sensors were characterized at a constant (V_{DS}= 1 V) bias voltage throughout the study with varied gate voltages (V_{GS}).

III. RESULTS AND DISCUSSIONS

(a) Material Characterizations

Morphological study of both the samples done by FESEM as shown in the Fig. 1. Fig. 1(a) clearly demonstrated very thin layered GO deposition in a continuous manner. Pure graphene oxide image showing discontinuity into the ordered structure and random aggregation of layers and forming a uniform distribution (Fig. 1a). Fig. 1b is showing Pd nanoparticle distributed on GO layer which is placed on SiO_2/Si substrate. Uniform, compact and continuous distribution of nanoparticles was observed in S2 (Fig. 1b). High resolution image of Pd/GO represented by arrow, demonstrating average diameter of Pd nanoparticles around 20-30 nm.

Raman spectroscopy scan from 1000 to 2500 cm^{-1} is displaying in (Fig. 2a) to identify the defect density in samples and to compare the change in GO properties after addition of noble Pd nanoparticles. Two characteristic peaks of graphene were found in pure GO sample at around 1344 cm^{-1} (D band) and 1608 cm^{-1} (G band). Both the peaks were also found in Pd/GO sample with slight shift in peaks towards the lower wave number at 1337 (D band) and 1590 cm-1(G band) as shown in Fig. 2a. Shifting in peaks may be due the strong bonding and carrier transfer between Pd nanoparticle and GO. The D peak to G peak intensity ratio in pure GO was 0.92 and in Pd/GO was 1.39. The increase in relative intensity of D peak reveals increase in number of disorders due to the incorporation of Pd nanoparticles (Fig. 2a).

UV-Vis spectra of pure GO and Pd/GO samples is showing in Fig. 2b. Absorbance is high in Pd loaded sample compare to the pure GO as depicted in UV Vis spectra in Fig. 2b. Pd nanoparticle loaded sample has an absorption edge at 274.8 nm while pure graphene oxide sample showing its absorption edge at 330 nm. Pure GO has a bandgap of 3.7 eV and their mixing with Pd nanoparticles (noble metal)

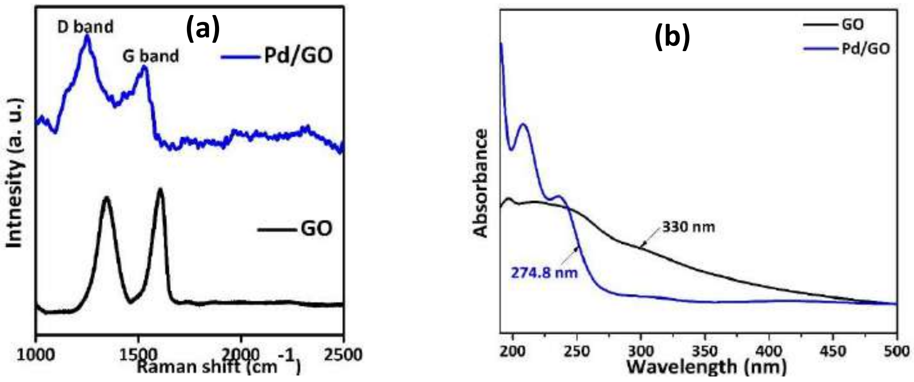

Fig. 2 (a) Raman spectra and (b) UV-vis spectra of pure GO, Pd/GO on Si/SiO_2 substrate.

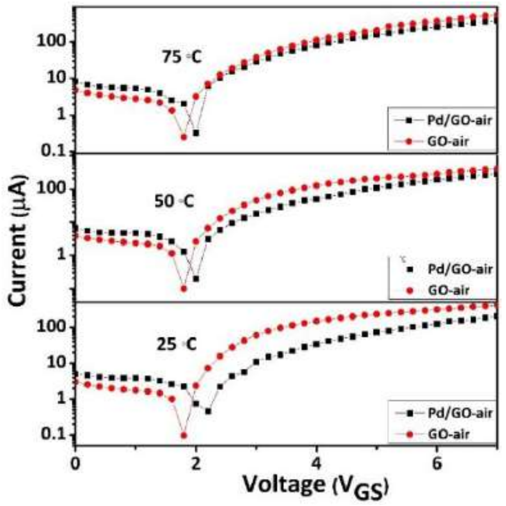

Fig. 3 I_D- V_{GS} characteristics of both FET sensors i.e GO and Pd/GO in air under V_{DS}= 1 V at a temperature range 25 °C - 75 °C.

show modification in bandgap and resulting bandgap was 4.5 eV in Pd/GO nanocomposite.

(b) I-V Characteristics of GO and Pd/GO FET sensors at different temperatures

Fig. 3 is showing I_{DS}-V_{GS} characteristic of both the GO and Pd/GO FET sensor in air for temperature range 25 ˚C- 75 ˚C. Modulation in the baseline current from GO to Pd/GO FET sensor was due to the conductivity difference between GO (*p*-type) and Pd nanoparticles (*n*-type). In Pd/GO FET sensor, accumulation/depletion of charge carriers between GO and Pd nanoparticles show shift in device current at (V_{GS}= 0V) and simultaneously in dirac point towards right as shown in the fig. 3. GO has very low majority charge carrier concentration and at applied V_{GS} the drain current start decreasing and at a particular voltage the drain current (I_{DS}) was found lowest with negligible carrier concentration. The value of V_{dirac} was related to the carrier concentration between source and drain terminal. As showing in the fig. 3, at each temperature range the value of the dirac point is contact for the both samples; for GO observed dirac point voltage was 1.8 V and for Pd/GO was 2.2 V. After dirac point the conductivity of the samples get changed as displayed in fig. 3.

(c) Acetone sensing performance with two terminals (V_{GS}= 0 V)

GO and Pd/GO FET sensors were tested for 80 ppm of acetone at (V_{GS}= 0 V) under the temperature range 25 to 75 ˚C as shown in Fig. 4. Response of the samples were increased linearly with increasing temperature and get saturated at 75 ˚C. At 25 ˚C, pure GO FET sensor was showing 4 % response with incomplete recovery and on the other side Pd/GO FET sensor was showing slightly high response around 6 % at V_{GS}= 0 V, as shown in Fig. 4a. However, 50 ˚C was considered as optimized temperature due to the favourable response for Pd/GO FET sensor around 8 % compare to the other temperature at V_{GS}= 0 V as shown in Fig. 4b. At higher temperature (75 ˚C), the response value of both the sensors gets decreased, from (fig. 4c). Moreover, Pd/GO showed high response magnitude for all the temperature range compare to pure GO at zero gate voltage possibly due to the electrical and chemical sensitization effect of Pd nanoparticles [23,12].

(d) Acetone sensing performance with three terminals (V_{GS}= Vdirac)

Fig. 5 shows the sensitivity modulation under the effect of applied gate voltage on GO and Pd/GO FET sensors for 80 ppm acetone and for the temperature range from 25 to 75 ˚C. Both the sensors were optimized under applied gate to source voltage which is very closed to the Dirac point voltage and have a different value for both the samples; for GO applied V_{GS}= 1.7 V and for Pd/GO applied V_{GS}= 1.9 V. The value of response magnitude significantly

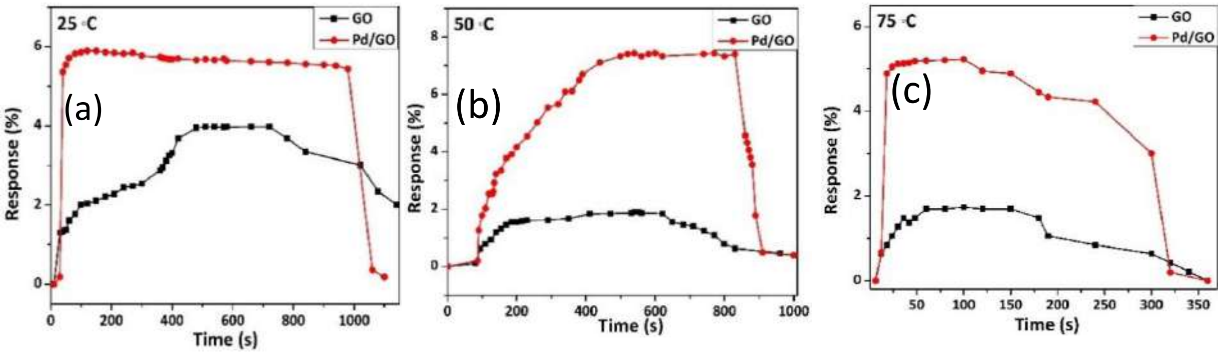

Fig. 4 The response variation curve of both FET sensors; GO and Pd/GO at 80 ppm acetone exposure with zero gate voltage at operating temperature (a) 25 °C, (b) 50°C and (c) 75 °C.

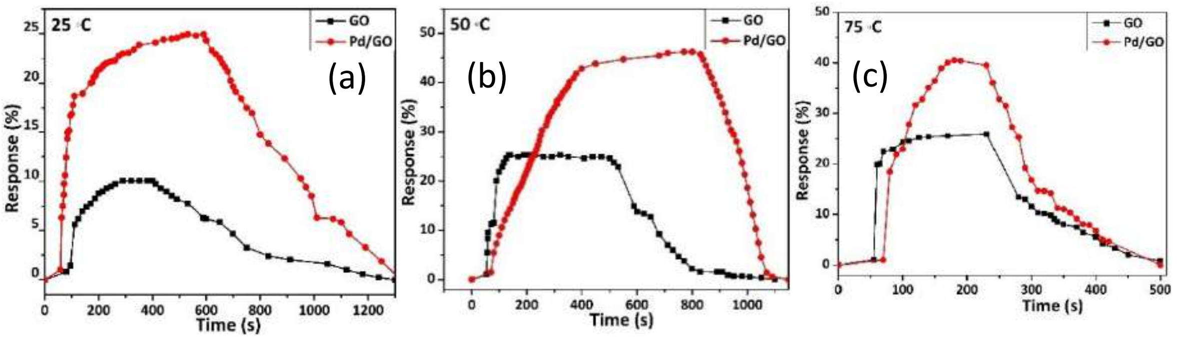

Fig. 5 (a) The response variation curve of both FET sensors; GO and Pd/GO at 80 ppm acetone exposure with corresponding applied gate voltage at operating temperature (a) 25 °C, (b) 50°C and (c) 75 °C.

get increased at applied V_{GS} and increase linearly with the applied temperature (Fig. 5). Here also the highest response value found at 50 ˚C applied temperature and showing response magnitude of 22 % and 45 % for GO and Pd/GO FET sensors respectively, at their corresponding V_{GS} as shown in (Fig. 5b). Moreover, response magnitude of sensors was comparably very high at applied V_{GS} at all the temperature range than zero gate bias. In contrast, Fig. 5 confirms that applied back gate voltage plays a key role in sensitivity modulation for both the sensors even at very low operating temperature (25 ˚C).

The general mechanism in acetone sensing involves chemisorption of oxygen groups (O^{2-}, O^{-}) on sensing material and also Pd/GO sensor form a junction between Pd nanoparticles and GO due to their work function difference and show a change in device current [5,9,12]. Introduction of reducing vapor, acetone molecules reacted with pre-absorbed oxygen species and the trapped electrons by oxygen molecules get released back to the conduction band of sensing layer and show modulation in device current. In the influence of gate voltage, the modulation in current value will be very high as we found in Fig. 5, due to the low carrier density in the channel at $V_{GS} \approx V_{dirac}$ and any change in carrier concentration by the analyte gas become very significant.

IV. CONCLUSION

Herein, we have prepared two sensors; GO and Pd/GO. Pd/GO FET sensor was showing efficient acetone sensing characteristics in the influence of applied gate voltage and Pd nanoparticles. FESEM image confirms the decoration of Pd nanoparticles on GO layer without an aggregation and discontinuity. Raman spectroscopy showed the characteristic peaks of GO in both the samples and Pd nanoparticles incorporation in GO results in peak shift. The ambipolar current-voltage behaviour of GO was visualized through the I_{DS}-V_{GS} characteristics at a temperature range 25-75 ˚C in air. An amplified sensitivity was found in both GO and Pd/GO under the effect of V_{GS}= 1.7 V and 1.9 V for GO and Pd/GO, respectively. Pd/GO FET sensor amplified response was ~6 times higher than the response obtained in two terminals configuration (V_{GS}= 0 V) for 80 ppm acetone at 50 ˚C operating temperature.

***Abstract*—The aviation sector has been experiencing an increased revolution in the last century. It becomes a vital transporter for different purposes such as transport, cargo, delivery, and military purposes. The importance of aviation attracts governments and researchers to focus intensely on the aviation sector to improve aviation modernity and be robustness. Recently, Cyber-Physical Systems (CPS) have emerged as intelligent embedded systems to improving areas such as aviation, smart grid, power systems, and aerospace sectors. Therefore, CPS has become prominent and eligible for the aviation sector to improve productivity and efficiency to meet the stakeholder's satisfaction. Consequently, applying the CPS to the aviation sector opens new challenges related to system security caused by its operation neutrality. This paper innovative a review Aviation Cyber-Physical Systems (CPSs) framework in terms of creating secure systems. Moreover, it discusses what are the possible policies and solutions to make this system robust and secure.**

***Index Terms*—Aviation systems, cyber threats, cyber attacks,cyber-physical systems, wireless sensor network, cyber security, physical layer security.**

I. Introduction

The aviation sector developed in the last century and played a crucial role in improving aviation's different aspects. Aviation is used for various purposes, such as transporting people, cargo or military uses to defend or attack. These facts attracted the governments, organizations, enterprises, and researchers to improve the aviation sector to meet their purpose. Productivity, efficiency, and controllability are the characteristics that are required. Recently, emerging the cyber physical system (CPS) attracted their intention of using this new intelligent embedded system in the aviation and aerospace sector. The applying of the CPS met their requirements and drove the aviation sector to its goals. The nature of the CPS is the integration cyber world with the physical world. That integration provides benefits and opened up the challenges represented by the integration's security issues and vulnerability. Aviation uses to transport passengers, cargo, and military purposes. This revolution makes using aviation is an integral part of future intelligent plans, modernization of the organization and government in the upcoming century. Besides, the aviation management system helps in this revolution and makes the aviation sector easier to use with less cost. These days Aviation cyber-physical systems (ACPS) integrate the cyber layer such as computation, network, digital storage with the physical layer such as sensor, actuator, camera, etc. [1]. This integration makes ACPS become an intelligent embedded system. ACPS is acquiring valuable characteristics such as automation, efficiency, controllability, productivity, which must be presented in the intelligent systems. In contrast, integrating these systems and applying them in aviation opened up some challenges, such as security issues and vulnerability. Therefore, the security of the ACPS must be addressed and investigated.

Security in the aviation cyber-physical systems must be addressed in the earlier design. The importance of the security of the ACPS is crucial, where the potential threat attacks are presented as threats to the other organization. This paper focuses on the security issues raised in the physical layer to the application layer through the network layer. besides, it shows in detail the typical type of attacks that execute on the cyber and physical components with their impacts and the solution to mitigates the threats.

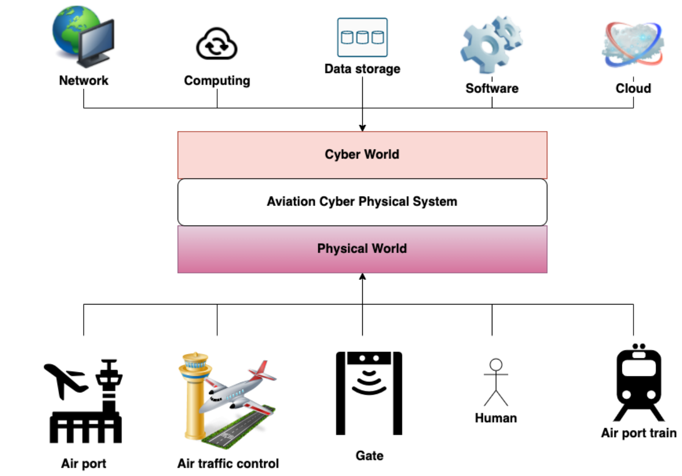

Fig. 1. Integrating cyber space with physical world

II. The importance of Security in the Aviation Cyber-Physical Systems.

The urgent needs and the nature of aviation's interoperation make the security considerations in the first line of the requirements. The ACPS is integrated into the two primary layers. Each one of them has a specific attack technique that occurs either active attack or passive. The cyber layer is represented by any intangible components such as a network, software, data storage, etc [1]. During transmission data, command signals, or measurement, this transmission expose to be damaged or data leak. On the other hand, the hacker intends to execute their malicious action on the sensor or actuator nodes in the physical layer. Therefore, Defense strategies and attack detection play a pivotal role in protecting commands and data transferred by the network.

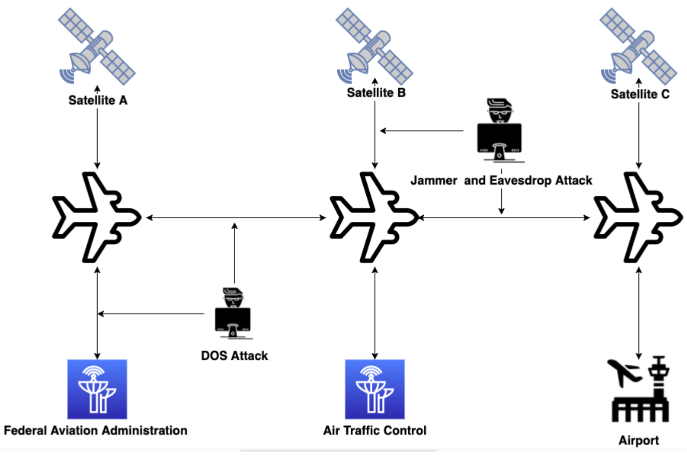

Fig. 2. Several potential paths of cyberattackss

The nature of the propagation of signal over the ACPS network is exposed to cyber-attacks. The security mechanisms are applied to the sensitive part in aviation such as cargo, passenger screen no-fly passengers, gates aircraft, etc., disclosing that information to the industry or airlines in the risk. The hackers can use some intelligent techniques to compromise the system.

III. Aviation cyber-physical systems Architecture

The basic concept of the ACPS is built on integrating the cyber layer with the physical world. This integration allows logically combining two layers to constitute the ACPS. The main three parts of the ACPS are the Application layer, Network Layer and Physical Layer.Each one of these layers its functionality relies on the one below [13]. Therefore, any compromising to any layer will affect all systems or at least one layer. Also, the operation way of ACPS is constrained, so; real-time plays a vital role in this performance. Securing each one of them is not a proper technique; the technique has to cover all security issues in all layers. The security technique must cover every single threat, bug, or vulnerability presented by the malicious attack. This section shows what the main layers that constitute the ACPS with their functionality . Also, the proper protection technique must be using to present stability to the system:

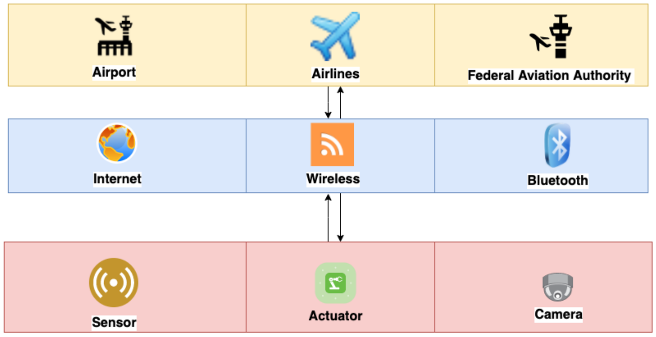

Fig. 3. ACPS architecture

1) Application Layer: The application layer is the layer that stores, analysis, and adjusts the physical world to the desired behavior. It consists of the controller of the system that decides and releases the commands based on the measurements that come from the Physical layer (source) [14]. The Application layer executed a complex algorithm on the aggregated data and transferred it back to the physical layer based on the system's status [2]. These layers also have sensitive data such as the airlines, passengers, airport, etc.

Attack on the application layer has an enormous impact on the entire system. In this layer, attacks are intended to damages the data either by violating privacy. It happens by leaking the data or unauthorized to this layer and manipulate the commands released to the physical layer[2]. Unauthorized access to this layer means that the system is driven by hackers who maliciously intended to damages the system for their purposes and goals. The type of attacks executes in this layer malicious code installed in the software deceptively or running buffer overflow against the resource to violate the availability and make the system unavailable [2]. Stack holders, organizations, and governments focus on this layer because it controls a physical layer's operation and service.

2) Transmission Layer: The transmission layer is the layer located between the application layer and the physical layer. The data in this layer fragment into small pieces calling as packets [2]. The packet is transferred and transmit, And the transmission layer rotates. This layer's data is transferred either via Bluetooth, local area network, wireless, or the Internet. The Internet is most commonly used to protect the transmitted data [2].

Security issues arise in this layer during the transmission, especially over wireless communication. The nature of the wireless communication propagating the data are suspicious to cyber attacks. In this layer integrity, confidentiality is violated as a result that the hacker can intercept the traffic and modify the data and inject commented data.

A. *Physical Layer*

The physical layer is the layer that has sensors to gathering information and acting on the physical world to adjust the system to work in the expected behavior. The aggregated data can be collected either by the sensor, camera light, etc [2] . the aggregated data is sent to the application layer to decide and release commands to be executed by the actuator.

The security issues in this layer are various, and the hacker can exploit some weaknesses in this layer. The limitation of the computation resources and memory are the main target of this equipment [15]. The hackers can use malicious action to consume the power or compromised the equipment, and sent an inaccurate measurement [16]. This equipment's nature is preferable for the hacker where the hacker can use the natural of wireless and damage the link between the sensor and the application layer.

IV. Cyber Attack on the Aviation Cyber-Physical System and it Suggested Solution

The importance of using aviation across the world makes it a primary goal for the hacker. They use an intelligent technique to disclose data and identify the vulnerabilities in the system components[17]. The hackers use a different type of attack to get their damage tasks completed.

According, to the architecture of the ACPS, it is integrated between the Cyber and Physical worlds. Each layer must be applied by an appropriate mechanism to protest their assessments, which can be, measurements, command signals, or equipment. The cyber layer presents vulnerabilities, such as malicious code, spoofing packets, and network protocol. In the physical world, the equipment's vulnerabilities or execution throw the jamming attack [10]. Therefore, the security engineer should address the security in all ACPS aspects where the influence compromising the cyber layer affects the physical layer directly. This section has shown the common cyber-attacks on the CPS.

A. *Evasdroping Attack*

This type of attack works on intercepting any data transferred over the system network. It does not need pre-knowledge about the system; it is just listing to the traffic. The eavesdropping attack does not do much to the system, such as a damaging or catastrophic consequence. It gathers valuable information about the aviation sector assessments either in the physical or cyber layers [18]. In the united state all planes mandatory to be equipped with Automatic Dependant-Broadcast (ADS-B). Its system is classified into two parts ADS-B in and ADS-B out [3]. This system broadcast unencrypted data of the airplane, such as location, altitude, speed, weather, etc [3]. This broadcasting allowing anyone can intercept these data and used them for a different purpose. Therefore, this kind of attack can gather data about the target to execute the attacks.

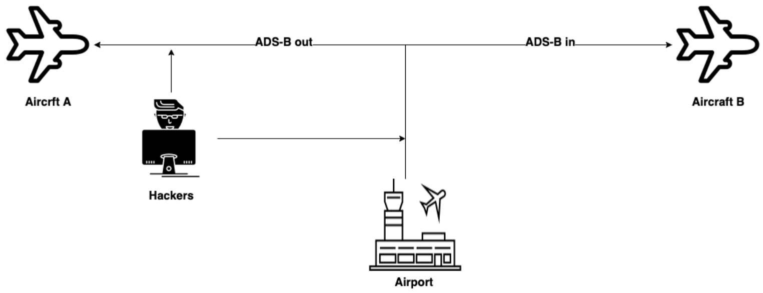

Fig. 4. Eavesdropping attack

B. *Denial of Service (DOS)*

Denial of Service is a typical attack that targets the network to make the system unavailable [2]. The hackers disrupt the network and service to make them inaccessible. The hacker to execute this attack has some techniques to achieve the attack [19]. For example, the hacker can target some airport resources, such as preventing the air traffic management system from sending their info to the airlines, planes, or stakeholders. Also, the hacker has another technique by filling the buffer of the airport systems to degrade the system performance to make them interact slowly until being shouting down useless.

C. *Jamming Attack*

A jamming attack is considered an active attack and works to disrupt the communication either by block the communication or interfered with it [8]. It has two main targets either modification the data stream or generating a false data stream [20]. The hackers block the links between the sensors node, so the measurement is blocked to be transmitted to the controller to operate services such as assigning gates, use baggage systems, and coordinate traffic on the runway.

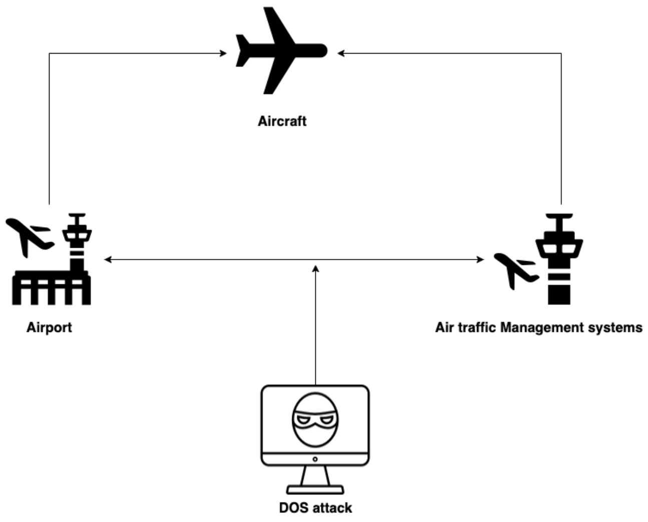

Fig. 5. DOS attack

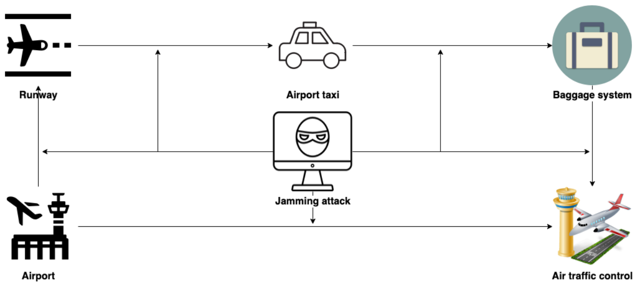

Fig. 6. Jamming Attack

D. Replay Attack

A replay attack is an attack that retransmits the data packet maliciously to repeat the measurements or signal commands to degrade the system [4]. Also, it aims to delay the valid measures from source to destination by repeating the packets [21]. These attacks compromise the sensor and actuator to execute their malicious action.Such as repeat the command to the aircraft to stay longer on the runway.

E. False Data Injection

A false data injection attack is an attack that violates the integrity of the packet data transmitted over the network; what hackers need in the malicious attack first unauthorized access to the network and start listening to the data traffic [5]. It does not require any knowledge about the system [5]. After that, the hacker injects its malicious data to drive the system to undesirable performance. False data injection can be used against the ground station or the aircraft [22]. The ground station packet injected directly affects the route and the arrival time by misleading the pilot and plane system control. This injection data drives aircraft to catastrophic consequences. The aircraft data packet injected broadcast fabricated ADS-B signals to the aircraft around or to the ground station [9]. Moreover, the connection link between the surrounding air crafts and the ground station might be injected. The destinations will not be able to define the valid data packet among the enormous received.

V. Threats in the Aviation Cyber-Physical System

Threats are actions used by a hacker to disrupt the system to reach undesirable behavior. The aviation sector is crucial, and addressing the threats at the beginning of designing the system is required [10]. The threats in aviation are presented in a different aspect [23]. It can be executed by installing malicious software, manipulating data transmitted over the network [26]. Therefore, The threats on aviation threats are presented in the cyber world, the physical world, or cyber-physical layers [1]. The cyber threats affect the physical world directly and vice versa. Therefore, this section, addressing the presenting threats in every aspect. In the cyber layer,

VI. Security of Wireless sensor network in the aviation sector

The wireless sensor network is one of the ACPS components. This technology plays a crucial role in enhancing the performance of the ACPS. It is intelligent, multi-function, and self-organizing technology [6]. It has limited the computation, battery, and memory resources. The sensors are the main components of the WSN and kinked each other through the link in short range. The WSN can increase the remotely level airport [24]. It can connect all operations such as assigning gate, taxi, and increasing interoperation in the airport. WSN uses widely in the aviation sector because of the low cost and high efficiency [11] .it can be used to sense and gather data from the physical world. Also, it is used to monitor and observe the behavior of the physical realm and adjusted it based on the erratic behavior. It is used in the terminals to sense the tempretautr on the airports, lounges, stores, etc. Also, it is used to drive the aircraft on the runway to the assigned gate.

The importance of securing the WSN in the aviation sector is an urgent request [25]. WSN is used to constitute in the airport to efficiently and effectively sense-data to keep the controller ready for any possible event. The security issues in the WSN such as damage to a data packet or drop when the congestion happened in the network [27]. Attacks cause to delay responded to the action where it would lead to a dangerous event. Also, the hacker containment the sensor channel to send the wrong measurement or data.

VII. Conclusion

The aviation sector has been evolving and becomes more efficient in the last century. The emerging of the CPS improves the aviation operation and makes that more efficient and effective. The CPS integrated a two-cyber and a physical layer. Therefore, the integration increases the performance and provide new services to airlines, stakeholders governments, and enterprise. In contrast, it opened up new challenges to the system where the security issues expanded and some vulnerabilities presented. The security engineer and researchers started to focus on the security issues to innovate new techniques to enhance the security and reliability in the ACPS.
